4.4.3 Establishment of factor loading matrix

Varimax rotation method is used to calculate factor loading matrix. Results are shown in Table 7.

TABLE 7 Factor loading matrix

	Component			
	1	2	3	4
Chinese to English x1	.926	-.084	.058	-.183
English to Chinese x2	.914	-.197	.187	.204
Correction x3	.906	.142	.227	.059
Writing x4	.901	-.129	.220	.270
Reading 1x5	.881	.359	.171	.002
Reading 2x6	.215	.888	.184	.060
Listening x7	-.437	.758	-.060	.375
Dictation x8	.358	.562	-.277	-.210

4.4.4 Scores of calculated factors

Score linear calculation model can be constructed for each factor based on the factor score matrix in Table 8, and the specific steps are as follows.

$$F_1 = 0.170x_1 + 0.047x_2 + ... - 0.101x_8,$$

$$F_2 = -0.039x_1 - 0.052x_2 + ... + 0.298x_8,$$

$$F_3 = -0.018x_1 - 0.470x_2 + ... + 0.063x_8,$$

$$F_4 = 0.120x_1 + 0.087x_2 + ... + 0.216x_8,$$

$$F = 0.35189F_1 + 0.16511F_2 + 0.16413F_3 + 0.12459F_4.$$

Then mathematical evaluation model of English translation ability can be concluded based on variance contribution rate of common factors in Table 6.

TABLE 8 Factor score matrix

	Component			
	1	2	3	4
Chinese to English x1	.170	-.039	-.018	.120
English to Chinese x2	.047	-.052	-.470	.087
Correction x3	.180	.150	-.021	-.019

Reading 2x6	-.017	-.023	.020	.252
Listening x7	.145	-.118	-.295	.356
Dictation x8	-.101	.298	.063	.216

5 Conclusions

In this work PCA analysis reveals the relationship between English proficiency and translation ability, as well as the quantitative relationship between English and translation teaching among English major students. Then the quantitative relationship between translation ability and English abilities – listening and reading comprehension, Chinese-English and English-Chinese translation – is obtained through extracting factors and calculating factor scores. In the end, quantitative calculation and evaluation for English translation are achieved, thus providing decision basis for teaching English translation.

Collaborative mechanism of project management based on complex system theory

Jiale Tian*

School of Civil Engineering and Architecture, Wuhan University of Technology, Hubei, 430070, China

Received 1 March 2014, www.cmnt.lv

Abstract

Although it is arguable that humans have been studying complex systems for thousands of years, the modern scientific study of complex systems is relatively young in comparison to conventional fields of science with simple system assumptions, such as physics and chemistry. The history of the scientific study of these systems follows several different research trends. The project management community is actively demonstrating substantial interest in the development of viable methods to assess and improve project management maturity. There is little empirical evidence on the benefits of deploying a project management office (PMO) and/or conducting project reviews. The increasing complexity of exploratory activities in pharmaceutical innovation makes less likely that a project can stand alone. Project managers not only resort to in-house innovation but also external sources to propel a central project. This paper introduces the notion of a quality function for individual tasks and uses the functional form of the bivariate normal, to model quality at the task level. Using real data from two case studies, a translation agency and a software development company, the quality function is specified and incorporated into a mathematical programming model that allows quality to be explicitly considered in project planning and scheduling. An alternative model formulation leads to the creation of quality level curves that enable managers to evaluate the nonlinear tradeoffs between quality, time, and cost for each of the example projects. The results of these analyses lead to specific decisions about the planned values for these three fundamental dimensions at the task level and provide insights for project planning and scheduling that can be gained through improved understanding of the choices and tradeoffs.

Keywords: project management, project planning, project scheduling, quality management

1 Introduction

A complex system is a damped, driven system (for example, a harmonic oscillator) whose total energy exceeds the threshold for it to perform according to classical mechanics but does not reach the threshold for the system to exhibit properties according to chaos theory. We have witnessed a dramatic and steady increase in the extent to which the modern enterprise adopts and relies upon project management to secure a competitive advantage. As project management becomes the dominant way that work is accomplished, organizations strive to become good at delivering projects successfully. The predictable consequence is widespread commitment to improvement initiatives that may include the establishment of an enterprise project management process, the development of a career path for project managers, the implementation of project management education and training programs, and investment in project management tools and information systems. But the modern enterprise cannot afford to improve recklessly or randomly. The modern enterprise must approach improvement purposefully. Committing an organization to a significant improvement effort requires a thorough understanding of where the organization is and, perhaps more importantly, where the organization needs to grow. This is the need that is addressed by the recent interest and attention devoted to the development of project management maturity models.

It is widely agreed that the choice of management structures used to implement innovative, temporary, cross-functional and complex project endeavours has important implications for project success. The discussion of alternative project management structures dates back to Galbraith's conceptual introduction of the matrix organization and its differentiation from functional and product organizations. He systematically compared the advantages and dis-advantages of alternative matrix organization structures. Based on Galbraith's typology some authors favoured matrix project organization structures for their flexibility, their economical use of resources, and the clear differentiation between project authority and functional authority. Others criticized matrix project organization structures due to their complexity and lack of unity of command. On balance, these conceptual discussions lack agreement, thus providing little conclusive theoretical direction concerning the relationship of specific project structures to project success. These conceptual disagreements are also reflected in the empirical research. With the exception of and empirical studies have not generally revealed significant associations between project organization types and project success. However, an alternative stream of empirical research suggests the importance of project management structures for project success. Several studies concordantly identified significant and strong associations between project

* ***Corresponding author's*** e-mail: 714823@qq.com

managers' (PM's) decision authority and project success. The differences between these two empirical research streams accentuate the inconclusive discussion of project management structures and their association with project success.

Project management addresses cost, schedule, and performance targets while providing an outcome that satisfies the client. A measure of the value of the project to the client is the level of quality associated with the completed project. It follows then that important managerial decisions relate to the level of quality achieved for each of the project's tasks, since the quality of the tasks defines the quality of the project. The emphasis in project planning and scheduling has been on managing the relationship between time and cost, with an implicit assumption of a fixed level of quality that is seldom explicitly examined. However, in many situations there are alternative approaches for completing each task, each having its own time, cost, and quality considerations. Differences in quality can arise due to bids offered by competing subcontractors to complete specific tasks. Even different bids by the same subcontractor could imply different quality levels. For example, subcontractors might have some flexibility with time and cost that would result in different quality levels for the same task. This can also be true for alternative work plans offered in-house. For example, in completing a foundation for a building there are choices related to the depth of the excavation and the compressive strength of the concrete used. Each of the possible alternatives will achieve different levels of time, cost, and quality associated with this task.

A complex system is a damped, driven system (for example, a harmonic oscillator) whose total energy exceeds the threshold for it to perform according to classical mechanics but does not reach the threshold for the system to exhibit properties according to chaos theory. Although it is arguable that humans have been studying complex systems for thousands of years, the modern scientific study of complex systems is relatively young in comparison to conventional fields of science with simple system assumptions, such as physics and chemistry. The history of the scientific study of these systems follows several different research trends.

This paper introduces the notion of a quality function for individual tasks and uses the functional form of the bivariate normal, to model quality at the task level. Using real data from two case studies, a translation agency and a software development company, the quality function is specified and incorporated into a mathematical programming model that allows quality to be explicitly considered in project planning and scheduling. An alternative model formulation leads to the creation of quality level curves that enable managers to evaluate the nonlinear tradeoffs between quality, time, and cost for each of the example projects. The results of these analyses lead to specific decisions about the planned values for these three fundamental dimensions at the task level and provide insights for project planning and scheduling that can be gained through improved understanding of the choices and tradeoffs.

2 Related works

In the field of project management, "Quality management has equal priority with cost and schedule management" [1]. This statement makes inherent sense, since project management is concerned with not only managing cost and schedule, but also the actual work completed in order to achieve the project goal. The quality of the work completed then is an important project outcome, since it directly relates to the value of the project deliverables. The Project Management Body of Knowledge (PMBOK) [2] has adopted the ISO 9000, clause 3.11 definition of quality as "the degree to which a set of inherent characteristics fulfils requirements" [3]. Quality issues must be addressed in both the management of the project and the product of the project [2]. Specifically, the PMBOK suggests that quality must be addressed throughout the project life cycle, beginning in the project planning phase and continuing through quality assurance and quality control [2]. Unfortunately, no guidance is provided in terms of how quality can be measured in a project context. The construction industry has been concerned about quality for a long period of time and has conducted research to address this issue. A study by the Quality Performance Measurements Task Force of the Construction Industry Institute resulted in the quality measurement matrix [4] and led to the development of an approach to measure quality performance of engineer-procure-construct (EPC) projects [5]. The measures were tied to four total quality management components: customer focus, leadership, delivery, and employee empowerment. Under delivery, for example, the subcategories include cost, time, safety/health/environment, and product deliverables. The focus of this approach is on identifying and then tracking critical quality measures for each project phase. A project quality performance model based on empirical study of project control variables was developed for Hong Kong construction projects [6]. These variables are grouped under the headings of client, project, project environment, project team leader, project management action, and project procedure. The literature on quality issues and problems in the construction industry is summarized in [7].

Several authors have attempted to develop methods to measure project quality. Paquin et al.[8] assess project quality by decomposing client satisfaction into a hierarchical structure of quality dimensions that are measured and aggregated using a multi-criterion approach such as the analytical hierarchy process (AHP) [9] or multi-attribute utility theory [10]. A limitation of the multi-criterion approach for quality measurement is the necessity of identifying and evaluating a possibly unique set of quality dimensions for each task. Pollack-Johnson and Liberatore [11] illustrate how the quality of a task option can be determined using the AHP. They extend the discrete time–cost problem by developing a mathematical programming model that determines optimal discrete options defined in terms of time, cost, and quality combinations for specific tasks to maximize overall project quality, whether determined by AHP or by some other method, subject to time, and cost constraints. Icmeli-Tukel and

Rom [12] present two models that integrate quality considerations into resource constrained project scheduling. In their study, quality is measured by the amount of time and money spent on reworking activities that do not satisfy specifications. Several methods of integrating rework times and costs into the models are proposed. An alternative approach for measuring quality at the task level is to make a direct subjective assessment of quality [13,14].

3 Method

3.1 THE MODEL

This research was conducted using the PM Solutions Project Management Maturity Model. The PM Solutions model was developed by a team of highly experienced project managers and has been used successfully to conduct maturity assessments in several organizations. This model adopts a two-dimensional (2-D) framework. Both of the dimensions are based on accepted industry standards. The first dimension reflects the level of maturity. It is based on the structure of the SEI Capability Maturity Model. The SEI model has received widespread acceptance as a standard for process modeling and assessment of organizational maturity in several process areas. Additionally, research evidence from several studies including case studies and survey research have demonstrated important organizational performance improvements are associated with improved process maturity. The second dimension depicts the key areas of project management addressed. This dimension adopts the structure of the PMI's nine knowledge areas. Each of the nine knowledge areas were further decomposed into key components that pro-vide for a more rigorous and specific determination of project management maturity based on specific capabilities. There were a total of 42 components included in this study, which is shown in Figures 1 and 2.

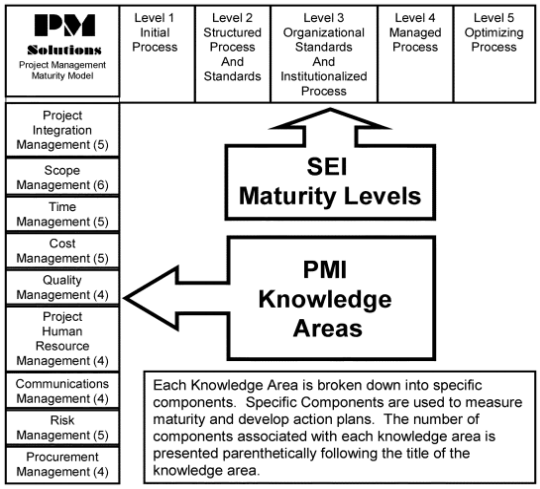

FIGURE 1 PM solutions project management maturity model

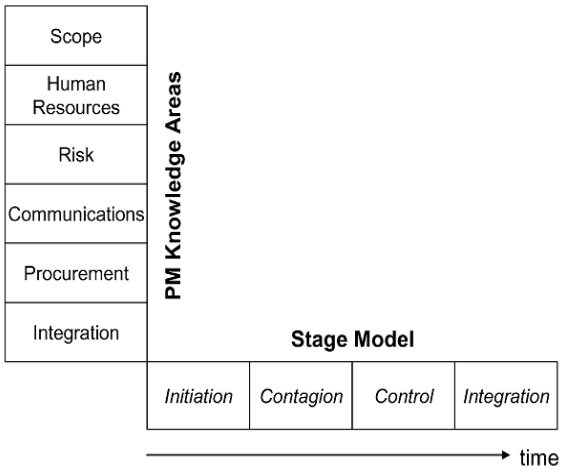

FIGURE 2 Project management knowledge areas and stage model

3.2 THE FORMULATION

In this study, we establish a triple-stage stochastic decision process, which illustrates a typical pharmaceutical R&D project in which the committee periodically reviews a project and decides whether to continue with in-house research or buy existing technology from outside.

a) Once the R&D project is initiated, it has two process lines: the monitoring process and the stochastic innovation process. The monitoring process is periodically scheduled (e.g., twice a year), whereas the innovation process is a random time duration.
b) The focal R&D project has a fixed total time span stipulated by the monitoring process, meaning, practically, that the project is not allowed to last forever.
c) The R&D project's innovation process can be divided into three phases as mentioned previously: the toxicity phase; the efficacy phase; and the clinical test phase. The duration of each phase is random.
d) Scientists develop a lead compound by exploring molecules (e.g., via HTS) and optimize the compound by adding more molecules to its basic structure or replacing old molecules with new ones. Scientists face uncertainties in the sense that their in-house developed compound may fail or their in-house research lasts too long and thus they run out of time without having a positive result.
e) The R&D project can buy existing molecular entities or novel entry technology developed by external sources as substitutes and combines them with its own in-house compound.
f) The committee decides at scheduled monitoring times whether to buy substitute molecular entities or continue a drug's in-house development. However, by using externally

procured molecules, we assume that the probability of producing a successful lead compound ultimately decreases. This condition reflects Pisano's argument that bought-in molecular entities may increase development uncertainty and thus reduce the probability of success. It also reflects the make-or-buy dilemma the committee has to face in science-based pharmaceutical R&D.

g) By "project success," we mean that the compound turns out to have positive effect within the project's allotted total time. By "failure," we mean that the compound either turns out to have negative effect or the research runs out of time. The following details our model's formulation.

3.3 THE DEVELOPMENT

Our overall goal is to find a rich method for modeling the relationship between quality, time, and cost at the individual task level within a project, as well as at the overall project level. Our approach begins by formulating a model of the quality of each task as a function of the time and cost allocated to it. We assume that there is an entity (an individual or group within an organization, a subcontractor, etc.) that could complete a given task with different allocations of time and cost. We further assume that there is a quality function that assigns to each combination of time and cost a corresponding quality value. We limit time and cost c to reasonable values for the task at hand and assume that, within that domain, the quality function for a task has two basic properties.

1) Holding time constant, quality q is an increasing function of cost. Thus, if time is fixed, we assume that allocating more money to the task will increase quality.
2) Holding cost constant, quality is an increasing function of time. Thus, if cost is fixed, we assume that allocating more time to the task will increase quality.

If we normalize quality to be on a 0–100 scale, based on the two non-decreasing assumptions earlier, we would expect the graph to show quality being lowest at the corner of the domain with the smallest values of time and cost and highest in the opposite corner (the highest values of time and cost). For a fixed quality, we would expect a standard time/cost trade off curve that is decreasing and convex. Thus, to maintain the same level of quality, to reduce the time, one has to pay increasingly more money per unit, such as in standard project activity crashing. This suggests a basic hill shape rising out of a plain, although we would only be interested in a one-quarter wedge of the hill.

3.4 THE MEASUREMENT

The questionnaires used in this study include 199 single items and some quantitative measures of project-specific characteristics. Out of these, 67 items were directly taken from questionnaire, with permission of the author. The remaining items were developed for the purposes of this study. Each item was assessed on seven-point rating scales with a range from strongly agree" to "strongly disagree." The original questionnaire was developed in the German language and the adopted Pinto's items were translated from German to English. Inorder to collect data on the U.S. projects the German questionnaire was translated into English. To demonstrate consistency and accuracy in translations the documents were back-translated using two experts who discussed the translations and together corrected any inconsistencies. Prior to final data collection in the U.S. the instrument was tested in a pilot of 20 projects.

Following our conceptual discussion we use a set of five variables measuring project management structure attributes and four variables measuring project success. All constructs consisting of multiple items were tested for composite validity using Cronbach's alpha and factor analysis. Some of the initial scales had to be modified to achieve satisfactory composite validity.

1) Project Management Structure Variables: The scales used to measure the project management structure attributes could be portrayed as follows. The PM project authority scale describes the level of authority delegated to the PM and covers different important decisions typically made or influenced by PMs. The PM functional responsibilities scale measures the position of the PM within the functional organization. The PM personnel authority scale measures whether the PM had the authority to reward project team members. The PM project responsibility scale is used to differentiate the project responsibility of the PM from the project responsibility of other constituents within the organization. The project influence of steering committees was measured by the level of top management involvement in project decisions.
2) Unidimensional Project Management Structure Scale: We used the scale developed by Larson and Gobeli. This scale is a blend of the scales suggested by Might and Fischer and Murphyet al. It differentiates between five project management structure types and describes the spectrum from a functional organization to a pure project organization.
3) Project Success Variables: Pinto and Mantel identified three distinct aspects of project performance: 1) the implementation process; 2) the perceived value of the project; and client satisfaction with the delivered project outcome. Shenhar et al. have suggested four different criteria to assess project success: 1) meeting design goals; 2) benefits to customers; 3) commercial success; and 4) future potential. In this study, we use four different project success measures: efficiency, effectiveness, customer satisfaction, and business results.

4 Analysis

The results of this study complement previously published results concerning overall project management maturity in which a clear majority of respondents indi-

cated that their organizations are relatively immature in terms of the project management maturity model. In the referenced study, nearly 67% of respondents indicated their organizations were operating at level 1 – initial processes (13.7%) or at level 2 – structured process and standards (53.2%). While a notable portion of respondents rated their organizations had reached level 3 – organizational standards and institutionalized process (19.4%), a mere 7.3% indicated their organizations were operating at level 4 – managed process and only 6.5% assessed their organizations to have achieved level 5 – optimizing process.

This instant research reveals very comparable results at the more detailed component level. Reviewing the results across all component areas, the median project management maturity level was level 2 out of 5 in 36 of the 42 areas. In fact, there was only one component area in which the median level of project management maturity was above level 2. In the change control component of the project integration management knowledge area, the median project management maturity was level 3. It is also instructive to note that reported practices in the project risk management knowledge area are the least mature of all knowledge areas. In fact, this area accounts for four of the five cases where the median level of project management maturity is level 1. In particular, the respondents indicated level 1 practice with respect to risk quantification, risk response development, risk control, and risk documentation. Risk management practices appear to deserve the attention of those charged with leading their organizations toward improved project management maturity.

The most significant difference between industries identified in this study occurs with respect to the schedule development component area. The median maturity reported by respondents in the professional services industry was level 3. This value is above the median results reported for the information and finance industries (level 2) and well above the median maturity level reported by those respondents engaged in the manufacturing industry (level 1). These results indicate that in the professional services industry, a majority of the organizations that participated in this study have adopted the practices that characterize level 3 maturity in schedule development. These practices include the definition of the project schedule at the appropriate level of detail, in line with the project scope and work breakdown structure. Additionally, the project schedules are established as baselines that are managed. Finally, the use of project management scheduling tools is standard across all projects. In the remaining three industries, a preponderance of respondent organizations are currently operating at level 2 or below. At level 2, schedule development is based on a repeatable process that relies on expert knowledge, access to industry methods, and access to commercial databases. Project teams develop staffing plans to support the project schedule and work with management to secure the resources required.

Finally, at level 2, project management software tools are standard for large, visible projects. We should also note that over 70% of respondents in the manufacturing industry indicated their organizations were operating at level 1 maturity. At level 1, scheduling occurs in an ad hoc fashion. The organizations lack a formal process for developing project schedules. The results for cost resource planning reveal that once again the respondents in the professional services industry report the highest level of project management maturity with over 38% reporting at level 3 or higher, and the respondents from the manufacturing industry report the lowest level of project management maturity with over 70% reporting practices at level 1. Among industries, project management maturity levels reported for cost resource planning are less than those reported for schedule development. In the case of professional services and finance and insurance companies, the majority of respondents report practices consistent with level 2 or above. These organizations are identifying resource requirements for all labour categories, equipment, and material. They are also employing planning processes that develop and document the resources required, as well as the methods for determining resource requirements. The planning process in level 2 organizations is supported by management and is gaining acceptance through the organization. In the manufacturing and information industries, level 1 practice is considerably more prevalent. The respondents indicated that project managers in their organizations employ methods to identify resources that vary from one project to the next. At times, the functional support areas are overlooked. Most indicated the cost resource planning process was undocumented.

5 Conclusions

The value of the project to the client can be measured in part by the level of quality associated with the completed project. Quality is acknowledged to be an important component of project management, but previously has received limited consideration in planning and scheduling. The implicit assumption behind standard time/cost tradeoffs is that some unspecified level of quality is maintained for each task. However, in many situations project managers must evaluate alternative options for accomplishing project activities, and these involve differing levels of time, cost, and quality. In such situations, it makes sense to analyze the relationship between cost, time, and quality, and decide on their levels for each project task that best achieves the project's objectives. We have introduced the concept of a quality function that represents the relationships between quality, time, and cost for each task. Using two case studies with real data, a translation agency and a software development company, the quality function is specified for each task and incorporated into a nonlinear programming model that allows quality to be explicitly considered in project planning and scheduling. An alternative formulation minimizes cost with bounds on project quality and completion time and leads to the creation of quality level curves. Both formulations can be very useful tools in making final project planning and scheduling decisions that explicitly model and incorporate quality.

Abstract

The key process indicator – coke oven flue temperature – is difficult to detect online with instruments in the coke oven heating process, thus an intelligent forecasting model is developed which is composed of four parts: the data gathering and handling unit, the optional forecasting unit, the online amendment unit and the effect evaluation unit. The optional intelligent forecasting model and its corresponding algorithm are established for different categories of practice operating conditions. In normal operating condition, the nearest neighbor clustering algorithm based on the principal component analysis and neural network with the radial basis function is selected. In unconventional operating condition, the case-based reasoning technology is selected. The models of different conditions are validated and applied according to the actual data in a steel enterprise coke production, the results show that the established forecasting model can reflect different practice conditions and meet the real-time control requirements.

Keywords: intelligent prediction, neural network, principal component analysis, neighbor clustering algorithm

1 Introduction

In the complex process of industrial production, some of the important variables closely related to the quality of products cannot be measured online directly due to various reasons by measurement instrumentation so that it has become a key factor to restrict the product quality and production efficiency. Coke oven flue temperature is a very important process parameter and refers to the measurement flue temperature average of the whole furnace chamber, which can reflect the whole oven temperature level. At present, the existing flue temperature soft measurement models are mostly linear regression models with the establishment of the regenerator top temperature and the coke oven flue temperature or creating the double parabolic model between them [1]. These models just regard the relationship of the regenerator top temperature and the flue temperature seen as a linear relationship or double parabolic relationship which exists certain limitations and low measurement accuracy. To meet the need of how to achieve the real-time control for coke oven flue temperature has become a constraint key issue.

Soft sensor technique is developed to solve such problems: According to some auxiliary variables being directly measured and the corresponding mathematical model in the process of industrial production to estimate the dominant variables not being measured online [2,3]. At present, soft sensor technique has more and more applications as the effective way to estimate some unpredictable variables in the industrial process. Main research content of soft sensor technology is: Mathematical model is established for a certain process variable. This mathematical model can be called the prediction model based on its characteristic and role modeling. Currently, the neural network soft measurement technology and the case-based reasoning soft measurement technology have been applied more and more widely.

Neural network has some itself characteristics: approximated to any complex nonlinear continuous function, the parallel handling of information and self-learning, adaptive, etc. Among them, the neural network of Radial Basis Function belongs to the local approximation network, and it has some significant features in the approximation capability, the classification ability and the learning speed, etc. [4,5]. Principal Component analysis method is a statistical analysis method to transform multiple related variables into a few independent variables. Soft sensor methods based on PCA and soft RBFNN is able to take advantage of neural network modeling at reduced dimensionality situation [6,7].

Case-Based Reasoning directly uses the past knowledge and experience, the model is easy to implement and maintain, and its training is simple and effective. Case-Based Reasoning adopts incremental learning method and has a strong self-learning ability, being good at using the knowledge and experience to learn [8,9]. The new cases are added increasingly in the learning process to modify the old cases for improving the judge reasoning ability.

The intelligent forecasting model is developed for the problems and needs above which is composed of four

[*]***Corresponding author's*** e-mail: honghai.liu@port.ac.uk

parts: the data gathering and handling unit, the optional forecasting unit, the online amendment unit and the effect evaluation unit [10,11]. The respective model and the corresponding algorithm are established with neural networks and case-based reasoning combined for different categories of actual operating conditions. In normal operating condition, the nearest neighbor clustering algorithm based on the principal component analysis and neural network with the radial basis function is selected. In unconventional operating condition, the case-based reasoning technology is selected. These two techniques are simultaneously applied to the coke oven flue temperature soft measurement of a coking plant, the practical application results show that the established forecasting model can reflect different actual conditions and meet the real-time control requirements.

2 The entire system of optional intelligent forecasting model

The optional intelligent forecasting model structure which can predict key variables of complex industrial process is displayed in Figure 1. $\hat{X}$ is the output of the optional prediction unit. $\bar{X}$ is the output after amendment; the distributed control system (DCS) generates the process data set Σ. Θ is the manual measurement data set from the online monitoring model. e is the amendment input parameters from the online amendment unit. u is the input of control object; y is the output of control object.

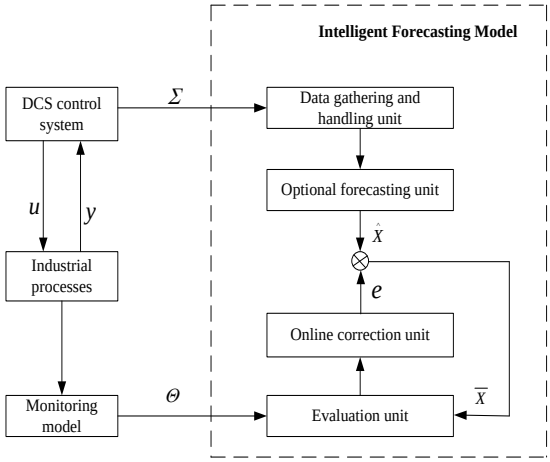

FIGURE 1 The entire system of optional intelligent forecasting model

a) Data gathering and handling unit: Data collected from the scene usually contains various interfering noise, such as the zero drift for the instrument, etc. In order to minimize these noise interference when modeling, these input data must be converted and difference handling, namely data pre-handling. Under certain circumstances, the output of prediction model should be appropriately processed, the reason is that the model is obtained in the context of a series of assumptions, it is impossible fully consistent with the practice situation and there is a model discrepancy.

b) Optional forecasting unit provides different categories forecasting model, depending on the actual condition, a prediction model and algorithm is selected. In normal condition, the neural network forecasting model is selected. Through learning and training, the neural network can obtain the knowledge of the key variables for the forecasting. In unconventional conditions, the case-based reasoning model is selected, the similar cases in the case base are retrieved according to the characteristics working conditions and the retrieved cases are matched and reused based on resemblance threshold to obtain the case solution of current condition which is the soft measurements of estimated dominant variable to predict.

c) Online amendment unit: the output of prediction model will drift with the passage of time after the forecasting model being put into use, therefore, some appropriate corrective measures must be taken to increase the accuracy of forecast values. Yet general, the online amended parameters is taken:

$$e = \frac{1}{n}\sum_{i=1}^{n}\left(X_i^* - \hat{X}_i\right), \tag{1}$$

$\hat{X}_i$ is the output of prediction model, X_i^* is the practical measured value.

The amended output is:

$$\bar{X} = \hat{X} + e\,. \tag{2}$$

This amendment pattern is easy to implement, the output of neural network prediction model should be calibrated to compensate for drift according to Equations (1) and (2) to increase the accuracy of forecast.

d) Evaluation unit will make corresponding evaluation results for forecasting the results of different categories, the output for neural network prediction model is compared with the manual measurement data obtained with the monitoring model, if the difference exceeds the set of upper and lower limit, the training and learning of neural network is conducted. The output of forecasting model for case-based reasoning is compared with manual measurement data obtained with monitoring model to evaluate the prediction accuracy.

3 Two different categories of the model structure in the optional prediction unit

3.1 THE FORECAST MODEL STRUCTURE FOR NORMAL OPERATING CONDITIONS

When the prediction model of flue temperature established, after considering the actual values of these factors: the statistics of regular testing T^*. The load pressure of furnace n, the flow of heating gas u, the pressure of heating gas p,

the energy value of heating gas *h*, the flow of heating air *v*, the flue temperature of combustor is analyzed by principal component analysis and neural network technology in order to achieve the intelligent prediction of flue temperature. The structural principle is displayed in Figure 2.

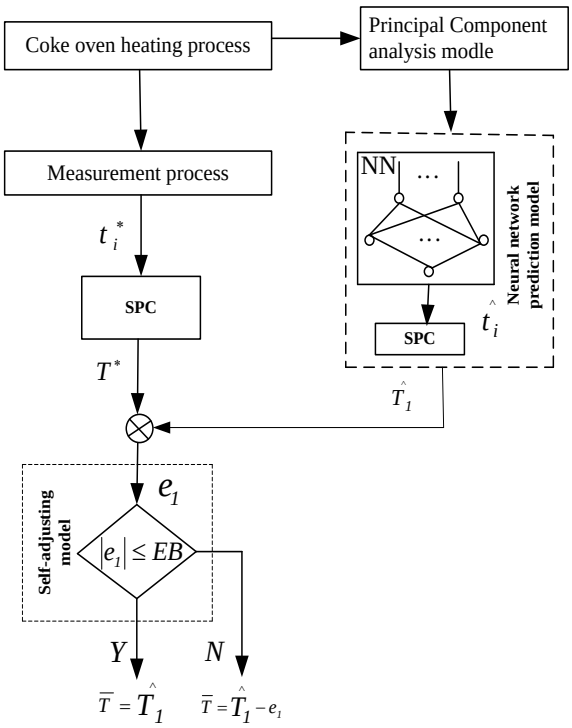

FIGURE 2 Neural network forecasting model of coke oven flue temperature

Intelligent forecasting model for flue temperature is composed of several parts which mainly are the principal component analysis model, neural network prediction model, self- amendment model. $\hat{T}_1$ is the output of neural network prediction model; $\hat{t}_i\,(i=1,2,...,n)$ is the output value of neural networks within a certain period of time. $t_i^*\,(i=1,2,...,n)$ is the actual measured value of flue temperature within a certain period of time. T^* is the statistics of manual measurement. e_1 is the difference between output value of neural network prediction model and manual measurement result; *TB* (>0) is the preset difference limit. $\overline{T}$ is the amended output of flue temperature.

The model structure of PCA and RBFNN is displayed in Figure 3. PCA extracts PCA components about some preliminary selection input variables to reduce the number of input variables and simplify RBFNN model under the premise of avoiding the loss of multi-variable information. RBF neural network is composed by three layers, the input layer nodes only pass the input signal to the hidden layer, the hidden layer nodes is composed by the effect function of radial structure like Gaussian functions, and the output layer node is a simple linear function. The basis function of hidden layer nodes will be generated in the local response for the input signal, that is, when the input signal is close to the central range of the base function, the hidden layer node will have a great output.

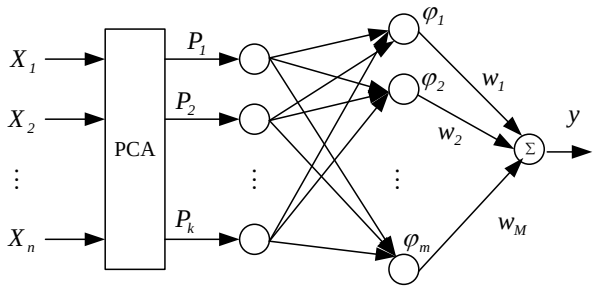

FIGURE 3 The model structure of PCA and RBFNN

The tasks of the hidden layer and output layer are different in the RBF neural Networks, therefore their learning strategies are also different. The hidden layer adopts nonlinear optimization strategy to adjust the mapping function parameters, thus it has the relative slower learning rate. The output layer adopts linear optimization strategies to adjust linear weights, thus the learning rate is faster.

There are many forms of radial basis functions, this paper selects the Gaussian function:

$$\varphi\left(\left\|P-P_i\right\|\right)=\exp\left(-\frac{\left\|P-P_i\right\|^2}{2\delta^2}\right), \tag{3}$$

In the type, $\varphi(\cdot)$ is the radial basis function; $\|\cdot\|$ is the European norm; $P_i \in R^{n_i}$ is the center of RBF; δ is the standard deviation of the neurons P_i determining the shape of the Gaussian function:

$$\delta=\frac{d_m}{\sqrt{2M}}, \tag{4}$$

where d_m is the maximum distance among the selected centers; *M* is the center number (the number of hidden layer units).

The output is:

$$F(x)=\sum_{i=1}^{M} w_i\varphi\left(\left\|P-P_i\right\|\right)+w_0, \tag{5}$$

where w_i is the weight of hidden unit to output unit; w_0 is the bias item.

PCA model needs a data set of the normal working conditions as the modeling data. Suppose the test data vectors matrix process $X \in R^{n\times n}$ is composed by *m* process variable and *n* data vector samples. In order to avoid different dimensions impact on the results and ease to handle mathematical, it is necessary to normalize the data. μ is the mean vector of set *X*, σ is the standard deviation vector, the normalized process variable is:

$$\tilde{x}_{ij}=\frac{\left(x_{ij}-\mu_j\right)}{\sigma_j}, i=1,2,...,n;\ j=1,2,...,m, \tag{6}$$

$\tilde{X}$ is the normalized vector of process variables, *V* is the covariance matrix for $\tilde{X}$. Based on principal component

analysis for $\tilde{X}$, the process of principal components selected as the input vector of RBF network based on Principal Component Analysis is as the followings.

a) The each eigenvalue λ_j and corresponding unit orthogonal eigenvector P_j are calculated for the covariance matrix;

b) The principal component t_j of the order j is calculated:

$$t_j = \tilde{X}P_j, \tag{7}$$

c) The model of principal component is calculated:

$$\hat{X} = t_1P_1^T + t_2P_2^T + ... + t_jP_j^T, \tag{8}$$

where $t_j \in R^n$ is called as the score vector; $P_j \in R^m$ is called as the load vector; P_j is the corresponding eigenvector matched with the order j eigenvalue in descending order for the matrix V, including various interrelated information among the variables. Each pair t_j, P_j is sorted by the descending of the eigenvalue λ_j for the corresponding eigenvector P_j. Where in the first pair intercepts the maximum information volume among all decomposition of the load vector and principal component vector. So on, $T = [t_1, t_2, ..., t_m]$ is the score matrix; $P = [P_1, P_2, ..., P_m]$ is the load matrix, the Equation (9) can be written as:

$$\hat{X} = TP^T. \tag{9}$$

d) The contribution rate is calculated before the principal component $k(1 \le j \le m)$:

$$\eta_k = \frac{\sum_{i=1}^{k}\lambda_i}{\sum_{i=1}^{m}\lambda_i}. \tag{10}$$

Next step, the number of principal component for PCA model should be determined. Since there is high correlation between the process variables based on experience, generally, the cumulative contribution rate of all principal components before the principal component k more than 85% is considered to reflect the body information of process variables. The k vectors for the corresponding principal components are selected main element vectors in the matrix as the input vector of RBF neural network training.

3.2 THE FORECAST MODEL STRUCTURE FOR UNCONVENTIONAL OPERATING CONDITION

The intelligent forecasting model of case-based reasoning is established for flue temperature after considering the actual values of these factors: the statistics of regular testing T^*, the load pressure of furnace n, the flow of heating gas u, the pressure of heating gas p, the energy value of heating gas h, the flow of heating air v. The model structure is displayed in Figure 4. Ξ is the set of measurement data obtained from the coke oven heating process. $\hat{T}_1$ is the output of case-based reasoning prediction model; $t_i^*(i = 1, 2, ..., n)$ is the actual measured value of flue temperature within a certain period of time. T^* is the statistics of manual measurement. e_1 is the difference between output value of case-based reasoning prediction model and manual measurement result. TB (>0) is the preset difference limit. $\bar{T}$ is the amended output of flue temperature. Model selector gets the measurement data from the coke oven heating process, the forecast values are completed by case-based reasoning model, and the self-correction model based on artificial measured temperature statistics to determine how to deal with the results of prediction, the target of forecast is to get at last.

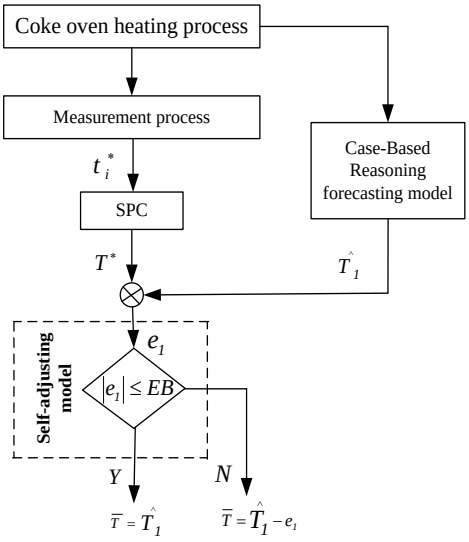

FIGURE 4 Case-based reasoning forecasting model of coke oven flue temperature

4 Model algorithms under different conditions

4.1 THE SELF- CALIBRATION ALGORITHM

The initial forecast results should be amended online to ensure the forecast accuracy, while the self-calibration algorithms for the prediction models of two conditions are the same, the same self-calibration algorithm is available [12,13].

Generally, the flue temperature of combustion is measured through the Infrared Thermometer held by the operator. Setting that the set for the manual measurement data is $\{t_i^*, i = 1, 2, ..., k\}$, statistical process control (SPC) mechanism is used to deal with these data.

$$T^* = \frac{\sum_{i=1}^{k} t_i^*}{k}, \tag{11}$$

$\hat{T}_1$ is the original forecast value of flue temperature from the forecasting model, the effect of flue temperature forecast can be assessed by the following equation:

$$e_1 = \hat{T}_1 - T^*, \tag{12}$$

where e_1 is the difference between the original forecast value of flue temperature and the manual measurement

data. If the absolute value of the difference e_1 is beyond a preset difference limit *TB*, thus $|e_1| > TB$, then the output of prediction model should be amended, the amended parameter is e_1. Otherwise, the output needn't be amended, the value of amended parameter e_1 is 0. The amended output is as follows:

$$\bar{T} = \hat{T}_1 - e_1. \tag{13}$$

4.2 THE NEAREST NEIGHBOR CLUSTERING LEARNING ALGORITHM OF RBF NEURAL NETWORK

K-mean clustering algorithm is a classical clustering algorithm to determine the centric value of RBF network, its main problem is that the number of network hidden layer nodes must match the number of input patterns, or it may seriously affect network performance. The number of centers is fixed in advance and depends on the initial position of the cluster center, there is likely to fall into local extreme point. This paper uses the nearest neighbor clustering algorithm with a variable number of hidden layer center to select the center of the hidden layer, the algorithm is as follows:

Select the appropriate width of the Gaussian function;

Begin from the first learning sample (P^1, Y^1), establishing the first cluster center for P^1, taking $C^1 = P^1$;

Consider a second study sample (P^2, Y^2); calculate the distance $|P^2 - C^1|$ of the cluster centers between P^2 and C^1, if $|P^2 - C^1| < r$, then C^1 is the nearest neighbor clustering for P^2, if $|P^2 - C^1| > r$ then P^2 is as the new neighbor clustering center, taking $C^2 = P^2$; then add a hidden unit in the establishment of the RBF network.

Suppose there are *M* cluster centers before consider the order *k* learning sample (P^k, Y^k). The central points are $C^1, C^2, ..., C^M$. The distance of these points to *M* cluster centers is respectively calculated, $|P^k - C^i|, i = 1, 2, ..., M$. If $|P^k - C^i|$ is the minimum distance among them, then C^i is the nearest neighbor clustering for P^k; if $|P^k - C^i| < r$, then C^i is the nearest neighbor clustering for P^k. If $|P^k - C^i| > r$, then P^k is as the new neighbor clustering, taking $C^{M+1} = P^k$, $N = M + 1$.

For each pair of the input – output data is likely to generate a new clustering, the self-adjust of two processes for parameters and structure is carried out simultaneously; therefore, the value of determines the complexity of the dynamic adaptive RBF network, reflecting one kind of generalization ability of the RBF network.

After determining the network center, the weights of the hidden layer of the network to the output layer can be adjusted, this paper adopts the recursive least squares algorithm with a weighted forgetting factor to adjust the weights of the output layer, the specific algorithm is as followings:

a) The initial values of the weights $w_i (i = 1, 2, ..., M)$ are given, the initial value $Q(0)$ of the inverse correlation matrix is the positive definite diagonal matrix for the matrix $M \times M$ (*M* is the hidden layer nodes).

b) Taking a loop variable $k = 1$.

c) The output hidden layer node output is calculated:

$$\varphi_k = \varphi\left(\left\|P^k - C^i\right\|\right) = \exp\left(-\frac{\left\|P^k - C^i\right\|}{2\delta^2}\right), \tag{14}$$

$$J(k) = Q(k-1)\varphi_k \left[\rho + \varphi_k^T Q(k-1)\varphi_k\right]^{-1}, \tag{15}$$

$$Q(k) = \frac{1}{\rho}\left[Q(k-1) - J(k)\varphi_k^T Q(k-1)\right], \tag{16}$$

$$\hat{w}(k) = \hat{w}(k-1) + J(k)y_d(k) - \varphi_k^T \hat{w}(k-1), \tag{17}$$

where $\rho(0 < \rho < 1)$ is the weighted forgetting factor; this article takes: $\rho = 0$. $\hat{w}(k)$ is the amendment result of weight matrix after the sample in the order *k* is input. φ_k is the output vector of hidden node after the sample in the order *k* is input. $y_d(k)$ is the expected output of the sample in the order *k*.

d) The target cumulative difference is calculated:

$$E(k) = \rho E(k-1) + \frac{1}{2}\left[y_d(k) - \varphi_k^T \hat{w}(k-1)\right]^2, \tag{18}$$

$E(k)$ is the cumulative difference between the network output and the actual output after the sample in the order is the input.

$E(k) < E$ is judged, if it do, then $k < N$ is judged, if this relationship $k < N$ is true, taking $k = k + 1$, going to the step 3, else going to the step 1. *N* is the number of samples, *E* is the preset target difference.

4.3 LEARNING ALGORITHM OF CASE-BASED REASONING

The specific algorithm of case-based reasoning is as the followings:

The case is expressed, the specific method is as the following: The following parameters are selected as the dominant variable for the flue temperature soft measurement model: the flow of heating gas, the suction of flue, the energy value of heating gas, the pressure of heating gas, and the load pressure of furnace. The cases of flue

temperature are stored in the computer in the form of database. The case database are composed of several of the case data, they is displayed in Table 1.

TABLE 1 The case for flue temperature of machine side and coke side

	Case for flue temperature of machine side	**Case for flue temperature of coke side**
Condition Expression	Machine-side gas flow	Coke side gas flow
	Machine-side flue suction	Coke side flue suction
	Gas heat value	Gas heat value
	Machine-side gas pressure	Coke-side gas pressure
	Furnace load pressure	Furnace load pressure
Case Solution	Machine side forecast value	Coke side forecast value

The resemblance of case is identified: The cases in the case base are defined as:

$$F_k = \left(f_{1,k}, f_{2,k}, ..., f_{n,k} \right), k = 1, 2, ..., m, \tag{19}$$

m is the number of cases in the case base.

Assuming the current operating condition is C_r. The resemblance function is defined as the following between the current condition C_r and the described case C_k:

$$Sim\left(C_r, C_k\right) = \sum_{i=1}^{n} w_i Sim\left(f, f_{i,k} \right), \tag{20}$$

where $Sim\left(f, f_{i,k} \right)$ is the resemblance between the feature $f_i \left(1 \le i \le n\right)$ of operating condition C_r and the described feature $f_{i,k}$ of the case, which is defined in the real interval $\left[0,1\right]$ and meets the symmetry and reflexivity. w_i is the weight coefficient of case described feature and $\sum_{i=1}^{n} w_i = 1$.

The resemblance threshold is identified. The threshold value of resemblance is determined before the case is matched, Sim_t is the threshold value of resemblance.

$$Sim_t = \begin{cases} X_t, Sim_{\max} \ge X_t \\ Sim_{\max}, Sim_{\max} < X_t \end{cases}, \tag{21}$$

where the threshold value X_t is decided by specific process or experience according to the situation of object, generally taking $X_t = 0.9$. The $Sim_{\max}$ is marked as $\max\limits_{k=1,2,...,m} \left(Sim\left(C_r, C_k\right) \right)$.

The case is retrieved and matched: $\tilde{C}$ is the case with the greatest resemblance $Sim_{\max}$. $\tilde{J}$ is marked as the solution after the case reused.

$$J_u = \begin{cases} \tilde{J}, \left(Sim_{\max} = 1\right) \vee \left(Sim_t = Sim_{\max}\right) \\ \sum_{k=1}^{h} Sim_k \times J_k \,/ \sum_{k=1}^{h} Sim_k, others \end{cases}, \tag{22}$$

In the type, $\vee$ is the "OR" operator, expressing the "or" relationship between before and after. The result is output after the case reused, and this time, the description working condition and its solution of solving this case are stored in real-time database.

5 Application example of intelligent forecasting model

The intelligent prediction model of coke oven flue temperature proposed in this paper has been successfully applied to the heating intelligent control system of a steel company's coke oven [14]. The forecast results of the machine side and coke side are shown respectively in Figures 5 and 6; According to the statistics, the model prediction difference of the machine side and coke side which is within ±7°C respectively reaches 92.5% and 90.8%, meeting the requirements of industrial production.

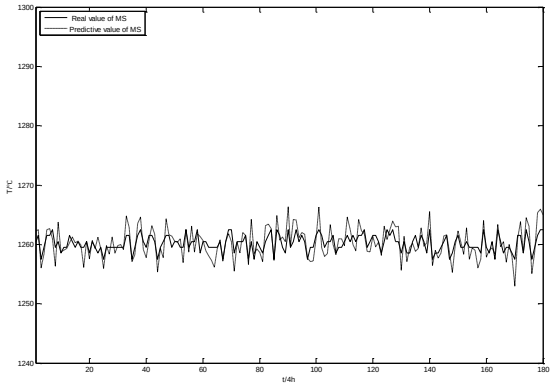

FIGURE 5 The forecast result for the machine side

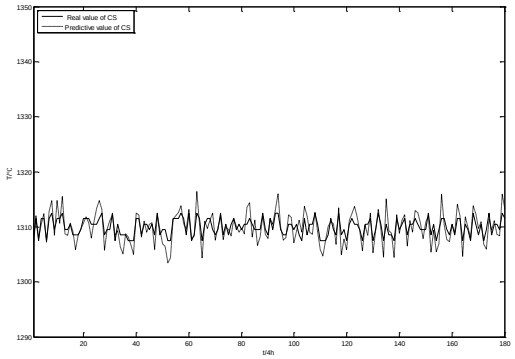

FIGURE 6 The forecast result for the machine side

6 Conclusions

The key process variables are difficult to detect online with instruments for the complex industrial processes, an intelligent forecasting model is developed which is composed of four parts: the data gathering and handling unit, the optional forecasting unit, the online amendment unit and the

effect evaluation unit. The optional forecasting model and its corresponding algorithm are established for different categories of practice operating conditions. In normal operating condition, the nearest neighbor clustering algorithm based on the principal component analysis and neural network with the radial basis function is selected. In unconventional operating condition, the case-based reasoning technology is selected. The two techniques are simultaneously applied to the intelligent forecast of coke oven flue temperature which can give full play to their strengths in different conditions. The model has a certain self-learning ability with higher intelligence. At the same time, the application results of the prediction model in the optimazation control of coke oven heating process show that the model has high accuracy. This method is effective and can be applied in real-time control of coke oven flue heating process.

Received 1 March 2014, www.cmnt.lv

Abstract

Road transportation is one of the main sources of greenhouse gas emissions, which lead to global warming and climate change. Promoting the decarbonisation of this sector through more efficient and greener mobility is a challenging task that can be achieved by intelligent transportation systems (ITS) enabled by vehicular communications. Intelligent Transportation Systems (ITS) have been developed for more than ten years in China. Furthermore, a new generation Intelligent Transportation Systems should be launched to meet the requirement of rapid development of transportation in China. For the last two decades, intelligent transportation systems (ITS) have emerged as an efficient way of improving the performance of transportation systems, enhancing travel security, and providing more choices to travellers. A significant change in ITS in recent years is that much more data are collected from a variety of sources and can be processed into various forms for different stakeholders. This paper presents an overview of the background, concepts, basic methods, major issues, and current applications of Parallel transportation Management Systems (PtMS). In essence, parallel control and management is a data-driven approach for modelling, analysis, and decision-making that considers both the engineering and social complexity in its processes. The developments and applications described here clearly indicate that PtMS is effective for use in networked complex traffic systems and is closely related to emerging technologies in cloud computing, social computing, and cyber physical social systems.

Keywords: agents, intelligent transportation systems (ITS), mobile agent systems, multiagent systems

1 Introduction

In the European Union (EU), the majority of the population (72%) and economic development [85% of the gross domestic product (GDP)] concentrates in urban areas according to [1]. However, mobility in these areas is strongly constrained, i.e., by traffic and inefficient (private and/or public) transportation. These inefficiencies lead to congestion, pollution, noise, increased energy consumption, and the associated economic losses. For instance, in the USA, congestion wastes a massive amount of time, fuel, and money. i.e., 1.9 billion gallons of wasted fuel, 4.8 billion hours of extra time, and 101 billion dollars of delay and fuel cost [2]. In the EU, congestion costs 1% of the total GDP annually [3].

Recently, there has been significant interest and progress in the field of intelligent transportation systems (ITSs) from both industry and academia. The main contribution of ITSs is to significantly increase road safety. However, the role of infotainment has rapidly taken an important place [4]. The new emerging infotainment applications or safety-related mobile applications call for vehicular communication networks to support seamless wireless Internet services in fast-moving vehicles [5]. Internet access in automotive scenarios is a particularly relevant case, particularly because people in modern cities spend much time in transportation and vehicles. Public transportation systems, such as subways, suburb trains, and city buses, represent one relevant scenario because of a group of users and the time spent by these users in transportation and vehicles [6].

There are many challenges in conducting full-scale ITS research, particularly when vehicles are involved. For example, modifying conventional vehicles to autonomous vehicles is usually costly in terms of money and time. Testing in real traffic environments is usually dangerous. Such challenges have posed significant obstacles to many researchers in ITSs and forced them to use pure computer simulation [7], in which it is extremely hard to mimic certain aspects such as communication, vehicle dynamics, and driving experience. For many ITS research problems, a scale-down platform may be very useful for preliminary study and feasibility tests. However, there is very limited previous work in developing such a multipurpose ITS research platform. First, congestion has become an increasingly important issue worldwide as the number of vehicles on the road increases. For example, Beijing, China, had a total of 4 million vehicles at the beginning of 2010 and added another 800,000 in that year. Congestion can lead to an increase in fuel consumption, air pollution, and difficulties in implementing plans for public transportation [8]. It can also increase the risk of heart attack, as indicated by a medical report [9]. Second, accident risks increase with the expansion of transportation systems, particularly in several developing countries. Zheng et al. [10] showed that in China, there were 104,373 fatalities in 2003 and 67 759 fatalities in 2009. It was pointed out by Malta et al. [11] that almost three fourths of all traffic accidents can be attributed to human error. The reports published by the

* ***Corresponding author's*** e-mail: honglixiao_bc@126.com

U.S. Federal Highway Administration indicated that traffic accidents that happened in cities account for about 50%–60% of all congestion delays [12]. Undoubtedly, there is a need to reduce traffic accidents and to detect accidents once they have occurred to minimize their impact. Third, land resources are often limited in several countries. It is thus difficult to build new infrastructure such as highways and freeways. After the terrorist attacks in New York City on September 11,2001, the effectiveness of transportation systems is increasingly tied to a country's capability to handle emergency situations (e.g., mass evacuation and security enhancement) [13]. The competitiveness of a country, its economic strength, and productivity heavily depend on the performance of its transportation systems [14].

The domain of traffic and transportation systems is well suited to an agent-based approach because of its geographically distributed nature and its alternating busy-idle operating characteristics [15]. From the traffic and transportation management perspective, the most appealing characteristics of agents are autonomy, collaboration, and reactivity. Agents can operate without the direct intervention of humans or others. This feature helps to implement automated traffic control and management systems. Agents are collaborative. In a multiagent system (MAS), agents communicate with other agents in a system to achieve a global goal. Agents can also perceive their environment and respond in a timely fashion to environmental changes. Agent-based transportation systems allow distributed subsystems collaborating with each other to perform traffic control and management based on real-time traffic conditions. A distributed vehicle monitoring test bed presented in [16] is an early example of the distributed problem-solving network. Recently, more and more agent-based traffic and transportation applications have been reported. Our literature survey shows that the techniques and methods resulting from the field of agent system and MAS have been applied to many aspects of traffic and transportation systems, including modelling and simulation, intelligent traffic control and management, dynamic routing and congestion management, driver-infrastructure collaboration, and decision support. This paper reviews agent applications in traffic and transportation systems. These applications are classified into five categories: 1) agent-based traffic control and management sys-tem architecture and platforms; 2) agent-based systems for roadway transportation; 3) agent-based systems for air-traffic control and management; 4) agent-based systems for railway transportation; and 5) multiagent traffic modelling and simulation. The selected projects in each category are listed in a tabular format with information of project name, research group, application domain, and key features.

2 Related work

ITS aim to streamline the operation of vehicles, manage vehicle traffic, and assist drivers with safety and other information, along with provisioning of convenience applications for passengers [17]. In [18], these applications have been classified into three main categories: 1) safety-related applications (e.g., collision warning); 2) traffic efficiency and management (e.g., speed management); and 3) infotainment and entertainment (e.g., cooperative local services). In this paper, we will rather focus on traffic efficiency and management applications since these have a direct impact on traffic flow, vehicle coordination, and information dissemination. This last application type can be further subdivided into (as partly done in [19]): 1) speed management (provide regulatory or recommended contextual speed information to drivers to improve road efficiency); 2) navigation (information and services provided to drivers to assist in-vehicle routing); 3) road systems (e.g., traffic management systems); 4) vehicle control [e.g., adaptive cruise control (ACC)]; and 5) driver-related services (e.g., eco-driving).

Over the past decade, ITS technologies have greatly improved traditional transportation conditions, and improved the traffic capacity of the road network and transport security in China. In 1999, the National Engineering Technology Research Center of Intelligent Transportation System (ITS) was established. Many universities and research institutions also set up ITS Research Center to research ITS theories and technologies. The Tenth Five-Year period (2001-2005) first took the fields of intelligent transportation systems as content of the national planning. In 2001, China had selected ten cities as model cities for ITS field testing and evaluation. Those cities included Beijing, Shanghai, Guangzhou and so on [20]. During this period, many important aspects and key issues in ITS research and development were addressed on a high scientific and engineering level: agent-based and vision-based technologies; traffic modelling, control, and simulation; communication and location-based services; and driving safety and assistance, etc. For instance, the digital bus station systems has come into use in many cities, such as Beijing, Guangzhou, Chongqing, Shanghai, Hangzhou, Shenzhen, Nanjing, Shenyang, etc. Many information technologies of this system, such as computer control technology, wireless network communication technology and LED display control had been completely developed. During the Eleventh Five-Year period (2006-2010), ITS had more opportunity to develop, especially in transport services for major international events. Olympic traffic management command and control system was established in Beijing in 2008. Which include bus operations management system, floating vehicle dynamic traffic information collection processing and publishing systems. These systems have four major functions: command, signal control, integrated monitoring and regional traffic optimization. The systems comprehensively support Beijing public security traffic management work in 2008 Olympic.

3 Simulation based ITS

The operation of agents is supported and managed by distributed software platforms known as agent systems. The name of MASs usually refers to systems that support stationary agents, and mobile agent systems support mobile agents. An agent system provides mechanisms for agent management, agent communication, and agent directory maintenance. A mobile agent system provides additional mechanisms to support the migration and execution

of mobile agents. In an agent system, agencies are the major building blocks and are installed in each node of a networked system, in which agents reside and execute. To facilitate the interoperation of agents and agent systems across heterogeneous agent platforms, agencies designed to comply with agent standards are highly desired.

The integration of a driving simulation and traffic simulation environment may be achieved by implementing a communication structure that can effectively exchange data between the two applications (see Figure 1).

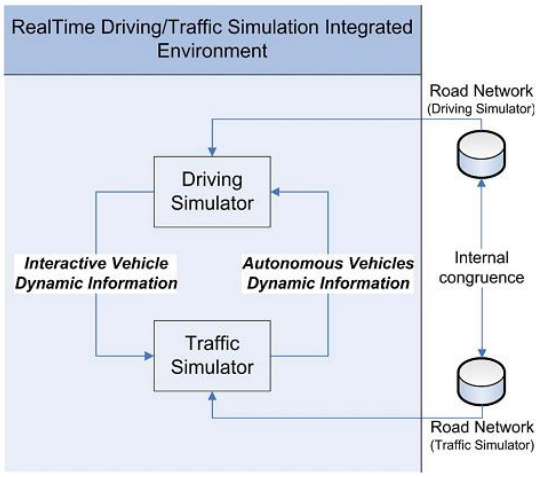

FIGURE 1 Communication framework

The integrated environment has to ensure that, during the driving simulation, the autonomous vehicles are consistently moved by the traffic microsimulation model with the movements of the interactive vehicle. Furthermore, during the simulation, the software that manages the driving simulator needs to send the kinematic characteristics of the interactive vehicle (e.g., position, angle, and speed) to the traffic-simulation model. Once such information has been received, the traffic-simulation model can calculate kinematics of the surrounding traffic for the step ahead and send them back to the driving simulation environment, which has the task of updating this information in the driving scenario.

To implement the communication framework, it is necessary to tackle several issues, which are summarized as follows. Accurate Road Matching Between Traffic and Driving Modules: The first issue for integration is the consistency between the road networks: Position related data to be exchanged have to be framed within a well-known reference system to allow appropriate conversion between the two environments during communication. The two road networks thus have to exactly match to have strict correspondence between the two simulation environments.

With regard to the first aspect, there is a simple way of overcoming the problem. Network creation usually starts in both software applications with importing the road alignment. Both types of applications should import drawing files (.dwg) or shape files (.shp). Thus, it is only important to avoid any transformation of geographical information during the import process to ensure the consistency of the two reference systems. This way, data retrieved by the two environments are ready to be exchanged. As for the road matching problem, this case is mainly because a driving simulator requires very detailed road geometry to present the road as realistically as possible for the driver, which is obviously far from the purposes of a microscopic traffic simulator, where, in most cases, for instance, the road alignment curvature, even when represented in detail, does not affect vehicle behavior.

Synchronization of Traffic and Driving Modules with Real Time: As aforementioned, the communication framework has to allow real-time data exchange required to perform a driving simulation. Unlike the driving simulation engine, traffic microsimulators are not designed to work in real time, but according to the hardware performance and scenario complexity, they try to perform all the needed calculations in the shortest time. This condition means that the time needed for a simulation is usually shorter than the real time and generally involves the need to slow down the computing speed of the traffic-simulation package. However, if the amount of data to be exchanged is large, the traffic module may slow down to less than real time. This case would naturally rule out any chance of successfully integrating the modules.

Consistency of the Updating Calculation Frequency: Each simulation model performs calculations at a given frequency. The finer the desired outputs are, the higher the updating frequency of calculations becomes. Both the microscopic traffic-simulation model and driving simulation software work this way. The difference is that the minimum simulation step in traffic simulation is usually 0.1 s, whereas realistic visualization in a driving simulation environment needs information to be updated at a higher frequency (generally 60 Hz). Therefore, if higher simulation frequency is not allowed by the microsimulation software (or it would slow down the simulation speed to below the real-time speed), outputs have to be augmented, e.g., through interpolation. Management of Autonomous Vehicle Visualization: This issue is twofold. First, a microscopic traffic simulation can manage thousands of vehicles at the same time. The management of such a large number of vehicles in a driving simulation environment is unfeasible for the aforementioned real-time issue and useless for driving simulation purposes. Hence, only the information of vehicles that surround the interactive one is exchanged during the simulation, which can be done by defining a "bubble" around the interactive vehicle. It is thus necessary to create, on the one hand, a vehicle in the traffic model to reproduce the movements of the interactive vehicle (maneuverer by the driving simulator) in the traffic simulation environment.

On the other hand, in the driving-simulation environment, a certain number of "ghost" vehicles have to be created, which come into action when some vehicles enter the bubble in the traffic simulation. When a vehicle enters the driving simulation, a clear one-to-one correspondence has to be created with the corresponding one in the traffic simulation. More specifically, as long as a vehicle in the traffic simulation stays within the surroundings of the interactive vehicle, it always has to be represented by the same vehicle in the driving simulation. Both aspects of this issue have to specifically be dealt with and, depending on

how the solutions are implemented, can seriously affect the possibility of having a real-time data exchange. The aforementioned issues do not constitute the exhaustive list of problems to deal with when implementing integration. They are, however, the most basic issues to obtain an effective framework. Additional issues may arise, depending on the particular driving and traffic simulation models used, as well as on the particular strategy adopted. The framework implemented in a particular case study, and the way in which such issues have been taken into account are shown as follows.

4 System Architectures and Operation Process

4.1 SYSTEM ARCHITECTURE AND OPERATION PROCESSES

Figure 2 presents the system architecture of ACP-based PtMS. It should be pointed out that normally, there is more than one ATS used in parallel traffic control and management. For example, different ATS can be created, respectively, for the purposes of historical traffic situations, normal and average performance, optimal and ideal operations, or worst-case scenarios for disasters and emergency management. Through interaction and parallel operations between an actual transportation system and its corresponding multiple ATS, the effectiveness of different traffic strategies under various conditions and expectations can be evaluated and analysed, both offline and online, and useful information can be obtained timely and combined to generate and select decisions for control and management.

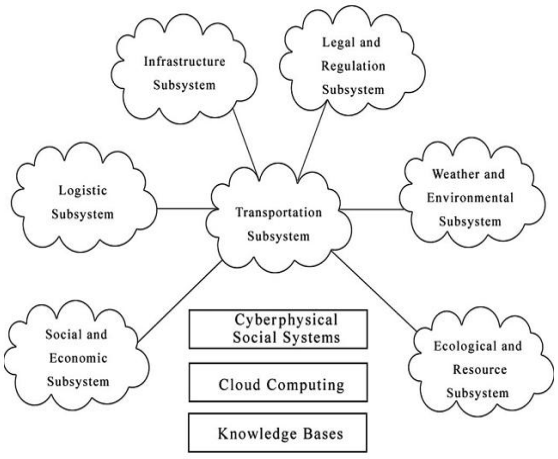

FIGURE 2 Scope, framework, and facilities of ATS

Typically, PtMS consist of five major components: 1) actual transportation systems; 2) ATS; 3) traffic operator and administrator training systems (OTSt); 4) decision evaluation and validation systems (DynaCAS); and 5) traffic sensing, control and management systems (aDAPTS). The operation process of PtMS is based on the co-evolution of real systems and the corresponding ATS. The operation process can be divided into three modes: 1) training; 2) testing; and 3) operating. General operational procedures can be derived from the functional specification of operating systems OTSt, Dyna CAS.

4.2 TRAINING AND LEARNING

Operator Training Systems for transportation (OTS) is developed for learning and training mode operations for traffic operators and administrators. The use of OTS was partially inspired by the applications and success of operator training simulation in many other advanced and complex industrial operations, such as in petrochemical production processes. Task requirements and procedures for both regular traffic operations and emergency situations are incorporated into OTS in order to make its functionality more useful and closer to reality. Sessions by OTS can be generated manually by human operators or automatically by agent programs. Manual sessions are also used to collect behavioral data from trainees and learners. Using agent-based behavioral modelling, automatic sessions can be employed when conducting accelerated testing and evaluation on the reliability and effectiveness of traffic operational procedures and regulations.

4.3 TESTING AND EVALUATION

Dynamic network assignment based on Complex Adaptive Systems (DynaCAS) is constructed to design, conduct, evaluate, and verify computational transportation experiments, detect existing and emerging traffic patterns, and support the use of advanced traveler information systems, advanced traffic management systems, and other ITS modules. DynaCAS facilitates the estimation and predication of traffic network conditions, performance testing and evaluation of different traffic control and management measures and information dissemination strategies, and decision support to traffic operators and individual drivers. Using ATS, DynaCAS is able to pay special attention to rule-based computational modelling of the social and behavioral aspects of people, vehicles, roads, and environments involved in transportation activities. In addition to conventional microscopic, mesoscopic, and macroscopic specification, a level of logic representation has been introduced in DynaCAS to represent the transportation networks so that factors in social and economic, ecological and resource, construction and infrastructure, logistical, legal, and regulatory aspects can easily be incorporated. On the logic level, transportation modelling extensively employs qualitative information in linguistic forms, and computing with words and methods in linguistic dynamic systems is used to achieve quantitative analysis. Data-mining techniques are also used to discover useful patterns from simulation results and computational experiments on all levels. Compared with other traffic estimation and predication systems (TrEPS), such as the well-known DynaSMART and DynaMIT, methods in AI and complex systems are much more extensively used in DynaCAS to provide additional flexibility and efficiency in traffic-condition analysis and decision evaluation.

4.4 CONTROL AND MANAGEMENT

Agent-based Distributed and Adaptive Platforms for Transportation Systems (aDAPTS) is built to provide supporting and operating environments to design, cons-

truct, manage, and maintain autonomous agent programs for various traffic tasks and functions. Those agents are delivered to traffic-control centers, roadside controllers, sensing devices, and information systems via communication networks to make the right decisions and collect the right information at the right time. We have designed and manufactured special intersection light controllers and sensing systems that are capable of hosting and processing traffic-control agents for different functions. Generally, an agent can autonomously move in networked environments, identify its tasks, and actively improve its performance. Transitioning from traffic-control and management algorithms to traffic-control and management agents is a natural step forward in this age of networks and connectivity. This step enables an intelligent and proactive mechanism that will significantly improve the performance and reliability of traffic operation control and management, yet it will have low cost for networked transportation systems.

Traffic task agents can be distributed at different operating centers and information sites. To ensure a coherent control and communication mechanism among those agents, we must integrate and coordinate their objectives and activities. A hierarchical intelligent control architecture consisting of organization, coordination, and execution levels has been used to facilitate the activities and operations of traffic agents, which is shown in Figure 3.

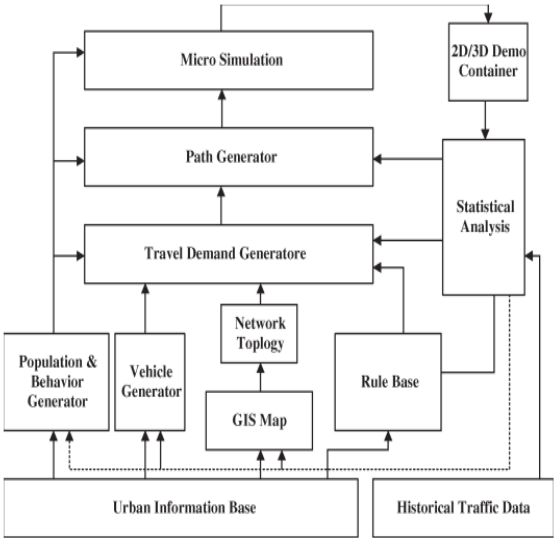

FIGURE 3 System architecture and components

InaDAPTS, a global traffic operating center (GTOC) (virtual or real) is designed to construct, organize, and maintain different types of agents for various traffic tasks, such as intersection light control, traffic-incident detection, and route guidance. WANs link the GTOC to several regional traffic-operating centers (RTOC), which host various agent repositories for regional demands and requirements of traffic control and management. RTOC coordinate and dispatch traffic agents to thousands of intersection light controllers, ad hoc networks, display devices, and guidance equipment at hundreds of locations. At each location, a gateway downloads task agents from WANs to traffic controllers, sensors, displayers, etc. through LANs and uploads information and requests from traffic devices to RTOC. Each location also has an agent coordinator to conduct cooperative control and management among traffic devices and within an individual device. Clearly, there is a natural link between PtMS and CPS, CPSS, and cloud computing. For example, CPS can be used to implement smart intersection traffic-control systems via aDAPTS, CPSS can be employed to build ATS in cyberspace and construct intelligent web-based DynaCAS and OTS t, and cloud computing is a cost effective way to host and operate the entire PtMS.

5 Conclusions

Road transportation is one of the main sources of greenhouse gas emissions, which lead to global warming and climate change. Promoting the decarbonization of this sector through more efficient and greener mobility is a challenging task that can be achieved by intelligent transportation systems (ITS) enabled by vehicular communications. Intelligent Transportation Systems (ITS) have been developed for more than ten years in China. Furthermore, a new generation Intelligent Transportation Systems should be launched to meet the requirement of rapid development of transportation in China. For the last two decades, intelligent transportation systems (ITS) have emerged as an efficient way of improving the performance of transportation systems, enhancing travel security, and providing more choices to travellers. A significant change in ITS in recent years is that much more data are collected from a variety of sources and can be processed into various forms for different stakeholders. This paper presents an overview of the background, concepts, basic methods, major issues, and current applications of Parallel transportation Management Systems (PtMS). In essence, parallel control and management is a data-driven approach for modelling, analysis, and decision-making that considers both the engineering and social complexity in its processes. The developments and applications described here clearly indicate that PtMS is effective for use in networked complex traffic systems and is closely related to emerging technologies in cloud computing, social computing, and cyber physical social systems.

Abstract

A new method is proposed to enhance robustness of complex supply chain network structure in uncertain conditions of market, costs and others. The researcher constructs the topology of a supply chain network firstly, and then explains the concept of central nodes of network and robust supply chain network based on scale-free network model from the perspective of quality control and places research emphasis on the method of enhancing the robustness of complex supply chain network structure. Finally, the supply chain network of auto parts enterprises in Zhejiang Province is cited as an example to verify the validity of the method.

Keywords: supply chain network, network quality control, scale-free network, robustness

1 Introduction

With the increasingly fierce market competition and complex economic environment changes such as variation of the users' needs, the uncertainty of the supply chain is more and more prominent; however, the uncertainty may arise from within the supply chain such as demand, production, sales, management, and operation [1]. Robustness of the supply chain is a universal basic attribute of it. Robustness is the ability to maintain the functions of its system when faced with changes in the internal structure or external environment. At present, a group of scientists led by Dirk Helbing found in the study of complex supply chain network that bullwhip effect in supply chain management is relevant with the topological properties of network [2,3]. This paper focuses on construction of a robust supply chain network under uncertainty, modeling analysis of complex supply chain network based on network static geometric quantities and analytical methods in graph theories and social network analysis, and exploration of the geometric properties of the network topology, robustness of the structure, dynamic robustness in the process of network evolution, etc. from the perspective of the quality control based on statistical principles and analytical method.

However, there are no existing studies on complex supply chain network topology and its robustness in the process of evolution under uncertainty. Most studies only point out the robustness and vulnerability according to the nature of the complex network [4-6]. Research on the complex supply chain network at home and abroad is mainly about supply chain adaptability analysis based on the complexity theory and knowledge sharing between the nodes of the supply chain companies [7-9], without taking the properties of the complex supply chain network topology under uncertainty into consideration. Complex supply chain network modeling based on network graph theory clearly shows the relationship between the enterprise nodes within the supply chain network [10], but can't express explicitly the robustness and vulnerability of the supply chain network. As a matter of fact, the robustness of the supply chain network is not only related to and the stability of the node enterprises in the supply chain but also to the structure of the supply chain network.

2 Construct scale-free supply chain network

Uncertainty is in most of the supply chain system. Robustness, a universal basic attribute of the uncertainty of a supply chain network, is the ability to maintain the functions of its system when faced with changes in the internal structure or external environment. The system of the supply chain develops from scratch gradually. The supply chain network, which is spontaneous and market-driven, has strong uncertainty. Currently, some scholars at abroad have found in the supply chain bullwhip effect – the amplification effects are all related to the supply network topology. Therefore, the effective supply network topology can weaken the bullwhip effect while enhance the stability and resistance to attack of the complex supply chain network.

First, we build a complex supply chain network modeling; the modeling process is shown in Figure 1:

FIGURE 1 Complex supply chain network modeling process

[*]***Corresponding author's*** e-mail: xuxing3220@163.com

The formation, development and changes of the complex supply chain network can be seen as the result of interactions between the elements of the supply chain system and the external environment. Supply chain network is not just supply chain management of a single enterprise, but a complicated Multi-layer industry supply chain network. The construction method is as follows: the different business entities in the supply chain are taken as the network nodes, and the connections between the enterprises as the edges of the network. The edge direction is from the higher-level enterprise to the lower-level one; the edge weight is the number of the child nodes contained in the parent node, which is shown in Figure 2.

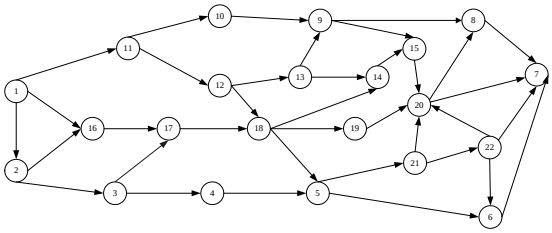

FIGURE 2 Supply chain network topology

In the supply chain network topology diagram shown in Figure 2, indegree refers to the number of edges pointing to the node, and outdegree refers to the number of edges starting from that point. We assume that x represents the node of complex enterprise cooperation network, and r represents the edge between the nodes in the network. i and j stand for any two nodes in the network. If there is an edge between i and j, the enterprise i and enterprise j are in cooperative relations, which is represented as $r(i, j)=1$. If N is the total number of the nodes in the network static statistics, the corresponding static statistics of the enterprise cooperation are defined as follows:

1) Degree of node: it is the number of edges the node connects with:

$$k_i = \sum_{i,j}^{N} r(i, j) . \tag{1}$$

2) Average path length of node: the distance between i and j in the network is d_{ij}, which is the number of the edges on the shortest path connecting the two nodes, namely:

$$L = \frac{1}{\frac{1}{2}N(N+1)} \sum_{i \geq j} d_{ij} , \tag{2}$$

where N is the number of the nodes in the network.

3) Clustering coefficient: it is the parameter used to measure clustering situation of a node. We assume that i has k_i edges in the network, then the number of the edges between these k_i nodes may be up to k_i (k_i–1)/2. The ratio of E_i (the actual number of edges) between these k_i nodes and k_i (k_i–1)/2 (the total possible number of edges) is defined as the clustering coefficient of the node:

$$C_i = \frac{2E_i}{k_i(k_i - 1)} . \tag{3}$$

Compile network processor based on the constructed supply chain network topology, and the aforementioned statistic eigenvalues of each node in the network can be achieved by applying the formulas mentioned above. Assuming that k_i (the degree of each node) is as shown in Table 1, the clustering coefficients of these nodes obtained by using Equation (3) are as follows.

TABLE 1 Node degree and clustering coefficient

No.	k_i	C_i	No.	k_i	C_i
1	3	0.06	12	1	0.00
2	22	0.01	13	1	0.00
3	1	0.03	14	23	0.00
4	1	0.00	15	45	0.07
5	39	0.09	16	8	0.13
6	56	0.12	17	4	0.02
7	86	0.15	18	5	0.01
8	1	0.13	19	12	0.01
9	12	0.00	20	23	0.02
10	112	0.04	21	20	0.04
11	1	0.04	22	1	0.03

By computing the clustering coefficient of each node in the supply chain network, it is found that the node with high node degree also has a high clustering coefficient; by performing statistical analysis on the distribution probability of each node degree, it is found that most nodes have a small number of connections in the network while a few nodes have a large number of connections, and there is no peak in the probability distribution of these node degrees, indicating that the node degree distribution follows the power-law distribution, in line with the characteristics of scale-free network.

3 Robustness analysis of the supply chain network under uncertainty

3.1 MODE AND FEATURES OF THE SUPPLY CHAIN UNDER UNCERTAINTY

The uncertainty of the supply chain contains two types. One is the uncertainty of the outer join. In scale-free supply chain network, partners often opt to quit due to reasons of their own. Such event, though occurs randomly, is considered to be attack on the network. For instance, the partners drop out of the supply chain network because they are in shortage of funds or stop producing some models of products. The other is uncertainty of emergency. Due to fierce market competition and inner motivation of achieving maximum interests, some important suppliers (i.e., core node) in the supply chain network are tempted by high profit from some other enterprises and some other enterprises or units are interested in inviting some important experienced intermediary retailers to enter into their network. Once these important suppliers and retailers are off the network, they will inevitably give a crushing blow to the core enterprises in raw material supply and sales of products. This is what vandalism means.

When the supply chain network is in uncertain conditions, the robustness of the scale-free supply chain network can be interpreted as: when a node in the network is des-

troyed, it continues to maintain its operational capacity, without causing significant impact to the entire network. A node which brings a catastrophic failure to the network when subjected to random external attack is judged to be unqualified. In accordance with the principles of quality control, only when the failure rates of the network nodes are all less than some expected number, this network is considered to be robust. Although Barabasi and some other scholars have pointed out that scale-free network shows unusual robustness when the node is under random attack [11,12], it is vulnerable to attack and leads to damage of the entire network. The robustness of scale-free supply chain network under conditions of uncertainty is to be analyzed from the perspective of network quality control in the following.

3.2 DEFINE THE CENTRAL NODE IN THE SUPPLY CHAIN NETWORK

First ($V(t)$, $E(t)$) represents a random complex supply chain network. $V(t)$ is a node set of the supply chain network at time t, that is, all enterprises in the supply chain; $E(t)$ is an edge set of the enterprises' nodes at time t; $N(t)$ is the number of enterprises in the network at time t; $E(N(t))$ is the average of the enterprises in the network at time t; $k_i(t)$ is the degree of the enterprises at time t; $P\{k_i(t)=k\}(k=1,2,...)$ is the degree distribution of enterprises at time t.

According to the robustness of the scale-free supply chain network, the central node of the scale supply chain network is defined firstly:

The central node of the scale-free supply chain network is defined as: if A and B are two proper subsets of $V(t)$, $A\neq\Phi$, $B\neq\Phi$, $A,B\subset V(t)$, $A\bigcup B=V(t)$, $A\bigcap B=\Phi$, $K>0$, when $k\geq K$, $\forall t>0$, $\forall i\in A$, $j\in B$, so that $P\{k_i(t)\geq k\}>P\{k_j(t)\geq k\}$, then A is named the central node of the scale-free the supply network. These nodes are the core enterprises in the supply chain.

3.3 DEFINITION OF ROBUST SUPPLY CHAIN NETWORK

This paper draws on SPC (Statistical Process Control) theory in quality control and mathematical statistical analysis theory to monitor and control the degree distribution of each node in the supply chain network, in order to realize the real-time regulation on node degree distribution and reduce variation of the robustness of the supply chain network. In the event that abnormal situation occurs to the central node of the network, i.e., the degree of the node exceeds the safety threshold σ, measures must be taken immediately to adjust it so as to ensure steady operation of the entire supply chain network [13].

The robust supply chain network refers to the network which is still able to maintain its functions when some nodes or edges in the network are under random attack. $p(t)=|A|/E(N(t))$ and $|A|$ is the potential of the set A. If $p(t)<\varepsilon$ and $\varepsilon\in(0,1)$, the failure rate of the central nodes in the network is less than the expected number ε. Such network ($V(t)$, $E(t)$) has certain robustness. The degree of each node in the supply chain network is often used in the study to facilitate the statistical analysis of robustness. In scale-free supply chain network, the degree of the central node is always very high, however, if it goes beyond a certain range and comes under attack, the entire network may malfunction. In accordance with quality control principles, the degrees of all nodes in the network are desired to be within the safety threshold. This kind of network has definite robustness [14,15].

The safety threshold is σ is divided into upper control limit σ_{UCL} and lower control limit σ_{LCL}, average is T, then:

Upper control limit: $\sigma_{\mathrm{UCL}}=T+A_2R$,

Lower control limit: $\sigma_{\mathrm{LCL}}=T-A_2R$,

where R is the average of the range of each node; A_2 is a constant. They vary with n (sample size). Please refer to Xbar-R coefficient table for the parameter values. In Table 1, n=22, A_2=*0.634*.

Therefore, for degree distribution of each node in the supply chain network, MSA (measurement system analysis) in SPC software is used for experimental statistics of the 24 subgroups. The following results can be obtained: control coefficient is 0; controls parameter: both upper control limit and the lower control limit are 22.27; stability judgment: the average number beyond the control limit is 8, which is judged to be unacceptable. Figure 3 is a diagram for stability analysis, from which the nodes beyond the control limits can be checked at any time.

4 Enhance the robustness of the supply chain network

Although the supply chain network is robust for random failure in the process of continuous preferential growth, it can't be ignored that the network is also vulnerable to attack. As long as the external attack impacts on the central high degree node, namely, the core enterprise in the supply chain network, it will lead to a destructive failure of the entire supply chain network, resulting in paralysis of the network. Therefore, how to enhance the stability of the network is essential. Two methods of enhancing the robustness in the process of supply chain network growth will be introduced in the following.

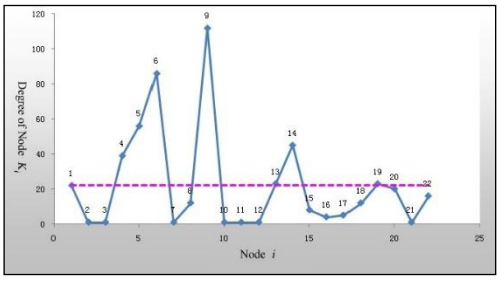

FIGURE 3 Diagram for stability analysis

4.1 CHANGE THE PREFERENTIAL MECHANISM

The first method: in the formation process of the entire supply chain network, the traditional way is to change the growth mechanism of the network so as to form a small-world network in the future development, in order to improve the stability of the entire network. In this paper, the referential mechanism is changed on the basis of two mechanisms growth mechanism and preferential attachment mechanism that the scale-free network follows so as to form a new network topology of exponential degree distribution. Network production model is as follows:

1) Growth: start from a network with m_0 nodes. Each time a new node is introduced, it is connected to m existing nodes, where $m \le m_0$.

2) Priority connection: the probability that a new node is connected to an existing node in the network i at time t is:

$$\prod_i(t) = 1/(m_0 + t - 1). \quad (4)$$

It is clear that in the network generated by the above-mentioned growth mechanism, the connection probability of its nodes has nothing to do with node degree. According to probability theory, the average degree distribution is $p(k) = \frac{e}{m} e^{-\frac{k}{m}}$, showing that its network nodes are exponentially distributed, so the role of core node in the network is weakened. Because of that, there is no major attack point in the entire network and the stability of the network is enhanced.

4.2 THE DYNAMIC ADJUSTMENT MODEL

The second method is: after an old node drops out, a new comparable point must be quickly found out to replace it. This requires real-time monitoring of the each node in the supply chain network to make different judgments in different situations.

1) In the operation process of supply chain network, a node may apply to quit the supply chain network due to some reason;
2) A node can't offer enough products because of its limited production capacity;
3) After a period of operation of the supply chain network, the clients' demand increases suddenly and the original supply chain network cannot satisfy the customers in time, quality and quantity;
4) After a period of operation of the supply chain network, the clients' demand decreases suddenly and the original supply chain network has overcapitalization, resulting in increase of operating costs in the supply chain network.

According to the aforementioned four situations, a dynamic adjustment model of scale-free supply chain network is constructed as follows, shown in Figure 4.

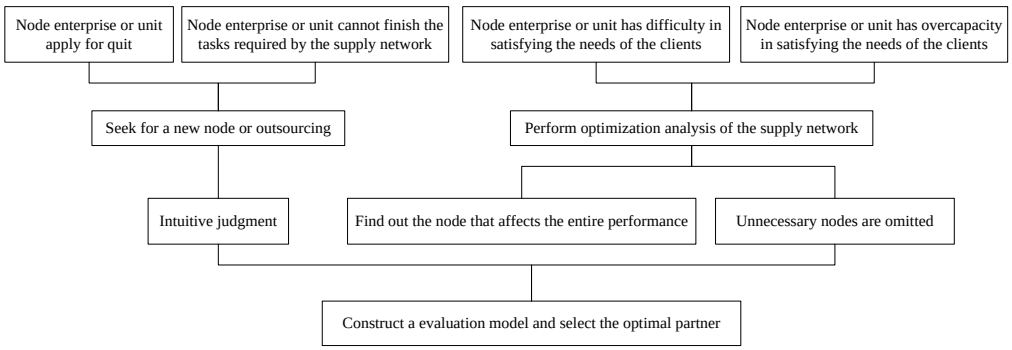

FIGURE 4 Scale-free supply chain network dynamic regulation model

The entire network needs to be adjusted continuously in the operation process. Only when the adjustment is finished and the new tasks of the adjusted supply chain network have been coordinated, can the new network realize effective conversion and start operation of new supply chain network. In this way, anti-risk capacity of the supply chain network is enhanced.

5 Application examples

Considering that components and parts of automotive industry have a wide range of distribution and are used in large quantity currently, auto parts enterprise clusters in Zhejiang province are taken as the object in this example, in order that automobile manufacturers can better manage the auto parts suppliers. By taking into account of various factors, with Matlab as the development tool, the researcher intuitively simulates the network distribution of the suppliers of automobile parts and motorcycle parts industry by studying the node degree distribution and random generation of point and edge, displays the central node of the supply chain network through the degree distribution of each node in the network, and checks if there are abnormalities in node distribution through network robustness test.

Here the information of 102 auto parts suppliers obtained from purchase department of China Youngman Automobile Group is taken as examples. We assume that the growth characteristics of the supply chain network are as follows: the initial number of nodes of the supply chain m_0=20; each time a new node is introduced, the number of

newly generated edges m=5; network size after growth N=102; network, m_0 nodes in the network are all isolated when the network is initialized.

Figure 5 is a diagram for supplier network topology generated by Matlab simulation software:

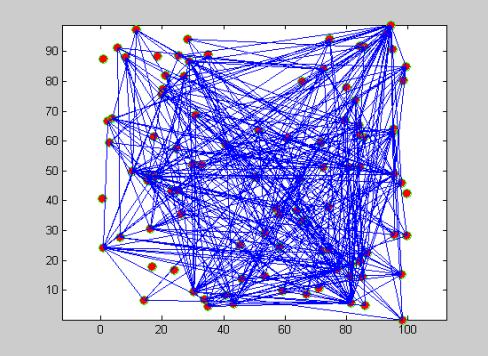

FIGURE 5 Diagram for network distribution

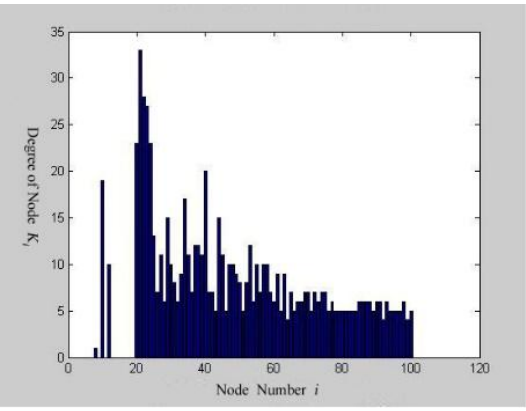
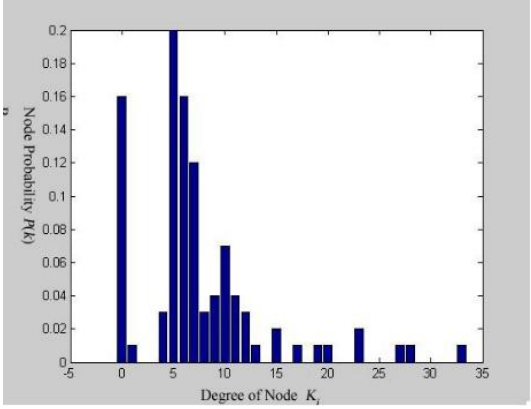
5.1 NETWORK DEGREE ANALYSIS

After growth in the above pattern, MATLAB program is used for statistics and analysis of the degree and distribution of each node. The final output of degree distribution and probability distribution of each node is shown in Figure 6.



a) Node degree distribution



b) Node probability distribution

FIGURE 6 Node degree distribution and node probability distribution

In Figure 6, there are 17 nodes with degree 5, 14 with degree 6, 10 with degree 7, 1 with degree 27, 1 with degree 28, 1 with degree 29, and 10 with degree 0. it shows that only few nodes have a high degree, for example, node 21, 22, and 23 meet the conditions in $P\{k_i(t) \geq k\} > P\{k_j(t) \geq k\}$ and become the central nodes of the supply chain network.

5.2 NETWORK ROBUSTNESS ANALYSIS

Previous data proves that the vast majority of nodes in the supply chain network have only a few connections, in line with the characteristics of scale-free network. By degree analysis of each node in Figure 3 and MSA analysis of degree distribution of the entire supply chain network, a few nodes have significantly exceeded the upper control limit. Therefore, if these enterprises are destroyed, the entire auto parts supply chain network will suffer a devastating injury. Attack on node 21, 22, or 23 will have an impact on the whole auto parts supply, while attack on node 1 or 0 will not.

It suggests that the supply chain network has a strong immunity to general random errors in the continuous growth process, but the central node in the supply chain network must be protected in order to maintain the stability of the network consistently, and as a result, the random network is shown to be in a steady state.

6 Conclusion

When the supply chain network is faced with many uncertain conditions, it is simple and intuitive to describe the supply chain network with the complex network theory. The theory of complex networks is a feasible method to complex supply chain network topology construction. The scale-free supply chain network is analyzed with emphasis through statistical analysis on each enterprise node in the supply chain network. The scale-free supply chain is observed from the perspective of quality control, and thus to propose the definition and quantitative analysis method of the robust supply chain network, providing a more scientific basis for scale-free analysis of the supply chain network. On that basis, two network optimization methods of enhancing the stability of the supply chain are proposed. Finally, practical examples show that the combination of network of quality control principles and complex network theory is a more practical and effective research method.

Housing price forecast based on rough-set extreme learning machine

Benxue Wang*

Institute for Economic and Social Development, Quzhou University, Zhejiang, 324000, China

Received 1 March 2014, www.cmnt.lv

Abstract

The work, based on various factors affecting housing price in 31 provinces cities as research object, firstly adopted rough set theory to reduce those factors. Then, the main reduced influence factors were used as the input of extreme learning machine. On such basis, the housing price forecast model based on rough-set extreme learning machine was ultimately established. According to the simulation results, the algorithm in this work has good prediction effect, and its prediction precision is higher than that of BP neural network and RBF neural network. Therefore, this algorithm, with a certain practical and theoretical value, can be promoted to other areas for predication and classification.

Keywords: rough set theory, neural network, extreme learning machine, real estate, forecast error

1 Introduction

At present, Chinese real estate industry is booming rapidly, which is beneficial to the sustainable development of current economy and the increase of GDP. However, housing price has become the focus of government and the burden of people's life due to the high price of current commodity house. Too-high housing price becomes a huge threat to social stability and harmony. Therefore, studying the influence factors of housing prices contributes to the formulation and implementation of policies, with positive significance to the control of housing price.

Many famous experts and scholars have conducted researches on housing price. In 2002, Qiao Zhimin and his team did some researches on the fluctuation of housing price, finding out that the fluctuation of production cost affected the fluctuation of real estate price. In 2004, Ju Hong analyzed the influence of the holding cost and production cost on the price of commodity house. In the same year, Ping Xinqiao and Chen Minyan empirically analyzed the relationship of real estate investment, commodity house sale price, land price and government credit functions.

In 2004, Shen Yue and Liu Hongyu, adopting sample regression and city annul dummy variable, put forward the hypothesis that commodity house was not in conformity with the efficient market in China.

In 2007, Duan Zhongdong analyzed the relationship between real estate price and inflation output based on real estate data of China, discovering that inflation output contributed to the rising of housing price.

In 2012, Peter Wallstrom and his team applied support vector machine algorithm to real estate price evaluation, and the simulation effect was superior to the effect of other methods.

In 2013, W.K.Wong,Z.X.Guo and some other experts combined extreme learning machine with intelligent algorithm, and put forward housing price forecast model based on genetic-algorithm extreme learning machine.

2 Combined algorithm of rough set and extreme learning machine

2.1 ALGORITHM IDEA

The work combined rough set with neural network due to their strong advantage complementary. Then, extreme learning machine neural network was used to forecast housing price after the reduction of influence factors of housing price. Following that, a comparison analysis was conducted to extreme learning machine neural network and BP neural network and RBF neural network.

After the analysis of sample data, an initial information table was generated according to the known domain knowledge. Then, an appropriate discrete method was used to discretize continuous features, and rough set theory was adopted to achieve a quick feature reduction for the data. The reduced features were considered as input layer neurons. In the end, extreme learning machine neural network was applied to train and forecast the processed data. The process is shown as Figure 1.

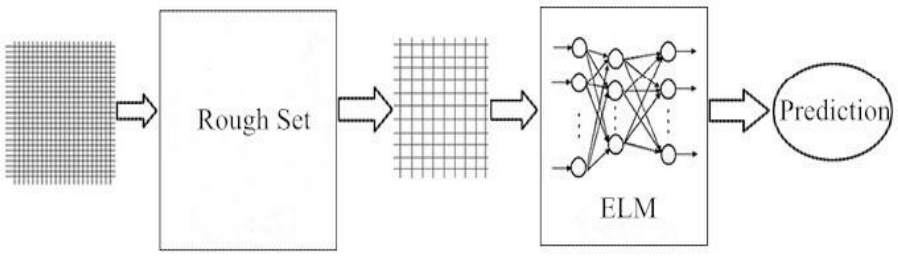

FIGURE 1 Process Diagram

2.2 ALGORITHM PROCESS

1) Discretization of Continuous Features: Continuous variables should be discretized before applying rough set method to data analysis. In essence, discretization is to divide N-dimensional space formed by condition feature into limited set of regions through selected breaking point, thus obtaining the same decision value of objects in each region.
2) Formation of Decision Tables: Quantized condition features and decision features were used to make a two-dimensional table with each line describing one object and each column showing one feature of corresponding object.
3) Reduction of Features: The reduction process of decision table feature is to eliminate unnecessary condition features of decision table system and figure out the decision principles of condition features in reduction to decision features.

Input: condition feature set $C = \{Y_{11}, Y_{12},\ldots, Y_{53}\}$, decision feature set $D = \{d\}$; output: reduction set of one feature REDU.

Step 1: Figure out the D positive domain $POSC$ (D) for condition feature C;

Step 2: As for feature $Y_{ij} \in C$, calculate and eliminate the D positive domain $POSC\backslash\{Y_{ij}\}$ (D) of its condition features subset $C\backslash\{Y_{ij}\}$;

Step 3: If $POSC\backslash\{Y_{ij}\}(D) = POSC$ (D), then feature Y_{ij} is unnecessary for decision feature D. Thus, it means $C = C\backslash\{Y_{ij}\}$ at this moment.

Go back to step 2; otherwise, the reduction of output feature REDU = C.

4) Reduction of Object: Eliminate inconsistent and redundant objects in data. Inconsistent objects are those with same condition feature but different decision features. Redundant objects are those with same condition features and same decision features.
5) Determination of Neural Network Model: The work adopted extreme learning machine neural network.
6) Network Learning and Testing: Choose corresponding training data and features from continuous features decision table according to neural network model input to train network and test it with corresponding test samples.

2.3 EXTREME LEARNING MACHINE NEURAL NETWORK

For N different samples $(\boldsymbol{x}_i, \boldsymbol{t}_i)$ where

$\boldsymbol{x}_i = [x_{i1}, x_{i2},..., x_{in}]^T \in \mathrm{R}^n$ and $\boldsymbol{t}_i = [t_{i1}, t_{i2},..., t_{im}]^T \in \mathrm{R}^m$, when the node number in one hidden layer is $\tilde{N}$, the unified SLFN model of activation function $g(x)$ will be:

$$\sum_{i=1}^{\tilde{N}} \boldsymbol{\beta}_i g_i(\boldsymbol{x}_j) = \sum_{i=1}^{\tilde{N}} \boldsymbol{\beta}_i g(\boldsymbol{a}_i \cdot \boldsymbol{x}_j + b_i) = \boldsymbol{t}_j, \quad j = 1,...., N, \quad (1)$$

where $\boldsymbol{a}_i = [a_{i1}, a_{i2},..., a_{in}]^T$ refers to the input weight of node connecting the i-th hidden layer; b_i the bias of i hidden layer nodes; $\boldsymbol{\beta}_i = [\beta_{i1}, \beta_{i2},..., \beta_{im}]^T$ the output weight of node connecting the i-th hidden layer; $\boldsymbol{a}_i \cdot \boldsymbol{x}_j$ the inner product of $\boldsymbol{a}_i$ and $\boldsymbol{x}_j$. The activation function can be "Sigmoid", "Sine" or "RBF".

The matrix form of N above functions can be: $\mathbf{H}\boldsymbol{\beta}=\mathbf{T}$, where

$$\mathbf{H}(\boldsymbol{a}_1,...,\boldsymbol{a}_{\tilde{N}}, b_1,...,b_{\tilde{N}}, \boldsymbol{x}_1,..., \boldsymbol{x}_N) = \begin{bmatrix} g(\boldsymbol{a}_1 \cdot \boldsymbol{x}_1 + b_1) & \cdots & g(\boldsymbol{a}_{\tilde{N}} \cdot \boldsymbol{x}_1 + b_{\tilde{N}}) \\ \vdots & \cdots & \vdots \\ g(\boldsymbol{a}_1 \cdot \boldsymbol{x}_N + b_1) & \cdots & g(\boldsymbol{a}_{\tilde{N}} \cdot \boldsymbol{x}_N + b_{\tilde{N}}) \end{bmatrix}_{N \times \tilde{N}},$$

$$\boldsymbol{\beta} = \begin{bmatrix} \boldsymbol{\beta}_1^T \\ \vdots \\ \boldsymbol{\beta}_{\tilde{N}}^T \end{bmatrix}_{\tilde{N} \times m}, \quad \mathbf{T} = \begin{bmatrix} \boldsymbol{t}_1^T \\ \vdots \\ \boldsymbol{t}_N^T \end{bmatrix}_{N \times m}, \quad (2)$$

$E(\mathbf{W})$ is the square sum of error between expected value and actual value. The problem solution is to figure out the optimal weight $\mathbf{W} = (\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{\beta})$, making cost function $E(\mathbf{W})$ minimum. Its mathematical model can be expressed as:

$$\begin{aligned} &\underset{\mathbf{W}=(\boldsymbol{a},\boldsymbol{b},\boldsymbol{\beta})}{argmin}\, E(\mathbf{W}) = \underset{\mathbf{W}=(\boldsymbol{a},\boldsymbol{b},\boldsymbol{\beta})}{argmin} \| \boldsymbol{\varepsilon} \|^2 \\ &s.t. \sum_{i=1}^{\tilde{N}} \boldsymbol{\beta}_i g(\boldsymbol{a}_i \cdot \boldsymbol{x}_j + b_i) - \boldsymbol{t}_j = \boldsymbol{\varepsilon}_j, \quad j = 1,..., N \end{aligned}, \quad (3)$$

where $\boldsymbol{\varepsilon}_j = [\varepsilon_{j1}, \varepsilon_{j2},..., \varepsilon_{jm}]$ is the error of the j-th sample.

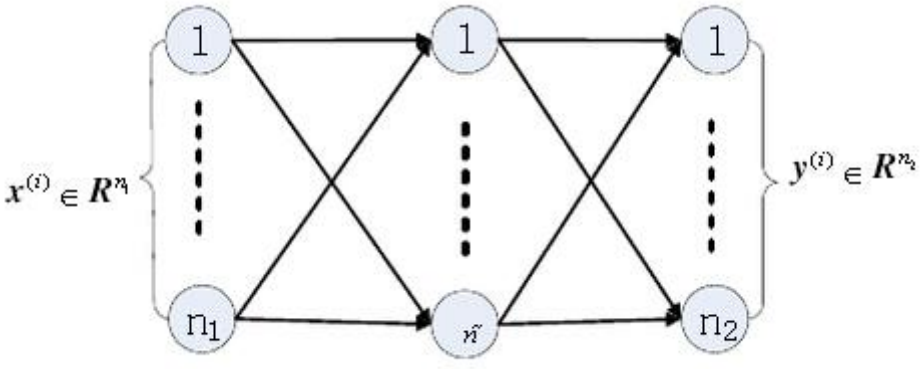

FIGURE 2 Extreme Learning Machine Schematic Diagram

3 Data sources

Data in this work, from *China Statistical Yearbook 2012*, cover all influence factors of housing price in 31 provinces, including building completion cost, land purchase expense, per capita disposable income, per capita GDP, population density, construction cost, consumer price index, land transaction price index and some other indexes.

There are various factors affecting housing price. Thus, this work firstly reduced those factors through rough set theory. Then, the reduced influence factors as the input and housing price as the output of extreme learning machine were applied to establish training model and forecast housing price. There are two sets of samples to validate the predication ability of extreme learning machine network: 31 training samples and 5 testing samples.

After rough-set reduction, the main factors affecting housing price refer to building completion cost, land purchase expense, per capita disposable income, per capita GDP and population density.

Figures 3-5 showed the predication results of extreme learning machine. Figure 3 represented the housing price forecast result of training samples, indicating a good predication and strong generalization ability. Figure 4 showed the forecast results of testing samples, mainly validating the effectiveness and correctness of extreme learning machine. It could be seen from the predication-error graph that the algorithm in this work has good prediction effect.

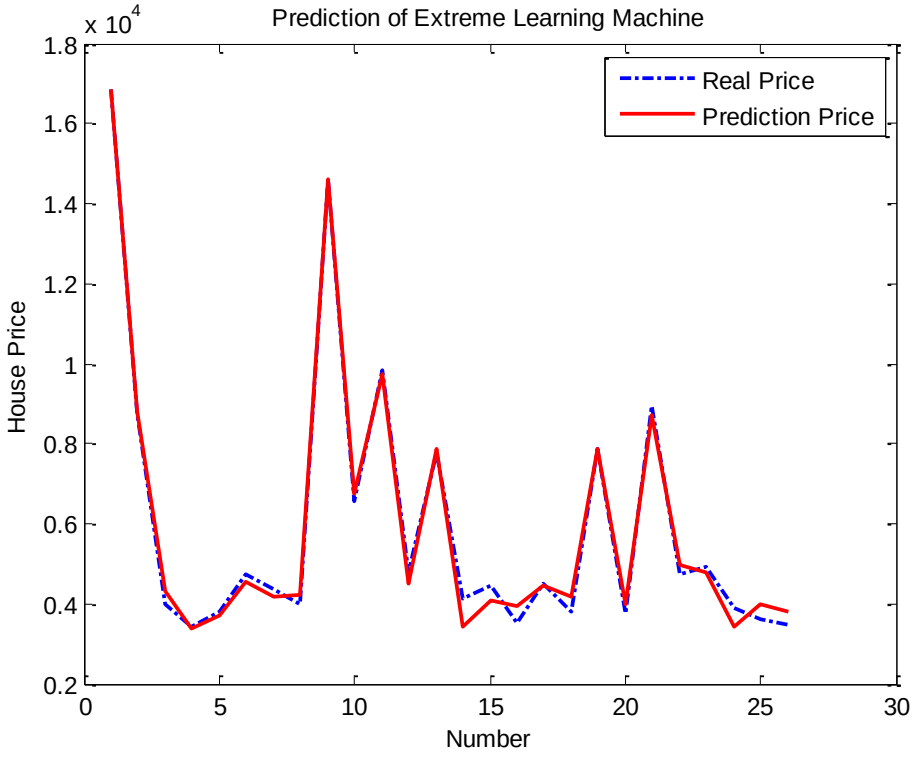

FIGURE 3 Housing Price Forecast Results of Training Samples Based on Extreme Learning Machine

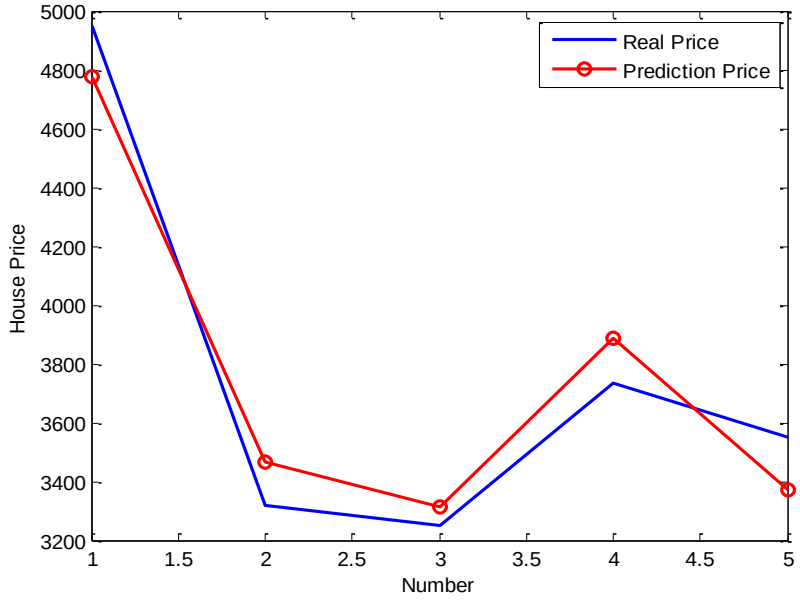

FIGURE 4 Forecast Results of Testing Samples Based on Extreme Learning Machine

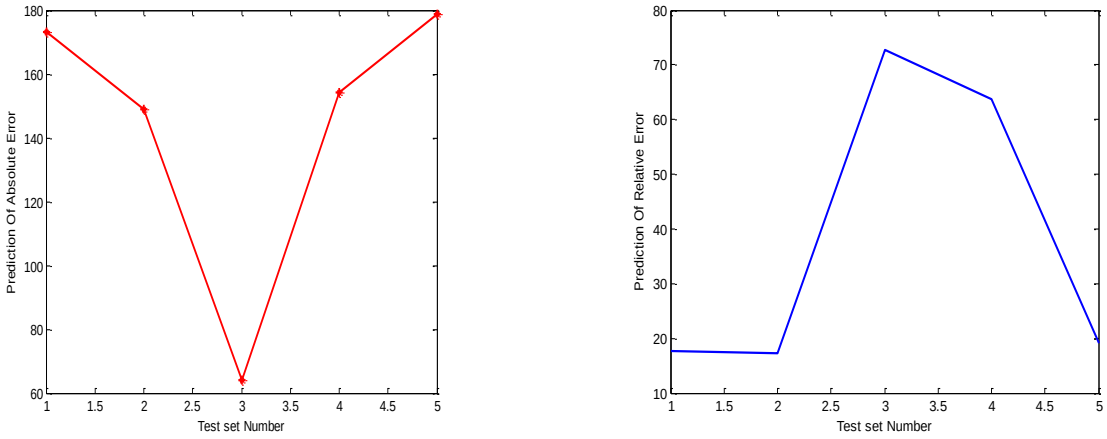

a) Absolute Errors b) Relative Errors

FIGURE 5 Predication Errors

The predication effects of extreme learning machine and that of BP neural network and RBF neural network were compared to further prove the superiority of the algorithm. Figure 6 and 7 showed the comparison results. It can be seen that extreme learning machine has the best prediction results; RBF neural network has relatively inferior prediction results; BP neural network has the worst. The comparison of these different algorithms can effectively validate the effectiveness and correctness of the algorithm in this work. Therefore, this algorithm, with certain practical application value, can be applied to classify and predict problems.

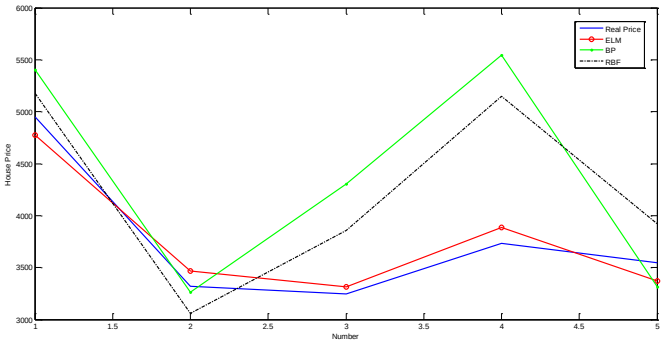

FIGURE 6 Comparison of the Predication Results of ELM, BP and RBF

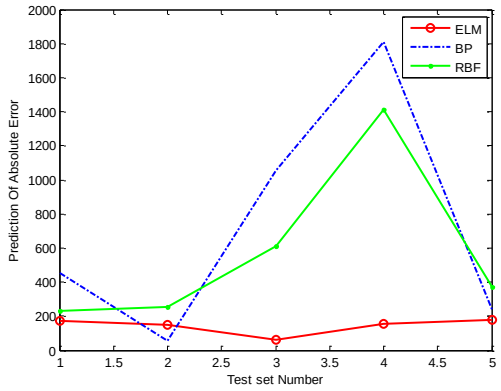

FIGURE 7 Comparison of the Predication Error of ELM, BP and RBF

4 Conclusions and analysis

With the combination of rough set theory and extreme learning machine, the work firstly reduced factors affecting housing price through rough set theory, thus obtaining the major influence factors. Then, the reduced influence factors (as the input of extreme learning machine) and housing price (as data) were used to establish the model to forecast housing price. Besides, The comparison of different algorithms – ELM, BP and RBF – proves the effectiveness and correctness of the algorithm in this work. Therefore, this algorithm, with certain practical application value, can be applied to the classification and predication of problems/

Prediction of employment figures in the three main industries based on extreme learning machine

Xiaoyan Li*, Min Zhang

Xi'an Technological University, Shaanxi, 710032, China

Received 1 March 2014, www.cmnt.lv

Abstract

Extreme learning machine, with a fast speed of training, achieves globally optimal solutions and excellent generalization ability. This work is based on the production value and employment figure of the three main industries in China during 1996-2012 as research objects. An ELM employment figure prediction model was constructed with production value and the employment figure of the three main industries respectively as the input and output of extreme learning machine. Simulation test results proved a good effect and high accuracy of ELM employment figure prediction model. Besides, the comparison of ELM, BP and RBF algorithms further proved the effectiveness and precision of ELM, which has certain practical application value.

Keywords: three main industries, extreme learning machine, production value, neural network, training samples, test samples

1 Introduction

With the rapid development of economy and continuous upgrading of industrial structure in China, the total employment and structure of labor force have experienced dramatic changes. Under the combined effects of incoming labor force and transfer of laid-off labor and rural labor, employment in China becomes an increasingly severe problem.

Since there are some interconnection influences between industrial structure and employment, additional investment to some industries can directly create large amount of employment opportunities. Additional investments to some industries may not create more employment opportunities, but it can directly or indirectly influence consumption of products in other industries, thus providing employment opportunities. Therefore, the employment opportunities of the whole economic system will be increased accordingly [1].

Adjusting industrial structure is an important way to realize optimization of internal structure of economic system, solving employment problems and increasing employment opportunities in each industry. Therefore, researches on the potential of employment in the three major industries are of great significances to employment.

In recent decades, China has achieved high-speed growth in economy, but employment growth is relatively slow. At present, rural surplus labor and college graduates become main employment forces. They are faced with various employment pressures; some of them are even faced with unemployment. As a result, Chinese people are facing big pressure from employment at present. Besides, the total labor force exceeds the demands of employment, but some places are in a shortage of labors. Therefore, employment structural contradictions become increasingly fierce [2-3].

With huge employment pressure, it is of important theory value and practical significance to broaden visions and fully consider national situations while absorbing employment theory from western economics researches. Only on such basis can prediction of employment figure be achieved effectively.

2 Extreme learning machine neural network

It is clear that the learning speed of feed forward neural networks is in general far slower than required and it has been a major bottleneck in their applications for past decades. Two key reasons behind may be: (1) the slow gradient based learning algorithms are extensively used to train neural networks, and (2) all the parameters of the networks are tuned iteratively by using such learning algorithms. Unlike the traditional implementations, we applied a new learning algorithm called extreme learning machine (ELM) for SLFNs which randomly chooses the input weights and analytically determines the output weights of SLFNs. This algorithm tends to provide the best generalization performance at extremely fast learning speed.

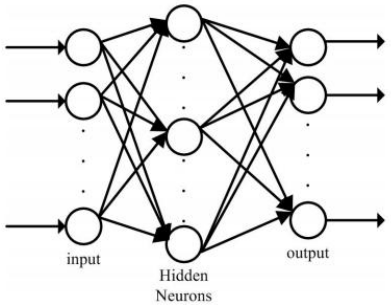

FIGURE 1 Extreme Learning Machine Schematic Diagram

* ***Corresponding author's*** e-mail: xiaoyanlixa@126.com

As pointed out by [4-9], for feed forward networks with many small weights but small squared error on the training examples, the Vapnik-Chervonenkis (VC) dimension (and hence number of parameters) is irrelevant to the generalization performance. Instead, the magnitude of the weights in the network is more important. The smaller the weights are, the better generalization performance the network tends to have. As analyzed above, our method not only reaches the smallest squared error on the training examples but also obtains the smallest weights. Thus, it is reasonable to think that our method tends to have better generalization performance. It should be worth pointing out that it may be difficult for gradient-based learning algorithms like back-propagation to reach the best generalization performance since they only try to obtain the smallest training errors without considering the magnitude of the weights.

3 Data sources and variable selection

In order to predict employment figure in the three main industries in China, this work selected the production value and employment data during 1996~2012 from each industry as samples (Table 1). Employment figure of each industry was considered as explanatory variable L_i, GDP of each industry as the explained variable Y_i. All data comes from *1996~2012 China Statistical Yearbook* [10,11].

TABLE 1 Production value and employment figure of each industry

Year	Y_1 / 100 Million RMB	L_1 / 10 Thousand People	Y_2 / 100 Million RMB	L_2/ 10 Thousand People	Y_3 / 100 Million RMB	L_3 / 10 Thousand People
1996	5866.6	38349	11699.5	14226	9357.3765	12979

Y_1 refers to the production value of the first industry; Y_2 the production value of the second industry; Y_3 the production value of the third industry. L_1 is the employment figure of the first industry; L_2 the employment figure of the second industry; L_3 the employment figure of the third industry.

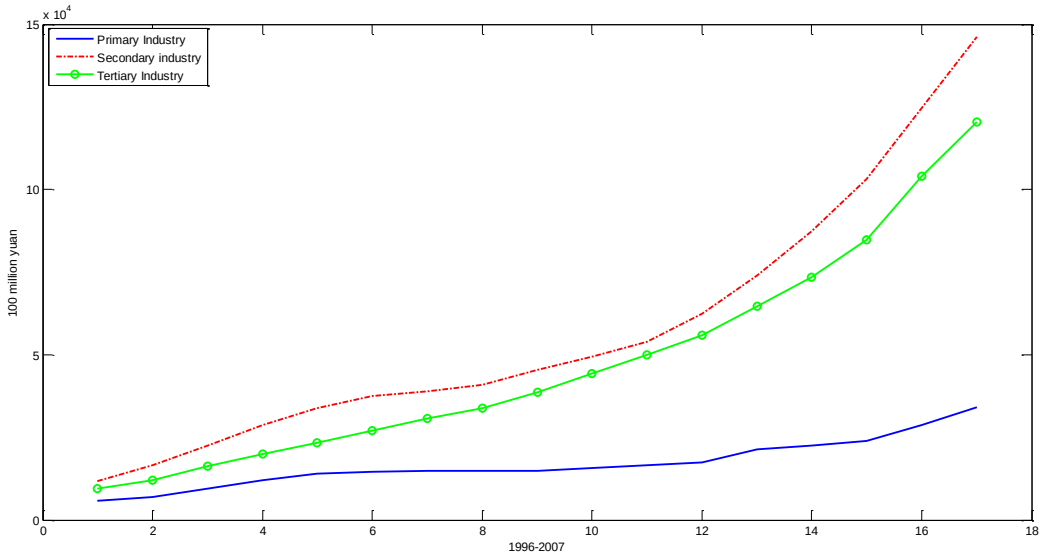

FIGURE 2 Change curve of production value in each industry over the year

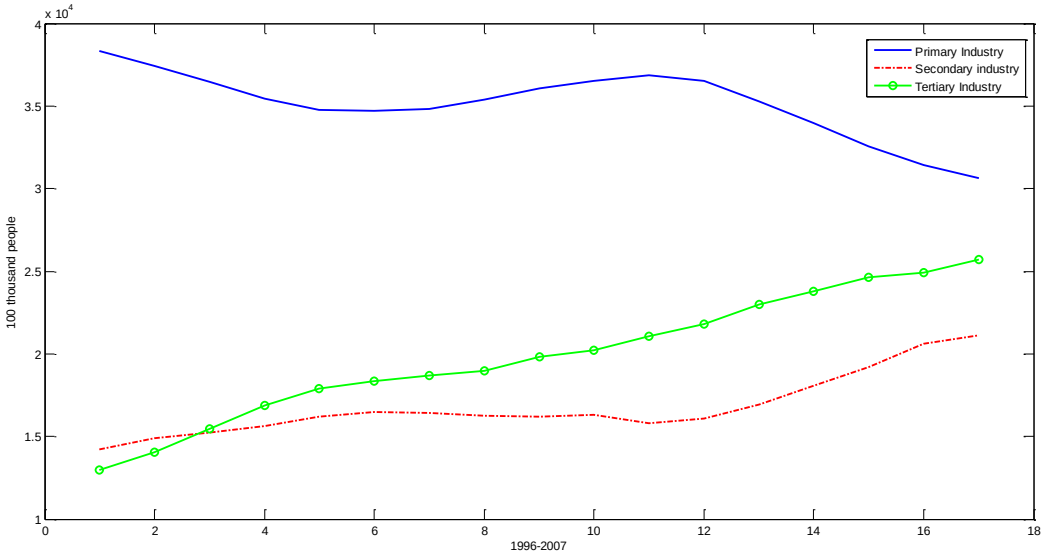

FIGURE 3 Change curve of employment figure in each industry over the year

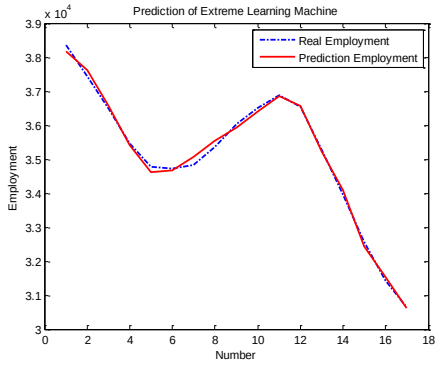
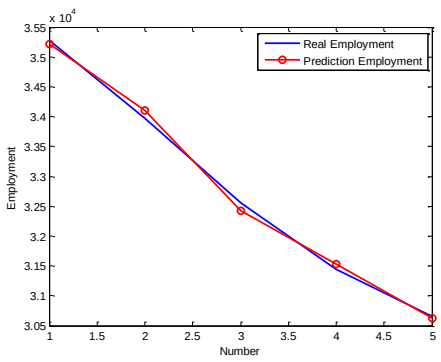
Figures 2 and 3 show that production values of the 2nd and 3rd industries increased year by year since 1996. And, the growth rate of the 2nd industry was greater than that of the 3rd industry. On the contrary, employment figure of the 1st industry declined year by year, implying that the 1st industry's allocation of labor ability was getting weaker. However, employment figures of the 2nd and 3rd industries also increased year by year. It means employment absorption capacity of the 2nd and 3rd industries is far greater than that of the 1st industry.

4 Employment figure prediction based on extreme learning machine

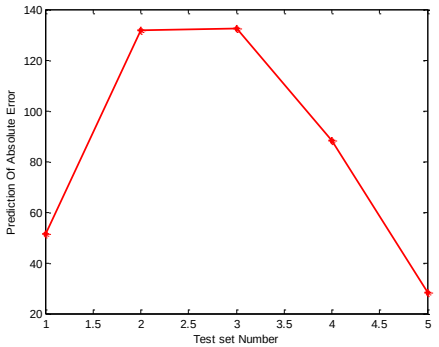
With production value and employment figure of the three main industries, respectively, as the input and output of extreme learning machine, a training model was established to predict employment figure. There were two sets of samples: 17 training samples and 5 test samples, all verifying the prediction ability of extreme learning machine network.



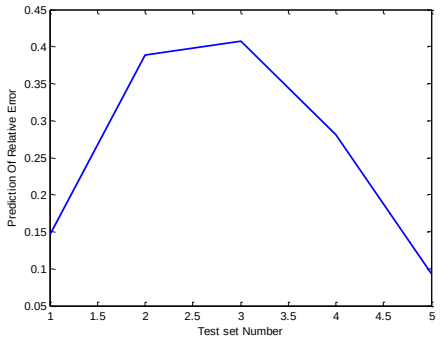
a) Prediction results of training samples



b) Prediction results of test samples

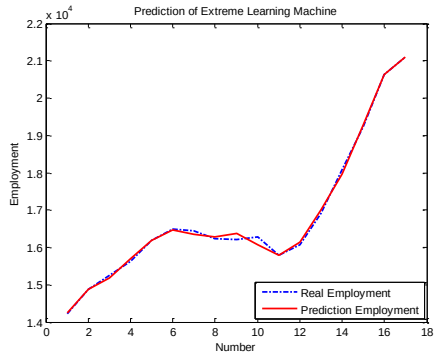


c) Absolute Error

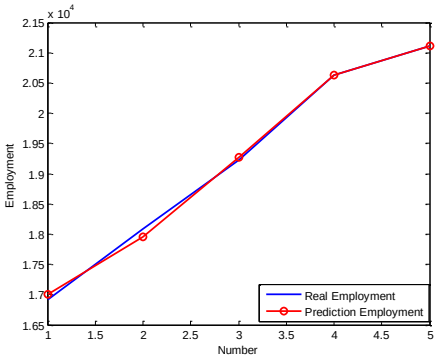


d) Relative Error

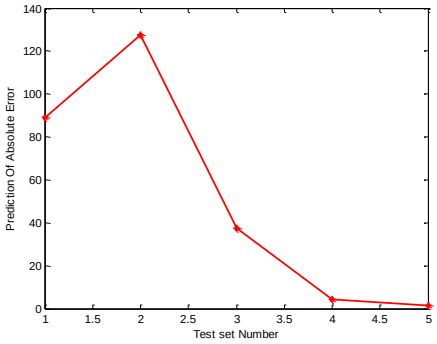
FIGURE 4 Prediction results and errors of employment figure of the 1st industry



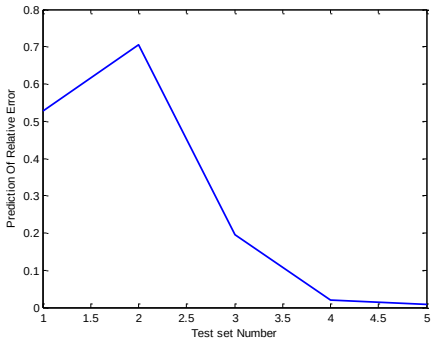
a) Prediction results of training samples



b) Prediction results of test samples

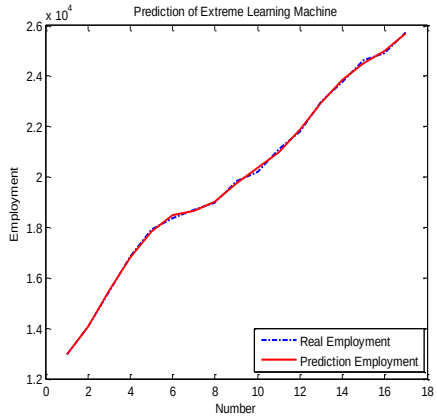


c) Absolute error

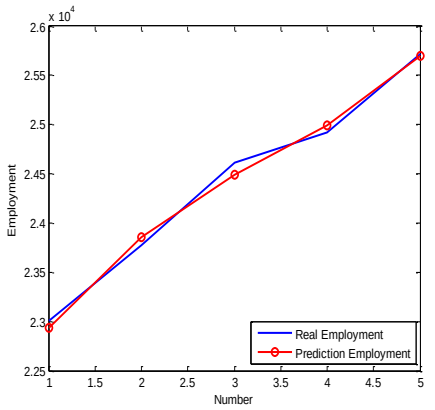


d) Relative error

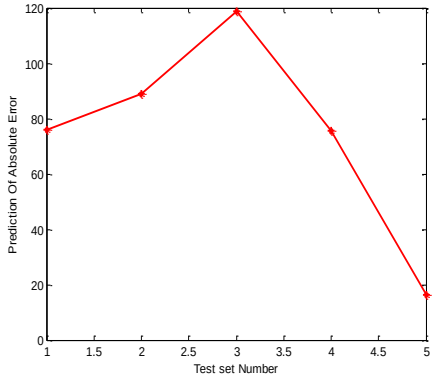
FIGURE 5 Prediction results and errors of employment figure of the 2nd Industry



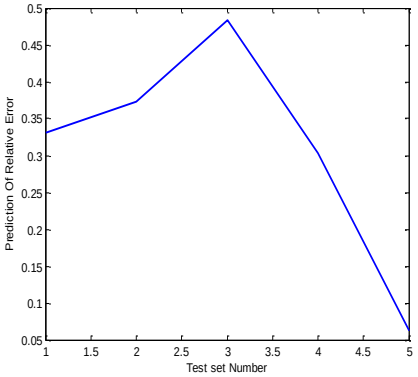
a) Prediction results of training samples



b) Prediction results of test samples



c) Absolute error



d) Relative error

FIGURE 6 Prediction results and errors of employment figure of the 3rd industry

Figure 3-5 respectively showed the prediction results of extreme learning machine. Figure 3a-5a, explained prediction results of training samples, presenting a good prediction and strong generalization ability. Figure 3 (b), Figure 4 (b) and Figure 5 (b) presented prediction results of test samples, mainly verifying the effectiveness and accuracy of extreme learning machine. It can be seen from Figure 3 (c) (d), Figure 4 (c) (d) and Figure 5 (c) (d) that this algorithm achieves good effects.

In order to compare and verify the superiority of this algorithm, the prediction results of ELM, BP neural network and RBF neural network were compared. It can be seen that ELM has the best prediction results; RBF neural has a worse prediction results compared with ELM; BP neural network has the worst. Comparison of those different algorithms verified the effectiveness and accuracy of ELM. Therefore, extreme learning machine, with certain practical application significance, can be used to classify and predict problems.

5 Conclusions

Based on production value and employment figure of the three main industries during 1996-2012 in China as research objects, this work established ELM employment figure prediction model. It was used to predict employment figures when production value and employment figure of the three main industries were respectively used as output and input of extreme learning machine. Comparison of ELM, BP and RBF further proved the effectiveness and high accuracy of ELM. Thus, this algorithm, with certain practical application value, can be used to classify and forecast problems.

Research on quality information integrated management for complex precision parts in multi-varieties and small batch manufacturing mode

Lihua Yu*, Qingsheng Xie

Key Laboratory of Advanced Manufacturing Technology, Guizhou University, China

Received 1 March 2014, www.cmnt.lv

Abstract

There were many problems such as quality information interaction low, real-time monitoring and tracing of production quality difficulty in workshops for multi-varieties and small-batch complicated precision parts. These problems restricted seriously the improvement of product quality. Therefore, a quality information integrated operation mode was built, combining with advanced management thoughts of lean management and integration. The main characteristics of quality information integrated management process were analysed. At last, the mode was applied in a manufacturing enterprise in CASTC 061 base for testing its effects. Results show that it is successful and satisfactory in practical application effect.

Keywords: workshop, integration, multi-varieties and small-batch, quality control

1 Introduction

With more and more various customer requirements and rapid product renewal, the production mode of manufacturer has been gradually changing from the traditional mass production into multi-varieties and small-batch production. More stringent requirements on quality control must be imposed for complex precision parts [1-4]. How to achieve quality information integrated management has become an urgent problem for the manufacturing enterprises.

A lot of research on quality information integration technology has achieved fruitful results at home and abroad. Gen-bao Zhang proposed a dynamic quality tracking model to achieve dynamic tracking and traceability of product quality in the manufacturing execution processes based on Computer Aided Process Planning (CAPP) and Manufacturing Execution System (MES)[5]. Liang Tong presented a function interoperation method of multiple heterogeneous systems in discrete manufacturing process according to problems [6]. Hui-ying Qi Proposed an integrated system scheme to realize uniform access of distributed and heterogeneous network resources [7].

In summary, domestic and foreign scholars have made many valuable results from the viewpoint of integration technology. However, research on quality information management is still relatively scarce from integration operation between departments and workshop. Therefore, the paper researched deeply the problem on quality information integrated management in the workshop.

2 Establishment of the quality information integrated operation mode

2.1 EXISTING PROBLEMS

Quality information has the characteristic of more sources, large volumes of data and frequent flow in workshops for multi-varieties and small-batch complex precision parts. Moreover, the traditional quality control mode often results in poor credibility, interactivity, utilization and traceability of quality information. Production quality cannot be controlled effectively. The main problems are as follows [8-16]:

1) Quality instruction information such as quality control tasks, CAD models and technology documentation was transmitted in hand-form in workshop, which made its adjustment and conversion inconvenient and often caused production confusion.
2) Dynamic quality information such as quality inspection, unqualified parts and equipment running information was collected in hand-form and recorded in paper-based way in workshop at present. The backward way made its consistency, confidence and systematization poor.
3) Various departments such as product design, materials, production and quality control department respectively managed their owner quality information. This kind of operating mode made quality information scattered, nonstandard, and isolated in the process relatively. Meanwhile, it became difficult to share, query and trace one for the workshop.
4) Quality information transmitting was by form and hand. This kind of ways not only made interactivity

* ***Corresponding author's*** e-mail: yulihua01@163.com

and utilization poor, but also showed abnormal quality-events not to be found in time and tackled efficiently. At the same time it was hard to monitor production quality effectively on line.

These problems above had not only seriously affected the comprehensive utilization and effects of quality information and reduced the quality control capacity, but also greatly restricted the improvement in quality management level.

2.1 THE GENERAL FRAMEWORK OF QUALITY INFORMATION INTEGRATED OPERATION MODE

According to quality information characteristics and management problems for this workshop, a quality information integrated operation mode was proposed. Its basic idea was that real-time interaction of quality information was extended to the workshop field, based on network multi-function interactive information terminal [17]. Quality information integrated operation has achieved among personnel, equipment, workshop scheduling, quality department, design department and enterprise senior by real-time transmission, adjustment and interactive feedback of quality information.

Based on the idea of establishing the operation mode, its general framework was constructed. As Figure 1 shown, it is mainly made up of five-level which is respectively objective, business execution, information interaction, status analysis and information collection level.

1) Objective level.
   In order to achieve operation mode above, according to quality information characteristics and management problems existed currently in workshop, an optimal operating objective set was established as follows:
   a) the collection efficiency, accuracy, interaction, comprehensive utilization and traceability for quality information was always expected,
   b) abnormal quality-events were processed as efficiently as possible,
   c) reject parts were as few as possible.
2) Business execution level.
   The achievement of operating objective needed the support for business activities under the operation mode. The departments related to business activities included design, production, quality, equipment and measuring instrument supplies department.
3) Information interaction level based on network multi-function interactive information terminals.
   Information interaction level described information interacting process of the operating mode. Network multi-function interactive information terminals were the key of information interaction. All quality information would eventually be pooled into interactive information terminals, which are from product and process design, production job scheduling arrangements, production information collection and quality management.

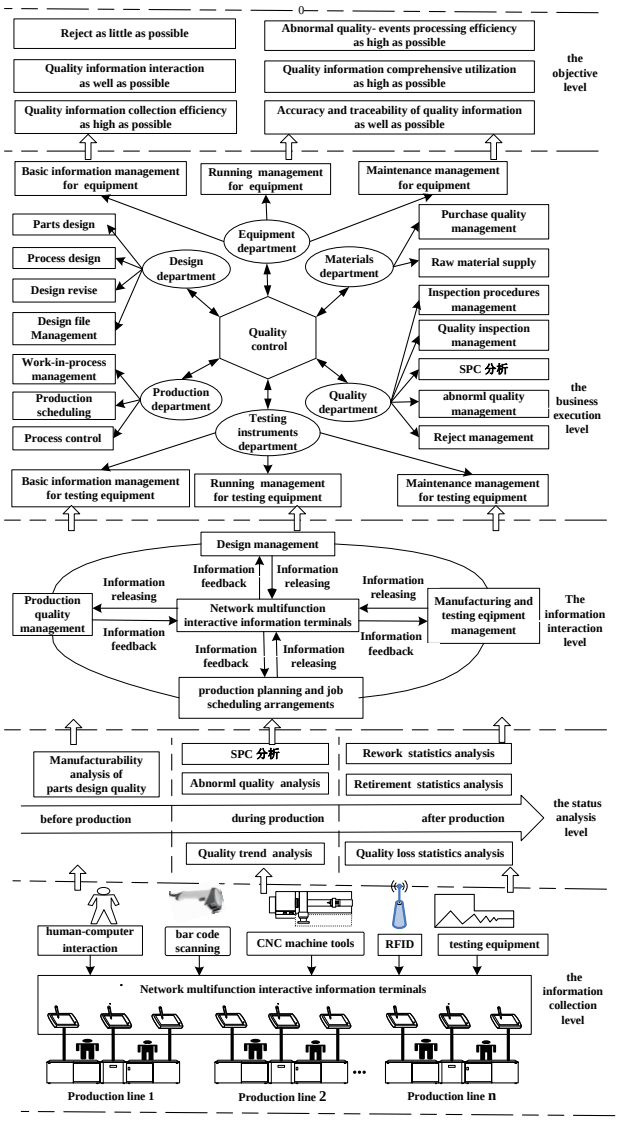

FIGURE 1 General framework of quality information integrated operation mode for workshop of multi-varieties and small-batch complex precision parts

4) Status analysis level.
   The status analysis level provided various analysis and decision-making tools of quality state for production quality control. The tools included as follow:
   a) manufacturability of parts design quality before production,
   b) SPC(Statistics process control)of key process, abnormal quality and quality trend analysis during production,
   c) rework, retirement and quality loss statistics analysis after production, and so on.
5) Information collection level.
   The information collection level obtained the quality-related information to support quality information integrated operation by various means during production in workshop. The information collecting was by means of testing equipment, bar code scanning, FRID, CNC machine tools, and human-computer interaction, and so on. All pro-

duction quality information collected were transferred and integrated into network multifunction interactive information terminals.

2.1 THE MAIN PROCESS FOR QUALITY INFORMATION INTEGRATED MANAGEMENT

The main purpose of quality information integrated management is to support the integrated operation of quality management activities. The management business includes the quality control plan made and issued, production quality information collected real time, quality inspection and control, statistical analysis and query for quality information, nonconforming product management, quality improvement, quality information feedback, etc. Quality information integrated management process is as shown in Figure 2.

The main characteristics of quality information integrated management process:

1) Based on the multi-function interactive information terminal, production workers and quality inspection personnel can receive quality control tasks, the machining process document and quality inspection procedures in real-time. They can collect and feedback quality data in real-time on site.
2) Based on the management terminal, the process management is realized easily. the process includes the disposition of nonconforming products, the process for scrap , the process for repair and so on. For another, the process management is integrated into the news system with a prompt, from "people work" into "thing for people". Then the efficiency of nonconforming products disposition is improved greatly.
3) Based on the management terminal, multi-function interactive information terminal and integrated interface, the organic connection of quality planning layer and workshop site and operation workers is established, Collaborative quality control capacity is improved through quality information interactive feedback and closed-loop control between departments.

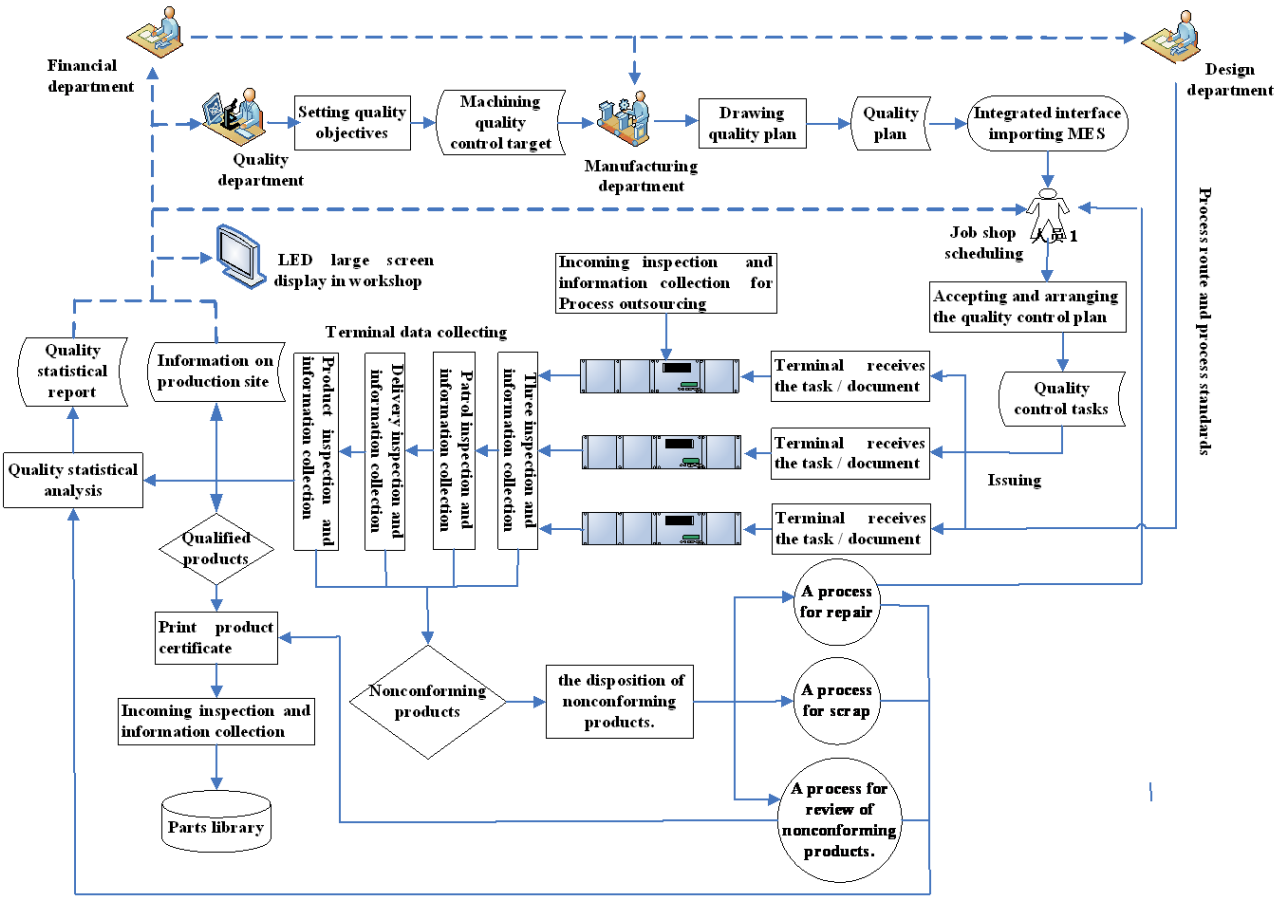

FIGURE 2 Main process of quality information integrated management for workshop of multi-varieties and small-batch complex precision parts

3 The application and practice of the mode

At present, the management mode above has been successfully applied in a manufacture enterprise in 061 manufacturing base of China Aerospace Science and Industry. The manufacturer is a large industrial enterprise, and has typical production mode for multi-varieties and small-batch complex precision parts. The characteristic of its workshop is diversified process rout and high-quality requirements, which makes information sources a lot, amount of quality information large and information flow frequent among departments. However the old mode had failed to meet the

confidence, interactive feedback and traceability requirements of quality information. So the manufacturer had implemented manufacturing process information systems lean production planning and manufacturing execution system (HTK-eMES). As a result, production management and manufacturing capabilities of the enterprise has improved effectively. Quality information integrated operation is an important part of the HTK-eMES in parts production workshop. Quality information integration and application is shown in Figure 3. The operating mode has achieved many processes integrated operation and improved the quality management. These achievements and improvements include as follows:

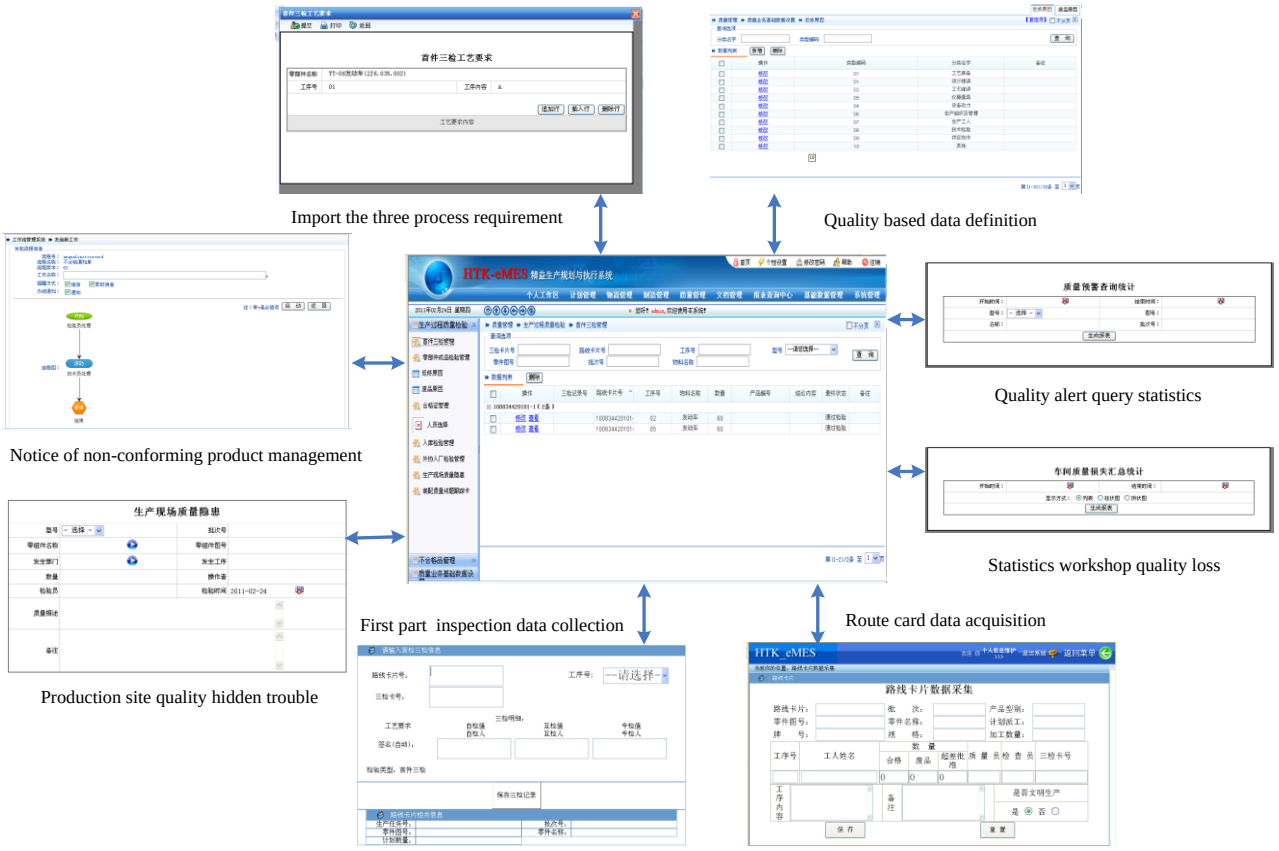

FIGURE 3 System integration and application diagram

1) The operating mode has achieved the efficient of quality information collection and improved its accuracy, real-time and systematic.
2) The operating mode has achieved the real-time, electronization of information transmission and improved information interaction and traceability.
3) The operating mode has achieved the real-time and hyalinization of quality control, and reduced reject and rework rate and quality loss.
4) The operating mode has achieved the interactive feedback of quality information and the close-loop operation of quality control, and improved the optimazed organization capacity of quality information management and cooperative quality control capacity.

Conclusions

There exits many problems on quality information management in workshops for multi-varieties and small-volume complex precision parts. These problems include low confidence, interactivity and utilization of quality information and difficulty in real-time monitoring effectively and tracing of production quality. In order to solve these problems, firstly a quality information integrated operating mode was proposed in this paper. Secondly, the general framework of the operating mode was build. And the main characteristics of quality information integrated management process were analysed. At last, the mode was applied in a manufacturing enterprise in CASTC 061 base for testing its effects. The operating mode gets many achievements including: realizing the accuracy, real-time and systematic of quality information collecting, achieving the real-time of information transmission, achieving the real-time and hyalinization of quality control, achieving the interactive feedback of quality information and the close-loop quality control. In a word, the mode had not only realized quality information integrated operation through whole quality information chain among departments, but also improved quality control efficient and reduced reject and rework rate and quality loss.

Incentive analysis of labour dispatch under asymmetric information theory

Yanli Yang*, Xianyu Wang

School of business, Sichuan University, Chengdu, 610000, Sichuan, China

Received 1 July 2014, www.cmnt.lv

Abstract

Under the circumstances of the fierce market competition, great importance is attached to labour dispatch as an innovative employment way since it saves more labour costs for enterprises. However, there exists obvious asymmetric information among the dispatched employees, employers and accepting entities. This paper makes an analysis of the incentive offered by accepting entities to the dispatched employees and employers under the circumstances of asymmetric information and symmetric information. It verifies through models that in the case of symmetric information accepting entities can offer incentive to the dispatched employees and employers so as to achieve Pareto optimality by means of linear contracts. In case of asymmetric information, the expected revenue of accepting entities will be influenced by the abilities, degree of risk aversion and effort costs of the dispatched employees and employers, which is of great reference value to the enterprise practice.

Keywords: Labour Dispatch, Symmetric Information, Asymmetric Information, Risk Aversion, Effort Costs

1 Introduction

As the present market competition increasingly intensifies, the profit margin gets lower and lower. In order to develop well, more and more enterprises opt to outsource their non-core business, which results in the business of labour dispatch. From the very beginning, labour dispatch has been valued greatly and widely applied in the practice of enterprises. The employment of Foreign Representative Office began to adopt the way of labour dispatch in China from 1979. In the 1990s, in order to tackle the employment of laid-off workers and migrant workers, labour dispatch experienced primary development. Since the promulgation of Labour Contract Law of the People's Republic of China in 2008, the business of labour dispatch saw a rapid development since enterprises tried to reduce the labour costs and avert non-fixed term contract. Up to now, the number of labour dispatch reaches about 10 million [1], widely spreading in the field of construction, telecommunications, banks, the power sector and public institutions.

Labour dispatch involves three parties of the dispatched employees, employers (the dispatching entities) and the accepting entities (the actual recruiting enterprises). In general, the dispatched employees and the employers have more information than accepting entities, such as the quality, credibility, professional competence, service level and the actual strength of the dispatched employees and the employers. In case of asymmetric information, the problem demanding prompt solution is how the accepting entities offer incentive to the dispatched employees and the employyers. From the perspective of symmetric information and asymmetric information, this paper probes into the incentive offered by accepting entities to the dispatched employees and employers. It verifies through models that in the case of symmetric information accepting entities can offer incentive to the dispatched employees and employers so as to achieve Pareto optimality by means of linear contracts. In case of asymmetric information, the expected revenue of accepting entities will be influenced by the abilities, degree of risk aversion and effort costs of the dispatched employees and employers, which is of great reference value to the enterprise practice.

2 Related literature

Labour dispatch is clearly stipulated by Labour Contract Law of the People's Republic of China. Labour dispatch is that employers sign the dispatching agreement with accepting entities in accordance with the demands of accepting entities and dispatch the employees with labour contract relations to accepting entities so as to establish a special labour relation that the dispatched employees provide labour under the management of accepting entities while the employers get dispatching payment from the accepting entities and pay the dispatched employees labour remuneration. The business of labour dispatch involves three parties and two contracts. Three parties refer to the dispatched employees, employers and accepting entities. Two contracts refer to the one between the dispatched employees and accepting entities and the other between employers and accepting entities. In general, when signing the dispatch agreement, the accepting entities cannot get a full understanding about the credibility, professional ability, service level and actual strength of the dispatched employees and employers. Therefore, there exists obvious asymmetric information among the three parties.

Current literature about the study of labour dispatch mainly focuses on qualitative analysis. Literature [2] to [4]

* ***Corresponding author's*** e-mail yydouble@sohu.com

mainly analyses the development and characteristics of labour dispatch. Literature [5] to [7] mainly elaborates the status quo and existing problems of labour dispatch in China and puts forward some suggestions. Literature [8] to [10] analyses the game relationship among the three parties of labour dispatch from a legal point of view. This paper makes a qualitative analysis of the incentive offered by accepting entities to the dispatched employees and employers.

3 Model description

The model involves three parties: the dispatched employees, the employers (the intermediary agent) and the accepting entities (the actual employing party). The dispatched employees and the employers sign the labour contract. The employers and the accepting entities sign the dispatching agreement. The income of the dispatched employee consists of regular wage plus performance bonus. The income of the employer consists of a fixed rate (which is related to the regular wage of the dispatched employee) plus performance bonus. The real income of the accepting entity is directly connected with the dispatched employee and the employer. For example, the personal quality and effort of the employee will influence the real income of the accepting entity. The employer's selection and training of the dispatched employee will directly influence the real income of the accepting entity. In accordance with the above explanation, the following hypotheses are made from the model:

The marginal revenue of the accepting entity's products is m, and the production is

$$Q = A_1 f(\mathrm{e}_1) + A_2 f(\mathrm{e}_2) + B + \varepsilon . \tag{1}$$

Here: A_1 is the dispatched employee's ability coefficient, $f(\mathrm{e}_1)$ is the output function of the dispatched employee's effort e_1, A_2 is the employer's ability coefficient, $f(\mathrm{e}_2)$ is the output function of the employer's effort e_2, B is the basic workload of the dispatched employee, and ε is a random variable. $f(\mathrm{e})$ is the output function of effort e. According to the actual situation, it should meet the requirement $f'(\mathrm{e}) \succ 0$, signifying that the more effort the dispatched employee and the employer make, the larger the output of the accepting entity. If the function is $f''(\mathrm{e}) \le 0$, it signifies that the effort's marginal output is digressive (The equal sign signifies the marginal output is invariant). The function of the dispatched employee's effort is $\mathrm{C}(\mathrm{e}_1) = \frac{b_1 \mathrm{e}_1^{\ 2}}{2}$, in which b_1 is the cost coefficient of the dispatched employee's effort. The function of the employer's effort is $\mathrm{C}(\mathrm{e}_2) = \frac{b_2 \mathrm{e}_2^{\ 2}}{2}$, in which b_2 is the cost coefficient of the employer's effort. ε is a random variable, and let it be normally distribute $(0, \sigma^2)$.

The income of the dispatched employee is:

$$S_{\text{the dispatched}} = w + \beta_1 Qm . \tag{2}$$

The income of the employer is :

$$S_{\text{the employer}} = \alpha w + \beta_2 Qm . \tag{3}$$

Here: w is the regular wage of the dispatched employee paid by the accepting entity; β_1 is the ratio of the dispatched employee's performance bonus sharing; α is the sharing ratio paid by the accepting entity to the employer, which is related to the dispatched employee's regular wage; and β_2 is the employer's performance bonus sharing ratio.

Thus the income of the accepting entity is:

$$\begin{aligned} S_{\text{the accepting}} &= Qm - w - \beta_1 Qm - \alpha w - \beta_2 Qm \\ &= (1 - \beta_1 - \beta_2) Qm - (1 + \alpha) w \end{aligned} . \tag{4}$$

To simplify the analysis, suppose $f(\mathrm{e}) = \mathrm{e}$, i.e., output is the linear function of effort. Here, suppose the accepting entity is risk neutral, and the dispatched employee and the employer are risk averse. Let the utility function of the dispatched employee and the employer be negative exponent function, and the utility function of the dispatched employee is $V_1(\mathrm{X}) = -e^{-r_1 x}$; the utility function of the employer is $V_2(\mathrm{X}) = -e^{-r_2 x}$. In the equation, r_1 and r_2 refer to the degree of risk aversion of the dispatched employee and the employer. If they are greater than zero, they stand for risk aversion; if equal to zero, risk neutrality; if less than zero, risk preference.

According to the above explanation, the utility functions of the three parties connecting with labour dispatch can be illustrated as follows, respectively:

$$\begin{aligned} &EUS_{\text{the accepting}} \\ &= (1 - \beta_1 - \beta_2) m(\mathrm{A}_1 \mathrm{e}_1 + \mathrm{A}_2 \mathrm{e}_2 + \mathrm{B}) - (1 + \alpha) w \end{aligned} , \tag{5}$$

$$EVS_{\text{the dispathced}} = EV[S_{\text{the dispathced}} - \mathrm{C}(\mathrm{e}_1)] , \tag{6}$$

$$EVS_{\text{the employer}} = EV[S_{\text{the employer}} - \mathrm{C}(\mathrm{e}_2)] . \tag{7}$$

According to the book Game Theory and Information Economics by Zhang Weiying, solution of equations (6) and (7) are equivalent to that of certainty equivalent value, then:

$$\begin{aligned} &CE_{\text{the dispathced}} \\ &= w + \beta_1 m(\mathrm{A}_1 \mathrm{e}_1 + \mathrm{A}_2 \mathrm{e}_2 + \mathrm{B}) - \frac{b_1 e_1^2}{2} - \frac{1}{2} r_1 \beta_1^2 m^2 \sigma^2 \end{aligned} , \tag{8}$$

$$\begin{aligned} &CE_{\text{the employer}} \\ &= \alpha w + \beta_2 m(\mathrm{A}_1 \mathrm{e}_1 + \mathrm{A}_2 \mathrm{e}_2 + \mathrm{B}) - \frac{b_2 e_2^2}{2} - \frac{1}{2} r_2 \beta_2^2 m^2 \sigma^2 \end{aligned} . \tag{9}$$

In the three parties of labour dispatch, the accepting entity is the Principal and have the advantage of priority selection in the game. While pursuing the maximizing of self-interest, the accepting entity must take into consideration the incentive compatibility constraint and participation constraint of the dispatched employee and the employer. Thus the following programming model is formulated:

$$(P)\max_{\{e_1,e_2,\beta_1,\beta_2,\alpha,w\}}(1-\beta_1-\beta_2)\,m(A_1e_1+A_2e_2+B)-(1+\alpha)\,w, \quad (10)$$

$$s.t.\ e_1\in\arg\max w$$

$$+\beta_1 m(A_1e_1+A_2e_2+B)-\frac{b_1e_1^2}{2}-\frac{1}{2}r_1\beta_1^2m^2\sigma^2, \quad (11)$$

$$w+\beta_1 m(A_1e_1+A_2e_2+B)-\frac{b_1e_1^2}{2}-\frac{1}{2}r_1\beta_1^2m^2\sigma^2\ge s_1, \quad (12)$$

$$e_2\in\arg\max \alpha w$$

$$+\beta_2 m(A_1e_1+A_2e_2+B)-\frac{b_2e_2^2}{2}-\frac{1}{2}r_2\beta_2^2m^2\sigma^2, \quad (13)$$

$$\alpha w+\beta_2 m(A_1e_1+A_2e_2+B)-\frac{b_2e_2^2}{2}-\frac{1}{2}r_2\beta_2^2m^2\sigma^2\ge s_2. \quad (14)$$

Here: s_1 and s_2 stand for the reservation utility of the dispatched employee and the employer respectively.

3.1 UNDER SYMMETRIC INFORMATION

Under the circumstances, the accepting entity, the dispatched employee and the employer possess symmetric information. The accepting entity can observe the action and effort degree of the dispatched employee and the employer and pursues the maximizing of self-interest, that is to say, expressions (12) and (14) can only take equality sign. So the above programming problem can be revised as:

$$(P')\max_{\{e_1,e_2,\beta_1,\beta_2,\alpha,w\}}(1-\beta_1-\beta_2)\,m(A_1e_1+A_2e_2+B)-(1+\alpha)\,w, \quad (15)$$

$$s.t.\ w+\beta_1 m(A_1e_1+A_2e_2+B)-\frac{b_1e_1^2}{2}-\frac{1}{2}r_1\beta_1^2m^2\sigma^2=s_1, \quad (16)$$

$$\alpha w+\beta_2 m(A_1e_1+A_2e_2+B)-\frac{b_2e_2^2}{2}-\frac{1}{2}r_2\beta_2^2m^2\sigma^2=s_2. \quad (17)$$

Substitute Eq.(16) and Eq.(17) into Eq.(15), we obtain:

$$e_1^*=\frac{mA_1}{b_1},\ e_2^*=\frac{mA_2}{b_2},\ \beta_1^*=0,\ \beta_2^*=0. \quad (18)$$

Substitute Eq. (18) into Eq. (16) and Eq. (17), we obtain:

$$w^*=s_1+\frac{m^2A_1^2}{2b_1},\ \alpha^*=\frac{2b_1b_2s_2+b_1m^2A_2^2}{2b_1b_2s_1+b_2m^2A_1^2}. \quad (19)$$

Now the marginal cost of the dispatched employee's effort is:

$$C'(e_1)=(\frac{b_1e_1^2}{2})'=b_1e_1=mA_1. \quad (20)$$

The marginal cost of the employer's effort is:

$$C'(e_2)=(\frac{b_2e_2^2}{2})'=b_2e_2=mA_2. \quad (21)$$

The marginal expected utility of the dispatched employee is:

$$\frac{\partial(EmQ)}{\partial e_1}=\frac{\partial[m(A_1e_1+A_2e_2+B)]}{\partial e_1}=mA_1. \quad (22)$$

The marginal expected utility of the employer is:

$$\frac{\partial(EmQ)}{\partial e_2}=\frac{\partial[m(A_1e_1+A_2e_2+B)]}{\partial e_2}=mA_2. \quad (23)$$

So it can be seen from above:

Eq.(20)= Eq.(22); and Eq.(21)= Eq.(23).

That is to say, the mariginal cost of the dispatched employee and the employer's respective effort is just equal to the effort's marginal expected utility, which conforms to Pareto optimality.

And the expected revenue of the accepting entity is:

$$EUS_{the\ accepting}{}^*=\frac{m^2A_1^2}{2b_1}+\frac{m^2A_2^2}{2b_2}+Bm-s_1-s_2. \quad (24)$$

The real income of the dispatched employee is:

$$S_{the\ dispathced}{}^*=s_1+\frac{b_1e_1^2}{2}=s_1+\frac{m^2A_1^2}{2b_1}. \quad (25)$$

The real income of the employer is:

$$S_{the\ employer}{}^*=s_2+\frac{b_2e_2^2}{2}=s_2+\frac{m^2A_2^2}{2b_2}. \quad (26)$$

Conclusion 1: Under symmetric information, the accepting entity may make the dispatched employee and the employer achieve Pareto optimality by means of linearity incentive contract.

3.2 UNDER ASYMMETRIC INFORMATION

In realitiy, it is difficult to achieve symmetric information among the three parties of the employer, the dispatched employee and the accepting entity. In general, the dispatched employee and the employer get hold of more information than that of the accepting entity, so the accepting entity cannot see clearly the effort degree of the dispatched employee and the employer. Then the dispatched employee and the employer will try to seek the maximi-

zing of self-interest – hence the following equivelent programme problem:

$$(\mathrm{P}^{''}) \max_{\{e_1,e_2,\beta_1,\beta_2,\alpha,w\}} (1-\beta_1-\beta_2)\,\mathrm{m}(\mathrm{A}_1\mathrm{e}_1+\mathrm{A}_2\mathrm{e}_2+\mathrm{B})-(1+\alpha)\,\mathrm{w}, \quad (27)$$

$$s.t. \quad e_1=\frac{\beta_1 m A_1}{b_1}, \quad (28)$$

$$w+\beta_1 m(\mathrm{A}_1\mathrm{e}_1+\mathrm{A}_2\mathrm{e}_2+\mathrm{B})-\frac{b_1 e_1^2}{2}-\frac{1}{2}r_1\beta_1^2 m^2\sigma^2\geq s_1, \quad (29)$$

$$e_2=\frac{\beta_2 m A_2}{b_2}, \quad (30)$$

$$\alpha w+\beta_2 m(\mathrm{A}_1\mathrm{e}_1+\mathrm{A}_2\mathrm{e}_2+\mathrm{B})-\frac{b_2 e_2^2}{2}-\frac{1}{2}r_2\beta_2^2 m^2\sigma^2\geq s_2, \quad (31)$$

To solve the programme problem P'':

$$\begin{cases} \beta_1^{SB}=\dfrac{A_1^2}{A_1^2+r_1 b_1\sigma^2} \\ \beta_2^{SB}=\dfrac{A_2^2}{A_2^2+r_2 b_2\sigma^2} \\ e_1^{SB}=\dfrac{\beta_1^{SB} m A_1}{b_1} \\ e_2^{SB}=\dfrac{\beta_2^{SB} m A_2}{b_2} \\ w^{SB}=s_1-\beta_1^{SB} m(\mathrm{A}_1\mathrm{e}_1^{SB}+\mathrm{A}_2\mathrm{e}_2^{SB}+\mathrm{B})+\dfrac{b_1 e_1^{SB2}}{2}+\dfrac{1}{2}r_1\beta_1^2 m^2\sigma^2 \\ \alpha=\dfrac{2s_2-2\beta_2^{SB} m(\mathrm{A}_1\mathrm{e}_1^{SB}+\mathrm{A}_2\mathrm{e}_2^{SB}+\mathrm{B})+b_2 e_2^{SB2}+r_2\beta_2^{SB2} m^2\sigma^2}{2s_1-2\beta_1^{SB} m(\mathrm{A}_1\mathrm{e}_1^{SB}+\mathrm{A}_2\mathrm{e}_2^{SB}+\mathrm{B})+b_1 e_1^{SB2}+r_1\beta_1^{SB2} m^2\sigma^2} \end{cases}. \quad (32)$$

Then, the expected income of the accepting entity is:

$$\begin{aligned} EUS_{the\ accepting}^{SB} &= m(A_1\mathrm{e}_1+A_2\mathrm{e}_2+\mathrm{B})-\mathrm{s}_1-\frac{b_1 e_1^2}{2} \\ &-\frac{1}{2}r_1\beta_1^2 m^2\sigma^2-\mathrm{s}_2-\frac{b_2 e_2^2}{2}-\frac{1}{2}r_2\beta_2^2 m^2\sigma^2 \\ &=\frac{A_1^2 m^2\beta_1}{b_1}+\frac{A_2^2 m^2\beta_2}{b_2}+Bm-s_1-\frac{A_1^2 m^2\beta_1^2}{2b_1} \\ &-\frac{1}{2}r_1\beta_1^2 m^2\sigma^2-s_2-\frac{A_2^2 m^2\beta_2^2}{2b_2}-\frac{1}{2}r_2\beta_2^2 m^2\sigma^2 \\ &=\frac{m^2 A_1^6}{2b_1(A_1^2+r_1\mathrm{b}_1\sigma^2)^2}+\frac{m^2 A_2^6}{2b_2(A_2^2+r_2\mathrm{b}_2\sigma^2)^2}+Bm-s_1-s_2 \end{aligned}.$$

The real income of the dispatched employee is:

$$\begin{aligned} S_{the\ dispathced}^{SB} &= w+\beta_1^{SB} m(A_1\mathrm{e}_1^{SB}+A_2\mathrm{e}_2^{SB}+\mathrm{B}) \\ &=\mathrm{s}_1+\frac{b_1 e_1^{SB2}}{2}+\frac{1}{2}r_1\beta_1^{SB2} m^2\sigma^2 \\ &=s_1+\frac{\beta_1^{SB2} m^2 A_1^2}{2b_1}+\frac{1}{2}r_1\beta_1^{SB2} m^2\sigma^2=s_1+\frac{m^2 A_1^4}{2b_1(A_1+r_1\mathrm{b}_1\sigma^2)} \end{aligned}.$$

The real income of the accepting entity is:

$$\begin{aligned} S_{the\ employer}^{SB} &= \alpha w+\beta_2^{SB} m(A_1\mathrm{e}_1^{SB}+A_2\mathrm{e}_2^{SB}+\mathrm{B}) \\ &=\mathrm{s}_2+\frac{b_2 e_2^{SB2}}{2}+\frac{1}{2}r_2\beta_2^{SB2} m^2\sigma^2 \\ &=s_2+\frac{\beta_2^{SB2} m^2 A_2^2}{2b_2}+\frac{1}{2}r_2\beta_2^{SB2} m^2\sigma^2=s_2+\frac{m^2 A_2^4}{2b_2(A_2+r_2\mathrm{b}_2\sigma^2)} \end{aligned}.$$

Conclusion 2: From the equations $\beta_1^{SB}=\dfrac{A_1^2}{A_1^2+r_1 b_1\sigma^2}$ and $\beta_2^{SB}=\dfrac{A_2^2}{A_2^2+r_2 b_2\sigma^2}$, it can be seen that when the dispatched employee and the employer are the type of risk aversion (i.e., $r_1\succ 0$ and $r_2\succ 0$), the value of β will be less with the value of r becoming bigger; that is to say, the lower the risk tolerance of the dispatched employee and the emplioyer, the less the commission ratio paid by the accepting entity to the dispatched employee and the emplioyer. When r tends to be infinite, $\beta=1$, and the effort degree of the dispatched employee and the emplioyer is same as that under symmetric information.

Conclusion 3: From the equation

$$EUS_{the\ accepting}^{SB}=\frac{m^2 A_1^6}{2b_1(A_1^2+r_1\mathrm{b}_1\sigma^2)^2}+\frac{m^2 A_2^6}{2b_2(A_2^2+r_2\mathrm{b}_2\sigma^2)^2}+Bm-s_1-s_2$$

it can be seen:

(1) $\dfrac{\partial EUS_{the\ accepting}}{\partial A_1}=\dfrac{m^2 A_1^5(\mathrm{A}_1^2+3r_1\mathrm{b}_1\sigma^2)}{b_1(\mathrm{A}_1^2+r_1\mathrm{b}_1\sigma^2)^3}\succ 0$,

$\dfrac{\partial EUS_{the\ accepting}}{\partial A_2}=\dfrac{m^2 A_2^5(\mathrm{A}_2^2+3r_2\mathrm{b}_2\sigma^2)}{b_2(\mathrm{A}_2^2+r_2\mathrm{b}_2\sigma^2)^3}\succ 0$,

which shows that the greater the ability of the dispatched employee and the employer, the higher the expected income of the accepting entity;

(2) $\dfrac{\partial EUS_{the\ accepting}}{\partial r_1}=-\dfrac{2m^2 A_1^7}{b_1(\mathrm{A}_1^2+r_1\mathrm{b}_1\sigma^2)^3}\prec 0$,

$\dfrac{\partial EUS_{the\ accepting}}{\partial r_2}=-\dfrac{2m^2 A_2^7}{b_2(\mathrm{A}_2^2+r_2\mathrm{b}_2\sigma^2)^3}\prec 0$ the greater the risk aversion degree of the dispatched employee and the employer, the lower the expected income of the accepting entity;

(3) $\dfrac{\partial EUS_{the\ accepting}}{\partial b_1}=-\dfrac{m^2 A_1^6(\mathrm{A}_1^2+3r_1\mathrm{b}_1\sigma^2)}{2b_1(\mathrm{A}_1^2+r_1\mathrm{b}_1\sigma^2)^3}\prec 0$,

$\dfrac{\partial EUS_{the\ accepting}}{\partial b_2}=-\dfrac{m^2 A_2^6(\mathrm{A}_2^2+3r_2\mathrm{b}_2\sigma^2)}{2b_2(\mathrm{A}_2^2+r_2\mathrm{b}_2\sigma^2)^3}\prec 0$

and the larger the effort cost coefficient of the dispatched employee and the employer, the the lower the expected income of the accepting entity.

4 Conclusion

This paper makes an analysis of the incentive offered by accepting entities to the dispatched employees and employers. It verifies through models that in the case of symmetric information accepting entities can offer incentive to the dispatched employees and employers so as to achieve Pareto optimality by means of linear contracts. In case of asymmetric information, the expected revenue of accepting entities will be influenced by the abilities, degree of risk aversion and effort costs of the dispatched employees and employers, which is of great reference value to the enterprise practice. The accepting entity should choose the dispatched employee and the employer with a greater ability, a weaker degree of risk aversion and a smaller effort coefficient so as to reach a better income level of the accepting entity.

Environment and Resource Management Department of Shaanxi Xueqian Normal University, Xi'an, Shaanxi 710100, China

Abstract

The small grid calculation model was used as the theoretical basis; A variety of meteorological data in 1971-2007 of Chinese Loess Plateau, remote sensing image (TM), DEM and other maps in 2000 were used; factor analysis, raster calculator, variance analysis and other methods in ArcGIS were used; the mathematical model of the latitude and longitude related to the main meteorological elements of the loess plateau and comprehensive index model for regionalization were obtained; the north and south boundaries of the Loess Plateau were determined.

Keywords: factor analysis, analysis of variance, raster data, comprehensive index model, boundaries, loess plateau

1 Introduction

Regional differentiation refers to the mutual differentiation between the unequal-sized earth's crust and its internal similar sections and the resulting differences.[1, 2]. Differences reflect a certain rule, and grasping the rule can guide the production and life, and optimize the layout, plan the developing policies with important significance, thus the deep understanding of regional differentiation, directly or indirectly affects the regional development and sustainability. The study of the regional differentiation is one of the important signs of people's geographic environment cognition depth and natural environment research level, and the delineation of district boundaries has become an important and urgent work, especially in the region with complex, diverse terrain.[3]. Therefore, many scholars have carried out relevant research, and obtained some achievements. [4, 5]. But at present, the study of using the grid and GIS technology, combining with vegetation type, soil type and soil erosion less for natural regional division is quite rare.

2 Overview of the study area

Loess Plateau is located in north and central China, including the vast region of west of Taihang Mountains, north of the Qinling Mountains, east Wushaoling, south of the Great Wall. It is across Shanxi, Shaanxi, Gansu, Qinghai, Ningxia and Henan province, with an area of about 62.3299 million square kilometers. Apart from a few rocky mountains, the Loess Plateau is covered with a deep loess layer with a thickness between 50 to 80 meters, and the thickest layer is up to 150 to 180 meters. The loess are with fine particles, soft soil, rich in minerals, beneficial for farming, Agribusiness history of the basins and valleys is long, and it is the cradle of ancient Chinese culture. However, due to the lack of vegetation protection, and with the concentrated summer rains and storms, the ground has been divided in many broken pieces under long-term water erosion, forming highlands, hillocks, and loess hills in the gully interlocks (Figure 1).

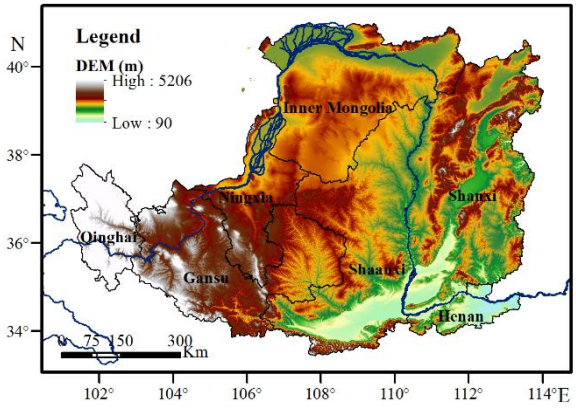

FIGURE 1 Overview of the Loess Plateau

3 Research Methods

3.1 DATA SOURCE AND PRE-PROCESSING METHOD

The data used included the daily precipitation, average speed, maximum speed, average temperature, average pressure, minimum temperature, maximum temperature, sunshine hours and relative humidity of 37 meteorological stations in the Loess Plateau and its surroundings in 1971-2000, the remote sensing (TM), the land use type map, the soil type map and the soil erosion map and DEM data of the Loess Plateau in 2000. First of all, the meteorological

* ***Corresponding author's*** e-mail: liqiangis@163.com

data of meteorological stations were processed in the aspect of the coarse grain into average monthly data for many years, the processing data of all the meteorological elements, and precipitation and sunshine time in April – September (growing seasons) were obtained. TM images were pre-processed in ERDAS8.7, including splicing, projection transformation, geometric correction and tailoring of the binary images. Then, the normalized model calculation of the vegetation index and soil information extraction index was established.

3.2 EVALUATION OF THE CONSTRUCTION OF FACTOR MODEL

3.2.1 Meteorological index

The data from the each station were used to conduct factor analysis for various meteorological factors to extract the main influence factors. The small grid calculation model was used as the basis, taking the effect of latitude and longitude and height above sea level on meteorological factors into account, so the three geographical factors of longitude, latitude, height above sea level were used as independent variables, climatic factors obtained by factor analysis were used as dependent variables to establish a multiple linear regression model. The model was as follows:

$$F = a_0 + a_1\phi + a_2 E + a_3 h, \tag{1}$$

where F is the dependent variable of meteorological model. φ, E, h are latitude and longitude and height above sea level respectively. a_0, a_1, a_2, a_3 are regression coefficient, which can be determined with the least square method according to some element value of each meteorological station and the data of latitude and longitude and height above sea level in this station. In which, φ, E, h are latitude layer, longitude layer and DEM respectively in layer calculation, the latitude and longitude layers were created by being imported into ArcGIS cross longitude and latitude data interpolation. The calculation results of various meteorological model layers represent the space distribution of meteorological factors [6].

Because the space change of terrain in the Loess Plateau had an increasing trend from southeast to northwest, the related analysis of meteorological model layers and DEM grid data layer were made, which was realized by the Band Collection Statistics Function of ArcGIS. According to the correlation coefficient obtained, each layer was standardized; negative correlation was standardized with lower effect measure, positive correlation was standardized with upper effect measure, to ensure that each layer changes in the same direction, the specific standard formula was as follows:

Standardization of upper effect measure:

$$Iscore_i = (x_i - x_{\min})/(x_{\max} - x_{\min}). \tag{2}$$

Standardization of lower effect measure:

$$Iscore_i = (x_{\max} - x_i)/(x_{\max} - x_{\min}), \tag{3}$$

where $Iscore_i$ represents the standardization value of an index in the i-th grid; x_i refers to the original data in an index in the i-th grid; $x_{\max}$ and $x_{\min}$ represents respecttively the maximum and minimum value of an index in all grid [7].

The meteorological index model was established as follows after the above models and standard:

$$MI = \sum_{i=1}^{m} a_i \times F_i, \tag{4}$$

where MI is the meteorological index; F_i is m meteorological elements. a_i is the corresponding weight of m meteorological elements. The weights are determined by the variation coefficient method.

3.2.2 Vegetation index

$$LCI = NDVI \times LT_i, \tag{5}$$

where LCI is the vegetation index; $NDVI$ is the normalized difference vegetation index of the cell; LT_i is the weight of each land use type. Land use types are obtained based on remote sensing image interpretation in 2010; the weight of each type can refer to the researches of Feng Zhiming and others [8].

3.2.3 Soil index

$$ESI = (TM5/TM7)/(TM4/TM3), \tag{6}$$

$$SI = ESI \times ST_i, \tag{7}$$

where ESI is soil information extraction index. TM_i is reflectance value of the corresponding band of remote sensing; SI is soil index. ST_i is the area percentage of each soil type.

Jin Ming et al thought (TM5/TM7)/ (TM4/TM3) not only highlighted the soil information, but also eliminated the influence of vegetation and terrain [9].

3.2.4 Erosion index

$$C = \sum A_i S_i, \tag{8}$$

where C is the comprehensive index of soil erosion in a cell. A_i is the area percentage of i-th soil erosion intensity within the cell. S_i is the corresponding index value of soil erosion intensity.

3.2.5 Comprehensive index

$$AI = \alpha \times NMI + \beta \times NLCI + \chi \times NEI + \delta \times NC, \tag{9}$$

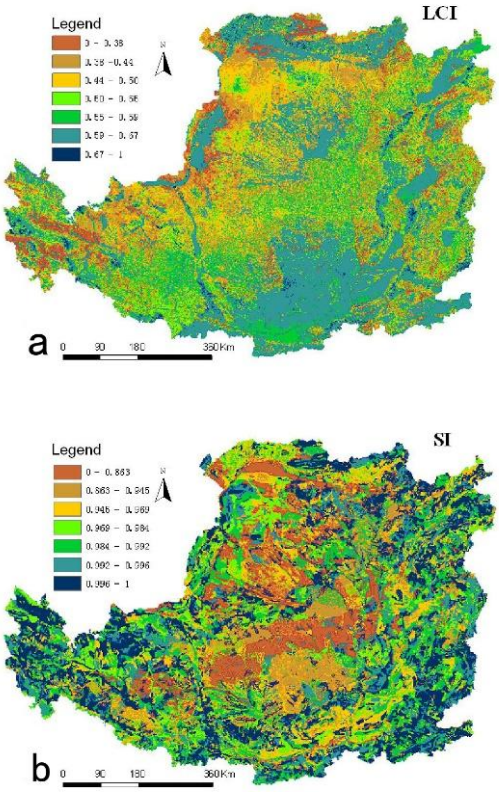
where AI is the comprehensive index for regional division; NMI is the standardized meteorological model

corresponding to various meteorological indexes; *NLCI*, *NEI* and *NC* are the standardized vegetation index, soil index and erosion index respectively. α, β, χ and δ is respectively the corresponding weight. Standard method was still calculated based on the correlation coefficient obtained from correlation analysis of DEM, and the weight was obtained by the AHP method.

4 Analysis of the Results

4.1 VEGETATION INDEX

Distribution of the vegetation in the space was a geographic unit of complete and continuous, and not repeated vegetation types and their combinations. As can be seen from Figure 2a, the vegetation distribution in the Loess Plateau had a stronger direction; vegetation was gradually in decline from southeast to northwest. Vegetation coverage of the Guanzhong Basin was quite good, in addition, Inner Mongolia, Shanxi, Yanan of Shaanxi and Henan also were distributed, and standardized vegetation index was mainly at 0.59 to 0.67; South and most of Shanxi, Shaanxi, south of Ningxia and southeast of Gansu had a worse vegetation coverage, standardized vegetation index was at 0.50 to 0.59; the vegetation coverage of Midwest of Erdos, Inner Mongolia, center of Ningxia and Dingxi, Gansu was relatively the worst, Qinghai province was also distributed occasionally, and the standardized vegetation index was at 0-0.50. This is mainly because terrain rises from the southeast to the northwest, and moisture decreases.



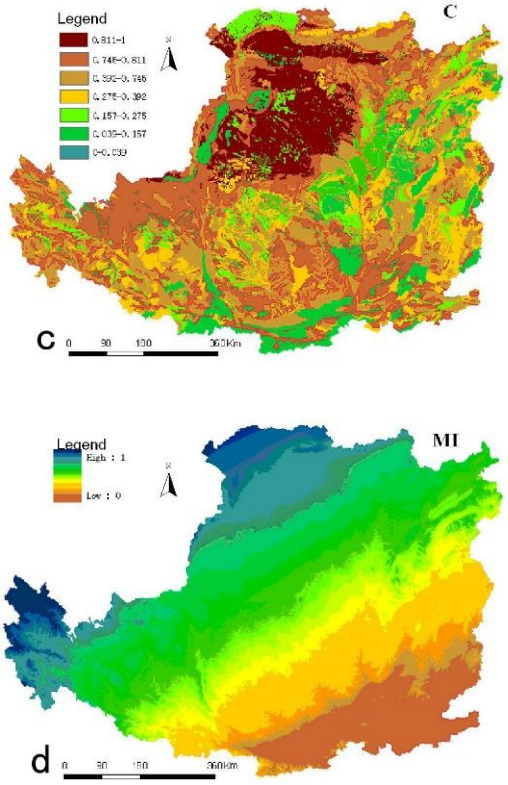


FIGURE 2 Standardized Index of Upper Effect Measure: a) Vegetation; b) Soil; c) Erosion; d) Meteorology

4.2 SOIL INDEX

According to Figure 2b, the spatial distribution of soil index was very scattered, but still has the difference in a certain direction, reducing the content of organic matter from southeast to northwest, and soil was pale in color, texture became light and crude. Among them, the standardized soil index of Shanxi, Guanzhong region of Shaanxi province and Henan, Inner Mongolia, north of Ningxia and Qinghai was at 0.945-1, and soil type was complicated; But the soil types in Shanxi, Guanzhong region of Shaanxi province and Henan had regosols, oil aquilegia soils, aquilegia clay soils, loessial soil, grey loess soils, good loess soils, light brown soils, cinnamon soils, leaching cinnamon soils; the soil types in Inner Mongolia, north of Ningxia and Qinghai had calcaric regosols, light brown soils, chestnut soils, light chestnut soils, light sierozem, chernozem, flow wind sands, cumulated irrigated soils, subalpine meadow soils, and alpine shrub meadow soils; the standardized soil index of Gansu, south central Ningxia, and Shaanxi was at 0-0.945, with a single soil type, mainly was sierozem, loessal soils, good loess soils, sandy loessial soils and grey loess soils.

4.3 EROSION INDEX

The purpose of the classification of soil erosion type is to reflect and reveal the erosion characteristics of different types and the law of regional differentiation, so that appro-

priate measures can be taken to prevent or mitigate erosion hazard. As can be reflected from Figure 2c, the intensity of Loess Plateau soil erosion also had a certain direction, increased from the southeast to the northwest, and the erosion type was also different. Among them, the erosion intensity of Guanzhong Basin of Shaanxi Province was the weakest, south central Shanxi was also sporadically distributed; the standardized erosion index was at 0.039-0.157; the erosion intensity at the junction of Shanxi and Northern Shaanxi was stronger, in addition, Inner Mongolia, Shanxi and Gansu also were distributed, and the standardized erosion index was at 0.157-0.275; the erosion intensity of Dingxi area, Gansu, most areas of Ningxia and Inner Mongolia obviously increased, and the standardized erosion index was at 0.745-0.811; the erosion intensity of the border between central south of Erdos, Inner Mongolia and Shaanxi was the strongest, and the distribution was concentrated.

4.4 METEOROLOGICAL INDEX

Due to obvious spatial difference of meteorological factors, it is necessary to take meteorological factors into consideration in the natural regionalization. There are many kinds of meteorological factors. However, the dominant factors are emphasized in the principle of natural regionalization, namely, the index of dominant factor reflecting the regional differentiation is selected as the main basis to determine the regional boundary. In this paper, the factors are analyzed, and annual average maximum wind speed and annual average wind speed are eliminated. Thus, other factors are used to establish the meteorological factor model (Figure 2d).

The multivariable linear regression model is established, with climatic factor which is obtained through factor analysis as the dependent variable as well as longitude, latitude and altitude as the independent variables, of which the upper limit measure effect is standardized. Then the other multivariable linear regression model is established, with the standardized climate factor as the dependent variable as well as longitude, latitude and altitude as the independent variable. The influence degree of the independent variable coefficient on dependent variable shall be achieved (Table 1), so as to compare the influence degree of the same independent variable corresponding to each dependent variable. It can be seen from Tab 1, the multiple correlation coefficient R of each model is more than 0.85, $F > F_{0.01}$, the model reaches the level of significance. Except for annual minimum temperature, annual maximum temperature and annual average temperature, the spatial and temporal variation of meteorological elements is very significant:

1) Under the same longitude and latitude, with the increase of altitude, annual average precipitation, precipitation in the growing season (April-September), annual average sunshine duration and relative humidity are increased, and their rates of change are 3.91mm/100m, 3.91mm/100m, 2.96h/100mand 0.13%/100m respectively, but other elements are decreased.
2) Uunder the same longitude and altitude, with the increase of latitude, annual average sunshine duration and sunshine duration in the growing season are increased, and their rates of change are 168.7411h/1°N and 89.3277h/1°N respectively, but other elements are decreased.
3) Uunder the same latitude and altitude, with the increase of longitude, the change of all elements is opposite to that of same longitude and altitude, namely, annual average sunshine duration and sunshine duration in the growing season are decreased, and their rates of change are 33.6667h/1°E and 15.8480h/1°E respectively, but other elements are increased.

In conclusion, combined with the influence degree of independent variables, the influence of longitude factor on annual average precipitation and precipitation of April-September is the most significant, followed by annual average relative humidity and atmospheric pressure. This is mainly because the terrain of high west and low east affects the degree of water vapor transport. With the increase of longitude, the higher the content of water vapor is, the easier it is cloudy and it rains. The influence of latitude factor on an annual average sunshine duration and sunshine duration of April-September is the most significant, followed by annual average precipitation and precipitation of April-September. This is primarily caused by the difference of north and south weather. Most are desert on the earth surface of the north, with no blockage and high wind, so there is a thin atmosphere, more sunny day and long sunshine time; the terrain of the south is gentle, so there is a thick atmosphere, the pollutants difficult to diffuse, low atmospheric visibility, more rainy day, short sunshine duration. In addition, the influence of altitude increasing gradually from the south to the north is also large. The influence of altitude factor on annual average temperature, average minimum and maximum temperature, as well as accumulated temperature of 10 or higher, followed by annual average precipitation and precipitation of April-September. The vertical lapse rate of annual average temperature, average minimum and maximum temperature is about 0.18°C /100m, quite different from the lapse rate of average temperature of free atmosphere (0.65°C/100m). This may be caused by the unique landform of the loess plateau as well as the different combinations of latitude, longitude and altitude. Therefore, it is concluded that the longitude, latitude and altitude affect greatly the natural factors of the loess plateau area.

TABLE 1 Projection model of meteorological factors

Regression coefficient/Degree of influence / Meteorological factors	a_0	a_1	a_2	a_3	Multiple correlation coefficient R	F (3.33)
Annual average precipitation	-467.2499	29.1348/0.67	-62.3635/0.77	0.0391/0.43	0.9023	48.2119
Precipitation of April-September	-573.7497	24.8187/0.72	-48.5759/0.76	0.0391/0.54	0.8750	35.9348
Annual average minimum temperature	2.3889	0.3840/0.37	-1.0346/0.53	-0.0018/0.81	0.8743	35.6973
Annual average maximum temperature	23.7370	0.1644/0.20	-0.6391/0.41	-0.0018/1.01	0.8561	30.1863
Annual average temperature	10.0353	0.2845/0.32	-0.7993/0.48	-0.0018/0.96	0.8729	35.2251
Accumulated temperature of 10°C or higher	8578.3357	730.2246/0.28	-1264.9502/0.26	-5.5423/1.02	0.8677	33.5060
Annual average atmospheric pressure	-46.4311	10.9787/0.49	-5.8929/0.14	-0.0316/0.67	0.9176	58.5876
Annual average sunshine duration	-124.9959	-33.6667/0.33	168.7411/0.89	0.0296/0.14	0.9318	72.5037
Sunshine duration of April-September	-191.4891	-15.8480/0.34	89.3277/1.02	-0.0103/0.10	0.9321	72.8853
Annual average relative humidity	49.7452	1.1864/0.49	-3.2894/0.73	0.0013/0.25	0.8817	38.4201

Based on meteorological data and the principle of variable coefficient method, the weight of each meteorological factor is obtained. Therefore, the meteorological index model is established. It is difficult to use the actual data to get the weight of ground cover index, soil index and erosion index, so each weight in the composite index model is calculated by using the AHP, among them, the comparative matrix is difficultly obtained. In this paper, based on the importance of each factor, first of all, the preliminary comparative results are obtained, and then the consistency ratio CR is calculated. Then various comparison results in the comparative matrix are adjusted according to the actual situation, until CR<0.1. At this moment, the consistency of comparative matrix is acceptable, as shown in Table 2.

TABLE 2 Comparative matrix of meteorological factors

	Ground cover index	Soil index	Erosion index	Meteorological index	Weight
Ground cover index	1	3	5	0.2	0.1999
Soil index	0.3333	1	2	0.125	0.0802
Erosion index	0.2	0.5	1	0.1111	0.0496
Meteorological index	5	8	9	1	0.6703

4.5 REGIONALIZATION RESULTS

The composite index layer is obtained through Equation 9, and the clustering method is used to divide the composite indexes into three levels from low to high, namely, I-III levels of different types of natural region (Figure 3). The overall distribution situation is a layered distribution from southeast to northwest, and then the regional statistics function of ArcGIS is used for different status values of different meteorological factors in three natural regions.

Level I natural region: The composite index is between 1.11 and 3.00. In this region, the lowest altitude is 91m, the highest altitude is 3681m, its average altitude is 1051.16m, and its pixel standard deviation is 469.435, indicating the change of topographic relief is small. Its land area is 19035376.2640hm^2, accounting for 30.6023% of the total area of Guanzhong region, mainly including Guanzhong region and the southern of Yan'an of Shaanxi, the south of Shanxi (the northern rim is basically the north end of Taiyuan Basin), the northwest of Henan, Tianshui City, Pingliang City and Dingxi area of Gansu Province. Among three natural regions, the precipitation, atmospheric temperature, atmospheric pressure and relative humidity of this region are the highest, but the sunshine duration is the shortest. The main vegetation is the cultivated vegetation, accounting for 54.2647% of the total vegetation area, followed by grasses and broad-leaved forest, and the vegetation coverage is the best. In terms of land use, the area of dry land is the largest, accounting for 40.7759% of the total area, followed by grassland, forest land and cultivated land. In terms of soil, the loessal soil is widely distributed, accounting for 37.5408% of the total soil area, followed by cinnamon soil and Lou soil. The erosion rate is the lowest, the typical erosion is surface erosion, accounting for 52.3126% of the total erosion area, followed by surface erosion-gully erosion-gravitational erosion, and the intensity of runoff erosion is smaller.

Level II natural region: The composite index is between 3.00 and 4.09. In this region, the lowest altitude is 367m, the highest altitude is 4914m, its average altitude is 1570.28m, and its pixel standard deviation is 540.374, indicating the change of topographic relief is the middle one among three natural regions. Its land area is 23810490.7610 hm^2, accounting for 38.2790% of the total area of Guanzhong region, mainly including the north of Yan'an and most parts of Yulin in Shaanxi Province, the north of Shanxi, the south of Ningxia and the southeast of Gansu Province. In addition, a small part of Level II natural region is also distributed in Qinghai Province. In three natural regions, the state of meteorological elements of this region is secondary. The main vegetation is the cultivated vegetation, accounting for 50.8289% of the total vegetation area, followed by grasses and grassland. The area of broad-leaved forest is smaller than that of Level I natural region, but its grassland is quite large, and its vegetation coverage is the better one. In terms of land use, the grassland area is the largest, accounting for 55.2701% of the total area. The area of dry land, forest land and cultivated land is much smaller than that of Level I natural region. In terms of soil, the loessal soil is widely distributed, accounting for 48.5126% of the total soil area, followed by cinnamon

soil, aeolian sandy soil, skeleton soil and dark loessial soil, and there is no Lou soil in this region. The erosion rate is secondary, the typical erosion is surface erosion-gully erosion-gravitational erosion, accounting for 52.3126% of the total erosion area, followed by surface erosion-gully erosion-gravitational erosion, and the intensity of gully erosion-gravitational erosion is smaller.

Level III natural region: The composite index is between 4.09 and 5.89. In this region, the lowest altitude is 783m, the highest altitude is 5067m, its average altitude is 1546.96m, and its pixel standard deviation is 655.918, indicating the change of topographic relief is the largest. Its land area is 19356553.9266hm^2, accounting for 31.1187% of the total area of Guanzhong region, mainly including Ordos Plateauof Inner Mongolia and the north of Ningxia. In addition, a small part of Level III natural region is also distributed in Shaanxi, Shanxi, Qinghai and Gansu. The state of all elements of this region is opposite to that of Level I natural region, namely, precipitation, atmospheric temperature, atmospheric pressure and relative humidity are the lowest, but the sunshine duration is the longest. The main vegetation is the grassland, accounting for 26.6676% of the total vegetation area, followed by cultivated land and meadow, and the vegetation coverage is the worst. In terms of land use, the area of grassland is the largest, accounting for 70.9113% of the total area. The area of dry land is much smaller than that of Level II natural region and the area of other land use is still increased. In terms of soil, the aeolian sandy soil is widely distributed, accounting for 25.9494% of the total soil area, followed by chestnut soil, Sierozem soil and skeleton soil. There is no cinnamon soil and Lou soil in this region, but a small part of desert soil and light brown soil is distributed. The erosion rate is the maximum, and the typical erosion is surface erosion, accounting for 29.4586% of the total erosion area, followed by runoff erosion (Figure 1).

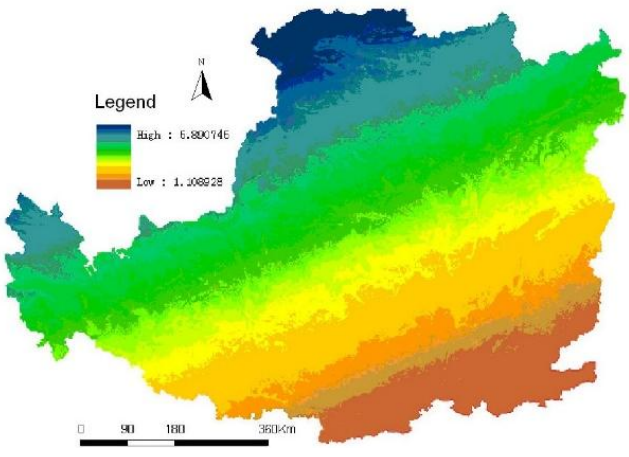

FIGURE 3 Diagram for Natural Regionalization of the Loess Plateau

5 Conclusions and discussion

Factor analysis and composite index are used for calculation to obtain the composite index model of the loess plateau, to determine the south boundary of the loess plateau. The conclusion is as follows:

1) The vegetation, soil and erosion rate have a consistent direction, so the selection of these three factors has a certain scientific nature.
2) The model set up based on meteorological elements, longitude, latitude and altitude is up to an extremely significant level, indicating that the accuracy of meteorological index model is higher. Through analysis, it is concluded that the longitude, latitude and altitude affect greatly the natural factors of the loess plateau area.
3) The overall distribution situation of the loess plateau composite index is a layered distribution from southeast to northwest. The size of meteorological elements is progressively increased or decreased in the sequence of regional level, gradually increasing with the direction of topographic relief. The vegetation coverage is reduced. The content of soil organic matter is decreesed, its color becomes lighter, and its texture becomes light and coarse. The erosion intensity is enhanced in turn. According to the results of the composite index regionalization, the south boundary of the Loess Plateau is basically determined, including Guanzhong region and the southern of Yan'an in Shaanxi Province, the south of Shanxi (the northern rim is basically the north end of Taiyuan Basin), the northwest of Henan, Tianshui City, Pingliang City and Dingxi area of Gansu Province. The north includes Ordos Plateau of Inner Mongolia and the north of Ningxia, Baiyin City and parts of Lanzhou in Gansu Province, Xining City and Haidong area in Qinghai and a few areas in the north of Shaanxi and Shanxi. The rest belongs to the central area of the Loess Plateau.

The research is involved in the modeling of meteorological factors. However, the meteorological data are limited, and only the data from 37 sites are available. Therefore, 12 meteorological factors are adopted to compensate for the inadequacy of data. In addition, the weights in the model of meteorological index and composite index are achieved respectively through two calculation methods, namely, the variable coefficient method and the AHP method. The variation coefficient method uses the actual data to obtain the weights, belonging to an objective weight method. But the partial actual data are difficultly obtained in the composite index model, so the AHP method is used to calculate the weight. Thus, in order to express the difference between regions accurately, besides the fine degree of the data should meet certain requirements, how to acquire the model parameters is also to be further studied.

Data mining applications research based on ISBN management

Yinglan Fang*, Bing Han, Binghui Chen

Department of Computer, North China University of Technology, Jinyuanzhuang Road 5, Beijing, China

Received 1 March 2014, www.cmnt.lv

Abstract

ISBN management systems existed irregularities publishing. How to summarizes the current book publishing rule according to publish information, it can better grasp the overall book market trends based on existing books. This paper introduced data mining ideas to the book publishing field through the study of real-name system to apply business processes. There were two data mining models. One was association rule analysis model based on subject field to book type distribution. It analyzed book type using classic Apriori association rule analysis algorithms to identify book publishing hot and the overall trend of publishing business. It can effectively regulate press book publishing behaviour and has great significant to the China's publishing industry healthy and orderly development.

Keywords: data mining, association rule analysis, ISBN

1 Introduction

The current society is in the period of an information technology, networks, data processing rapid development. How to apply suitable method extract valuable data from the large precious data, it has became an important issue. Data mining techniques emerged. Many universities, research institutions and companies worldwide are turning to data mining and knowledge discovery techniques and gain a lot of researches. So that data mining technology has been rapid development.

This issue research data is come from the ISBN real-name application system. ISBN real-name application system was major project which initiated and promoted by the Chinese General Administration of Press and Publication. It has improved the efficiency and quality of service book publishing industry. Over time, business data among the publishers and audit unit and the General Administration of the system have become rich. As a manager, the Press and Publication Administration eager to get useful part of the existing mass book publishing data to assist them to grasp book publishing direction and standard publishing industry. The research of this issue is to solve the book publishing industry currently facing problems using data mining technology. It would has great importance for the publishing industry.

2 ISBN management data mining analysis

ISBN real-name application system is an reform measures ISBN name to proposed by the Press and Publication Administration in 2006. Its rules is "See draft to get ISBN", "one book only one ISBS," "ISBN real name application." The purpose is to completely change the previous ISBN management and further strengthen publishing management and standardize the behavior of publication. With the accumulation of time, ISBN real-name application system has accumulated one million data, and it had to spend a lot of manpower and resources to maintain these data every year. Managers wanted to get useful information from these chaotic by data some means. Therefore, the data mining in ISBN real-name application system would have a very important significance.

2.1 DATA MINING SUBJECT FIELD

The issue starts from the existing ISBN data items, combining with the relevant provisions of how to optimize and book publishing administration reform publishing behaviour. It determines four sides subject area. They are ISBN distribution usage amount and book type distribution and audience and publishing books standard degrees. ISBN real-name application system's database table name were:

T_B_BOOKINFO (report books basic information table),
T_B_PUBLISHINFO (press basic information table),
T_D_ISBNINFO (audit and pass ISBN data table),
T_D_PLANADD (press add ISBN table),
T_D_PLANTOTAL (press publishers plan to distribute ISBN),
T_D_BOOKINFO_ STATUS (declaration book status table)

and so on nearly 10 table and more than 60 million data items. It creates corresponding data table around the data items needed by selected subject areas and ultimately establishment appropriate data warehouse.

2.2 ASSOCIATION RULE MINING MODEL ANALYSIS

Association rule analysis model is mainly comprehensive

* ***Corresponding author's*** e-mail: jlufangyl@163.com

analysis through the ISBN data items and ISBN real-name application system operation flow. It combines with the basic needs of decision makers, establishes the improved association rule analysis model. it includes selecting data items, filtering and integration, researches and implements Apriori algorithm, selects the appropriate threshold (support, confidence), analysis the resulting data and obtains corresponding conclusions or visualization rendering.

The association rule analysis model in this issue is created according to the press publishing book situation. Its purpose is to find the current book publishing rule within a certain period. For example, from the overall analysis 585 publishers, publishing arts (J category) and the history, geography (K category), 100% of publishers will be publish culture, science, education (G category) books. Which found that the country's book publishing trends and characteristics. The books in ISBN apply real-name system are classified according to the classification of Chinese Library Classification from A category to Z category.

- A Category: It represents the Marxism-Leninism, Mao Zedong Thought, Deng Xiaoping Theory and so on category.
- B Category: It represents the philosophy and religion category.
- C Category: It represents the social sciences category.
- D Category: It represents the political and legal category.
- E Category: It represents the military category.
- F Category: It represents the economic category.
- G Category: It represents the culture, science, sport and education category.
- H Category: It represents the language and writing category.
- I Category: It represents the literature category.
- J Category: It represents the art category.
- K Category: It represents the history and geography category.
- N Category: It represents the natural sciences category.
- O Category: It represents the mathematical science and chemistry category.
- P Category: It represents the astronomy and earth science category.
- Q Category: It represents the biological science category.
- R Category: It represents the medicine and health category.
- S Category: It represents the agricultural sciences category.
- T Category: It represents the industrial technology category.
- U Category: It represents the transportation category.
- V Category: It represents the aerospace category.
- X Category: It represents the environmental science and safety science category.
- Z Category: It represents the general books category.

Due to the every press's basic conditions is different, the different publishing book ability or some other causes leads to the published books type which is scattered. Some rare and poor sale books have small publishing amounts. Some popular and highest-selling books have high issue.

So only from single book publishing number and ISBN circulation amount, it cannot be seen in the overall trend and found publish association rule. Research data mining association rules model and data mining process is the same. They are divided into three processes: data extraction, data processing, association rule analysis.

The first step is data extraction. According to the selected subject areas, the book publishing type, ISBN real-name application system classify the book type, the basic situation of each country published book publishers can be obtained from the database system. It statistically analysis books information resource library and books type distribution of each publishing press. Combined with the actual needs, it select the appropriate data entry according to the association rules and create database table structure. Because it aims at the country's 585 presses and for nearly one million book information in six years, it can extract database in accordance with the certain period of time and different database tables corresponding data. based on these reasons it has created such a table structure: book the original information sheet named Original Book Type (include book serial number, ISBN number, book title, author, introduction, book type, publishers ID, extraction time), so it can prepare data items for the next step of data pre-processing.

The next step is data pre-processing. Book raw information obtained from last step data extraction, it needs for further processing and final processing to these data so as to obtain experimental data of books type distribution and use for analysis of Apriori association rules algorithm. Association rules was analyzed through books type distribution. It extracts book data according to the press group and statistics for each publishing house within a certain period of time books published by type. The statistics result was stored in the statistics books Information table named Book Type Count. Every presses are handled as a single transaction. Each transaction has a number of data items. Books type in the table is the statistics of the total book type within a certain period of time. Association rules algorithm requires incoming data is Boolean variable with the value 0 or 1. That the book publishing house types need to represent with value 0 or 1. These data distribution directly affect the results of association rules, so when it sets this threshold it needs repeated testing to find the most appropriate threshold and compare the various book type statistics value with the threshold. When the book type value is larger than the threshold value it is set to 1 and otherwise its value is set to 0. The handled books is stored to book conversion table named Book Type Static according to its rule. Association rules analysis data table structure is shown in Figure 1:

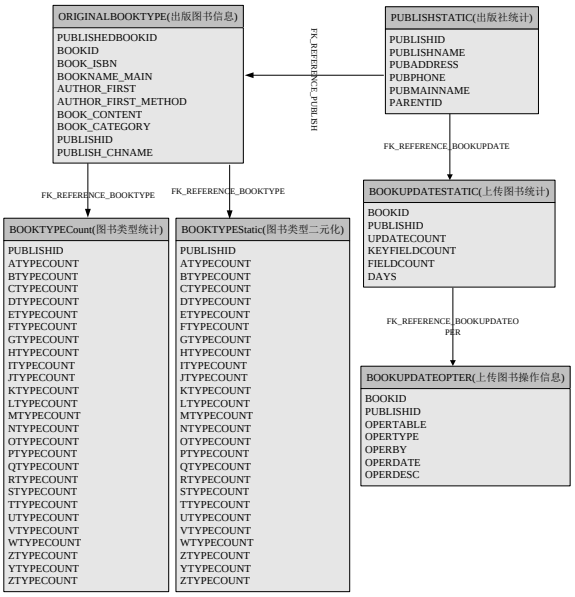

FIGURE 1 Association rules Analysis Database Design E-R

The next step is the results and analysis of association rules. There are two sides. The first side is the parameter setting in Apriori algorithm that is support and confidence threshold. The quality of selected value directly affects the accuracy of the association rules analysis, therefore it requires the combination of the actual situation and the repeated sampling test to help determine the final threshold. The second side is the result of the analysis. It derived some abstract data information after data mining. Researchers and professionals can clearly understand the meaning of the data represents. For general managers it need for appropriate process and convert the data so they can easily accept and understand with text presentation or graphic presentation, and ultimately achieve the purpose of data mining.

3 ISBN data mining design

It can be seen from the research background that the applicable targets to ISBN manage mining system is press administrative department and ISBN issuing departments, including the press and publication administration departments, barcode centres and 31 provincial bureau issued centres. Users can log in the system accordance with their own username and password and use their corresponding function. They can statistically classification analysis and supervise to published books and ISBN usage. It include four aspects. The first is the overall trend in publishing books to current national book press and timely tracking and analysis to book publishing rule. So it can adjustment and control to prevent overheating of some vulgar books published and some less famous books publishing phenolmenon occurs. The second is to supervise the whole process from the application publishing a book to publishing a book so as to discover problematic Press and eradicate illegal acts as "One multi-use", "trading ISBN" and so on. The third is manage publishers sample information cannot be uploaded books by press and the pending book cannot be audited by department. The fourth is the detailed statistical analysis to national book publishing situation. It divides from the time dimension, spatial dimensions and regional dimensions in order to understand the current overall situation of the book publishing industry.

3.1 SYSTEM NETWORK STRUCTURE DESIGN

The system uses B/S architecture model. The user can issue through the browser to many distributed servers on the network request to complete the corresponding business functions. The basic topology of the network structure is shown in Figure 2:

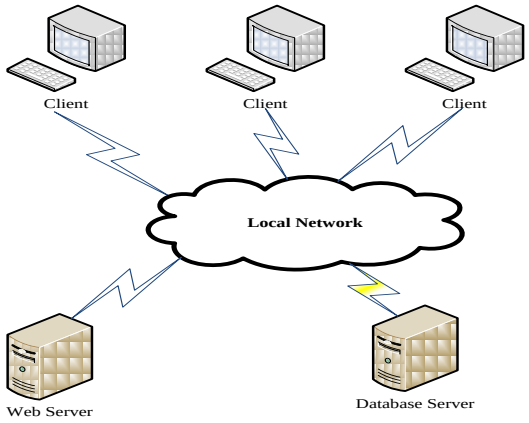

FIGURE 2 ISBN information data mining system network topology

Interaction between the user and the system are described as the below:

- User fills out the network address of the system in the browser and request a service to a Web server on the network via a Web browser. Web server user identity verification after transferring to the desired page using the HTTP protocol client and displayed in a Web browser.
- Web servers accept user requests and connect the database. Then put forward data processing request to the database server through SQL and transfer the results to the Web server.
- Web servers obtains visualization results from data service processing results and returns to the browser user.

3.2 SYSTEM MAIN CLASS DESIGN

In this paper, it has designed the interfaces and classes in association rules analysis algorithm (Apriori algorithm). Apriori algorithm is mainly read transaction data in the data warehouse by Get-Source method. Then through combination of internal processing transaction data, it fits

the data structure in line with the main function, and ultimately get frequent data mining item sets. The Apriori algorithm class design of association rules analysis are as follows (Table 1):

TABLE 1 Apriori Test class method function

Class name	method name	function
AprioriTest	Public String getRules ()	get related combination of frequent items
	Public Integer getconfidence ()	get a given minimum confidence
	Public Integer getSupport ()	get a given minimum support
	Public void mine ()	mining each frequent item sets
	Public void associationRule ()	mining frequent association rules
GetSource	getBookTypeCount ()	get the book information to data type
	getBookTypeStastic ()	get book type information
	getSet ()	get association rule analysis datasets

4 ISBN Data Mining Implementation

This section describes the main functions of association rules analysis modules. It includes raw data extraction, data conversion, data filtering, association rules analysis and graphical display.

FIGURE 3 Raw data statistics Schematic of association rules analysis

4.1 APRIORI ALGORITHM FOR DATA PRE-PROCESSING

1) Data statistics. It statistics and classifies source data extracted from the previous step and classifies according to classify method. Specific statistical results are shown in Figure 4.
2) Data filtering and data cleaning. It further processes data counted by the previous step, converts into binary data structure representation by a given threshold and provides analytical data for the association rule algorithm. It is as shown in Figure 5:

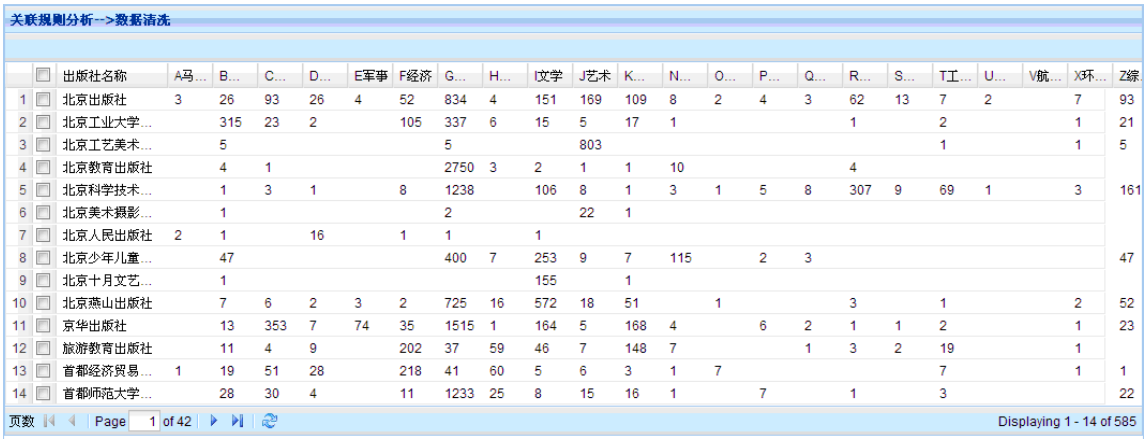

FIGURE 4 Association rules analysis data filtering schematic

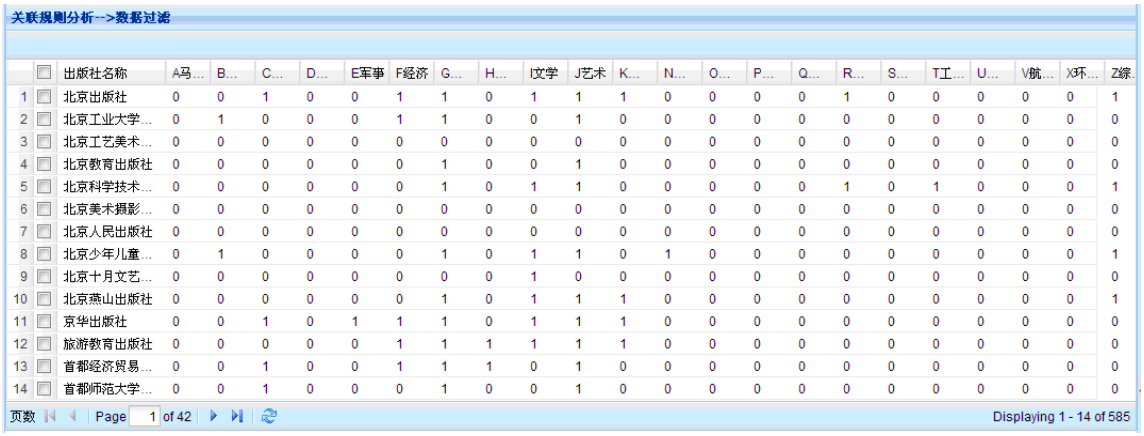

FIGURE 5 Data conversion schematic in association rules analysis

4.2 APRIORI ALGORITHM DATA ASSOCIATION ANALYSIS

The purpose of this analysis is the association rule 585 publishers across the country to conduct the type of book publishing association rules analysis, which found that the association between a certain period of time and the overall trend of analyzing summarizes book during this time.

It can be seen from the Figure 5 that it has 633,591 books and 585 press, namely the number of transaction in association rules analysis process is 585. In line with the specified degree of support minSupport equal to 0% and confidence minConfidence equal to 30%, there are frequent item sets conditions. Namely: {[I, J] =>G}, {K=> [G, J]}, {[G, K] => J}, {I => [G, J]}, {G =>J}, {[J, K] => G}, {[G, I] => J}, {J => G} which rules is [I, J] => G and confidence levelis 48% and degree of support is 100%.

It illustrates that 100% nationwide press publishes science books and economic books and culture, science, education, sports books. Among 48 percent press which published class I (social sciences) and J books (economy class) may also publish books of the class G (culture, science, education, sports).

From an overall perspective, we can see that the economic books, culture, science, education, sports books, literature books almost become mainstream during this time.

关联规则集	置信度	支持度
I,J => G	0.47692308	1.0
K => G,J	0.36923078	0.875
G,K => J	0.33333334	0.9692308
I => G,J	0.53675216	0.91719747
G => J	0.53675216	0.91719747
J,K => G	0.32307693	1.0
G,I => J	0.4923077	0.96875
J => G	0.774359	1.0

FIGURE 6 Association structure data shows in association rules analysis

4.3 ASSOCIATION RULES ANALYSIS RESULTS SHOW

The results association rules analysis is a string of characters and numbers. For which the system user is difficult to understand the meaning. It can be very clearly seen through the graphical display that the roughly distribution of books types and can help verify the accuracy results information of the association rules analysis (Figure 6-7).

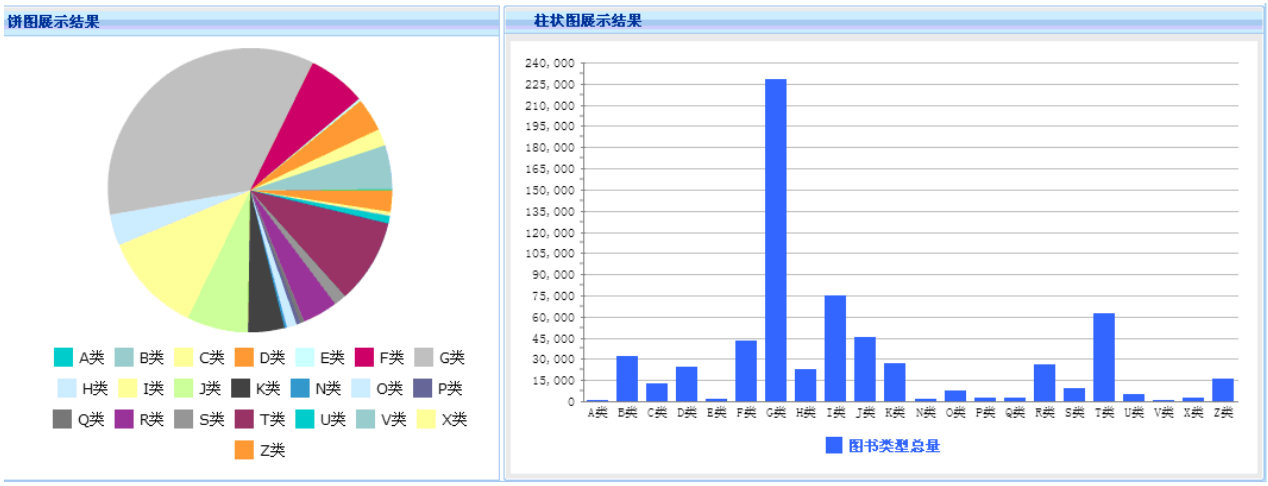

FIGURE 7 Graphical association rules analysis shows

5 Conclusions

In this paper, data mining technology has been imported into the book publishing industry, and conducted in-depth theoretical study and specific mining algorithm experiments. This paper mainly studied the association rules analysis Apriori algorithm. According to the needed analysis problems and actual application, it deeply sees the business of the ISBN real-name application system. Combined with existing data mining techniques, it has analyzed and created around the theme of type press books domain analysis model and association rules around behaviour publishing books degree of clustering model specification subject areas. From different angles ISBN statistical analysis of the data item information, the evaluation and mining results graphically is shown.

Recommendation system based on collaborative filtering in RapidMiner

Zhihang Tang, Zhonghua Wen

School of Computer and Communication, Hunan Institute of Engineering Xiangtan 411104, China

Abstract

Recommender systems facilitate decision-making processes through informed assistance and enhanced user experience. To aid in the decision-making process, recommender systems use the available data on the items themselves. Personalized recommender systems subsequently use this input data, and convert it to an output in the form of ordered lists or scores of items in which a user might be interested. These lists or scores are the final result the user will be presented with, and their goal is to assist the user in the decision-making process. The application of recommender systems outlined was just a small introduction to the possibilities of the extension. Recommender systems became essential in an information- and decision-overloaded world. They changed the way users make decisions, and helped their creators to increase revenue at the same time. Bringing recommender systems to a broader audience is essential in order to popularize them beyond the limits of scientific research and high technology entrepreneurship. The recommender systems will assist you in reaching quality, informed decisions.

Keywords: recommender systems, collaborative-based systems, nearest neighbour

1 Introduction

Making choices is an integral part of everyday life, especially today when users are over- whelmed with information, from the Internet and television, to shelves in local stores and bookshops. We cope with this information overload by relying on daily recommendations from family, friends, authoritative users, or users who are simply willing to offer such recommendations. This is especially important when we lack information to make a rational decision, for example, choosing a hotel for vacations in a new city, selecting a new movie to watch, or choosing which new restaurant to visit.

Recommender systems [1] facilitate decision-making processes through informed assistance and enhanced user experience. To aid in the decision-making process, recommender systems use the available data on the items themselves, such as item taxonomies, descriptions and other, and/or data on user experience with items of interest, for example, user choices, rankings, scores, tags, etc. Personalized recommender systems subsequently use this input data, and convert it to an output in the form of ordered lists or scores of items in which a user might be interested. These lists or scores are the final result the user will be presented with, and their goal is to assist the user in the decision-making process.

Recommender systems represent a broad and very active [2-4] field of research and were, from their origins in the 1990s [5], somewhat detached from the data mining field. This was mostly due to the specific form of data that recommender systems used. There are three basic types of recommender systems: collaborative filtering, content-based, and hybrid systems. Collaborative filtering recommender systems use social information, preferences, and experiences of other users in order to find users with similar taste. The assumption of these systems is that users of similar tastes might enjoy and consume similar items. Content filtering recommender systems use the available structured and unstructured information on users or items to recommend further items of interest. They assume that the user might be interested in items similar to the ones in which an interest has already been displayed. Both of these systems have their advantages, which are additionally reinforced, or disadvantages, which are diminished with the usage of hybrid systems-systems which combine both the collaborative and the content-based recommendation approach.

Recommender systems are ubiquitous, and an average Internet user has almost certainly had experiences with them, intentionally or not. For example, the well-known Internet commerce, Amazon.com employs a recommender system that recommends products its users might be interested in, based on the shopping habits of other users. Social networking sites like Facebook or LinkedIn use recommender systems for recommending new friends to users based on their social network structure. The music website Last.fm uses a recommender system to recommend new music to a user, based on the listening habits of users with similar music taste. The Internet Movie Database (IMDb) recommends similar movies, based on the content and style of the movies user previously browsed. Streaming provider Netflix tries to predict new movies a user might be interested in based on his watching habits and movie ratings, compared to other users. These, and numerous other examples like Stumble Upon, Google AdSense, YouTube, etc., which differ in services provided, like audio, video, general item, social network, other Internet content, books, etc., demonstrate the importance of these systems.

Recommender systems facilitate making choices, improve user experience, and increase revenue, therefore should be easily accessible for deployment to interested

parties. This led us to write a paper on recommender systems in a clearly understood and easily applied way through RapidMiner. We believe that RapidMiner's workflow approach entices systematic research and facilitates its implementation in combination with Rapid Analytics. The combination of research and production environment renders itself as an excellent environment for understanding recommender systems through practice. Throughout this paper, you will learn the basics of theory related to recommender systems, with a strong emphasis on practical implementation. This practical work will introduce you to all the necessary knowledge for rapid prototyping of recommender systems, thus enabling you to master them through application of your data. The implementation of recommender systems in RapidMiner has been additionally simplified through the Recommender Extension.

2 Basic conception

2.1 RECOMMENDATION OPERATORS

The Recommender Extension has a total 26 recommendation operators. These operators are grouped in the following categories: Item Recommendation, Item Rating Prediction, and Recommender Performance. The overview of operators supported in the Recommender Extension is given in the Table 1.

TABLE 1 Recommendation operators supported by the Recommender Extension.

Item Recommendation (IR)	Collaborative Filtering-based Item Recommendation	Item k-NN, Most Popular, Bayesian Personalized Ranking Matrix Factorization, User k-NN, Weighted Regularized Matrix Factorization, Random
	Attribute-based Item Recommendation	User Attribute k-NN, Item At-tribute k-NN
Item Rating Prediction (RP)	Collaborative Filtering-based Rating Prediction	Random, Global Average, User Item Baseline, User k-NN, Item k-NN, Slope One, Bi-Polar Slope One, Matrix Factorization, Biased Matrix Factorization, Factor Wise Matrix Factorization
	Attribute-based Rating Prediction	User Attribute k-NN, Item At-tribute k-NN

Item recommendation operators operate over large matrices that contain information about which user consumed which item. These input matrices often contain large numbers of empty entries, and can thus be used in a more space-efficient way. We describe the appropriate format used for efficient data loading and storage in the next subsection.

2.2 DATA

Typical recommender systems, operating on user usage data, are built on top of large matrices called utility matrices. These matrices usually contain elements from a limited set of numbers, for example from 0, 1, 2, 3, 4, 5, where 0 typically denotes that the user had no interaction with the item, and the rest describes the level of that interaction in a form of rating. Due to a large number of both users and items, these matrices are typically very large. In addition, since users mostly consume a very small portion of items out of the total number of items, these matrices tend to contain a lot of zeros – they tend to be very sparsely populated. This is why special data structures for handling sparse data need to be implemented. In RapidMiner, we can use AML reader operators to read such datasets. Input datasets used to learn a recommender system model must be formatted in two columns; for example, the first column can contain user IDs, while the second can contain item IDs. Attributes names, and their positioning can be arbitrary. Prior to applying recommendation operators to input datasets, proper roles have to be set for these attributes, as seen in Table 1. Any additional attributes will not be considered. An example of an AML, and a related DAT file for item recommendation operators is given in Figure 1.

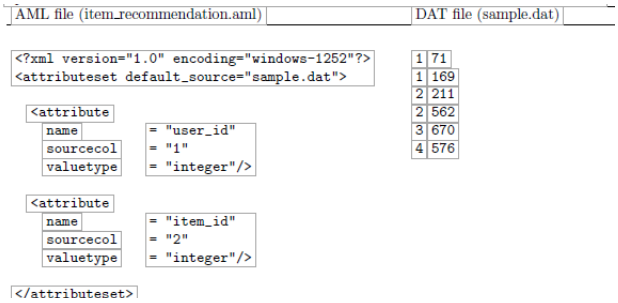

FIGURE 1 An example of an AML and a related DAT file for item recommendation operators

The recommender system datasets used throughout this paper consists of content and collaborative data. Content data was taken from the ALIDATA DISCOVERY (http://102.alibaba.com/competition/addDiscovery/index.htm)

The content dataset described contains the following content attributes for each item:

brand ID: a unique integer that represents a lecture;

brand name: a text string containing a name of a particular lecture;

brand description: a text string denoting a description of a particular lecture.

A particular item identifier is denoted by the small letter i and the set of all items is denoted by the capital letter I. Collaborative data contains synthetic click streams of users, where each click stream is a sequence of items viewed by a particular user in some time interval. In the following text, we refer to the synthetic users as users. A particular user identifier is denoted by the small letter u and the set of all users is denoted by the capital letter U. Click streams are transformed into the sparse matrix A, which is called the usage matrix. The non-zero elements of

the usage matrix (A (i, u)) tell us that the item i was consumed by the user u. Using this dataset, we construct collaborative and content recommender systems in the following sections. The collaborative recommender systems rely on the usage matrix A while the content recommender systems rely on items textual descriptions. We can get Figure 2.

2.3 COLLABORATIVE-BASED SYSTEMS

The main idea of collaborative recommendation approaches is to use information about the past behavior of existing users of the system for predicting which item the current user will most probably like and thus might consume. Collaborative approaches take a matrix of given user-item ratings or viewings as an input and produce a numerical prediction indicating to what degree the current user will like or dislike a certain item, or a list of n recommended items. The created list should not contain items the current user has already consumed.

Neighborhood-based recommender systems work by counting common items two users have viewed for every pair of users in the system, or the number of common users that viewed the same pair of items. Using this count, similarity between two users or items is calculated. Neighborhood systems use intuition that two users who have viewed a large number of common items have similar tastes. That information can be used to recommend items that one user consumed and the other one did not. We are interested in finding pairs of users having the most similar taste, or pairs of items having the most users that viewed both items. Those pairs of users/items are called "the closest neighbors". We describe two main approaches of the neighborhood-based recommender systems: user and item-based nearest neighbor recommendation.

2.3.1 User-based nearest neighbor recommendation

Given a user-item viewing matrix and the ID of the current user as input, identify other users having similar past preferences to those of the active user. Subsequently, for every product the active user has not yet consumed, compute prediction based on the product usage of the selected user subset. These methods assume that users, who have previously shared similar tastes, will share similar tastes in the future, and that user preferences remain stable and constant over time.

To calculate similarity between users, two typical similarity measures are used: the Pear- son correlation and the Cosine correlation [6]. In our item recommendation problem we used cosine correlation as a similarity measure. Typically, we do not consider all users in the database when calculating user similarity, rather the k most similar ones.

2.3.2 Item-based nearest neighbor recommendation

When dealing with large problems, consisting of millions of users, user-based collaborative filtering approaches lead to increased memory usage and execution time. Since the system is required to calculate a large volume of potential neighbors, it becomes impossible to compute predicttions in real time. In some cases, the number of users dominates the number of items in the system so it would be natural to try to use items for making recommendations. That is the reason for creating a second neighborhood-based recommender system based on items instead of users.

As opposed to the user-based approach, the item-based recommendation approach computes prediction using the similarity between items. We use a cosine similarity measure, as we did in the user-based approach. Likewise, as in the user-based approach, we use k-nearest neighbors, i.e. the k most similar items for prediction.

3 Personalizing Recommender Systems

Collaborative recommender operators use the user-item matrix to build a recommendation model. This user-item matrix is presented as an example set of user-item pairs describing user consumption history. The recommendation model built with this matrix is used to recommend items to

users from a query set. The query set is an example set containing identification numbers of users for which we want to make recommendations. For each user in the query set we recommend only the items not consumed by this user. Figure 3 depicts a basic collaborative recommender operator workflow.

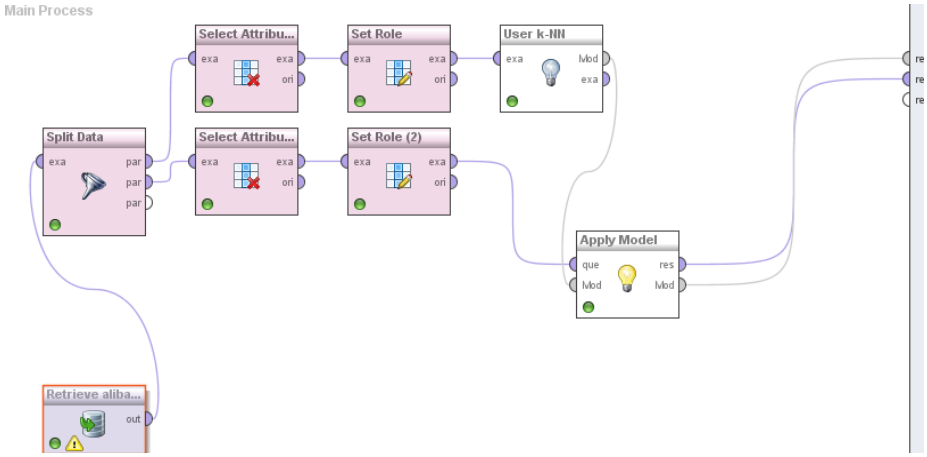

FIGURE 3 An example of an item recommendation workflow

The recommended results shown in Figure 4.

FIGURE 4 The Recommended results

In the item recommendation workflow, the first two operators read the train and the query example sets using the Read AML operators (1,4). Following, the appropriate roles are set to attributes using the Set Role operator (2). The user identification role was set to user id attribute and item identification role to item id attribute. Data attributes can have arbitrary names but roles for those attributes must be set. Next, we use the train data with the appropriately set roles to train an Item k-NN model (3). At this point we can use our trained model to recommend new items to users in the query set using the Apply Model operator (6). Prior to model application, the user identification role was set for the query set (5). The Apply Model operator (6) returns an example set containing the first n ranked recommendations for every user in a query set. In Figure 3 we have seen how to make recommendations for particular users. In the following figure, Figure 4, we show how to measure performance of a recommendation model.

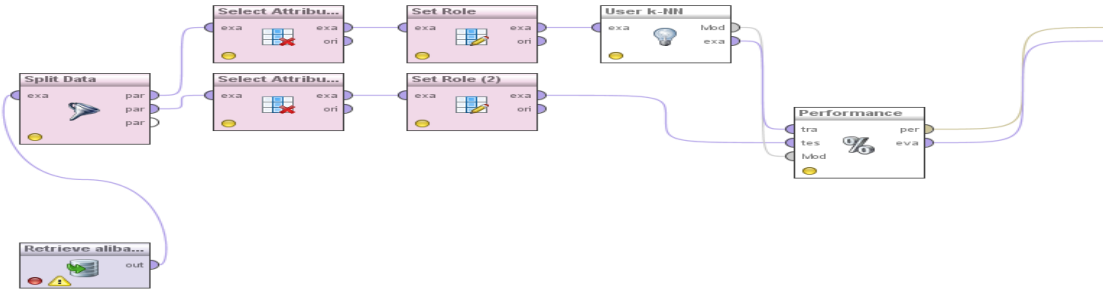

FIGURE 5 Measuring performance of a recommendation model.

The data management part of the workflow for measuring recommender model performance in Figure 5 is the same as in Figure 3. We use the Read AML operators (1,4) to load the data input, and the Set Role operators (2,5) to set the appropriate roles. In this workflow we use the test data (4) containing two attributes, the user id and the item id attribute and we set user identification and item identification roles to those at-tributes, respectively. The difference from the previous workflow is the need to calculate the performance of our built recommendation

model (3). We use the Performance operator (6) to measure standard recommendation error measures we previously defined: AUC, Prec@k, NDCG, and MAP. The Performance operator (6) returns a performance vector and an example set containing performance measures. This enables a user to choose which format suits his or her needs. We can get Figure 6.

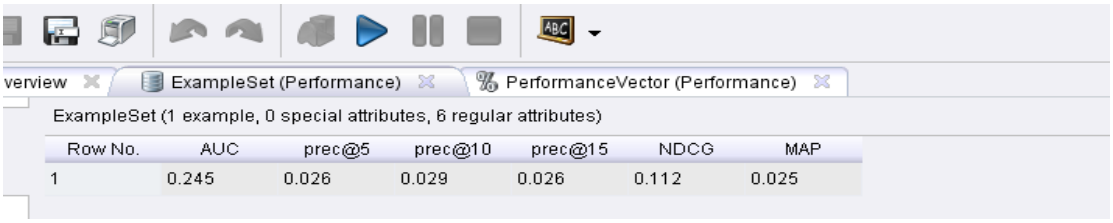

FIGURE 6 the performance of Recommender Systems

4 Conclusions

Recommender systems became essential in an information- and decision-overloaded world. They changed the way users make decisions, and helped their creators to increase revenue at the same time. Bringing recommender systems to a broader audience is essential in order to popularize them beyond the limits of scientific research and high technology entrepreneurship. The goal of the Recommender Extension for RapidMiner and this paper was to bring recommenders to a broad audience, in a theoretical, practical, and above all, application way.

In this paper we presented recommender systems and their different techniques: collaborative filtering, content-based recommender systems, and hybrid systems. We presented the advantages and disadvantages of each of those systems and demonstrated how they could be implemented easily in RapidMiner. The application of recommender systems outlined was just a small introduction to the possibilities of the extension. We hope you will use the knowledge obtained through this paper in your own applications, problems, and businesses, and that recommender systems will assist you in reaching quality, informed decisions.

Abstract

Region division is the foundation of regional socio-economic development planning. Traditional regional division is only built upon the information of attributes in each spatial unit. However, the spatial relationships and their spatial interaction between units are ignored. In the study, based on the spatial linkage theory, the principle and steps of spatial units fusion of clustering algorithm is proposed. According the spatial range of Chinese railway as a case, determine the spatial units and the linkage model was built based on the proximity and attribute characters, the experiments of regional division for Chinese railway are achieved. The experiment shows the results are highly accordant with the real situations and have proved the feasibility of the algorithm.

Keywords: spatial linkage theory, region division, spatial units fusion of clustering algorithm, Chinese railway

1 Introduction

Regional planning is an important part of regional socio-economic development planning. Region division is the foundation of regional planning, and the division foundation in current research is classified into two types. One take the economic attribute as the main basis [1,2], as economic belt [3], economic region [4] and metropolitan area [5]. But the academe has not come to an agreement with it, the reason is the principles and methods are different and can also affect the regional planning establishment and implementation. Another take the spatial units attribute as the main basis [6]. But this method only consider the individual attribute data and the relationship are ignored in practice.

Based on the spatial linkage theory [7], starting with the relationship with the contiguous spatial units, the fusion of clustering algorithm [8,9] were studied and so as to realize the region division.

2 Spatial units fusion of clustering algorithm

2.1 ALGORITHM PRINCIPLE

Within the selected spatial range, the spatial set can be formed under the proper spatial units are selected, by computing the units correlation data, the correlation coefficient set is determined, fused with the two adjacent spatial units which has maximum correlation coefficient, connect the units in one direction according to the units attribute until there are not any external connection by the fusion units, so the units which have fused cluster a class. According to this algorithm, all the spatial units are clustered several classes in the spatial range.

2.2 ALGORITHM STEPS

Step 1: Determination of the spatial range *s*.

Step 2: Determination of the spatial units s_i:

$S = \{S_1, S_2, ..., S_i\}$.

Step 3: Determination of the model of the relation coefficient *f*.

Step 4: Take a spatial unit as the starting point S_1, computed the relation coefficient f_{1j} with the neighboring spatial units, fused with the two neighboring spatial units which has maximum relation coefficient max f_{1j}.

Step 5: Determination of the neighboring spatial units in one direction connection T_{1j}. The units attribute data is used to represent the (Q_1, Q_2), determine the connect direction T_{1j} by comparing Q_1 and Q_2, if $Q_1 / Q_j > 1$, $T_{1j} = 1$, otherwise $T_{1j} = 0$.

Thus, the two contiguous units have only one direction connection.

Step 6: In the same way, by computing as step4 and step5 until there are not any external connection by the fusion units, so the units which have fused cluster the first class C_1.

Step 7: According to this algorithm, all the spatial units are clustered several classes, $S = (C_1, C_2, ..., C_k)$.

3 An example of region division of Chinese railway

3.1 DETERMINE THE SPATIAL RANGE

Regional railway planning is the effective link to the "Medium and Long-term Railway Network Planning" [10], so the spatial range of region division of railway transportation should be carried out within the scope of national railway space (except Hong Kong, Macau and Taiwan).

3.2 DETERMINE THE SPATIAL UNITS

Chinese railway transport mainly presented as inter-provincial transport relationship, and the volume of freight flow mostly completed between 1,000~2,000 *km* [11]. So the spatial units selection are based on the provinces, municipalities and autonomous regions. Considering the uniqueness of the adjacent space, fused the only adjacent units to each other at first and the number of spatial units are 28. As shown in Table 1.

TABLE 1 Spatial units of region division of Chinese railway

Region code	Region name	spatial unit code	Region code	Region name	spatial unit code
110000	Beijing	S_1	410000	Henan	S_{15}
120000	Tianjin	S_1	420000	Hubei	S_{16}
130000	Hebei	S_1	430000	Hunan	S_{17}
140000	Shanxi	S_2	440000	Guangdong	S_{18}
150000	Mongolia West	S_3	450000	Guangxi	S_{19}
150000	Mongolia East	S_4	460000	Hainan	S_{18}
210000	Liaoning	S_5	500000	Chongqing	S_{20}
220000	Jilin	S_6	510000	Sichuan	S_{20}
230000	Heilongjiang	S_7	520000	Guizhou	S_{21}
310000	Shanghai	S_8	530000	Yunnan	S_{22}
320000	Jiangsu	S_9	540000	Tibet	S_{23}
330000	Zhejiang	S_{10}	610000	Shaanxi	S_{24}
340000	Anhui	S_{11}	620000	Gansu	S_{25}
350000	Fujian	S_{12}	630000	Qinghai	S_{26}
360000	Jiangxi	S_{13}	640000	Ningxia	S_{27}
370000	Shandong	S_{14}	650000	Xingjian	S_{28}

3.2 SPATIAL UNITS CORRELATION MODEL

Spatial units correlation model was built from the method of spatial transport linkage theory [7], according to the data of $O-D$ matrix and considering the bidirectional transport data transfer. The model can be used to evaluate the correlation strength with the adjacent spatial units, as shown by Equation (1):

$$f_{ij} = a_i \frac{O_{ij}}{O_i} + a_i \frac{D_{ij}}{D_i} + a_j \frac{D_{ij}}{O_j} + a_j \frac{O_{ij}}{D_j}, (i, j = 1, 2, ..., n), \quad (1)$$

where f_{ij} is the correlation coefficient, O_{ij} is the freight flow from unit i to j, D_{ij} is the freight flow from unit j to i, O_i and O_j is the total output freight flow with unit i and j, D_i and D_j is the total input freight flow with unit i and j, a_i and a_j is the standardization coefficient, n is the number of spatial units.

Regional division of Chinese railway has based on the analysis on the freight flow in china. a_i and a_j were obtained from "China Statistical Yearbook for Regional Economy-2013" [12], O_{ij}, D_{ij}, O_i, O_j, D_i, D_j were obtained from "China Transportation Yearbook 2013"[13].

3.3 CALCULATION PROCESS

Take S_1 as the starting point, search for the adjacent spatial units as S_2, S_3, S_5, S_{14}, S_{15} and calculate the f_{1j}. As shown in Table 2.

TABLE 2 The f_{1j} between the adjacent spatial units

Variable / Adjacent units	a_1	O_{1j}/O_1	D_{1j}/D_1	a_j	D_{1j}/O_j	O_{1j}/D_j	f_{1j}
$S_1 - S_2$	0.96	0.03	0.53	0.88	0.49	0.05	1.00
$S_1 - S_3$	0.96	0.01	0.19	1.58	0.29	0.02	0.68
$S_1 - S_5$	0.96	0.01	0.01	1.41	0.04	0.02	0.10
$S_1 - S_{14}$	0.96	0.07	0.04	1.37	0.11	0.05	0.33
$S_1 - S_{15}$	0.96	0.02	0.01	0.81	0.01	0.03	0.02

From Table 2, we note that S_1 and S_2 have the maximum correlation coefficient, $\max f_{1j} = 1.00$. Determine S_1 and S_2 in one direction connection, the exchanges of freight volume can be regarded as (Q_1, Q_2), as $Q_i = O_{ij}$, $Q_j = D_{ij}$, $O_{12}/D_{12} = 0.02 < 1$, so the only direction connection between S_1 and S_2 was $S_1 \leftarrow S_2$.

Take S_2 as the starting point, search for the adjacent spatial units as S_1, S_3, S_{15}, S_{24} and calculate the f_{2j}. As shown in Table 3.

TABLE 3 The f_{2j} between the adjacent spatial units

Variable / Adjacent units	a_2	O_{2j}/O_2	D_{2j}/D_2	a_j	D_{2j}/O_j	O_{2j}/D_j	f_{2j}
S_2-S_1	0.88	0.49	0.05	0.96	0.03	0.53	1.00
S_2-S_3	0.88	0.01	0.01	1.58	0.01	0.02	0.06
S_2-S_{15}	0.88	0.04	0.01	0.82	0.01	0.20	0.22
S_2-S_{24}	0.88	0.01	0.02	0.90	0.02	0.04	0.07

From Table 3, we note that S_2 and S_1 have the maximum correlation coefficient, $\max f_{2j}=1.00$. Determine S_1 and S_2 in one direction connection, as $O_{21}/D_{21}=64.3>1$, so the only direction connection between S_2 and S_1 was $S_2 \to S_1$.
Take S_3 as the starting point, search for the adjacent spatial units as S_1, S_2, S_{24}, S_{25} and calculate the f_{3j}. As shown in Table 4. From Table 4, we note that S_3 and S_1 have the maximum correlation coefficient, $\max f_{3j}=0.68$.

TABLE 4 The f_{3j} between the adjacent spatial units

Variable / Adjacent units	a_3	O_{3j}/O_3	D_{3j}/D_3	a_j	D_{3j}/O_j	O_{3j}/D_j	f_{3j}
S_3-S_1	1.58	0.29	0.02	0.96	0.01	0.19	0.68
S_3-S_2	1.58	0.01	0.02	0.88	0.01	0.01	0.06
S_3-S_{24}	1.58	0.01	0.01	0.90	0.01	0.02	0.03
S_3-S_{25}	1.58	0.01	0.01	0.54	0.01	0.03	0.04

Determine S_3 and S_1 in one direction connection, as $O_{31}/D_{31}=57.6>1$, so the only direction connection between S_3 and S_1 was $S_3 \to S_1$.

Take S_{14} as the starting point, search for the adjacent spatial units as S_1, S_9, S_5 and calculate the f_{14j}. As shown in Table 5.

TABLE 5 The f_{14j} between the adjacent spatial units

Variable / Adjacent units	a_{14}	O_{14j}/O_{14}	D_{14j}/D_{14}	a_j	D_{14j}/O_j	O_{14j}/D_j	f_{14j}
$S_{14}-S_1$	1.37	0.11	0.05	0.96	0.07	0.04	0.33
$S_{14}-S_9$	1.37	0.03	0.01	1.76	0.04	0.06	0.24
$S_{14}-S_{15}$	1.37	0.10	0.02	0.82	0.04	0.13	0.30

From Table 5, we note that S_{14} and S_1 have the maximum correlation coefficient, $\max f_{14j}=0.33$. Determine S_{14} and S_1 in one direction connection, as $O_{141}/D_{114}=1.72>1$, so the one direction connection between S_3 and S_1 was $S_{14} \to S_1$. There are not any external connection by the unit S_1, so the units S_1, S_2, S_3, S_{14} which have fused cluster the first class $C_1=(S_1,S_2,S_3,S_{14})$, the fused path was $S_2 \to S_1; S_3 \to S_1; S_{14} \to S_1$.

As the calculation process is same, the other class calculation is not repeated, the fused cluster steps as shown in Table 6.

TABLE 6 The fused cluster steps of the class

Class	Step	Starting unit	Maximum relation unit	max f_{ij}	T_{ij}
C_1	1	S_1	S_2	1.01	$S_1 \to S_2$
	2	S_2	S_1	1.01	$S_2 \to S_1$
	3	S_3	S_1	0.68	$S_3 \to S_1$
	4	S_{14}	S_1	0.33	$S_{14} \to S_1$
C_2	1	S_4	S_5	0.66	$S_4 \to S_5$
	2	S_5	S_6	0.73	$S_5 \leftarrow S_6$
	3	S_6	S_5	0.73	$S_6 \to S_5$
	4	S_7	S_6	0.53	$S_7 \to S_6$
C_3	1	S_8	S_{10}	0.51	$S_8 \leftarrow S_{10}$
	2	S_9	S_8	0.48	$S_9 \to S_8$
	3	S_{10}	S_8	0.51	$S_{10} \to S_8$
	4	S_{11}	S_9	0.68	$S_{11} \to S_9$
C_4	1	S_{12}	S_{13}	0.66	$S_{12} \to S_{13}$
	2	S_{13}	S_{12}	0.66	$S_{13} \leftarrow S_{12}$
C_5	1	S_{15}	S_{16}	0.24	$S_{15} \leftarrow S_{16}$
	2	S_{16}	S_{15}	0.24	$S_{16} \to S_{15}$
	3	S_{24}	S_{16}	0.23	$S_{24} \to S_{16}$
C_6	1	S_{17}	S_{18}	0.81	$S_{17} \leftarrow S_{18}$
	2	S_{18}	S_{17}	0.81	$S_{18} \to S_{17}$
C_7	1	S_{19}	S_{21}	0.54	$S_{19} \to S_{21}$
	2	S_{20}	S_{21}	0.67	$S_{20} \leftarrow S_{21}$
	3	S_{21}	S_{20}	0.67	$S_{21} \to S_{20}$
	4	S_{22}	S_{20}	0.43	$S_{22} \to S_{20}$
C_8	1	S_{23}	S_{26}	0.11	$S_{23} \leftarrow S_{26}$
	2	S_{25}	S_{27}	0.29	$S_{25} \leftarrow S_{27}$
	3	S_{26}	S_{25}	0.13	$S_{26} \leftarrow S_{25}$
	4	S_{27}	S_{25}	0.29	$S_{27} \to S_{25}$
	5	S_{28}	S_{25}	0.1	$S_{28} \to S_{25}$

The transport relation with spatial units has its own characteristics and the characteristics distributed on the geospatial form the different transportation regions.Shown in Table 7.

TABLE 7 Name and composition of transportation regions

No.	Code	Name of region	Composition of region
1	C_1	Northern	Hebei, Beijing, Tianjin, Shanxi, Mongolia West, Shandong
2	C_2	Northeast	Heilongjiang, Jilin, Liaoning, Mongolia East
3	C_3	East	Shanghai, Jiangsu, Anhui, Zhejiang
4	C_4	Southeast	Fujian, Jiangxi
5	C_5	Central	Shaanxi, Henan, Hubei
6	C_6	Southern	Guangdong, Hainan, Hunan
7	C_7	Southwest	Guangxi, Guizhou, Sichuan, Chongqing, Yunnan
8	C_8	Northwest	Gansu, Ingria, Xingjian, Qinghai, Tibet

4 Conclusion

Traditional regional division model for spatial units is only built upon the information of attributes in every unit. However, the spatial relationships and their spatial interacttion between units are not considered sufficiently. In this study, based on scale-space theory, the spatial units cluster fusion algorithm is proposed so that the elements of spatial relationship between units could be integrated besides considering the information of attributes. By this approach, considered both of the spatial proximity and attribute similarity at certain spatial range, the spatial units could be clustered into one class if their connective direction is the same and achieve the regional division.

This paper uses the spatial transport linkage theory to construct the spatial units correlation model for railway freight transportation regional division. According to the data of $O-D$ matrix with the adjacent spatial units and considering economic parameters as limitation, the regional division is divided 8 parts of railway freight transporttation in china. As Northern, Northeast, East, Southeast, Central, Southern, Southwest and Northwest. As shown in Figure 1. The results are highly accordant with the real situations and can offer spatial background for regional railway freight transportation planning and development.

Further research is also proposed to improve spatial units correlation model. The data selection should not only reflect the present but also reflect the future trends of the regional development. Economic indicators should be further improved when considering the link between transportation and economic and also considering the impact of macroeconomic policies and geographic and other factors and make the model more comprehensive.

FIGURE 1 The spatial layout of railway freight transportation regional division

Received 26 April 2014, www.cmnt.lv

Abstract

With the changes of market supply and demand, as well as increasing business competition, service quality has become a key factor constraining rural supermarket survival and development. This article targets at the rural supermarkets in Jiangsu Province. In the context of constructing an indicator system of rural supermarket service quality evaluation, it acquires data by questionnaires, uses AHP to establish the weights, and applies the multi-level fuzzy AHP to assess rural supermarket service quality. It concludes that there are some spaces for further improvement of rural supermarket service quality and proposes relevant solutions.

Keywords: FAHP, rural supermarkets, service quality

1 Introduction

In the urbanization process of China, the primary task should be the construction of rural infrastructure. In order to improve the life quality and convenience of rural residents, we should focus on the improvement of rural supermarket. However, in China the development of rural supermarket is still in its infancy. There are many problems in operations. Rural supermarket service quality needs to be improved. First of all, we must find out the factors affecting the quality of service and why consumers are not satisfied with rural supermarket service quality, which is the precondition of improving the quality of service and market competition. Make prospect for the improvement of rural supermarket service quality and promote the sustainable healthy development of rural supermarket [1]. Previous studies show that there is a linear positive correlation between customer satisfaction and customer loyalty (Chen Yuan, 2012). Besides, the quality of service affects customer loyalty, both directly and indirectly (Chen Shaojie, 2011). Lots of studies adopt a perceptual model or structure equation model to discuss the service quality of supermarket chains, but seldom specifically focus on rural supermarket service quality. Few articles concerning rural supermarket service quality use the grey relational evaluation method and grey cluster model (Yang Yanbo, et al., 2008), and service quality gap model (Liang Na, et al., 2009). In 2008, Guo Yuexian et al. proved that the FAHP model was appropriate for the evaluation of rural supermarket service quality. Therefore, this article targets at rural supermarkets in Jiangsu Province and adopts the FAHP model to assess their service quality, in the hope of finding out solutions for rural supermarkets improving service quality to keep same space with modern social development in the new urbanization process.

2 Generation of the data

2.1 FAHP COMPREHENSIVE EVALUATION MODEL

FAHP, namely fuzzy analytic hierarchy process, is a comprehensive evaluation method to assess the hierarchical condition of evaluation target from multiple factors, which is on the basis of fuzzy mathematics, applies the principle of fuzzy relationship synthesis, and quantifies some ill-defined and difficult-to-quantify factors [2]. As we analyze a large system, we should take lots of factors into consideration, while there are different levels of the hierarchy between these factors. Thus, we need to collect the evaluation factors and divide them into different categories according to some set of attributes. Perform a comprehensive evaluation on each category firstly, and then make the high-level comprehensive evaluation on the results, so that the final evaluation will be more comprehensive and scientific [3].

The FAHP evaluation procedures are shown as follows:

- Establish the evaluation factors sets. Assume the fist-level evaluation factors set $A=\{\alpha_1,\alpha_2,.....\alpha_n\}$ and the second-level evaluation indicator a_{ij}, where $i=1,2,...,n; j=1,2,...,m$ n the number of first-level indicators, and m the number of second-level indicators beneath each first-level indicator.

- Establish the evaluation results sets. Assume the set of all evaluation results of each level $B=\{\beta_1,\beta_2,\cdots,\beta_s\}$. Define them based on actual situations, such as "better", "good", "general", "bad", and "worse" the five levels.

* ***Corresponding author's*** e-mail: mtmxb@163.com

- Establish the weights of each evaluation indicator at each level by means of the analytic hierarchy process. Firstly make pair comparison of indicators based on judgment scale table [4] and expert scoring method and construct the judgment matrix of evaluation indicator factors X (Equation (1)). Calculate the sum of every row of judgment matrix and make it normalization. Get the weight vector δ_i (Equation (2)). In order to improve the reliability of weights, we need to apply the consistency ratio CR (Equation (3)) to conduct a consistency test on the judgment matrix.

$$X = \begin{bmatrix} \chi_{11} & \chi_{12} & \cdots & \chi_{1n} \\ \chi_{21} & \chi_{22} & \cdots & \chi_{2n} \\ \cdots & \cdots & \ddots & \cdots \\ \chi_{n1} & \chi_{n2} & \cdots & \chi_{nn} \end{bmatrix}, \tag{1}$$

$$\delta_i = \frac{\sum_{j=1}^{n} \chi_{ij}}{\sum_{k=1}^{n}\sum_{j=1}^{n} \chi_{kj}} \quad i = 1,2,...,n, \tag{2}$$

$$CR = \frac{CI}{RI} = \frac{(\lambda_{\max} - n)/(n-1)}{RI}, \tag{3}$$

where, $\lambda_{\max}$ is the maximum characteristic value. RI is the average random consistency index. As $CR < 0.1$, the degree of inconsistency of X is within the allowable range. Otherwise, re-construct the matrix.

- Build the single-factor fuzzy evaluation matrix. Use the membership degree of fuzzy mathematics to make synthesis and get the single-factor fuzzy evaluation matrix (Equation (4)).

$$Y_t = \begin{bmatrix} \eta_{11} & \eta_{12} & \cdots & \eta_{1m} \\ \eta_{21} & \eta_{22} & \cdots & \eta_{2m} \\ \cdots & \cdots & \ddots & \cdots \\ \eta_{n1} & \eta_{n2} & \cdots & \eta_{nm} \end{bmatrix}, \tag{4}$$

where $\eta_{ij} = \frac{q_{ij}}{Q}$. The value is between 0 and 1. Here, η_{ij} refers to the membership degree of the comment β_j of indicator α_i, and $i = 1,2,...,n; j = 1,2,...,m$. q_{ij} is the number of the indicator i at the level j. Q is the total number of respondents in the survey[2].

- The multi-factor fuzzy comprehensive evaluation matrix. It is chiefly to construct the multi-level comprehensive evaluation matrix based on primary comprehensive evaluation matrix. The primary fuzzy comprehensive evaluation matrix is Equation (5), and the general fuzzy comprehensive evaluation matrix is Equation (6).

$$R_i = X_i \times Y_i, \tag{5}$$

$$R = X \times Y. \tag{6}$$

- Calculate the comprehensive score of three-level evaluation. Firstly get the score of each item C_j (Equation (7)). Then, get the score of each dimension F_i (Equation (8)). And finally get the total score of service quality Q (Equation (9)).

$$C_j = V^T \times Y_j, \tag{7}$$

$$F_i = V^T \times R_i, \tag{8}$$

$$Q = V^T \times F_i. \tag{9}$$

Classify the results and establish the membership degree of comprehensive scores on the principle of weighted average. Results are shown in Table 1.

TABLE 1 the level of comprehensive scores

Level	Evaluation Results	Comprehensive Scores
*E*1	better	[0, 1.5]
*E*2	good	(1.5, 2.5]
*E*3	general	(2.5, 3.5]
*E*4	bad	(3.5, 4.5]
*E*5	worse	(4.5, 5]

2.2 SELECT THE RIGHT EVALUATION INDICATORS

As early as 1955, Parasuraman Zeithaml & Berry defined service quality as the gap of customers' expectation for services and their feelings about actual services, namely the service quality = expected service – perceptual service. They further established the "five dimensions" for evaluating the level of service quality, i.e. the tangibles, responsiveness, reliability, assurance, and empathy of customers [5]. According to the five-dimension factors and considering the rural supermarket service conditions in Jiangsu Province and the expert investigation, we establish the indicator system for evaluating the rural supermarket service quality in Table 2.

TABLE 2 The indexes for rural supermarket service quality evaluation

Dimension	Number	The Second-level Evaluation Factors
Tangibles α_1	α_{11}	appropriate clothes for salesperson
	α_{12}	comfortable shopping environment
	α_{13}	abundant commodities
	α_{14}	size of shop
	α_{15}	diversified payment
Responsiveness α_2	α_{21}	solving problems with patience
	α_{22}	special accelerated service
	α_{23}	fast payment
	α_{24}	easy counsel from salesperson.
Reliability α_3	α_{31}	complete the committed service
	α_{32}	goods return or exchange rate
	α_{33}	convenient working time
	α_{34}	accurate and safe settlement.
Assurance α_4	α_{41}	commodity quality
	α_{42}	professional knowledge of employee
	α_{43}	employees' reliability
Empathy α_5	α_{51}	personalized service
	α_{52}	respect for customers
	α_{53}	understand customers' needs
	α_{54}	sincerely care about customers

2.3 QUESTIONNAIRE DESIGN AND COLLECTION

In this survey, we design each item in the questionnaire according to the second-level indicator in the evaluation indicator system, including 5 first-level indicators, 20 second-level indicators, i.e. the questionnaire contains 20 questions. Each question has five options, i.e. better, good, general, bad, and worse, and each option is given certain score, i.e. 5, 4, 3, 2, and 1 respectively. This questionnaire focuses on the customers in rural supermarkets in Jiangsu Province. We use a sample survey, handing out 150 copies, and finally collecting 145 copies. The recovery rate is 96.7%. Exclude 5 invalid questionnaires. Then, the recovery rate is 93.3%.

2.4 DATA PROCESSING

Use the fuzzy comprehensive evaluation method to analyze the data from the survey on rural supermarket service quality in Jiangsu Province. Detailed calculations and analyses are displayed as follow.

Establish the set of rural supermarket service quality evaluation factors, $A=\{\alpha_1,\alpha_2,\alpha_3,\alpha_4,\alpha_5\}$. Here, the first-level evaluation factors are respectively: tangibles α_1, responsiveness α_2, reliability α_3, assurance α_4 and empathy α_5. The second-level evaluation factors α_{ij} refer to the specific evaluation indicators of the first-level evaluation factors. The tangibles α_1 contain five second-level indicators, namely five questions, i.e. α_{11} appropriate clothes for salesperson, α_{12} comfortable shopping environment, α_{13} abundant commodities, α_{14} size of shop, and α_{15} diversified payment. The responsiveness α_2 contains four second-level indicators, namely four questions, i.e. α_{21} solving problems with patience, α_{22} special accelerated service, α_{23} fast payment, and α_{24} easy counsel from salesperson. The reliability α_3 contains four second-level indicators, namely four questions, i.e. α_{31} complete the committed service, α_{32} goods return or exchange rate, α_{33} convenient working time, and α_{34} accurate and safe settlement. The assurance α_4 contains three second-level indicators, namely three questions, i.e. α_{41} commodity quality, α_{42} professional knowledge of employee, and α_{43} employees' reliability. The empathy α_5 contains four second-level indicators, namely four questions, i.e. α_{51} personalized service, α_{52} respect for customers, α_{53} understand customers' needs, and α_{54} sincerely care about customers.

Establish the evaluation set of rural supermarket service quality $V=\{better, good, general, bad, worse\}$, namely $V=\{5,4,3,2,1\}$.

Use the AHP to establish the weights. Respectively get the first-level evaluation matrix according to the Equation (1) and (3).

$$X=\begin{bmatrix} 1 & 3 & 5 & 2 & 3 \\ \frac{1}{3} & 1 & 2 & \frac{1}{2} & 2 \\ \frac{1}{5} & \frac{1}{5} & 1 & \frac{1}{3} & \frac{1}{2} \\ \frac{1}{2} & 1 & 3 & 1 & 2 \end{bmatrix}.$$

Run the MCE comprehensive evaluation software and get $\lambda_{\max}=5.0755$, $CI=0.0189$, $RI=1.12$.

Then $CR=0.0169<0.1$, which meets the consistency test of evaluation matrix. According to the Equation (2), the weight of first-level evaluation indicator is $\delta=(0.413,0.155,0.074,0.241,0.117)$.

Similarly, get the weight vector of second-level indicator, i.e. respectively:

$$\delta_1=(0.096,0.214,0.479,0.157,0.054),$$

$$\delta_2=(0.488,0.089,0.248,0.175),$$

$$\delta_3=(0.274,0.158,0.065,0.503),$$

$$\delta_4=(0.630,0.218,0.152),$$

$$\delta_5=(0.136,0.280,0.114,0.470).$$

Construct the single-factor fuzzy evaluation matrix for rural supermarket service quality. According to Equation (4), respectively the fuzzy evaluation matrixes of the five dimensions of first-level indicators are gotten:

$$Y_1=\begin{bmatrix} 0.086 & 0.243 & 0.471 & 0.171 & 0.029 \\ 0.114 & 0.414 & 0.357 & 0.1 & 0.015 \\ 0.072 & 0.544 & 0.258 & 0.126 & 0 \\ 0.136 & 0.264 & 0.493 & 0.1 & 0.007 \\ 0.229 & 0.614 & 0.157 & 0 & 0 \end{bmatrix},$$

$$Y_2=\begin{bmatrix} 0.121 & 0.272 & 0.407 & 0.121 & 0.079 \\ 0.214 & 0.136 & 0.314 & 0.157 & 0.179 \\ 0.157 & 0.372 & 0.443 & 0.021 & 0.007 \\ 0.129 & 0.186 & 0.529 & 0.114 & 0.042 \end{bmatrix},$$

$$Y_3=\begin{bmatrix} 0.2 & 0.25 & 0.436 & 0.078 & 0.036 \\ 0.343 & 0.307 & 0.264 & 0.072 & 0.014 \\ 0.271 & 0.3 & 0.429 & 0 & 0 \\ 0.35 & 0.307 & 0.2 & 0.114 & 0.029 \end{bmatrix},$$

$$Y_4=\begin{bmatrix} 0.121 & 0.493 & 0.336 & 0.036 & 0.014 \\ 0.164 & 0.072 & 0.686 & 0.057 & 0.021 \\ 0.093 & 0.157 & 0.7 & 0.036 & 0.014 \end{bmatrix},$$

$$Y_5=\begin{bmatrix} 0.036 & 0.243 & 0.557 & 0.093 & 0.071 \\ 0.272 & 0.307 & 0.35 & 0.05 & 0.021 \\ 0.007 & 0.072 & 0.914 & 0.007 & 0 \\ 0.021 & 0.086 & 0.893 & 0 & 0 \end{bmatrix}.$$

Conduct the fuzzy comprehensive evaluation. According to Equations (5) and (6), get the fuzzy comprehensive evaluation matrix vector of each dimension and the fuzzy

comprehensive evaluation matrix vector of overall service quality, respectively:

$$R_1 = X_1 \times Y_1 = (0.101, 0.447, 0.331, 0.114, 0.007),$$

$$R_2 = X_2 \times Y_2 = (0.140, 0.270, 0.429, 0.098, 0.063),$$

$$R_4 = X_4 \times Y_4 = (0.126, 0.350, 0.468, 0.041, 0.015),$$

$$R_5 = X_5 \times Y_5 = (0.092, 0.168, 0.698, 0.027, 0.015),$$

$$R = X \times Y = (0.127, 0.352, 0.419, 0.082, 0.020).$$

Calculate the comprehensive score of three-level evaluation. Firstly get the score of each question C_j and introduce them into Equation (7). Obtain the matrix of each question score:

$$C_1 = (3.186, 3.512, 3.562, 3.422, 4.072),$$

$$C_2 = (3.235, 3.049, 3.651, 3.246),$$

$$C_3 = (3.500, 3.893, 3.842, 3.835),$$

$$C_4 = (3.671, 3.301, 3.279),$$

$$C_5 = (3.080, 3.759, 3.079, 3.128).$$

Then, calculate the score of each dimension F_i and get the matrix of each dimension score by Equation (8):

$F_1 = 3.521$,
$F_2 = 3.324$,
$F_3 = 3.753$,
$F_4 = 3.531$,
$F_5 = 3.292$.

Finally, calculate the total score of service quality by Equation (9): $Q = 3.484$.

3 Results analysis

According to the fuzzy comprehensive evaluation scores, we know that:

Firstly, the comprehensive score of current rural supermarket service quality in Jiangsu Province is 3.484, in the range of (2.5, 3.5), at the general service level of E3. Therefore, we need to make adjustment and reformation as a whole immediately, implement service management and innovation, and improve the overall service quality of rural supermarket.

Secondly, the comprehensive scores of five dimensions (tangibles, responsiveness, reliability, assurance, and empathy) are respectively 3.521, 3.324, 3.753, 3.531, and 3.292. Obviously, for rural supermarkets, the tangibles, reliability, and assurance win relatively better evaluations from customers. But in terms of responsiveness and empathy, customers' evaluation is just ordinary.

Finally, according to the detailed analysis of all items, rural supermarkets win better evaluation in terms of tangibles, which is represented by 3.512 grades for comfortable shopping environment, 3.562 for abundant commodity, and especially 4.072 for payment. Customers agree that the three aspects are better in general. As for the clothes of salesperson and the size of shop, the score is respectively 3.186 and 3.422, what are relatively lower. The scores of questions for reliability spread in the range of (3.5, 4.5]. The evaluation is relatively better. As for the assurance, the commodity quality is scored 3.671, which is better. Employees' professional knowledge and employyees' reliability is respectively scored 3.301 and 3.279, which is general. Although the evaluation on responseveness and empathy is both general, the payment speed under the responsiveness is scored 3.651 and the respect for customers under empathy is scored 3.759. The two items are better. In addition, the general evaluation on rural supermarket service quality also includes personalized service, understanding of customers' needs, sincerely caring about customers, solving problems with patience, providing fast service, and convenience of consulting salesperson.

4 Conclusions and suggestions

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hard returns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads – the template will do that for you.

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar.

4.1 CONCLUSIONS

Whether from the comprehensive scores of dimensions or the score of each item, the evaluations are mainly at the level *E*3 and *E*4, which means "general" or "better", but no "good". Therefore, there is a large room for rural supermarkets improving their service management and innovation. As for the "better" aspects, the supermarkets have more comfortable shopping environment, compared with the traditional rural purchasing environment. The payment channels are diversified, such as card, cash, or membership, which makes shopping more convenient. Besides, rural supermarkets keep the good traditions, such as being loyal to commitment, quick for return or exchange goods, convenient hours, accurate settlement, and safety. All these characteristics make customers feel more reliable. Supermarkets give assurance for qualified products because of their inbound channels. And the fast settlement gives rural customers different shopping experiences. Thus, it gets higher score for the item of respecting for customers.

For some "general" evaluations on the clothes of salespersons and the size of shops, the reason is that rural supermarkets are still at the starting stage, plus the weak rural consumption capacities and management abilities, compared with cities. Therefore, the clothes of salespersons and the size of shops in rural supermarkets are lagged behind cities. The scores of the two items are relatively lower. In rural supermarkets, the employees are mainly from local. The civilization quality and professional knowledge are insufficient. However, by means of pre-service training, they can be equipped with basic techniques for the job. In serving customers, they are reliable and basically understand customers' needs. They can genuinely care about customers, help them solve problems with patience, and provide special fast services. The salespersons are familiar with their commodities and capable of responding to customers' various questions. Only under the circumstance of all aspects with better scores, can it trigger rural customers' needs for personalized services. In short, rural supermarkets perform not too bad or too excellent in rural area. Therefore, it is necessary to further strengthen the service management and implement service innovation in order to the sustainable development of rural supermarkets.

4.2 SUGGESTIONS

4.2.1 Perform management innovation and improve service image

By taking references from the successful management pattern and approaches of urban supermarkets, we can improve rural supermarkets' shopping environment and convenience on the basis of rural conditions, guaranteeing customers' satisfaction and loyalty. In rural supermarkets, the light should be bright, the signs should be lean and eye-catching, the salespersons should be wearing neat uniforms, and the shelves should be arranged appropriately. A comfortable environment could stimulate customers' desire for buying. Maintain diversified payment methods and update the hard facilities frequently, such as tickers and shopping carts. Aim at the "one-stop" purchase and provide all kinds of commodities, including food, clothing, decorations, and daily appliances. Ensure customers can enjoy all the convenience of rural supermarkets. Besides, rural supermarkets must keep to their commitments and accomplish the work with high requirements. Guarantee fast and timely commodity return and exchange. As the saying goes, "success depends on details". Make innovations from details. For example, adjust commodity structure periodically and meet customers' constantly changing needs and hobbies. Offer special channels for the weak. Present some small knowledge cards or magazines at the checkouts. Provide shuttle vehicles for some festivals in rural area. We should run the rural supermarkets with the ideology of serving customers and ensure the image of supermarkets in the minds of customers.

4.2.2 Pay attention to employees' knowledge reconstruction

In rural supermarkets, the employees are mostly from local area. Most of them did not get the chance of completing the college study for various reasons. However, they have the desire for knowledge deep down in the heart. Managers should pay attention to employees' development and cultivation, offering relevant trainings for special techniques, service management, and CRM. Perform target trainings. For example, help cashiers to accelerate the scanning speed and make them be familiar with all kinds of payments. Give special trainings for people displaying the shelves. Find out management talents based on special positions and give them a chance of promotion. By means of investting in employees and helping them achieve the reconstruction of knowledge, rural supermarkets can stimulate the employees' enthusiasm for their work, ensuring better services for customers.

4.2.3 Strengthen employees' awareness of service

Typically, in order to increase sales, supermarkets arrange more salespersons at the center or the front, where the most popular or promotional commodities locate. While at the front of shelves with common commodities, only one or two salespersons are necessary. They can give immediate responses to customers' needs. For this kind of arrangement, the precondition is that the salespersons must be familiar with supermarkets' overall structure and knowledge of commodities. Once they catch the confusing faces of customers, they must take initiatives to offer their help. Ask whether the customer need help and give answer for any question with patience. Help employees build the awareness of service. Everything must take customers' interests as the primary and fundamental point. Try to improve customers' satisfaction and loyalty. Solve customers' problems properly and timely. Each employee should focus on establish positive relationships with customers, serve them with passions, and communicate with them actively. Respect for customers and genuinely care about customers. Provide qualified services with positive attitudes. Train employees with capabilities of communicating and coordinating with customers. When customers give advices for certain employee's services, the employee should take the advice and promise to make an improvement. Supermarkets should provide convenient ways for customers' complaints. For example, give the free phone number for complaints and present detailed directions for customers how to make complaints. Improve the transparency of receiving and handling complaints and set up rewards for customer complaints. Construct the mechanism of encouraging employees to actively take and deal with customer complaints, so that customers will grow great enthusiasm for expressing complaints or getting consultation. By this way, supermarkets can collect more advices and serve customers better.

4.2.4 Provide personalized and humanized services

In the process of communicating with customers, the employees usually focus on promoting the commodity rather than emotional exchange, which might trigger the disgusting feelings among customers. The supermarkets should advocate the emotional services. As contacting with customers, employees should be active and enthusiastic, with smiles all the time, instead of blindly giving product bombing. Salespersons should establish a nice and friendly relationship with customers based or special knowledge and life experiences, cultivating a warm and kind communication atmosphere. Salespersons should introduce not only the name or the price of commodity, but also the ingredients, the main performance, the usage, and the maintenance. Different customers possess different expectations and requirements for commodities in supermarkets, which require supermarkets segment customer groups, analyze the purchase behaviors and motives of different groups, understand there practical and potential needs, provide the right commodities to satisfy or exceed their needs and expectations. Provide some convenient services. For example, set up a playing zone at the toys' area. Ask one or two employees to be in charge of customers' parking and look after the cars for free. Build a seating area and automatic lockers.

Face recognition algorithms for embedded entrance guard system

Jun Li *

Institute of Computer Science, Guangdong Polytechnic Normal University, 510665, Guangzhou, P.R. China

Received 1 March 2014, www.cmnt.lv

Abstract

Biometric identification technology is used to identify individuals based on their unique physiologica1 characteristics under sampling and measurement. The hardware platform of our entrance guard system is based on SAMSUNG S3C6410 embedded development board with ARM11 processor, and we adopt ordinary camera as facial image capture device, 7-inch touch-screen LCD display as an input, electronic door locks as executing components by the onboard port control. The software platform is based on Linux operating system to design and optimize face recognition algorithm, which is combined with local binary pattern (LBP) algorithm, principal component analysis (PCA) algorithm, and ridge regression algorithm. Also, the face recognition system is divided into two parts, namely, a face database training part and a face recognition part. Precisely, the face database training part acquires face information through the processes of face detection, feature extraction and stores the face information to serve as the detection basis of the face recognition part; then the face recognition part is connected with the entrance guard system and sends out an instruction for executing related action to the entrance guard system according to the face recognition result. Specially, the embedded face recognition entrance guard system is contactless and easy to collect the facial database, less in power consumption, low in cost, and has easy installation and stable performance.

Keywords: face recognition, local binary patterns, principal components analysis, embedded system

1 Introduction

The face recognition process is to identify or verify one or more persons in the scene using a stored database of faces for some given still or video images of a scene. Compared to fingerprint recognition, retina recognition, iris recognition, gene recognition, handwriting recognition, voiceprint recognition, the advantages of face recognition are hidden operation and contactless collection, and it accords with the human recognizing habits. By further analyzing the facial expression and pose, one can get some information that is not available on other recognition systems.

Biometric identification technology is used to identify individuals based on their unique physiologica1 characteristics under sampling and measurement. Since biometric characteristics are not easy to be stolen as the certificate holdings, and be forgotten or cracked as passwords, biometric identification has been extensively applied in public security for these unique benefits of biometric characteristics. And recently, face recognition technologies have been extensively studied and applied in China and abroad. In particular, the face recognition system based products lead to small volume and low power, meanwhile the face recognition technologies lead to contactless mode, thus one need not worry the situation whether they would be willing to touch the collection equipment because of public health. On the other hand, current application of face recognition technology has three main respects, i.e., criminal detection, identification inspection, and access control. For example, at the entrance of the building, district, factories, house and the parking lot, the frequent in-and-out causes high management difficulty in verifying procedure by security personnel. However, face recognition technology can be used in entrance guard system to realize the entrance controlling based on face recognition, supplemented by other recognition [1-3].

Traditional face recognition entrance guard system is based on the PC or server, which has some defects such as high cost and large size. With the rapid development of embedded technology, the face recognition for embedded application system is becoming increasingly intelligent, miniaturized and portable.

2 Overall design

Face recognition system consists of five modules: facial image acquisition module, image pre-processing module, face detection and localization module, facial feature extraction module, and face classification module. The overall design of entrance guard system is (Figure 1):

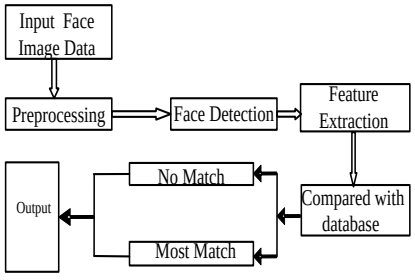

FIGURE 1 The overall design of Entrance Guard System

* ***Corresponding author's*** e-mail: lijunjanet@gmail.com

The face recognition for embedded entrance guard system is the aggregation of computer hardware and software, including the face recognition subsystem and entrance guard system, wherein the main function of the face recognition subsystem is to collect face information and execute and output the results. Additionally, main related hardware and software include camera, computer hardware system, Linux operating system, Open Source Computer Vision Library (Open CV), and some self-designed application software. Under such entrance guard system, one can realize the following modules:

1) Face Detection Module: in the system initialization phase, the computer will detect the image captured from the camera whether or not a human face exists.
2) Face Recognition Module: in the face detection phase, after collecting the face information, do the face localization, feature extraction and comparison with database, and output the results.
3) Face Register Module: the registration function is enabled to make a new record input after successfully recognizing a person's face. To improve the safety, only the users whose face information is collected in the database can be authorized to make a register.
4) Face Training Module: the training function is to train the face in the database. In fact, one extracts the face feature and then classifies and labels for saving. The purpose of the face training database is to compare with the extracted feature by face recognition process and then output the results.
5) Access Control Module: the entrance guard system is one part of the hardware platform, whose main function is to receive signals from face recognition software system, then it will drives the switch of electronic lock.

3 Hardware design

The hardware platform is based on the Samsung S3C6410 board with ARM11 processor,600MHz CPU frequency, 256MB RAM memory capacity, 2GB NAND Flash capacity, and we adopt ordinary USB camera as facial image capture device, 7-inch LCD screen as display device, touch screen as an input, electronic door locks as executing components by the onboard port control [4].

The drive of face recognition for entrance guard system is used to drive the electronic pin, whose function is to control the switch of the door. When the input is connected to the S3C6410 board, it will detect and successfully recognize the facial information, then the development board outputs high level signals, turns on the thyristor and suctions the electronic pin. Herein the electronic pin is a coil with one diode in each end in order to avoid the breakdown of thyristor by instant high pressure. The manual control switch is not only used to suction the electronic pin, but also reset it by making the signals of the anode and cathode of thyristor in the low level.

The layout of embedded entrance guard system is shown (see, Figure 2), in which the electronic pin is situated above the door.

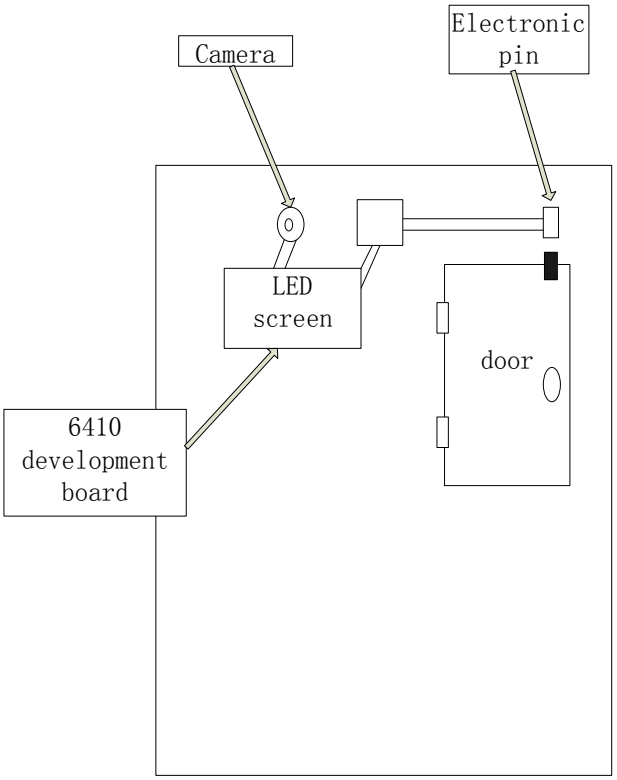

FIGURE 2 The layout of the embedded entrance guard

The door will open when the electronic pin suctions, while the door will close when the electronic pin resets.

4 Algorithm design

The face recognition system is composed of facial image acquisition, facial image pre-processing, face detection and localization, facial feature extraction, and face classification. The face recognition algorithm is combined with local binary pattern (LBP) algorithm, principal component analysis (PCA) algorithm, and ridge regression algorithm. The flow chart of face recognition system is shown (Fig. 3):

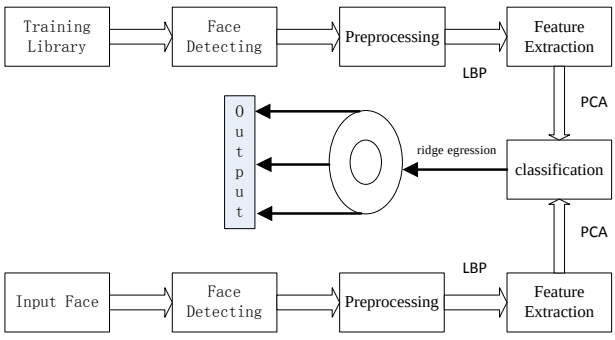

FIGURE 3 The flow chart of face recognition system

Firstly, the LBP algorithm can describe some tiny features (light spots, dark spots, stable area and the edge of various directions), and reveals the distribution of these features, which improves the performance of facial image recognition. Secondly, the PCA algorithm can map the high dimensional data to low dimensional to reduce the amount of calculation for one side and extract the key data

to minimal interference for the other. Finally, the ridge regression algorithm is applied to classify the mapping data by PCA algorithm in order to get the mapping vector of face training dataset and then save the training results.

4.1 LBP ALGORITHM

The basic idea of LBP algorithm is to label the pixels of an image by thresholding the neighborhood of each pixel and consider the result as a binary number [5-7]. For the face recognition system, we apply the LBP algorithm to each divided block of preprocessing image and analyze the LBP histogram, and then we obtain the feature histogram [4-6]. The so-called uniform patterns can be used to reduce the length of the feature vector and implement a simple rotation-invariant descriptor. A local binary pattern is called uniform if the binary pattern contains at most two bitwise transitions from 0 to 1 or vice versa when the bit pattern is traversed circularly. For example, the patterns $U(00000000) = 1$, $U(11111111) = 2$ and $U(11001111) = 2$ are uniform whereas the patterns $U(11001001) = 4$ and $U(010100010) = 6$ are not.

The uniform patterns LBP algorithm is defined by

$$\mathrm{LBP}_{P,R}^{riu} = \begin{cases} \sum_{i=0}^{p-1} s(g_i - g_c), U\left(LBP_{P,R}\right) \le 2, \\ P+1, other, \end{cases} \quad (1)$$

where:

$$\mathrm{U}\left(LBP_{P,\ R}\right) = |\mathrm{s}(g_{P-1} - g_c) - s(g_0 - g_c)| + \sum_{i=1}^{P-1} |s(g_i - g_c) - s(g_{i-1} - g_c)|. \quad (2)$$

From Equation (1), there are $P + 1$ uniform patterns when using P pixel neighborhoods. These uniform patterns are labelled as 0, 1, …, P, while the non-uniform pattern is labelled as $P + 1$. According to LBP operator feature, the face image is divided into 4×4 blocks. In this paper, the height and width are set at 96 pixels, and the LBP codes in an image are collected into a histogram.

4.2 PCA ALGORITHM

The eigenface approach began with a search for a low-dimensional representation of face images. In 1991 M. Turk and A. Pentland presented the eigenface method of face recognition [8-10].

Denote the facial data by:

$$X^i = \left(X_1^i, X_2^i, \cdots, X_d^i\right), i = 1,2,\cdots,k., \quad (3)$$

Then the covariance matrix is

$$\mathrm{S} = \frac{1}{k-1}\sum_{i=1}^{k}(X_i - \bar{X})(X_i - \bar{X})^T. \quad (4)$$

Next we adopt a computationally feasible method to determine the eigenvalues λ_i and eigenvectorsv_i of S, where i = 1, 2, …, d. Then we sort λ_i from largest to smallest and choose the first n ones, where $n < d$ to build a transfer matrix $\mathrm{A} = [v_1, v_2, \cdots, v_n]$. For the X data, $Z^{'} = A(X - \bar{X})$ its eigenvalues yields.

In our test, the face image is considered as a high dimensional vector, so that a typical image of size 100 by 100 becomes a vector of dimension 10,100, or, equivalently, a point in 10,100-dimensional space. We then adopt LBP algorithm for texture analysis, and output the histogram equalization with P=8, which implies that there may be $10(P + 2)$ uniform patterns. Also, the face image is divided into 4×4 blocks, and then this high dimensional vector reduces to a vector of dimension 160. Next, through the face training database, and save the LBP outcome as declared variable 'CvMat*', and face feature before reducing dimension as matrix 'm_pTrainingFaceX' with 160 rows and N columns, where N is the total number of images of face training database. Herein we collect 10 images for each person and save them to separate directory named by ID.

4.3 RIDGE REGRESSION ALGORITHM

The last processing flow of face training is to classify the face data by ridge regression algorithm [11,12]. We first introduce the main idea of this regularization method. Motivated by the fact that the m vertices of a regular simplex is the most balanced and symmetric separate points $v_i(i = 1,2,\cdots,m)$ in the m-dimensional space. We choose these vertices as the targets for m distinct face images, and apply ridge regression to train a linear model W, which maps the training face images $I_i(i = 1,2,\cdots,n)$ into the m-dimensional subspace such that the distance between each mapping result and the vertex is minimum. Herein each training sample$I$and each vertexvcorrespond to the independent variable x and dependent y variable of multivariate linear model, respectively.

Assume that there are n training samples for face classification $\{(x_i,\ y_i)|i = 1,2,\cdots,n\}$, where x_i denotes p-dimensional vector for face images of high dimension, and y_i denotes r-dimensional vector for face images of low dimension. As a result, the task of learning classifier in multivariable ridge regression algorithm is to find a matrix $\mathrm{W} \epsilon R^{P\times R}$ that can model the linear dependency between the image x_i and the label y_i to minimize the objective function:

$$J(W) = \sum_{i=1}^{n}\|W^T x_i - y_i\|^2 + \lambda\|W\|^2 = \mathrm{tr}(YY^T + WTXXTW - 2WTXYT + \lambda trWTW, \quad (5)$$

where $\mathrm{X} = [x_1, x_2, \cdots, x_n]$, $\mathrm{Y} = [y_1, y_2, \cdots, y_n]$ and tr stands for the trace of matrix.

Taking derivative of Equation (5) with respect to the W and equalling it to zero, we have:

$$\mathrm{W} = (XX^T + \lambda I)^{-1}XY^T. \quad (6)$$

Let x be a new image, the projecting value in the subspace is $W^T\boldsymbol{x}$, the class of minimum distance of x.

Suppose there are m face images to be recognized, we can construct m points in R^{m-1}such that these m points keep isometric under translation and rotation. In summary, the procedure of ridge regression algorithm for face recognition can be formally stated as follows:

1) Compute the mapping matrix W from (6).
2) Compute the map $y = W^T \boldsymbol{x}$ for a new face *x*.
3) Compute the distance $\|y - T_i\|$ between y and each label $T_i (i - 1,2,\cdots,m)$, and denote $\arg\min_i \|y - T_i\|$ as the class of *x*. The input is the data after reducing dimension, which is the matrix 'm_pTrainingDataX' with 70 rows and *N* columns, where *N* is the total number of images of face training database.

We firstly label the data after reducing dimension and construct the label function, and then compute the classifier by ridge regression algorithm. Here the input parameter of the function 'trainW()' is the directory of face training database. Also this function can save the key data such that it avoids the training procedure of face recognition.

The key data and saved variables and their description are listed in Table 1:

TABLE 1 The Variables and their file name and description

Variable	File Name	Description
m_pTrainingResW	TrainingRes.txt	TRAINING RESULTS
m_pRegSimVerT	T.txt	MATRIX MARK VECTOR ALL FACE CATEGORIES
m_pMeanOfFaceX	Mean.txt	AVERAGE VECTOR FOR PCA BEFORE REDUCTION DIMENSION
m_pEigVecs	EigenVectors.txt	FEATURE MATRIX PCA REDUCING DIMENSION
m_vecPersonName	PersonName.txt	THE ID OF FACE CATEGORIES
m_ifaceHeight **m_ifaceWidth**	ImageSize.txt	FACE IMAGE SIZE(HEIGHT AND WIDTH）

ID recognition can be carried out independently with face recognition, but the recognition must adopt the face training results, therefore one need to check whether the variable is null before face recognition. If yes, one must import the data according to variables and file name from Table 1.

Next combination with the LBP pre-processing, PCA reduction dimension and ridge regression mapping results in a map vector, and compare this vector with the training result in order to find the ID with minimum distance. Finally these operations are wrapped to drive the application program.

5 Application software design

Our software platform is based on Linux kernel (2.6.29), and we adopt Qt 4.73 as the user interface, Open CV 1.0 as face database. The framework of our application software is shown (Figure 4):

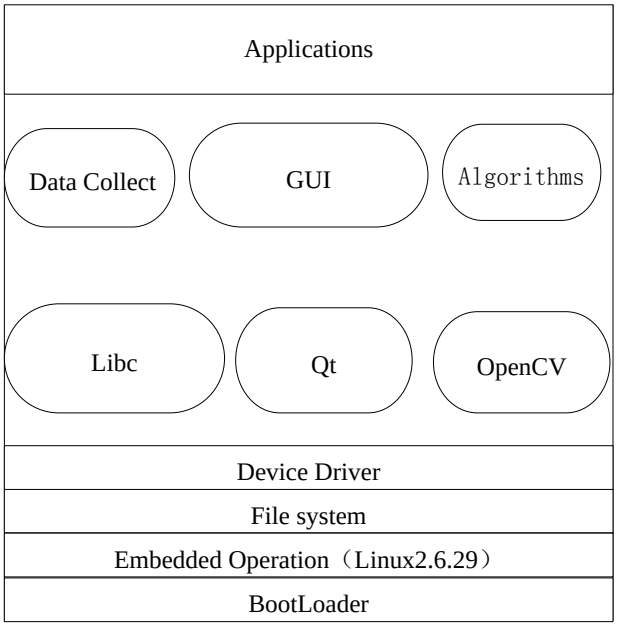

FIGURE 4 The framework of application

The applications are composed of Bootloader, Linux operation system (2.6.29 kernel), Qt libraries, Open CV library, embedded file system, driver program and GUI. Herein Open CV is a popular computer vision library started by Intel in 1999. The cross-platform library sets its focus on real-time image processing and includes patent-free implementations of the latest computer vision algorithms. Qt is a cross-platform application framework that is widely used for developing application software with a graphical user interface (GUI) (in which cases Qt is classified as a widget toolkit), and also used for developing non-GUI programs such as command-line tools and consoles for servers. Qt is fully object-oriented, easily extensible, and allows true component programming [13, 14].

In the Samsung S3C6140 development board, we compile the vivi bootloader, and configure Busybox with dev support. Licb library is the standard C libraries on Linux, and the compiler is installed in the user directory, and then it is copied into embedded root directory. Thus we complete the basic embedded root file system and make it as mapping commands by 'mkyaffsimage' program, and then to write vivi to flash root partition.

Additionally, the source codes need to be compiled before transplanting the Qt library in order to accommodate the Samsung S3C6410 platform. Since it takes the touch screen as input, one must import 'tslib' library to ensure that the touch screen driver can be used normally by GUI interface designed by Qt library.

Next we compile the Open CV library and V4L2 camera driver to get the video frames and map them to user memory, and then convert the frames encoded in YUV format to RGB format to generate the picture on a computer screen. According to the YUV/RGB conversion formula, we write the conversion function. So the RGB frames can display in Qt, and thus we can use some image processing function in Qt to process or save.

This system can achieve the following objectives: the recognition rate reaches more than ninety-eight percent; users can import a new member by the user registration function; the recognition speed can be five second or less; it provides a good interactive interface; it minimizes the energy consumption as much as possible; the whole system has high integration.

6 Face recognition system testing

The implementation of detection of face recognition system is divided into two parts, namely, a face training part and a face recognition part, and the latter use the parameters and outcome from the former, while both use the same face detection technology.

The testing program is to test the recognition rate and the accuracy of face recognition algorithm, where face database includes the internet open access resources and the face images appended by user. The design principle of our face database is to extract 16 people from in the face database from internet open access resources, each with 20 images, where we use 10 images as face training database and others for testing. On the other hand, we append two people (one with 20 images and another with 23 images) into the face database, and extract each with 10 images as face training database and others for testing.

Now we introduce the procedure of face recognition testing. Firstly, we activate the camera to capture face and recognize it. If that face to be recognized is not saved in the database then the algorithm program will display 'nobody'. If the face to be recognized is registered in the system, then the training function will build a folder with the name 'cj', and save 10 shots with different facial expression. Therefore, the face recognition system will activate the camera to capture image and compare it with the backend database, then it will recognize the information of 'cj', and save 10 shots with different facial expression, shown in Figure 5.

Therefore, the face recognition system will activate the camera to capture image and compare it with the backend database, then it will recognize the information of 'cj', so it will activate the embedded application system to open the door for this authorized person.

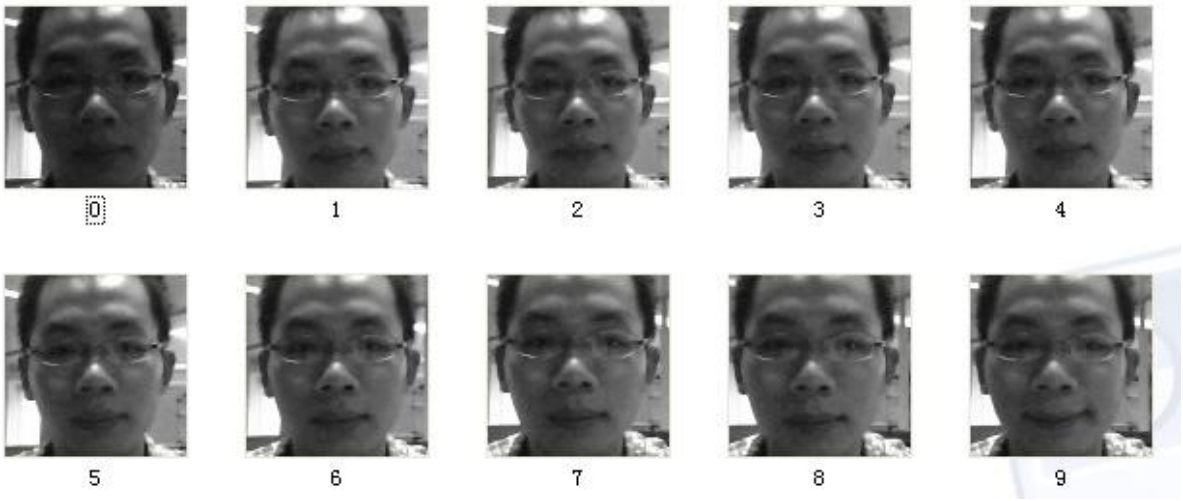

FIGURE 5 Face data

7 Conclusions

Face recognition technology is a hi-tech security way, which has superiority beyond comparing with other recognition approaches. Since it has a high accuracy rate, fast speed and difficultly counterfeited, the face recognition system is very suit for places where high safety is called for. Compared to some unique feature such as DNA, fingerprint, or iris, the face will change as one grows old, and collected images are disturbed by illumination, pose, expression, and makeup. But there exist some similar faces like the identical twins, so there may be uncertainty about face recognition. To improve the information security, one can adopt various recognition approaches to control the access.

For the current urgent need for security, we design an entrance guard system by face recognition and combine the ID registration technology to pre-register personnel in and out. Furthermore, we should update the samples in face database [15]. Finally, our system can be applied to finance, securities, social security, police, entry/exit port and other security authentication industry and sector.

Abstract

The control particle swarm optimization (CPSO) algorithm is introduced to solve the unit commitment problem under the background of emissions reduction. Because the standard particle swarm optimization algorithm is easy to fall into local optimal solution. The closed loop control concept and feedback mechanism of classical control theory are posited, each particle is considered as controlled object to meet the changing needs in searching process, while dynamically adjust the inertia weight by proportion-Integra-derivative (PID) controllers according to the adaptation value of each step. These strategies greatly ensure the diversity of particles and improve the global search ability of the algorithm. The simulation results show that CPSO algorithm can reduce the dimension of the problem and ensure the feasibility of the particle in the optimization process, while it also has good convergence characteristics and global search ability.

Keywords: power system, emissions reduction, unit commitment, control particle swarm optimization

1 Introduction

From the view of mathematical, the unit combination problem is a multi-constraint non-deterministic polynomial (NP) hard combinatorial optimization problem (K. H. Abdul-Rahman et al.) [1]. It is difficult to obtain theoretically optimal solution. The typical algorithms for solving model include heuristics approach (S.K. Tong et al.) [2], dynamic programming (C.K. Pang) [3], branch and bound method (G.S. Lauer) [4], Lagrangian relaxation method (S.Dekrajangpetch et al., C.P. Cheng et al., W. Ongsakul et al.) [5-7] and the modern intelligent algorithm (S.S. Li et al., Z. Li et al., J.L. Lu, X.H. Zhang et al.) [8-11]. However, these algorithms have one or another defect (K. Han et al.) [12]. If the environmental constraints are considered into the model, the problem will become more complexities. But it is important to economic operation of power systems through improving the accuracy and speed of solution under various constraints. In this context, an objective function of emission reduction unit commitment is posed which considering the minimum cost and minimum emission targets together by introducing emission price factor, and then, the original multi-objective problem can be transferred into a single objective problem, while a variety of constraints can be easily considered, in order to obtain the reasonable compromise between energy consumption and emissions.

In the specific solving algorithm, this paper presents a new set of inertia restructuring strategy through introducing the concepts of feedback mechanisms and closed-loop control system of control theory into the PSO system, then a control particle swarm optimization (CPSO) algorithm is formed. In this algorithm, a closed-loop control system is constructed while each particle sets as a controlled object-tive. Fitness value of particle is used as the output variable and feed backed to closed-loop in the iterative process, and the updated inertia weight is calculated through a designed PID controller which has been widely used in industrial due to its single structural and robustness, then the velocity and position of the particle is adjusted. CPSO algorithm can satisfy the needs of each particle and greatly ensure the diversity of the population of particles, while improving the search capabilities of PSO algorithm.

2 Mathematic models

The goal of unit commitment optimization is to optimize the status and contributions of generators in the calculation scheduling cycle, while satisfying the some constraints, in order to achieve minimum energy cost or minimum pollutant emissions.

2.1 OBJECTIVE FUNCTION

2.1.1 Minimum Energy Cost

The objective function can be expressed as follows:

$$\min F\left(\eta, P^{gen}\right)=\sum_{t=1}^{T}\sum_{i=1}^{N}\left\{f_i\left(P_{i,t}^{gen}\right)\eta_{i,t}+S_{i,t}^{up}+S_{i,t}^{down}\right\}, \quad (1)$$

$$f_i\left(P_{i,t}^{gen}\right)=\rho_i+\mu_i P_{i,t}^{gen}+\varphi_i\left(P_{i,t}^{gen}\right)^2, \quad (2)$$

$$S_{i,t}^{up}=S_i^{up}\eta_{i,t}\left(1-\eta_{i,t-1}\right), \quad (3)$$

$$S_{i,t}^{down}=S_i^{down}\eta_{i,t-1}1\left(-\eta_{i,t}\right), \quad (4)$$

* ***Corresponding author's*** e-mail: xm510@163.com

i is index for the number of units, *i*=1,2, …, *N*, *N* is the total number of units; *t* is index for time, *t*=1,2, …, *T*, *T* is the total number of periods in the scheduling period. $\eta_{i,t}$ is the start-up and shut-down statue of unit *i* at time *t*. The start-up of unit is 1 and shut-down of unit is to 0. $S_{i,t}^{up}$ is the cost of start-up -and $S_{i,t}^{down}$ is the cost of shut-down for unit *i* at time *t* respectively. S_i^{up} is the constant coefficient of cost of start-up and S_i^{down} is the constant coefficient of cost of shut-down for unit *i* at time *t* respectively. $f_i(P_{i,t}^{gen})$ is the generation costs of unit *i*, in \$, ρ_i, μ_i and φ_i are cost coefficients of unit *i*. $P_{i,t}^{gen}$ is the generation level of unit of unit *i* at time *t*, in MW.

2.1.2 Minimum Pollutant Emissions

The objective function can be expressed as follows:

$$\min E\left(\eta, P^{gen}\right)=\sum_{t=1}^{T}\sum_{i=1}^{N}\left\{e_i\left(P_{i,t}^{gen}\right)\eta_{i,t}+S_{i,t}^{up}+S_{i,t}^{down}\right\}, \quad (5)$$

$$e_i P_{i,t}^{gen}=\alpha_i+\beta_i P_{i,t}^{gen}+\gamma_i\left(P_{i,t}^{gen}\right)^2, \quad (6)$$

$e_i(P_{i,t}^{gen})$ is the emission costs of unit *i*. α_i, β_i and γ_i are cost coefficients of unit *i*, in \$. The other symbols are same as those in last section.

2.1.3 Total Objective Function

Considering the minimum energy cost and minimum pollutant emissions together by introducing an emissions price factor $\theta_{i,t}$, the multi-objective problem turned into a single objective problem and the total objective function is defined mathematically as follows:

$$\min F^{total}\left(\eta, P^{gen}\right)=\sum_{t=1}^{T}\sum_{i=1}^{N}\left\{\left[f_i\left(P_{i,t}^{gen}\right)+\theta_{i,t}e_i\left(P_{i,t}^{gen}\right)\right]\eta_{i,t}+ S_{i,t}^{up}+S_i^{down}\right\}, \quad (7)$$

The emissions price factor $\theta_{i,t}$ is defined as the proportion between maximum energy cost and maximum pollution emission of unit *i*, $P^{gen}_{i,max}$ is the maximum generation capacity of unit *i*:

$$\theta_{i,t}=f_i\left(P_{i,\max}^{gen}\right)/e_i\left(P_{i,\max}^{gen}\right), \quad (8)$$

2.2 CONSTRAINTS CONDITION

Power balance constraints:

$$\sum_{i=1}^{N}P_{i,t}^{gen}\eta_{i,t}-L_t=0. \quad (9)$$

Spinning reserve constraints:

$$\sum_{i=1}^{N}P_{i,\max}^{gen}\eta_{i,t}\geq L_t+R_t, \quad (10)$$

Up and down generation constraints of unit:

$$P_{i,\min}^{gen}\leq P_{i,t}^{gen}\leq P_{i,\max}^{gen}, \quad (11)$$

Minimum operation time constraints:

$$t_i^{on}\geq M_i^{on}, \quad (12)$$

Minimum out of operation time constraints:

$$t_i^{off}\geq M_i^{off}, \quad (13)$$

Unit Ramp Rate Constraint:

$$\left|P_{i,t}^{gen}-P_{i,t-1}^{gen}\right|\leq Z_{i,\max}, \quad (14)$$

where, $P^{gen}_{i,max}$ and $P^{gen}_{i,min}$ are the maximum and minimum generation capacity of unit *i*, in MW. L_t is system load demand at time *t*, in MW. R_t is system spinning reserve demand at time *t*, in MW. M_i^{on} is the minimum number of periods unit *i*, it must remain on operation statue after it has been start-up at time *t*, in hours. M_i^{off} is the minimum number of periods unit *i*, it must remain on out of operation statue after it has been shut-down at time *t*, in hours. t_i^{on} is the continuing number of periods unit *i* remains on operation statue after it has been start-up at time *t*, in hours. t_i^{off} is the continuing number of periods unit *i* must remains on out of operation statue after it has been shut-down at time *t*, in hours. $Z_{i,max}$ is the maximum ramp rate of unit *i*, in MW/h.

3 Outline of PSO

PSO algorithm was proposed to solve optimization problems by Kennedy et al. [13], it was a kind of numerical optimization techniques which similarly with genetic algorithm. It is easy to know from the above literature that the forward movement of the particle swarm including the size and direction of the particles were decided based on the original speed, individual and global extreme weighted.

$$v_{j,b+1}=\omega v_{j,b}+\phi_1 c_{rand}\left(q_{j,b}^{best}-x_{j,b}\right)+\phi_2 c_{rand}\left(g_b^{best}-x_{j,b}\right), \quad (15)$$

where *j* is index of particles, *j*=1,2, …, *J*. *b* is index for iterations, *b*=1,2, …, *B*. $q^{best}_{j,b}$ is the individual best position of particle *j* in the iteration *b*. g^{best}_{b} is the best position of all the particles in the iteration *b*. $v_{j,b}$ and $x_{j,b}$ are the velocity and location of particle *j* in the iteration *b*. ω, ϕ_1 and ϕ_2 are weight coefficients when velocity renewed. c_{rand} is the random number between 0 and 1. The particle swarm will be:

$$x_{j,b+1}=x_{j,b}+v_{j,b+1}. \quad (16)$$

Each particle in swarm will execute parallel optimazation during the iterations according to its own inertial velocity and the best location in memory, while considering the best location which other particles experienced. Then the best optimization solution will be found through several iterations.

4 CPSO algorithm

The inertial weight of each particle is always set as a relatively large initial value at the beginning of searching process, in order to make the particle moves fast. But this approach obviously has a weak point, which will lead to some particles located at the better location move too large distance to neglect some valuable searching area. If the inertial weight adjusted to a small value at the final stage of searching process, in order to make the particle to do more detail search. But this method will prevent some particles located at the worst location to overtake the other particles. So the same inertial weight value of particle swarm is not appropriation for each particle. The feedback mechanism and closed loop concept are introduced into PSO algorithm in order to overcome the shortcoming described above.

Figure 1 shows a simple input and simple output (SISO) feed back control system, the controlled values $y(t)$ and input values $u(t)$ of object are usually defined as controlled variable and manipulated variable of object respectively. The controlled variable $y(t)$ is fed back through a sensor measurement H and transfer value $h(t)$ to the reference value or set-point $r(t)$.

Each particle actually can be treated as an object. Its dynamic characteristics include current location, fitness value of last iteration and velocity. So the closed loop control system can be built for each particle, the fitness value is defined as controlled variable which is fed back to controller in iterations. Then a new suitable inertial weight will be calculated by controller according to the current fitness of particle and used for renewing the velocity and location.

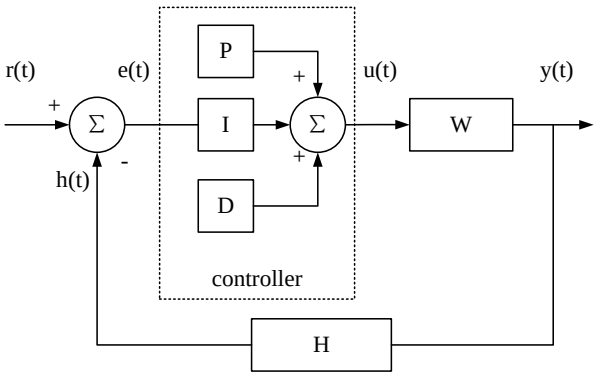

FIGURE 1 Structure of a SISO closed control system.

4.1 STRUCTURE OF PID

PID controller is a control loop feedback mechanism (controller) widely used in industrial control systems and has historically been considered to be the best controller with simple structure and best robustness. So the PID is selected as controller in this CPSO algorithm. There are three separate constant parameters which also be named as three-term control in the PID controller algorithm: the proportional values denoted as P, the integral values denoted as I and derivative values denoted as D, the structure of PID controller is show at Figure 1.

The output value Ξ^{out} which is proportional to the present error value $e(t)$ is produced by the proportional term. The proportional response value can be revised in term of multiplying the current error value through a constant defined as K^{prop}, this term is also named the proportional gain constant. The proportional term is set as follows:

$$\Xi^{out} = K^{prop} e(t). \tag{17}$$

The integral term I^{out} of a PID controller is the sum of the instantaneous error value during the time. This term will supply the accumulated offset value which should have been adjusted previously. The accumulated error term is then multiplied through the integral gain term defined as K^{iteg} and acted to the output value of controller. τ is the variable of integration which takes on values from time 0 to t. The integral term I^{out} is set as follows:

$$I^{out} = K^{iteg} \int_0^t e(\tau) d\tau . \tag{18}$$

The main purpose of the integral term is to accelerate the movement of the object towards the reference value and reduces the residual steady state error term which produced with a pure proportional controller.

The derivative term D^{out} of the object error is calculated through the determining the slope of the error value over the period of the time and multiplying this change magnitude according to the derivative gain constant K^{deri}. The role of the derivative term to the overall responding control action is effected on the basis of the derivative gain constant K^{deri}. The derivative term D^{out} is set as follows:

$$D^{out} = K^{deri} \frac{de(t)}{dt}. \tag{19}$$

The final standard form of the PID controller algorithm is given by:

$$u(t) = K^{prop}\left[e(t) + \frac{1}{T^I}\int_0^t e(\tau)dt + T^D \frac{de(t)}{dt} \right], \tag{20}$$

$$e(t) = r(t) - h(t), \tag{21}$$

where, each parameter has a clear physical meaning in this form. T^I is defined as the integral time constant and T^D is defined as the derivative time constant.

$$K^{iteg} = K^{prop} / T^I , \tag{22}$$

$$K^{deri} = K^{prop} T^D . \tag{23}$$

Sometimes it is useful to rewrite the PID controller in Laplace transform form. It is easy to determine the closed loop transfer function if this form is adopted.

$$G(s) = K^{prop}\left[1 + \left(1/T^I s\right) + T^D s\right]. \tag{24}$$

PID controller can be adjusted according to K^{prop}, T^I and T^D, these parameters are constructed as gain vector.

4.2 DEFINITION OF CPSO

There are J numbers of particles in whole swarm. W_j is the j particle, j=1,2, …, J. The manipulation variable u_j is defined as inertia weight factor. The output value of object is y_j defined as the fitness value of last iteration. H_j is the transfer function of feed back tunnel. It is also named as measurement sensor. Its output value is h_j. These parameters are given by the following equations:

$$u_j = \omega_j, \tag{25}$$

$$H_j = \varepsilon\left|1/y^{ave}\right|, \tag{26}$$

$$h_j = H_j y_j = \varepsilon\left|y_j / y^{ave}\right|, \tag{27}$$

where, ε is adjust factor and generally to be set as 1. y^{ave} is average value of current fitness for all particles. The parameter h_j is the evaluation term for particle W_j. The particle can be treated as a relative optimization location if h_j is larger than 1, on the contrary the particle is considered as lag location. The reference value is set as 1, and then the error term e_j is given as follows:

$$e(t) = r(t) - h(t) = 1 - \varepsilon\left|y_j / y^{ave}\right|. \tag{28}$$

The ζ is defined as gain vector of PID controller for j particle.

$$\zeta = \left[K_i^{prop}, \quad T_i^I \quad, T_i^D\right]^T = \left[-1, \quad \Re^{ite}/20, \quad 0\right]^T. \tag{29}$$

The gain proportion parameter K_i^{prop} will to be set lower than zero, because the movement magnitude of the particle which traps into local extreme value needs to be given larger inertia weight. The particle at a relatively optimization position need to be given a smaller inertia weight, in order to do more meticulous searching. Because the stability error will be introduced if the controller just include the proportion module, so the integral term should be added into the controller to eliminate the error term. The integral time constant T_i^I means it can play the same role as proportion term past T_i^I time. The specific problem is that the excess overshooting will be shown if integrator term is added into PID controller. Further more the integral windup will be caused. Some measures must be adopted to prevent this phenomenon. There is a simple anti integrator windup strategy for control PSO is given as follows:

$$T_i^I = \begin{cases} \Phi^{ite}/20, & \delta_j^{low} < \omega_j < \delta_j^{up} \\ 0, & \omega_j = \delta_j^{low} or \omega_j = \delta_j^{up} \end{cases}, \tag{30}$$

$\delta_j{}^{low}$ and $\delta_j{}^{up}$ are low and up limit of inertia weight ω_j. Φ^{ite} is the maximum iteration number. Because inertia weight and particle search area ranges are predefined between bounded set. Therefore, the output variables which are fitness value of the particle are bounded, the situation does not appear divergent. That means the closed-loop stability is guaranteed.

There will be more effective control if the derivative term added into controller, but at the same time the probability of unstable statute is also increased, so the derivative time constant is defined as zero in CPSO.

4.3 SOLVING STEP OF CPSO

The solving step of control PSO is as follow.

Step 1: Initialize the particles swarm and the initial iteration number φ_i is set as zero.

Step 2: Iteration calculation of particles.

Step 3: Renew the current individual particle best position $q_{best,j}$, the current best position g_{best} of all the particles swarm and the fitness value.

Step 4: If the iteration number φ_i does not reache the maximum iteration number Φ^{ite}, then the inertia weight ω is calculated through:

$$\omega = K^{prop}\left[1 + \left(1/T^I s\right) + T^D s\right]e. \tag{31}$$

Iteration calculation of particles by using new inertia weight ω, iteration number φ_i increases as follows:

$$\varphi_i = \varphi_i + 1. \tag{32}$$

Go to Step 2.

Step 5: If the iteration number φ_i reaches the maximum iteration number Φ^{ite}, then the evolution stops and the best position value is outputted.

5 Solving unit commitment problem under emissions reduction

5.1 CODING METHOD

The generation of all the units in different period will be connected as an individual of CPSO and represented by $N \times T$ matrix. This matrix is shown as follows:

$$P_k^{gen} = \left(Q_1 \;,\; Q_2 \;,\; \cdots \;,\; Q_t \;,\; \cdots \;,\; Q_T\right) = \left(R_1 \;,\; R_2 \;,\; \cdots \;,\; R_i \;,\; \cdots \;,\; R_N\right)^T = \begin{bmatrix} P_{1,1}^{gen} & P_{1,2}^{gen} & \cdots & P_{1,t}^{gen} & \cdots & P_{1,T}^{gen} \\ P_{2,1}^{gen} & P_{2,2}^{gen} & \cdots & P_{2,t}^{gen} & \cdots & P_{2,T}^{gen} \\ \vdots & \vdots & & \vdots & & \vdots \\ P_{i,1}^{gen} & P_{i,2}^{gen} & \cdots & P_{i,t}^{gen} & \cdots & P_{i,T}^{gen} \\ \vdots & \vdots & & \vdots & & \vdots \\ P_{N,1}^{gen} & P_{N,2}^{gen} & \cdots & P_{N,t}^{gen} & \cdots & P_{N,T}^{gen} \end{bmatrix} \tag{33}$$

where, P_k^{gen} is the k individual of particles swarm. $P_{i,k}$ is element of the i row and t column in the coding matrix, it represents the generation of unit i during the period t. Q_t is the t column vector in the coding matrix, it represents the unit statute of all units during the one period of all dispatch times, this vector can be used to calculate the cost of production and economic dispatch. R_i is the i row vector in the coding matrix, it represents the start-up and shut-down statute of all units during the all dispatch periods, this vector can be used to calculate the cost of start-up and shut-down for unit, but it must satisfy the minimum operation time constraints or out of operation time constraints.

The operation status of unit is decided by the element of matrix, furthermore the start-up or shut-down status is decided according to the generation of unit, this is given as following:

$$\eta_i(t)=\begin{cases}0, & P_{i,t}^{gen}=0\\ 1, & others\end{cases}. \tag{34}$$

Velocity matrix of CPSO algorithm is set as follows, where, V_k^{gen} is the velocity component of element P_k^{gen} in the particles swarm.

$$V_k^{gen}=\begin{bmatrix} V_{1,1}^{gen} & V_{1,2}^{gen} & \cdots & V_{1,t}^{gen} & \cdots & V_{1,T}^{gen}\\ V_{2,1}^{gen} & V_{2,2}^{gen} & \cdots & V_{2,t}^{gen} & \cdots & V_{2,T}^{gen}\\ \vdots & \vdots & & \vdots & & \vdots\\ V_{i,1}^{gen} & V_{i,2}^{gen} & \cdots & V_{i,t}^{gen} & \cdots & V_{i,T}^{gen}\\ \vdots & \vdots & & \vdots & & \vdots\\ V_{N,1}^{gen} & V_{N,2}^{gen} & \cdots & V_{N,t}^{gen} & \cdots & V_{N,T}^{gen}\end{bmatrix}. \tag{35}$$

5.2 FITNESS FUNCTION

The objective function of unit commitment optimization under emissions reduction is set as fitness function of CPSO algorithm. The lowest fitness value means the lowest operation cost, moreover it is the best solution.

5.3 INDIVIDUAL STRATEGY ADJUSTMENT

Because the individual particle may not satisfy the constraint conditions after initialization or renewable, so the individual particle needs to be adjusted in order to meet the constraints. The procedure is given as follows.

5.3.1 Reduce Dimension

Unit commitment is a high dimension optimization problem. The dimension is reduced in the searching process by using the implicit information through mining the constraints. The minimum number of operation unit during the period t is given by spinning reserve constraints Equation (10). And only the previous χ unit during period t under the operation status according to the priority sorting, that means the following constraint is satisfied:

$$P_k^{gen}\geq P_{i,\min}^{gen},\ 1\leq i\leq \chi. \tag{36}$$

The Equation (37) also can be obtained according to the power balance constraints Equation (9) and up and down generation constraints of unit Equation (11):

$$\sum_{i=1}^{N}P_{i,\min}\eta_{i,t}\leq L_t \tag{37}$$

There are γ units are out of operation during t, moreover, it means the maximum number of operation unit can also be obtained according to Equation (37). So only χ+1 to N-γ status *for* element $P_{i,t}^{gen}$ of matrix P_k^{gen} needs to be optimization:

$$P_{i,t}^{gen}=0,\ N-\gamma+1\leq i\leq N. \tag{38}$$

5.3.2 Constraints Handling

The individual of particle swarms adjusted to meet the constraints will be implemented as follows:

(i) Adjust the components of location matrix in order to make it meet the generation constraints of units, according to the (39).

(ii) Adjust the start-up and shutdown status of units to satisfy the spinning constraints. If the sum of maximum generation of units under the operation status is lower than the sum of total load and spinning at current time, then the units under the out of operation status while meet the minimum out of operation time constraints need to be start-up, in accordance with the order of priority until the total generation reaches the requirement of system. The unit start-up order of priority is decided according to the literature (S. Dekrajangpetch et al.) [5], it means the units which have the lower incremental rate of cost will be set as the higher priority level. On the contrary, the units will be treated as lower priority level.

$$P_{i,t}^{gen}=\begin{cases}P_{i,\max}^{gen} & P_{i,t}^{gen}\geq P_{i,\max}^{gen}, i\geq N-\gamma,\\ & t_i^{on}\geq M_i^{on}\ or\ \ t_i^{off}\geq M_i^{off}\\ P_{i,t}^{gen} & P_{i,\min}^{gen}\leq P_{i,t}^{gen}\leq P_{i,\max}^{gen}, i\geq N-\gamma,\\ & t_i^{on}\geq M_i^{on}\ or\ \ t_i^{off}\geq M_i^{off}\\ P_{i,\min}^{gen} & P_{i,t}^{gen}\leq P_{i,\min}^{gen}, i\geq N-\gamma,\\ & t_i^{on}\geq M_i^{on}\ or\ \ t_i^{off}\geq M_i^{off}\\ 0, & otherwise\end{cases}. \tag{39}$$

(iii) The total generation of all units probably not equals the total load demand during some periods. So the load needs to be adjusted. If the total technology generation of units under operation status is larger than the total load at current time, then these units which satisfy the minimum operation time constraints need to be shutdown according to the priority sorts.

(iv) If the total generation is lower than the total demand at current time, then the generation of units needs to be increased, in order to meet the power balance constraints. If the total generation is larger than the total demand at current time, then the generation of units under operation status should be reduced. But the ramp rate constraints and generation constraints of unit must be satisfied in the process of adjustment.

Some problems may be appeared after the above adjustment of individual. Furthermore, the total maximum of technology generation of units under operation status is still lower than the sum of total demand and spinning reserve at current period. Because the demand increases so fast, which induced by some units were shut-down during some periods, but this units cannot start-up according to

the change of demand for minimum start-up time constraints. So the shut-down decision of units need to be re-evaluated before this period, the shutdown decision should be replaced by reducing the technology generation of units, while satisfy the power balance constraints.

6 Simulation and analysis

The 9 units system is used to test the proposed method. The main parameters are given as following tables. Table 1 and Table 2 show the unit system data. The result of economic dispatch of unit commitment is shown as Table 3. The emission quantities of three different dispatch models are shown as Figure 2. The first scene represents the objective function is set as minimum economic dispatch and the average emission quantity is 346.7458lb, this is the highest scene. The second scene represents the objective function is set as minimum emission dispatch and the average emission quantity is 279.9292lb, this is the lowest scene.

TABLE 1 9-units system data (Unit cost data and emission data)

Unit	ρ_i($/h)	μ_i($/MWh)	φ_i($/MW^2-h)	Start cost($)	α_i(lb/h)	β_i(lb/MWh)	γ_i(lb/MW^2-h)

The fuel cost of three different dispatch models are shown as Figure 3, the first scene represents the objective function is set as minimum economic dispatch and the average fuel cost is \$5861.38, this is lowest scene. The second scene represents the objective function is set as minimum emission dispatch and the average cost is \$9345.38, this is the highest scene. The third scene represents the objective function is set as comprehensive dispatch of unit commitment and the average cost is \$6227.13, this scene is interposed between the two cases described in the foregoing. All these problems are solved by control PSO algorithm. The total cost of three different dispatch models are shown as Figure 4, the first scene represents the objective function is set as minimum economic dispatch and the average cost is 12687.7625\$, this is interposed between the scene1 and scene 2.

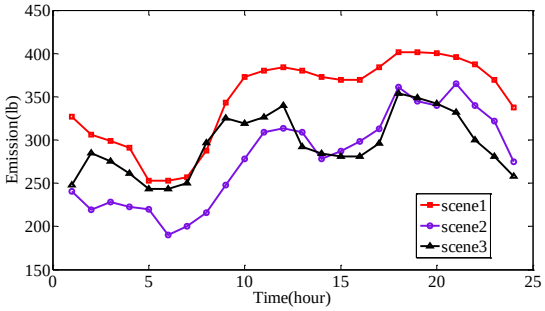

FIGURE 2 The emissions under different dispatch models by CPSO

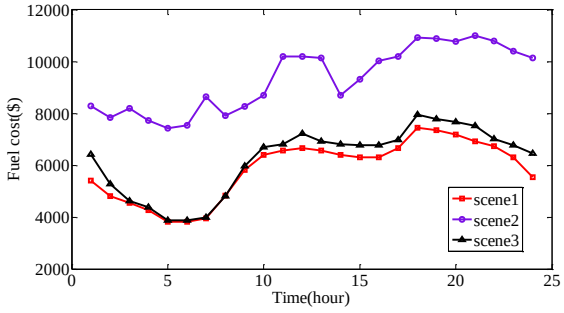

FIGURE 3 The fuel cost under different dispatch models by CPSO

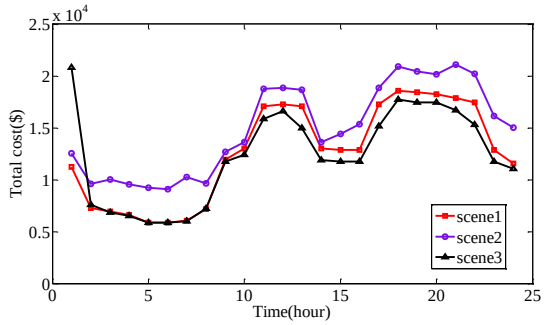

FIGURE 4 The total cost under different dispatch models by CPSO

The second scene represents the objective function is set as minimum emission dispatch and the average cost is \$14954.04, it is the highest scene. The third scene represents the objective function is set as comprehensive dispatch of unit commitment and the average cost is \$11918.88, it is lowest. Above results show that the total cost will increase so fast if too emphasize the emission reduction, so the relatively balance approach considering the emission reduction and economic dispatch together is needed.

Figure 5 shows the results distribution of total cost of comprehensive unit commitment under emission reduction by different algorithms including PSO, GA, and CPSO. Continuous simulating 30 times, the best solution of PSO is \$286882.55, the worst solution of PSO is \$294377.14. The deviation of the worst solution with respect to the best solution is 2.91%, and about 53.4% solution deviates from the best solution is lower than 1.5%.

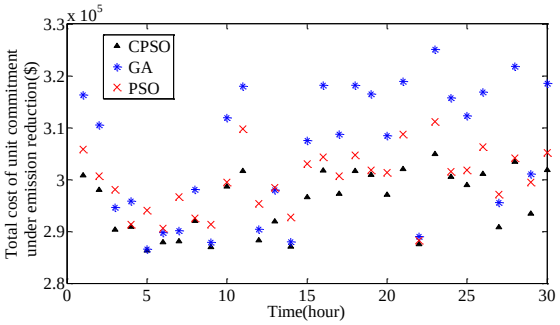

FIGURE 5 The results distribution of total cost of comprehensive unit commitment under emission reduction through different algorithms

The best solution of GA is \$286682.31, the worst solution of GA is £305275.76. The deviation of the worst solution with respect to the best solution is 6.34%, and about 26.3% solution deviates from the best solution is lower than 1.5%. The best solution of CPSO is \$286253.24, the worst solution of CPSO is \$291573.82, the deviation of the worst solution with respect to the best solution is 1.93%, and about 76.7% solution deviates from the best solution is lower than 1.5%. So the robustness and precise of CPSO are obviously best than the other algorithms.

7 Conclusions

There are following conclusions according to the simulation:

(i) The objective function considering the minimum cost and minimum emission targets together is more reasonable to discuss the unit commitment problem, because the environmental factor has same important role as economic factor.

(ii) The emission price factor is introduced into the model, this will helpful to transfer the multi-objective optimization problem to the single-objective optimization problem.

(iii) The total cost will increase so fast if too emphasize on the role of emission reduction, so the balance need to be selected between the target of economic and emission.

(iv) CPSO algorithm shows robustness and precise than the other algorithms.

Abstract

Investment estimation phase of power transmission line project is an important stage of project cost control, the traditional unit investment forecasting methods, however, cannot meet the need of engineering rapid estimation. The research objective of this paper is to forecast the unit investment of the Transmission Line Project applying the case-based reasoning system. Based on the factor analysis tools of multivariate statistical software SPSS, the correlation coefficient matrix of characteristics factors are identified, and weight coefficient of characteristics factors is calculated. Based on the formula of European weighted distance, the similarity is calculated and case similarity is retrieved. Finally, the model is constructed to predict the unit investment of Transmission Line project, and the correctness and usefulness of the model is verified. It is shown that this case-based reasoning system of unit investment can achieve real-time updating of cost index database. The primary contribution of this research is the combination of the cost forecast and Case-based reasoning system of artificial intelligence. It is expected that this work will provide a reference and guidance for transmission line project investment decision in estimating phase.

Keywords: case-based reasoning, transmission line projects, forecasting

1 Introduction

Setting up the prediction model in line with the actuality, accurately and rapidly estimating the construction cost has dramatic theoretical significance and practical value. The accuracy of the transmission lines project cost prediction has a close relationship with the selection of prediction methods. The common predicting method can be divided into three categories:

The first is the approximate deduction method. According to the characteristics of all kinds of engineering projects, some uncertain factors are classified and made hypothesis. Then based on the mechanism of deductive reasoning, project cost prediction model is established. Such as artificial neural network, unit cost factor is the key to construct artificial neural network structure model. Only the various influence factors and influence mechanism are found, the artificial neural network model can be constructed, including the influence of the engineering geologic and topographic conditions, the influence of the transformer substation type, the influence of conductor cross section size of the transmission line, the influence of the cable laying mode, etc.

The second is statistical induction. Based on the finished engineering cost information, the engineering cost and index database is established. Through mathematical means, looking for the change rule of all kinds of construction project cost, project cost prediction model is established [1]. Such as engineering analogy method and fuzzy mathematics method, the difficulty of this method lies in the selection of fuzzy analogy estimate model category. Fuzzy system lacks self-study ability, the membership functions and fuzzy rule of which are chosen by experts subjectively, potentially skewing results.

The third kind is the time series method [2]. Such as moving average, exponential smoothing, autoregressive moving average method, the constant ratio regression method and Markov prediction method, regression analysis and grey prediction method. Using month as the unit to gather the cost information, and to generate a variety of cost index data sequence, fitting model is established on the basis of corresponding theory. Moving average method and exponential smoothing method usually lag and it is difficult to determine the weight coefficient. Autoregressive Moving Average (ARMA) model only adapts to the stationary time series. Constant ratio regression method requires regression analysis, however, missing individual data and uneven distribution will lead to the accuracy reduction or even failure of analysis result. Owing to the poor extrapolation, the model has the feature of high-precision and fitting unless the detailed scale and scope of the project are described in the selected completed project. It is difficult to decide the state transferring probability matrix which is the core. A function curve is hard to be established to describe the change trend of engineering cost, which brings limitations to the application of trend extrapolation.

Considering the shortage of the existing unit investment estimate method, this paper puts forward on estimating construction cost of transmission lines project which on the basis of case-based reasoning technology, and analyzes the necessity and feasibility of forecasting system based on the Case-Based Reasoning. The performance of this model is verified by an illustration.

2 The establishment of the case-based reasoning system

2.1 THE PRINCIPLE OF CASE-BASED REASONING SYSTEM

The Case-Based Reasoning is a new strategy to demonstrate knowledge and its primary feature is to use previous similar experiences to solve current problems [3]. In CBR, to solve the problem or situation is known as the target case, and the memorized or completed case is called the source case. Case-Based Reasoning is a strategy which obtains the most similar source case in memory by the hints of the target case and finds the answers by the instruction of the source case. The artificial intelligence technology is often used in project cost system design [4], project cost risk control [5], real estate marketing [6], and project cost quickly estimation [7], etc.

2.2 ANALYSIS OF THE APPLICABILITY OF THE CASE-BASED REASONING SYSTEM

Compared to the existing measures, Case-based reasoning system shows more suitable for forecasting the unit investment of transmission lines. First of all, the knowledge of case-based reasoning system is organized in the form of case structure. Moreover, it is difficult to use the function model to describe the engineering cost of transmission lines and the multi-factors of complex misalignment relations characteristic. However, the form of case can provide more abundant information than that of a set of rules.

Second, fuzzy reasoning is a kind of incremental learning method, and neural network method has similar advantages. With the increase of cases, the coverage of the case (the range of solving the problem) and predictive accuracy are improved. Both fuzzy system and neural network are dynamic system. Neural network is suitable for processing unstructured information, while the fuzzy system deals with the structured knowledge more effecttively. Case-based reasoning shows better expandability, for the reason that it is a reference case experience, and requires little field knowledge, which avoids the integrity and consistency of the knowledge base with the increase of knowledge.

2.3 DESIGN OF THE CASE-BASED REASONING SYSTEM OF COMPLETED PROJECT

Based on the analysis of characteristics of transmission lines construction project, and combined with the working process of the case-based reasoning, a case-based reasonning unit investment forecasting system of transmission lines is built as follow.

The first step is acquiring knowledge from completed projects in the database, and extracting the representative attributes of engineering projects. The second step is establishing a completed project database, namely, to establish an extensible engineering database which saves project overview, the main technical and economic indices and unit investment and other attributes. The third step is confirming the target weigh coefficient, that is to say, factor analysis of SPSS is adopted and each attribute is assigned corresponding weights. The forth step is case retrieval. Based on the previous steps, the similarity between two cases is measured by the distance formula. Case retrieval includes two steps: firstly, searching the projects in the case base as similar as possible, secondly, matching up to the most similar item from the similar projects. The fifth step is case revision. Case revision aims at adapting to the problem to be solved, and on the basis of the predicting result it can set a certain minimum threshold to confirm the corresponding adjustment strategy. The sixth step is case study and maintenance. The existing case base can be complemented along with adding or removing case, adjusting the structure of the case, and resetting the indexes to meet the demand of continuous change and expending requirement of cost management.

3 The implementation of case-based reasoning system

3.1 CASE REPRESENTATION AND ORGANIZATION

Case representation is the premise and basis of case-based reasoning, and belongs to a kind of knowledge representation, which turns out to be “cases transition from our experience”. Problem to be solved are structured, and attributes are extracted. Case representation is a description of the current prediction problem, and the corresponding eigenvalue solutions needs to be obtained through reasoning system. On the one hand, it is the descriptive method of the case, on the other hand it is content contained in the case description. According to the basic data approved by a province in China in 2012 at feasibility research stage, the main factors influencing the unit investment of transmission lines engineering have two aspects. One is the project summary information, including voltage grade, overhead line type, topography, ice, and the path length of the overhead line, etc. The other is main economic indexes such as the proportion of corner, tower, ground wire, iron tower, steel, foundation pit concrete, earth rock and number of insulator string index, etc. Unit kilometer cost is needed to be predicted.

The common methods of case representation currently contain causality graph, object-oriented knowledge representation, logic representation, semantic network, frame representation, full-text representation. The framework representation uses a structure or organization to store the past experience, cases of which are structured in the form of “node-slot-value” of semantic network. So the general structure of framework is a semantic network, by the framework and a set of framework is used to describe various aspects of specific attributes of the slot. Frame-

work is a general structure of semantic network, consists of a framework and a set of slots used to describe all aspects of the specific properties. Each slot can be further equipped with "side" to be specified [8]. In the transmission line projects, slots are described formally as follow:

Item number:
Framework name: <Transmission lines project summary>
Slot 1. Project overview
Side 1. Completion date
Side 2. Construction site
Side 3. Construction type
Side 4. Voltage grade
Side 5. Overhead line types(normal, compact, shrunk, long-span)
Side 6. Altitude

Slot 2. Project properties
Side 1. Line length
Side 2. Tower type
Side 3. Tower base quantity
Side 4. Tower material quantity
Side 5. Wire type
Side 6. Conductors bundled number
Side 7. Cover ice
Side 8. Wind speed
Side 9. Terrain proportion
Side 10. Geological proportion
Side 11. Design of the joint and one standardization

Framework name: <Cost information>
Slot 1. (Property Value Inheritance) project profile inherited

Slot 2. Cost indicators
Side 1. Total cost
Side 2. Ontology construction cost
Side 3. Auxiliary construction cost
Side 4. Other expenses

Slot 3. Major material and labor consumption
Side 1. Artificial man-days
Side 2. Concrete
Side 3. Steel
Side 4. Wire
Side 5. Cement

Slot 4. Bill of civil part quantities
Side 1. Earthwork and rockwork
Side 2. Basic engineering

Slot 5. Bill of installation quantities
Side 1. Tower engineering
Side 2. Wiring project
Side 3. Attachment engineering

Slot 6. Result sets
Side 1. Cost of per kilometer
Side 2. Number of per kilometer tower base
Side 3. Wire consumption of per kilometre

Slot 7. Related instructions
Side 1. Analysis of representative case

The case number is the unique identification of engineering cases, represented by a string. Engineering properties are briefly introduced, including the profile information referred construction time, site, time schedule. Engineering metrics includes major staff and technology arrangement technical index, which corresponds case retrieving information. The result sets show better fidelity to the solutions, which includes engineering unit investment and major staff and technology consumption. Relevant specification is the analysis of the typical engineering cases, the relevant cost information of which will be explained or extended. The referred cost information reflected by the cases will be explained and extended.

In order to express case more methodically, cases are organized and arranged to form corresponding completed project database according to the characteristics of the case and retrieval need. Case organization directly affects the efficiency of case retrieval, whose key is the selection of key indicators of transmission line project. Key indicators are determined by the problem to be solved and the characteristics of certain cases.

3.2 CASE RETRIEVAL

3.2.1 Case index

Case indexing method has three types: nearest neighbor, inductive reasoning and knowledge-guided approach. According to the case representation and organization form, case retrieval is conducted by means of the combination of nearest neighbor approach and knowledge-guided approach in the engineering cost estimation system based on case-based reasoning.

Knowledge-guided strategy selects the optimum cases through searching the target case and completed cases in the database, whose attributes, including voltage grade, overhead line type, topography and other indicators, are determined by domain knowledge. Case sets in line with the features of pending cases domain can be output as the candidate sets to be selected in the nearest neighbor approach.

Nearest neighbor approach is a kind of strategy that target case to be resolved and completed cases in the case base are retrieved and traversed, respectively obtaining the similarity between cases of each index field. According to the established weighted vector, the similarity among cases and the problem to be solved are calculated. In addition, users can also get the cases whose similarity exceed the threshold, then modify and retrieve them.

The engineering unit investment factors of transmission lines will be divided into two categories: control attributes and comparison attributes. Among them, control attributes refers to the project profile and basic information of attributes, such as voltage grade and overhead line type, which is essential for judging the similarity of transmission lines projects. Primary retrieval is kind of searching the feasible

candidate sets by matching exactly the target case and the case base by the attribute index. Then, by applying the results of paired comparison, an index structure is established. When control properties of transmission line engineering match completely, comparing attributes can be retrieved through advanced searching. On the premise of same control properties, main characteristics of comparing attributes and cases of largest number of matched features are taken into first consideration.

In order to realize the initial matching of the control properties between the cases to be solved and the case base, c++.net is applied to set primary retrieval rules. Combined with representation and organization characteristics of engineering case, the primary search selects the voltage level for the first retrieval conditions, altitude for the second retrieval conditions, overhead line type for the third retrieval conditions, which finally form the candidate sets based on the nearest neighbor algorithm.

The main code of primary retrieval is as follows:

```
int JuniorSearch()
 {
 int count = 0;
 juniorData[count] = targetData[0];
count++;
 for (int index = 1;index<totalCount;index++)
 {
array<String^>^ rowData = tableData[index];
// Matching the first condition?
                if(Convert::ToInt32(rowData[1])!=Convert::ToInt32(
tarValue[1]))
                {
                continue;
}// Matching the second condition?
if((Convert::ToInt32(rowData[2])>Convert::ToInt32(tarValue[2])
)||(Convert::ToInt32(rowData[3])<Convert::ToInt32(tarValue[3]))
)
{
continue;
}// Matching the third conditions?
if(TransformType(rowData[4])!=LINE_TYPE(int(tarValue[4])))
{
continue;
}//Meeting all the three conditions?
juniorData[count] = rowData;
count++;
}
 return count;
 }
```

3.2.2 Similarity retrieval

Through primary index we can find candidate set of cases in the completed project as little as possible, which has reference significance to the target problem to be resolved. Then the similarity of comparing attributes are retrieved and evaluated, in order to find the relative matching case to forecasting unit investment. Due to the incompleteness of information, only the cases whose characterizing attribute are similar can be matched and retrieved, difficult to matching completely. So this section will use SPSS statistical analysis software[9], according to the correlation analysis between each variable, the main factors that influence the engineering cost are determined, furthermore the weight of each comparing attributes influencing the case similarity was defined.

Similarity is basis of the case-based reasoning, the measure method and standard of which determine success or failure of case-based reasoning and the accuracy of the prediction to a great extent. The similarity metrics between cases is represented by S. The closer the control attributes and comparing attributes of x and x' in two cases are, the higher the value of $S(x,x')$ will be. The further the control attributes and comparing attributes of x and x' in two cases are, the lower the value of $S(x,x')$ will be. Generally the similarity between cases is measured by the distance in feature space. The distance metrics which are frequently used include Euclidean distance, City Block, Minkowski distance, Chebyshev distance weighted variance distance and Markov distance.

The similarity of the prediction model in this paper is measured by Euclidean distance[10]. A case is represented with a data vector x. In this article $x_i = \{x_{i1}, x_{i2}, \cdots x_{in}\}$ represents case, where n is the dimension of vector, m is the case numbers in the space X. The calculation steps are as follow:

1) Standardization of data: $x_{mn} = \dfrac{x_{mn} - \min\limits_{m} x_{mn}}{\max\limits_{m} x_{mn} - \min\limits_{m} x_{mn}}$.

2) Determination of the weight: each influence of the comparison properties to transmission line project varies greatly. Some of attributes, including tower index, wire index, foundation pit concrete index, are crucial, while others, such as the number of the insulator string, have little effect. Similarity is sensitive to the change of the weight, so reasonably setting the weight ensures that the results of prediction accuracy. Many methods could be used to calculate the weight, such as expert discussion method, analytic hierarchy process, however, the strong subjectivity of which can lead to similarity deviation if the weight is allocated unreasonably. Factor analysis tools in SPSS software is used to assign the value of relevant weight, which greatly reduces the subjective influence on the prediction result. The article extracts 13 factors from 139 cases according to the engineering characteristics of transmission line projects of a province in 2012.

Based on the selected case database, cases of different voltage levels are selected, in order to examine the selected variable distribution. The unit investment varies greatly among different voltage levels, including 220kV, 110kV, 35kV. In order to identify the important deviation value of

the distribution of the variable based on the transmission line projects of different voltage levels, box plot in the software SPSS is used to remove the outlier spots. The result is shown below in Figure 1.

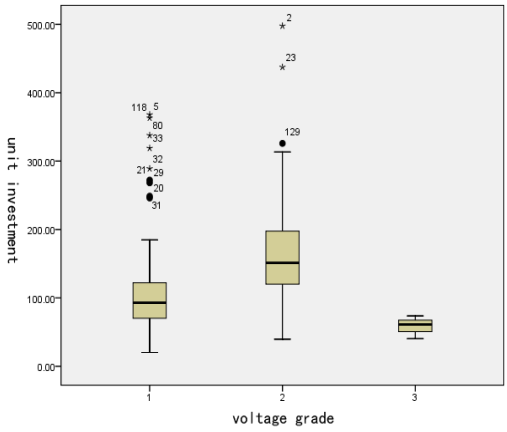

FIGURE 1 Box of voltage grade and unit investment

Based on the factor analysis tools of software SPSS, correlation matrix table is obtained after inputting the data of 13 factors for correlation. Unit investment is the factor to predict, the correlation between other attributes and the target attributes shall be strong, while the correlation between other factors shall be as weak as possible in order to minimize collinearity between them. After inspection, the correlation coefficient between tower index and the material of iron tower is 0.849 which means strong liner correlation and they are merged into tower index. Cast-in-situ foundation and other foundation pit concrete index, bored concrete pile foundation index, are merged as foundation pit concrete index. After calculation, the correlation coefficient between the foundation pit concrete index and foundation pit earthwork index is 0.793, which means strong correlation, and foundation pit concrete index is reserved. The correlation coefficients between unit investment conductor insulator composite index, conductor insulator index without composite are inferior to 0.4, which means weak correlation, and two indexes are deleted. After using factor analysis, the final correlation coefficient matrix is shown in the following Table 1.

TABLE 1 Correlation matrix

		Angle proportion	**Tower index**	**Wire index**	**Grounding line index**	**Foundation pit concrete index**	**Foundation steel index**	**Unit investment**
correlation	Angle proportion	1	-0.03	0.424	-0.136	-0.316	0.358	0.322
	Tower index	-0.03	1	0.234	0.196	0.027	0.276	0.416
	Wire index	0.424	0.234	1	-0.183	-0.282	0.725	0.434
	Grounding line index	-0.136	0.196	-0.183	1	-0.034	-0.168	-0.261
	Foundation pit concrete index	-0.316	0.027	-0.282	-0.034	1	-0.199	-0.202
	Foundation steel index	0.358	0.276	0.725	-0.168	-0.199	1	0.57
	Unit investment	0.322	0.416	0.434	-0.261	-0.202	0.57	1
Sig. (one-sided)	Angle proportion		0.434	0.006	0.221	0.034	0.019	0.032
	Tower index	0.434		0.091	0.133	0.441	0.057	0.007
	Wire index	0.006	0.091		0.15	0.053	0	0.005
	Grounding line index	0.221	0.133	0.15		0.425	0.172	0.068
	Foundation pit concrete index	0.034	0.441	0.053	0.425		0.129	0.125
	Foundation steel index	0.019	0.057	0	0.172	0.129		0
	Unit investment	0.032	0.007	0.005	0.068	0.125	0	

As shown in the Table 1, twelve attributes are extracted from the database, six of which are comparing indexes, including angle proportion, tower index, wire index, ground wire index, foundation pit concrete index, and foundation steel index. As the unit investment index is the target prediction index, the larger the correlation coefficient between comparing attributes and unit investment index is, the strong similarity between the target case and case set is. Based on the correlation coefficient between 6 comparing attributes and unit investment respectively in the correlation matrix table of SPSS factor analysis, the similarity weight of the cases are calculated [11], which is shown in Table 2.

TABLE 2 The weight of Case similarity impacted by characteristics factors

Engineering characteristics	The correlation coefficient to unit investment	The weight
Angle proportion	0.322	0.16
Tower index	0.416	0.19
Wire index	0.434	0.20
Ground wire index	0.216	0.10
Foundation pit concrete index	0.202	0.09
Foundation steel index	0.570	0.26
	2.16	1.00

3) Similarity calculation: to calculate the similarity, the users should input new cases, the attributes of which mainly include angle proportion, tower index, wire index, ground wire index, foundation pit concrete index, and foundation steel index. $d(x_i, y_j)$ represents the distance between the new case x_i and a certain case y_j from the database. The distance is defined by weighted Euclidean distance method [12].

$$d(x_i, y_j) = \left[\sum_{k=1}^{p} w_k (v_{ik} - v_{jk})^2 \right]^{\frac{1}{2}},$$

where p represents the total number of attributes. v_{ik} represents the value of k-th attributes of case i-th. w_k represents the weight of k-th attribute.

The target case and the candidate case base are traversed to retrieve with the maximum value $d_{\max}$, and three cases with the closest distance which is represented as d_1, d_2, d_3 respectively.

The similarity between new case and the case from the database is defined as $sim(x_i, y_j)$. The similarity calculation formula is as followed [13]:

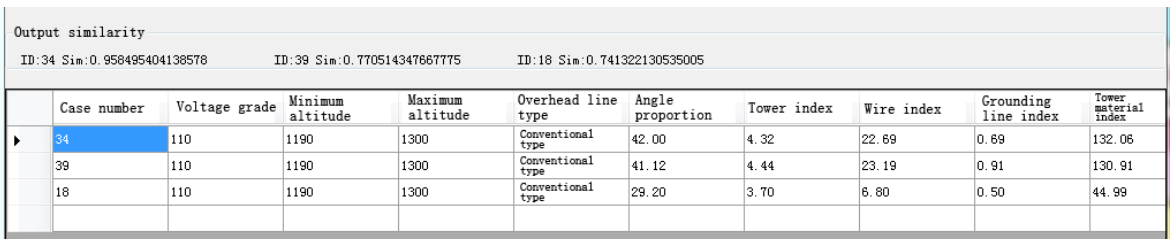
$$sim(x_i, y_j) = 1 - \frac{d_i}{d_{\max}} (i = 1, 2, 3).$$

The output of similarity value should between 0 and 1. The closer the sim value is to 1, the greater the similarity is.

4) Case similarity retrieval: firstly, Similarity is calculated as the followed program code:

```
double CalSim (int P, array <double> ^W,array
<double>^Vi,array<double>^Vk)
{
 double sumUp = 0;
for (int index=0;index<P;index++)
{
double w = W[index];
double vi = Vi[index];
double vk = Vk[index];
 //sum the squares of numerator
 sumUp += w * (vi - vk) * (vi - vk);
 }
 return (System::Math::Sqrt(sumUp));
 }
Advance search is conducted, and the program code is as follow,
int HighSearch()
 {
 if(juniorCount <= 1)
 {
 return 0;
 }
 int count = 0;
 highData[count] = juniorData[0];
 count++;
 int colTotal = juniorData[0]->Length;
 array<double>^ temp = gcnew array <double> (colTotal);
array<double>^ retList = gcnew array <double> (juniorCount -
1);
array<int>^ retIndex = gcnew array<int>(juniorCount - 1);
for (int index = 1;index<juniorCount;index++)
 {
 // The original data
 array<String^>^ rowData = juniorData[index];
 // Convert to processing dataTransformData (rowData,temp);
 // Calculate the similarity
 double sim = CalSim(colTotal,tarW,tarValue,temp);
 // Save the result?
 retList[index-1] = sim;
retIndex[index-1] = Convert::ToInt32(rowData[0]);
 }
 // sort
Array::Sort(retList,retIndex);
//Select the maximum data Y
 int length = retList->Length;
 Dmax = retList[length - 1 ];
 for (int index = 0;index < length && index < 3 ;index ++)
 {
 int id = retIndex[index];
highData[count] = tableData[id];
count++;
 }
 // show result?
showResult(retList,retIndex);
 return count;
 }
```

The case No.34, No.39, No.18 are selected with similar value of 98.85%, 77.05%, 74.13% respectively, which are the top three cases with the largest similarity. The result is shown in the following Figure 2:



Output similarity

ID:34 Sim:0.958495404138578 ID:39 Sim:0.770514347667775 ID:18 Sim:0.741322130535005

Case number	Voltage grade	Minimum altitude	Maximum altitude	Overhead line type	Angle proportion	Tower index	Wire index	Grounding line index	Tower material index
34	110	1190	1300	Conventional type	42.00	4.32	22.69	0.69	132.06
39	110	1190	1300	Conventional type	41.12	4.44	23.19	0.91	130.91
18	110	1190	1300	Conventional type	29.20	3.70	6.80	0.50	44.99

FIGURE 2 Prediction system based on case-based reasoning

3.3 CASE REVISION

Based on similarity calculation, the similarity between the target case and the candidate case in the case base is obtained. An appropriate minimum threshold is set according to the influence of similarity to the target case. Cases whose similarity are greater than or equal to the lower threshold are selected as the matching case of the target case, which provides decision support for new projects. If the similarity of the model doesn't reach the threshold, case will be amended according to the voltage level, overhead line type and other attributes in the case base.

If the similarity threshold is set to 0.9 in the above case-based reasoning system, the similarity between case 24 and the target case is 95.85%, above the threshold, which needs no adjustment. Case 39 and case 18 need appropriate amendments according to the expert experience and human-computer interaction, because the similarity of which are below the threshold. After case revision the similarity is above the threshold, which guarantees the precision of the prediction.

Comparison between main engineering characteristics of target case and similar case is shown in Table 3.

TABLE 3 The main engineering characteristics of target case and similar cases

Case No.	Angle ratio	Tower index	Wire index	Ground wire index	Iron tower material index	Basic steel index	Foundation pit concrete index	Unit investment
Target case	39.00	4.50	24.92	0.70	133.24	25.36	269.71	
34	42.00	4.32	22.69	0.69	132.06	28.00	99.78	279.63
39	41.12	4.44	23.19	0.91	130.91	24.94	270.99	153.16
18	29.20	3.70	6.80	0.50	44.99	17.68	161.28	178.84

As for case revision, the inconsistent between target case and senior retrieved case needs considering mainly, in order to find out the optimal solution. For example, the perception of angle steel tower, steel towers and steel rods needs to be considered in similar cases, for the iron tower indices differ greatly. The influence of different factors including wire type and wire section needs to be considered in order to correct the wire indicator. Casting type of basis needs to be considered to rectified foundation pit concrete index. After the above factors are considered comprehensively, the cases whose similarity are below the threshold are modified, and unit investment is derived from appropriate forecasting model.

Based on the comparison of the cost index and the actual situation of the project, the prices of case No.39 and No.18 increase 35%, namely, 206.766 and 236.07 ten thousand yuan/km, respectively. The prediction of unit investment is 2408200 using arithmetic average, which is 3.92% lower than actual estimate. The predicted results are accurate and convincing.

3.4 CASE LEARNING AND MAINTENANCE

Case learning takes a new round of case decision by adding the newly completed project to the corresponding decision-making environment through the case description and index. The case learning process can update the case base, so as to provide a rich case database for case reasoning. With the quantity of the case increasing, however, the efficient of the program may fall, emerging redundancy, repetition and obsolete. When the cost of retrieving similar case is greater than the benefit it offers, index mechanism of the case database should be adjusted and the case data should be maintained, including improving obsolete case and deleting the invalid case. The forecasting system's capacity to solving problems is gradually strengthened and improved through the case study and maintenance.

4 Conclusions

Based on artificial intelligence methods, case-based reasoning forecasting system of unit investment is analyzed, which provides a quick and effective approach for unit investment rapid estimation at estimate stage. Firstly, completed engineering data is organized, stored and managed using ACCESS. Secondly, the software SPSS is used to data denoising, and the cost index weight coefficient is built by factor analysis tools. Then, the programming algorithm of dynamic case reasoning system component is designed by C++/CLI language. The program dynamically associates the activities of the execution program with the completed engineering database, which realizes the primary search, advanced search and similar case output. Based on the completed transmission line projects in 2012, the essay accomplishes the rapid search of similar cases and optimizes the output of the program after adjustment.

At present, the case-based reasoning system prediction for transmission line projects is still at its initial stage. The uncertainty of the index weight setting still exists because of the strong dependence of historical database. Similarity distance formula is the key to the precision of prediction which directly affects the accuracy of the prediction results. The modification of the similar case is the difficulty of the research due to the objective of expert evaluation.

The combination of the unit transmission line project with the artificial intelligence greatly improves the speed of the unit investment fast calculation. The system provides reference for the foundation of the building cost index database, which also provides reference for the data accumulation of the owners' projects.

Received 1 March 2014, www.cmnt.lv

Abstract

In order to distinguish the different patterns and evolving trends on turnovers of agricultural products futures between Zhengzhou Commodity Exchange and Dalian Commodity Exchange. A time-frequency analysis approach, i.e. wavelet packet energy spectrum, is investigated in this paper. Firstly, wavelet packet energy spectrum is briefly introduced. Secondly, two different non-stationary signals of turnover of agricultural products futures from 2009 to 2013 coming from Zhengzhou Commodity Exchange and Dalian Commodity Exchange are described in wavelet packet energy spectrum. First, reconstructed coefficients of main analysis wavelets packet of signals of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian Commodity Exchange are calculated. The obtained frequency band power ratios are used to show the different characteristics and evolving trends on turnovers of agricultural products futures between Zhengzhou Commodity Exchange and Dalian Commodity Exchange. With these results, the two signals are distinctly different from each other. It is proved that the technique of wavelet packet energy spectrum is effective for the purpose of distinction of turnover of agricultural products futures in commodity exchanges.

Keywords: turnover amounts, time-frequency analysis, non-stationary signals, wavelet packet energy spectrum, frequency band power ratios

1 Introduction

Turnover of agricultural products futures of Zhengzhou Commodity Exchange (Z-CE) and Dalian Commodity Exchange (D-CE) includes so much information that it can be used to diagnose, treat or predict economic trends. The data turnover of agricultural products futures has one or more of the following problems, (a) the total data span is too short, (b) the data is non-stationary and (c) the data represents nonlinear process [1-3].

In this paper, we choose turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange to analysis. From their time domain waveforms and their power spectrum densities, they are not easily to be distinguished.

Wavelet packet energy spectrum analysis features multi-definition in time-frequency domain as follows: signal is decomposed into two parts in a wavelet transform, low frequency part and high frequency part. Then the low frequency part is decomposed as mentioned above again while the high frequency part remained. Repeatedly, multi-level frequency decomposition can be achieved. Wavelet packet energy spectrum is based on this, and it conducts an equal-band and orthogonal decomposition in the whole frequency domain. After that, energies of the reconstructed signal in the related frequency band are calculated, and frequency-band energy ratio (FBER) is obtained [4].

In this paper, wavelet packet energy spectrum is adopted to decompose the turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange in the whole domain, and using proper frequency bands signals are reconstructed according to the turnover of agricultural products. Energies of the corresponding reconstructed signals are estimated by calculating the frequency-band energy ratio, which is used as a qualitative index for estimating different sleeping states. Plenty of experimental data [5] are used to validate the method, and the FBER is confirmed to be effective.

2 Basic algorithm procedure of wavelet packet energy spectrum

Wavelet transform is used to describe the signal, which is a 1-dimension signal in time domain originally, as a 2-dimension signal in time-frequency domain. Wavelet transform of function is defined as follows:

$$Wf(a,b) = (1/\sqrt{a})\Phi(\frac{t-b}{a})f(t)\mathrm{d}t, \tag{1}$$

where $\Phi(t)$ is called the mother wavelet, a and b are scale parameter and position shift parameter, respectively.

Wavelet packet features orthogonal, independent and multi-definite decomposition, the general form is

$$W_j = \bigoplus_{m=0}^{2^k-1} U_{j-k}^{2^k+m} \qquad (j,k,m \in Z), \tag{2}$$

where $j = 1,2,\cdots$; $k = 1,2,\cdots,j$; and $m = 0,1,2,\cdots, 2^k-1$.

According to multi-definition theory, wavelet packet transform treated Hilbert space as orthogonal summation of all the sub spaces, namely $L^2(R) = \oplus W_j$, $j \in Z$. Therefore, wavelet packet transform can decompose the signal into independent frequency bands orthogonally, and with

**Corresponding author's* e-mail: what_han@163.com

no redundancy or leakage. In a wavelet packet transform with a definition *j*, $x^{k,m}(i)$ represents the discrete signal in subspace $U_{j-k}^{2^k+m}$ corresponding to x_{2^k+m}.

The number of levels in the wavelet packet energy spectrum is determined according to the signal itself and the characteristic parameter. The frequency range of the bands obtained after decomposition is

$$f(j,i)=\left[\frac{f_s(j-1)}{2^{(i+1)}},\ \frac{f_s j}{2^{(i+1)}}\right], \tag{3}$$

where, $f(j,i)$ represents the range of band j in level $i(j=1,2,\cdots,2^i)$, f_s is sample frequency.

Schematic plan of wavelet packet decomposition is shown in Figure 1

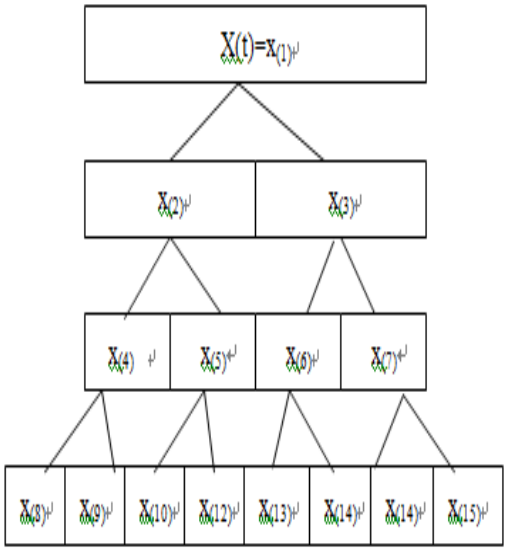

FIGURE 1 Schematic plan of wavelet packet decomposition

Assume that the data length of discrete signal $x^{k,m}(i)$ is *N*, the energy can be represented as

$$E_n\left(x^{k,m}(i)\right)=\frac{1}{N-1}\sum_{i=1}^{N}\left(x^{k,m}(i)\right)^2, \tag{4}$$

where, k is the times of decomposition, *m* is the sequence number of the frequency bands after decomposition.

According to conversation of energy theory, we have

$$E_n\left(x(t)\right)=\sum_{m=0}^{2^k-1}E_n\left(U_{j-k}^{2^k+m}\right)=\sum_{m=0}^{2^k-1}E_n\left(x_{2^k+m}\right)=\sum_{m=0}^{2^k-1}E_n\left(x^{k,m}(i)\right). \tag{5}$$

The ratio of energy of frequency band m to that of the signal, namely, frequency-band energy ratio in unitary wavelet packet transform is:

$$E_n(m)=\frac{E_n\left(x^{k,m}(i)\right)}{E_n\left(x(t)\right)}. \tag{6}$$

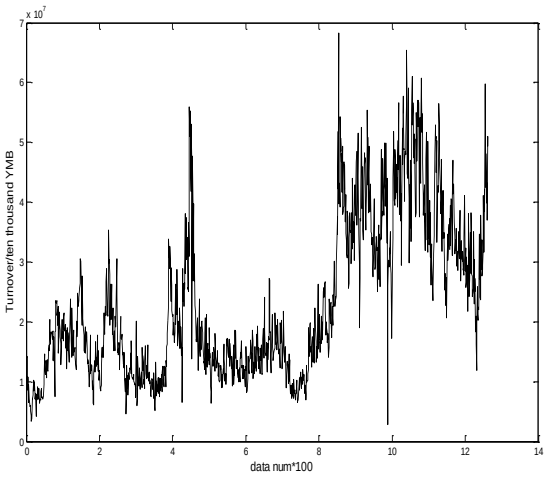
The summation of all the frequency-band energy ratios is 1, namely

$$\sum_{m=0}^{2^k-1}E_n(m)=1. \tag{7}$$

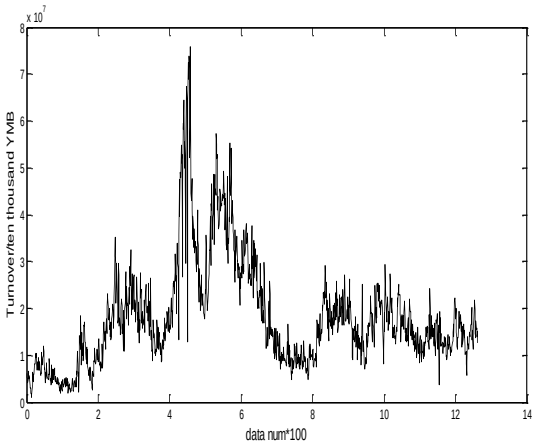
3 Results

We choose two time series of turnover of agricultural products futures between Zhengzhou commodity exchange and Dalian commodity exchange to be analyzed. These two time series are recorder as turnover of every day agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange from the beginning of 2009 to the end of 2013.

There are two different non-stationary signals are shown in Figure 2. From Figure 2, the difference is obviously, but it is not easy to identify one from each other.



a) Turnover of agricultural products futures of Z-CE



b) Turnover of agricultural products futures of D-CE

FIGURE 2 Original signals of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange

The method above is verified in signals of turnover of agricultural products futures of Zhengzhou commodity exchange and turnover of agricultural products futures of Dalian commodity exchange. The original signal is sampled in 500 Hz priory to make sure that the frequency range of wavelet packet analysis is consistent with the frequency bands of the turnover of agricultural products futures of Zhengzhou commodity exchange and turnover of agricultural products futures of Dalian commodity exchange. Frequency range of 4th level of turnover of agricultural products with wavelet packet decomposition is shown in Table 1. There are 16 wavelet packets in the high scale; each frequency width is 31.25 Hz.

4 Conclusions

Turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange as two different non-stationary signals are used as examples to be described and distinguished in the time-frequency analyses of wavelet package decomposition in the paper. The technique of wavelet package decomposition is proved to be effective on processing and distinguishing the differences of the non-stationary signals.

For the original non-stationary signals of turnover of agricultural products futures of Zhengzhou commodity

exchange and Dalian commodity exchange given here, the obtained wavelet package decomposition are easily distinguished from each other. The frequency spectra are also different between them. These results demonstrate that the wavelet package decomposition can offer a more effective way for identifying the different features of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian commodity exchange.

Research on Cooper ethical decision model based on Chinese opera

Yuan Qin*

Conservatory of Music, Suzhou Unierversity, Anhui, 234000, China

Received 1October 2014, www.cmnt.lv

Abstract

The effectiveness of Chinese opera decision directly affects the quality of traditional opera. In the era of rapid development of internet technology today, the transmission mode of opera has changed. Its spreading range is wider, and its propagation speed is faster. For not considering the ethical factors, traditional opera decision is easy to have decision deviation. With reference to the theory of Cooper ethical decision model, the basic framework of Chinese opera ethical decision is constructed, including its definition, criterion, flow block diagram, etc.

Keywords: Chinese opera decision, ethical decision, Cooper's ethical decision model

1 Introduction

The nature of opera determines the reciprocal interaction between opera activity and social development. From the transmission mode of word of mouth to printing transmission and to the electronic transmission until now, technique has brought tremendous impact and changes to the video record and lineage of opera. Everyone who engages in the performance, direction and even the practice and research of different operas will be more or less involved in it. It is a series of decision process [1-3] in nature about how to conduct identification and selection of all kinds of opera script, performing form, etc. To have opera activity and social development interact harmoniously, the quality of opera decision must be improved. However, the tendency of decision utilitarianism has appeared in many aspects, such as the change of transmission mode, appearance of decision deviation, opera compilation, opera performance, etc. In order to pursue economical benefits, the decision deviation appears. To some extent, it violates moral theory and affects the quality of opera. Therefore, traditional decision should transform into ethical decision. In decision-making process, it should comply with moral ethic and set up correct view of life value.

2 Overview of Cooper's ethical decision model

Terry L Cooper, American administrative ethicist, proposed the construction of responsible management model based on administrative ethical problem and divided the ethical thinking into four levels [4,5]: emotional expression level: to show one's own emotion tendency for ethical problems. This expression level is the initial form of one's value judgment which has no influence on the event itself; moral rule level: the first level of seriously raising question and seriously answering it. To think with the moral criteria of daily life; ethical analysis level: when the available moral rule is still unable to make the decision, then it is necessary to conduct basic rethink of our moral rule. Ethic code has clearly connected value and way of act together, which makes it more specific and explicit; after the ethic level: the last level of ethical thinking of administrative staff. Most of the administrators cannot reach this abstract philosophical thinking level. Only under the coerce of specific stubborn and grumpy opponent, or been tightly grasped by a kind of deeply disappointed feeling of disillusionment of dream, or facing comprehensive personal crisis, will we use this level.

From the perspective of practice, Cooper further put forward the process of ethical decision model: to cognize ethical problems, that is to determine ethical problems by describing facts; to demarcate alternative way, that is to assume as much ways as possible to solve ethical problems and to evaluate these ways; to imagine the consequences and to compare the "the profit and lose value" of each consequence; after comparison, to determine the combination of some or several ways and to make the decision.

At last Cooper ethical decision model was proposed: to combine the elements of responsible behavior and the elements of personal ethical autonomy, and to generate resultant force through interaction in practice.

3 Researches of traditional opera decision and opera ethic

Opera is a unique comprehensive national traditional art in China. It not only includes literature, music, dance, painting, etc, but also involves various performing arts, such as

* ***Corresponding author's*** e-mail: yuanqinqy@163.com

martial art, acrobatics, etc. It has more than 300 types of opera and numerous s [6]. Traditional opera decision generally includes two levels: the setting of the positioning, collection, ways of evaluation, etc is determined by the opera committee; the selection and adoption of opera script. At present, only a few of scholars conduct researches on opera ethical decision from many aspects, such as the ethical principle, ethical value, ethical basic content, ethical puzzle of opera [1].

Opera ethical principle refers to the basic principles that should be followed when opera decision makers adopting script. That is to combine social moral requests with practice, which mainly include subject free, principle of autonomy, principle of justice, equality and honesty, etc; opera decision ethical value refers to the actual contribution of decision maker to the society. The features and particularities of opera activities determine that serving the people is the basic principle of opera decision ethical value. The true, the good and the beautiful is the ideal state of opera decision ethical value. The basic content of opera ethics include devoting to professional dedication, sticking to principle, insisting on socialist, respecting opera maker and performer, etc. The ethical confusion of opera is caused by conflicts, such as opera goal, role, responsibility or benefits, etc. In the current opera, popularize and commercialize things are increasingly increased, while innovative and unique things are relatively insufficient.

The ethical research of opera in this paper mainly focuses on the analysis from decision maker. There is a close correlation between opera decision and opera ethics, and opera decision must be conducted that conform to the requirement of social ethics and morals. Therefore, the promotion of opera ethical decision is benefit to the perfection of opera decision theory.

4 The impact of the opera transmission method evolution to opera ethical decision

Chinese opera has a long history, and it is a shining card of Chinese nation. The transmission mode of opera has greatly changed, which is changed from word of mouth to printing and to the current electronic transmission mode. Thus, transmission, communication and sharing of opera become more convenient and efficient, which provides platform for improving the attention of whole nation to opera, stimulating the cultural creativity of opera worker and lifting spirituality of whole nation [6]. However, under interconnection technique, no limitation for delivering content has produced impact to opera ethics. According to personal likes and dislikes or to cater to audience tastes, opera creator and disseminator would spread immoral opera content. This situation would happen sometimes, which has caused adverse effect on society. The ordinary opera decision is unable to meet the requirement of new transmission situation. Therefore combined with the proposal application of Cooper's ethical opera decision, opera creator and transmitter conduct selection on opera in the core idea of opera. They also supervise and control the transmission of opera from internal and external two aspects. The external control refers to control the creator and transmitter from the outside through ethical legislation and regulations. The internal control refers to intensify the inner values and ethics of creator and transmitter and to perfect opera ethical decision through ethical training.

5 Enlightenment of the model theory of modern ethical decision and Cooper's ethical decision to opera decision

A. MODERN ETHICAL DECISION THEORY.

Modern ethical decision derives from the west and is applied to the management of business decision. The ethical decision model is established because of the business scandals that frequently outbreak in western society in the 1970s. It had attracted people's attention to the ethical problems of enterprises. Ethical conduct refers to the behavior that does harmful or good to others and society under the certain moral consciousness. Ethical conduct is produced after ethical decision process, of which refers to the appearance of corresponding ethical behavior is after the appearance of ethical or not decision process [7].

There exist certain commonalities between ethical decision and ordinary decision, which generally has the following characteristics: both were acted as cognitive activity, thus any decision is the behavior of process rather than isolation; for decision makers live in social relations and they have emotionality. Therefore, both decisions will be influenced by emotional and social factors; any decision should be measured the needs and preferences by decision maker.

There also exist certain distinctions between ethical decision and ordinary decision: ethical decision maker object will conduct ethical defense for decision plan and conduct ethical instruction for their behavior. Ethical decision includes the inner psychological activities of the ethical judgment of decision maker (behavior of right and wrong) and ethical evaluation (good or bad and good and evil of behavior), no matter whether the decision maker was asked to do that by the exist pressure in the outside world. In addition, ethical decision involves moral emotion. Ordinary decision maker will not facing moral choice and they do not have moral emotion, such as compunction, shame, etc. However, moral emotion is the by-product of ethical decision and the influencing factor throughout decision process.

Modern ethical decision divided it into four phases: ethical cognition: to realize the ethical issues; ethical judgment: to conduct moral evaluation for alternative behavior plan; ethical intention: what kind of behavior that the individual subjectively choose; ethical behavior, that is the implementation of intention. It shows the external moral or immoral behavior. The four phases describes the inner

process before the explicit of behavior. Though the four parts in practical decision are not appeared successively, on the whole process, the ethical decision process has shown these phases and there are influences among each other.

B. ENLIGHTENMENT ON OPERA ETHICAL DECISION.

Although ethical decision derives from business management and Cooper's ethical decision derives from administrative management decision, Chinese opera has the three conditions of ethical decisions: opera decision object and the opera of been decided involve ethical problems; the opera decision maker and the maker himself have the ethical subject of free will, they can realize the existence of ethical problems and make judgment and action; opera decision maker can judge the "ethical " and "not ethical" of decision result. Therefore, according to the above ethical decision, ethical decision theory can be applied to opera decision so as to construct opera ethical decision.

6 Framework of Chinese opera ethical decision

A. DEFINITION OF CHINESE OPERA ETHICAL DECISION.

Opera ethical decision refers to the process of evaluation, comparison and screening of opera script, opera performance way, opera transmission mode, etc by decision maker and decision team who have certain ethics, which is based on certain ethical criteria.

B. CRITERIA OF CHINESE OPERA ETHICAL DECISION.

The conduct of opera ethical decision needs certain ethical criteria, including the subject ethical criteria and the object ethical criteria of opera ethical decision.

The decision subject ethical criteria refer to have the moral and ethical requirement of ordinary decision maker and main principal with specific opera decision-making power. The subject ethical criteria of opera ethical decision are reduced to the following several aspects: autonomy. In respect for their own autonomies, decision maker should also.

C. PROCESS OF CHINESE OPERA ETHICAL DECISION

1) Judge the opera legality: examine whether the opera content is conforming to the requirements of national laws and regulations, veto those that do not conform that, and conduct authenticity judgment of those that conform that.
2) Judge the opera authenticity: examine whether there exist phenomena in opera creator, such as copying, plagiarism, etc. Conduct moral judgment if conform, otherwise to veto.
3) Judge the opera morality: conduct moral judgment of operas that meet the above requirements and examine whether it has adverse influence on society. If there has immoral content, then it should be vetoed. If it conforms to the requirement, then it will be as the alternative script.
4) Conduct comprehensive evaluation on the alternative script from aspects of society, technicality and standard ability, and select the best opera script for performance.

This ethical decision procedure is formulated mainly based on the object ethical criteria of opera decision. However, subject ethical decision often interacts with the object ethical decision. Therefore, much attention should be paid to opera ethic, and opera decision should convert from ordinary opera decision to opera ethical decision. Flow diagram of Chinese opera ethical decision is shown in Figure 1:

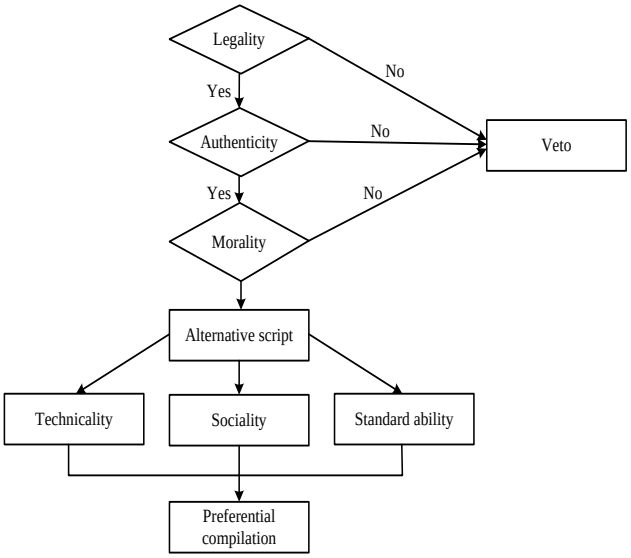

FIGURE 1 Flow diagram of Chinese opera ethical decision

7 Conclusions

Opera ethic is an important problem that opera decision maker need to face. Cooper's ethical decision has provided beneficial enlightenment for Chinese opera both in theory and practice. Much attention should be paid to the core "opera decision responsibility". Then the theoretical learning and the related skill training of opera ethical decision should be strengthened. Decision maker should be cultured to reflect the value problems and principle problems. Decision mechanism should be controlled and integrated from the inside and outside aspects, that is, the inter-coordination and development together of ethic and law. At last, personal moral quality is implanted into institutional framework and practical decision, which provides theoretical foundation and decision guidance for Chinese opera decision [4].

A construction of an autonomous vocabulary self-study system aided by the web pages

Dongling Sun*

Changchun Institute of Technology, Changchun, China

Received 1 March 2014, www.cmnt.lv

Abstract

The thesis conducted a survey to confirm the hypothesis that vocabulary is the stepping stone in English Study to have an innovative application of modern educational technology to enrich the ways, methods and devices of enlarging the students' vocabulary. From the survey, it is easy to see that the hypothesis is true and the most students of the researcher felt vocabulary affected their motivation and interest in English study. So it is necessary to enlarge the vocabulary of the students in order to promote their application ability of foreign language. Vocabulary study is a process of self-study, and based on the theory of English study, the researcher has designed an autonomous vocabulary self-study system aided by the web to give flexible help for the students. The research is at its designing period and needs further assessments with a case study.

Keywords: construction, vocabulary, autonomous, system, web

1 A survey

English teaching and studying is comprehensive and it ranges from listening, speaking, reading, writing to translating. How to deal with the relations among the preceding five aspects in language skill improvement is what an English teacher should consider [1]. A survey was carried aiming to the question--"What is the most overwhelming element that affects your motivation and interest in English study, listening, speaking, reading, grammar or vocabulary?" Interviews of 123 students were made by the research to decide the teaching emphasis in the following term. The result shows 64 persons (48.12%) thought vocabulary was their big headache; 21 persons (17.07%) listening; 18 persons (14.63%) speaking; 13 persons (10.57%) reading; 7 persons (5.69%) grammar. From the investigation it can be easily seen that most of the students felt vocabulary was the impeding element in their English study. According to the interview result, the emphasis would be put on vocabulary study in the following teaching. However, memorization in most cases needs autonomous completion, and the teacher's task is to provide students environments and guidance. Technology is the productive force of education. Modern technology means the application of modern educational theory and the results of modern science and technology, especially the information and Web technology on the basis of the computer. Modern educational technology is the re-modification, reformation and derivation [2]. In this research the vocabulary study automation is designed based on the web pages, the integration of the teacher's personal web pages and online dictionary web pages.

2 The cutting point of the vocabulary source

According to *the General Requirements of College English* the College students should at least have a vocabulary of 4,795 words and 700 phrases, among the 4,795 words, 2,000 words are active words which are required to be applied skill fully in speaking and writing. *The Requirements* also gives the standard which the students should achieve in listening, speaking, reading, writing and translating. It means the vocabulary *the Requirements* regulate is reasonable for certain English level. For example, the regulations for writing in *the requirements* like the following:

1. To be able to complete the general writing task and give a description of personal experience, feelings and happenings etc.
2. To be able to give common practical writings.
3. To be able to write a complete coherent composition of not less than 120 exact words within half an hour based on the outline and general topic, which has a clear theme.
4. To be able to master the basic writing skills [3].
5. From teaching experience of many years, many students cannot even remember the words in the text, let alone the flexible application. So the research designs vocabulary tasks from the actual conditions of the students. In the textbook, *Experiencing English*, there are 16 passages containing 8,320 words. In the 8,320 words, about 600 words are the new words [4]. From *youdao* software the 600 words can be enriched with large amount of information for the student's reference. The teacher will design practice which will be sent to

* ***Corresponding author's*** e-mail: 1229058230@qq.com

the teacher's personal Web Pages. Generally there are two kinds of practice, multiple choices and gap filling. In the practice the stem is from the text, and the choices are from the word lists of the text book. The students are advised to do multiple choices before the text study and do gap filling after the text study. When they do practice on the platform of the teacher's personal Webpage, they are suggested that *youdao* software be used.

3 Theoretical background

Human recognition is closely connected with context. In broad sense context indicates the social atmosphere of humans and the physical environment of survival, and in narrow sense it indicates the structure of the passage and the relationship between words. The contextual elements are connected with the target study materials in a meaningful way. When the target information is coded, the contextual information is also coded in the same way, so the contextual information becomes the explicit clue. According to the theory of context dependent memory, the environment of memory occurrence has a big effect on the effectiveness of memory [5]. A word can be remembered alone in one second and forgot in one minute. If the context of the word occurrence is provided, the time spent to memorize it is a little longer, but it can be changed into long-term memory, so the effectiveness of word memorization would improve. Because the students know the context of the word occurrence which serves as the explicit clue in memory, they can always associate the context with the target word. Thus what the students remember is not the single word, but the context which is coded in the same way in reminiscence. In this research, the design of the vocabulary tasks is based on the theory of context dependent memory and the contexts of the new word occurrence are offered via the teacher's personal Web Pages and *youdao* software.

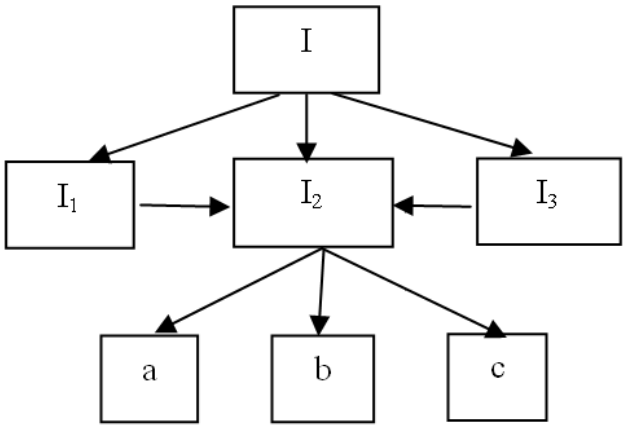
4 The construction of an autonomous vocabulary self-study system aided by the Web Pages

Vocabulary study automation in this research means students study vocabulary aided by automatic Web Pages without the supervision of the teacher. The rapid development of the Web provides the powerful tool for language learning. In vocabulary study Web serves as both information carrier and information source which is a platform that information can be put on and gained from. The research catches the characteristic of Web to design a system to assist the students to remember vocabulary in and out of the text book. In this system two kinds of Web Pages are involved, online dictionary Web Pages and the teacher's personal Web Pages. The employment of the online dictionary can be used directly, but as for the teacher's personal Web Pages, the technical problem is still needed solving.

4.1 THE PERSONAL WEBPAGES ARE CONNECTED

Not all the people can have a construction of personal website, but they can have their own Personal Web pages which depend on the whole Web system. With the popularization of the Web, the personal Web Pages can reach everyone. Personal Web Pages are popular, convenient, and flexible which provide good conditions for their application in teaching. It is easy to have an account of your own Personal Web Pages; however, there are technical problems, too. The personal Web Pages cannot be altered freely to suit your own needs. For example, the layout of it cannot be freely adjusted. This is why some teachers just use them to send e-mails or talk with the students via QQ. Therefore the glaring problem is that the personal Web Pages are scattered, and apparently they are not in a system.

Teaching and learning are interactive which are in a system [6]. How to make the scattered Web Pages into a system is a point in case to solve the technical problems. The personal Web Pages are in fact in a system, too, which escape the people's eyes because their apparent scattered traits. The following figure shows the connection among the Web Pages.



Connections among the WebPages

FIGURE 1
I=QQ account passageway; I_1=contact list page;
I_2 =Q zone homepage; I_3 =email-box page;
a =the owner's words; b=the message board; c=QQdiary

From the above figure, we can see the personal Web Pages are interrelated that construct a recessive system that needs to be discovered the technical connections. In the recessive system, we cannot change the general layout, but we can make a creative use and add items.

4.2 YOUDAO ONLINE SOFTWARE AUTOMATICALLY PROVIDES NEEDED INFORMATION

Youdao translation is China's largest free online translation which carries 23 million examples and 1.8 million encyclopedia articles with one-stop knowledge inquiry platform [7]. *Youdao* translation provides new video examples, including international prestigious public class and America and European classic film video examples make users to experience pure English. The recurring audio examples are from the English original radio recording are authoritative.

It is the first time that *Youdao software* supports IE9 browser bingmuquci function. Cross word definition function in the software is strengthened comprehensively, and, you can easily get translated results and more information with the mouse choosing paragraphs, long sentences and phrases. It is more helpful that there are bilingual examples with explanations word by word and controls sentence by sentence. *youdao* translation provides an ocean of information.

4.2 THE DESIGN OF THE VOCABULARY STUDY AUTOMATION SYSTEM BASED ON THE INTEGRATION OF THE TEACHER'S PERSONAL WEBPAGES AND YOUDAO ONLINE TRANSLATION SOFTWARE [8]

The scattered Web Pages can be built into a recessive system which is built the further connection in some way with the online dictionary Web Pages into a vocabulary study automation system.

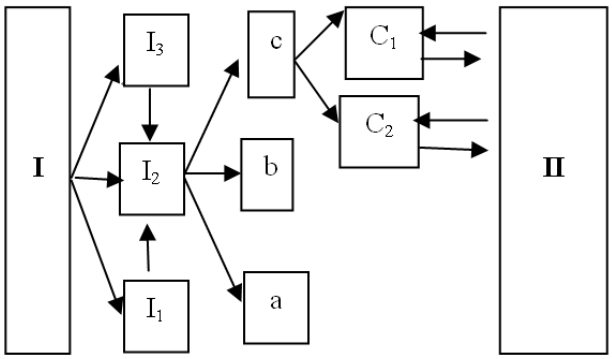


FIGURE 2
I=QQ account passageway; I_1=contact list page;
I_2 =Q zone homepage; I_3 =email-box page;
a=the owner's words; b=the message board; c=QQdiary;
C_1=multiple choice; C_2=gap filling;
II=*youdao* online dictionary interface

In this system the personal Web Pages and *youdao* online dictionary Web Pages can all be clicked. According to the concrete demand the needed Webpage is shown and restremain inactive. The teacher's personal Web Pages are the main part of the system and *youdao* online dictionary Web Pages are ready for use as assistance. Web Pages Qzone can serve as a center, and the column of "the owner's words" can serve as a notification board which provides vocabulary practice information; the message board for communication or left message. QQdiary for the vocabulary practice carrier. On the contact list page, communication and submission can be done. Email-box page submission and off-line communication.

In this system C1 (multiple choices) and C2 (gap filling) are concrete practice contents sent by the teacher. Multiple choices should be done by the students before the text study. The disturbance terms are from the new word list in other texts, so the students can consult *youdao* online dictionary to find out the equivalent meaning of the choices and choose the best one responding to the sentence context. Gap fills for enhancement of the new words after the text study. The students are supposed to master the words in the text, but it is possible that the students still need to consult the online dictionary for enhancement.

5 Assessment of the design

The research aims to exploit the Web technology to innovatively enrich the ways, methods and devices of enlarging the students' vocabulary. The scientific, practicability, efficiency and popularization of the design of the vocabulary study automation system based on the integration of the teacher's personal Web Pages and *youdao* online translation software should be checked in the practical study. In order to prove the value of the study, questionnaires, observations, visits, diaries, comparisons, and the analyses and summaries will be done through the device of materiallization and quantization. The scientificity of the design of vocabulary tasks will be analyzed by using social science statistics software.

6 Conclusion

The present research is going to be carried out in the following term. The subjects are the freshmen the researcher will teach. During the process of implementation it is possible that the necessary improvements of the design will be made, though the proof materials haven't been made. However the expected effects are in following aspects: The English vocabulary of subjects is enlarged much; Vocabulary expansion indirectly promotes students' language application ability; the original application cases of the online vocabulary study automation system resources are formed; the results of the study can be shared and discussed with the fraternity. With the implementation of the study, the research will provide further reports.

A design for simulation model and algorithm of rail transport of molten iron in steel enterprise

Bin Ge*, Kai Wang, Yue Han

School of Computer Science and Engineering, Anhui University of Science & Technology, Huainan, Anhui, 232001, China

Received 28 August 2014, www.cmnt.lv

Abstract

An emulation method can be chosen according to the characteristics in rail transport of molten iron in steel companies and a simulation model can be established based on the basic conditions for model, distributed tank mode and path selection, etc. By studying the automatic collision avoidance algorithm, a method of shortest path optimization for rail transport scheduling of molten iron was proposed based on ant colony algorithm. Simulation results show the validity and the feasibility of the algorithm. Programs and strategies of implementing visual simulation platform are proposed laying the theoretical foundation of further research and application for rail transport scheduling model of molten iron and intelligent optimization algorithm.

Keywords: dynamic routing, selection model, ant colony optimization algorithm, collision avoidance algorithm, mode of allocated tank, rail transport of molten iron.

1 Introduction

Rail transport of molten iron is an important step to guarantee steel production. Rail transport of molten iron system transports TPC (Torpedo Car, TPC) which has been ironed under the blast furnace from the blast furnace (BF) to the station before arriving specified point to pre-processed before-steak, desulfurization and after-steak, then it will be transported to the steel factory to pour molten iron. After that, the empty TPC will be hauled back to blast furnace, which completes one course of transporting molten iron [1,2]. In order to better carry out research on the railway transport system of molten iron in steel enterprises, it requires to mimicking the operation of existing systems and simulating progress of future system, and providing a theoretical basis for the simulation and optimazation of transport by improving and perfecting the design.

The research on models and algorithms about rail transport of molten iron has been carried out currently. Some results have also been achieved. Such as: in literature [3], relying on plant railway network. A road collision detection mechanism and reservation model are established and a neighbor distribution. Process scheduling and packet-optimized scheduling for rail transport of molten iron are proposed the with rail transport of molten iron in steel companies as the background and the locomotive and torpedo car TPC as means of transport. The adoption of dynamic programming to determine the optimal number of vehicles is related to the needs of molten iron and transportation distance and other factors. In literature [4] through systems analysis of the molten iron transport, this problem is solved by computer simulation method. The project and the time during rail transport of molten iron are measured. The distribution and the main parameters of random variables are determined by statistical test. Furthermore, there is precision analysis of the computer system simulation and simulation results. In literature [5] using modeling and system simulation technology, the corresponding object model is established through analysis of system objects. The transport path selection of rail transport of molten iron in steel enterprises and automatic collision avoidance algorithm implemented by virtual detection and competition rules are achieved based on the strategy of hierarchical event scheduling simulation.

In order to overcome some shortcomings of static path selection, this paper introduces a dynamic path selection algorithm to solve the problem of adjusting the path of collision avoidance in train operation. When conducting path selection, we change road weights for dynamic under the new constraints reselect path according to the needs of adjusting collision avoidance.

In literature [6,7] using linear programming methods to build analytic model of transportation systems. In literature [8] introducing a heuristic algorithm to study the transportation scheduling problem. Because of a lot of thinking and reasoning process in transport schedule of molten iron, including task allocation, process coordination, time arrangement, vehicle arrangement, route selection and intelligent decision-making behavior of analog and motorists based on dynamic traffic, these mathematical models cannot meet the requirements of simulation research. In recent year's artificial intelligence and expert systems technology is widely used in scheduling research providing a new adjunct of real-time and intelligence, especially the artificial ant colony algorithm for solving scheduling problems of rail transport of molten iron can provide a better solution.

Ant colony algorithm is a new intelligent optimization algorithms proposed by Italian scholar M. Dorigo, V. Maniezzo and A. Colorni [9-11] inspired by the shortest

* ***Corresponding author's*** e-mail: bge@aust.edu.cn

path from the nest to a food source when ants foraging. Currently people working on ant colony optimization algorithm have penetrated from the original single traveling salesman problem into a number of applications. Now the algorithm having achieved good results has been optimized in function, combinatorial optimization, graph coloring, vehicle scheduling and so on [12-14].

In this paper, simulation models rail transport of molten and algorithms iron are studied. Pathway selection model collision avoidance algorithm and improved ant colony optimization algorithm are proposed which has been proved to be effective and feasible by the experiment.

2 Simulation method

Depending on whether the continuous state variables change over time Simulation is consisted of continuous system simulation, discrete event simulation and continuous-discrete hybrid system simulation [15]. Continuous system simulation model can be parsed into differential equation; Discrete event simulation can be expressed with logical conditions or flowcharts [16,17]; Continuous-discrete simulation hybrid system is expressed with the first two mixed. However, in the simulation design of molten iron transport system, state of the system only changes at discrete moments. So, discrete event simulation is chosen.

Nevertheless, as there are lots of factors in actual production influencing transportation and production of molten metal, some factors may be left out. Main factors affecting the production are as follows: blast furnace fluctuations, half a deal in principle, car transfer system features, and road traffic. For other factors, such as traffic scheduling, simulation pathways need to consider when selecting models. Thus, the simulative design of molten iron transport system is so complex that we need to make a systematic plan.

2.1 THE ESTABLISHMENT OF SIMULATION MODEL

2.1.1 Model input

The basic conditions for model input are volume X (m^3) of ironworks blast furnace, the average designed tapping speed Y (t/min) of blast furnace, the designed maximum fluctuation coefficient C, maximum and instantaneous tapping speed Y max (t/min), average time Z (min) of two overlapping iron tap hole and tapping of each iron times W (t). It ought to establish the corresponding transport organization program and allocate reasonable transportation equipment based on design parameters of blast furnace and actual production situation.

2.1.2 Mode of allocated tank

General configuration mode is the "3-2-1" mode. Namely, "tap hole at one time" allocated with 3 TPC", tap hole at next time" allocated with 2 TPC", tap hole at third time" allocated with 1 TPC.

Definite: suppose in an engineering company, there are 6 sets of locomotive cars, assuming the length of locomotive car is 15 cm and locomotive speed is 3-5 km/h, the capacity of mix stickers car is 400t, the length of mix stickers car is 30 cm, load factor is 0.9 [18,19].

Division of locomotive. There are 5 sets of locomotive invested initially with 1 sets of locomotive available. (Locomotive distribution: 2 locomotives for each station of blast furnaces, 1 locomotive for intrusion station), locomotive operation using transport practices with a large loop (BF→ intrusion blast station→ BF). If there is not enough capacity of locomotives, then the sixth car will be put into production.

Mode of allocated tank. Assuming the sequence of using iron mouth is 1#→2#→3#→4#, 4# as a spare overhaul iron mouth, as shown in Figure 1.

Step1. 1#iron mouth railway line 1 ① torpedo car during iron, machine A in line 1 waiting for hanging heavy, machine B hang two cans in a field waiting with empty.

Step2. 1# iron mouth railway line 1 ① torpedocar finished by iron, then swing to iron TPC ② on line 2, TPC ② by iron; machine A hang on heavy TPC ①, changing lanes to a safe location waiting outside the line 2;machine B send ⑦, ⑥ empty TPC to line 1, empty TPC ⑥ registration uncoupling, machine B tow empty TPC ⑦ waiting outside.

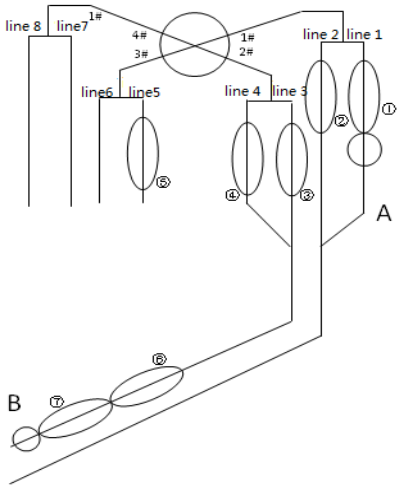

FIGURE 1 The locomotive schedule mode

Step 3. 1#iron mouth railway line ② iron by iron mixed with iron chariots is completed, the nozzle swing after swing stream is mixed with iron chariots of iron a line ⑥ by iron, A machine push ① heavy torpedo car into the iron ② TPC, tow ①, ② TPC to steelmaking intrusion station; machines B and ⑦ empty TPC transfer ran from line 1 to line 2 on the bit, and then turn to line 1 waiting outside after the completion of the ⑥ car to take iron; machine C push two empty torpedo car station to the intrusion from a steel blast furnace operation to its original position of machine B.

At this time, machine A, B, C have completed one bit position conversion, A→C, B→A, C→B.

3 Routing selection model

Regarding the valuable cut-off points at the apex of the rail network as nodes constituting a new network, denoted as G=(v, E), where v={v_1, v_2,...,v_m} is a set of m nodes; E={e_{ij}|1≤i, j≤m} is a set of directed edges(between the junction section).

When searching for the shortest path in the railway network diagram with the help of algorithm Dijkstra, due to the excessive number of network nodes and locomotives and the huge amount of computation, which cause more computation time than simulation step size, the static pathway selection model cannot meet the requirements of simulation system. Therefore, a dynamic pathway selection model is needed to adopt.

Let q denote locomotive number, P denotes a set of locomotives priority; d_{ij} denote the length of directed edge e_{ij}, γ^{kt}_{pij} denote flow from node k to node t of locomotives with priority of p through the directed edge e_{ij}. T_i denotes travelled distance when locomotive i avoid. H_{ij} denote time during which locomotives wait on the directed edge e_{ij}. Gij denotes the driving speed of locomotive on the edge e_{ij}. Dynamic Routing selection model can be defined as follows:

The objective function: opt Z={Z1, Z2, Z3, Z4}.

The shortest total driving distance of locomotive:

$$\min Z_1 = \sum_{k\in V}\sum_{t\in V}\sum_{p\in P}\sum_{n=1} d_{ij} r^{kt}_{pij} . \tag{1}$$

The shortest total mileage of vacant locomotive:

$$\min Z_2 = \sum_{n=1}^{q} T_n . \tag{2}$$

The least total waiting time of locomotive:

$$\min Z_3 = \sum_{n=1}^{q} H_{ij} . \tag{3}$$

The least total driving time of motorcycle:

$$\min Z_4 = \sum_{k\in V}\sum_{t\in V}\sum_{p\in P}\sum_{n=1}^{q} (d_{ij}/G_{ij}) r^{kt}_{pij} + \sum_{k\in V}\sum_{t\in V}\sum_{p\in P}\sum_{n=1}^{q} \mathrm{H}_{ij} r^{kt}_{pij} . \tag{4}$$

4 Research of collision avoidance algorithm

During the study of molten iron transport system, the trains can follow certain traffic laws and avoid colliding with each other through the establishment of collision detection mechanism. According to collision avoidance algorithms and priority of task, high priority trains go first. Meanwhile, every train need to get basic information of others providing more information to support decision-making for the transportation safety.

The length of train T in the simulation model is set n. During driving, the reservation section number of railway is m ($0 \le m \le n$), the current section of railway is S_i ($0 \le i \le n$), occupancy and reservation path is represented by a collection of array $A(S_i, S_{i+1}, S_{i+2}, \ldots, S_{i+m})$. It can be seen that there are many reservation section when $m=n$ and railways are smooth. However, the utilization of the railway and efficiency of running trains are very low. When $m=0$, there is no reservation section, while trains are easily collided. Given the actuality of transport system in steel company and the need of experiment and simulation, we select $m=2$.

Set two trains T_1, T_2, occupation and reservation paths are represented by a collection of array $A_1(S_i, S_{i+1}, S_{i+2})$, $A_2(S_i, S_{i+1}, S_{i+2})$. The task priority numbers are respectively P_1, P_2. T_1 is treated as the research object. S_{i+2} denotes the reservation section in the current road sections S_i of train T_1. Collision avoidance algorithm is as follows:

1) Comparing the size of P_1 and P_2. if $P_1=P_2$ then obeying the rules of FCFS, first appointment S_{i+2} with high default task priority. If $P_1 < P_2$, there will be the same travel in path S_i and T_2 , then T1 need to transfer the right of using S_i to T_2.
2) Appointment success: T_1 traveling on the path S_i.
3) Appointment failed:
   - **a.** If $S_{i+2}=S_j$, T_2 is running. P_1 is lower than the b default P_2. Set T_1 is the waiting time. The value of *time* denotes ratio of the traveling distance of train T_2 from current position to the end of path S_{i+2} and speed of the train T_2. At the moment by adjusting the speed mechanism of the train, such as speeding up T_2 to reduce the waiting time of T_1.
   - **b.** If $S_{i+2}=S_{j+1}$ or $S_{i+2}=S_{j+2}$, sections S_{i+2} has been reserved by T_2. Appointment T_1 failed.

For the research of multiple trains collision avoidance we can use priority algorithm based on the contents of the train running task space to let high-priority trains go first.

5 The optimization of shortest path algorithm

5.1 DEFINITION OF ALGORITHM

Definition:

Assuming that there are m ants, d_{ij} $(i, j = 1, 2, ..., n)$ denotes the distance between the city i, and the city j, $b_i(t)$ denotes the number of ants located in the city i at the moment t, $\tau_{ij}(t)$ denotes remaining pheromone concentration in attachment between city i and city t. It is equal of initial pheromone concentration on all paths, set $\tau_{ij}(0) = C$ (C is constant), the ants k, $(k = 1, 2, ..., m)$) choose its path in the process of movement according to the pheromone concentration on the path. $p^k_{ij}(t)$ denotes the probability of ants k transferring from city i to city j at the moment

$$p^k_{ij}(t) = \begin{cases} \dfrac{\left[\tau_{ij}(t)\right]^{\alpha}\left[\eta_{ij}\right]^{\beta}}{\sum_{k\notin tabuLk}\left[\tau_{ik}(t)\right]^{\alpha}\left[\eta_{ij}\right]^{\beta}}, & j \notin tabu_{k,} \\ 0, & otherwise \end{cases} , \tag{5}$$

where η_{ij} denotes heuristic information transferring from city i to city j. Its value is generally $1/d_{ij}$. α denotes the importance of the residual pheromone on path ij; β denotes the importance of the heuristic information; List $tabu_k$ record cities which ants pass through, it dynamically change as the moving process of the ants.

When all the ants traverse city *n*, we need to calculate path L_k the ant k, then to solve the shortest path $L_{\min} = \min\{L_k \mid k = 1,2,...,m\}$, and update pheromone concentration on every path.

$$\tau_{ij}(t+1) = \max(\rho\tau_0(t) + \sum_{i=1}^{n}\Delta\tau_{ij}^k + \sigma\Delta\tau_{ij}^*, \tau_{\min}(t)), \quad (6)$$

$$\Delta\tau_{ij}^k = \begin{cases} \frac{Q}{Length}, & (i,j)\in T \\ 0, & (i,j)\notin T \end{cases}, \quad (7)$$

$$\Delta\tau_{ij}^* = \begin{cases} \frac{Q}{L_{opt}}, & (i,j)\in T_{opt} \\ 0, & (i,j)\notin T_{opt} \end{cases}, \quad (8)$$

where ρ denotes the pheromone sustained. Parameters, $\Delta\tau_{ij}^k$ denotes the increased concentration of pheromone of ant k on the (i,j) edge from time t to $t+1$, Q is a constant that denotes the total amount of hormone released of the ants by a search. T denotes the exploring path of the ants, *Length* denotes the exploring path length of the ants, T_{opt} denotes the exploring optimal path of the ants, L_{opt} denotes the exploring optimal path length of the ants.

5.2 THE HYBRID ANT COLONY OPTIMIZATION (HACO) ALGORITHM FOR SOLVING OPTIMAL PROCESS ROUTE OF VEHICLE

A colony consists of N ants and all the ants distributed in continuous space S. The point x_i denotes the location of ant i in space S and the corresponding to a random sequence $S_i = \{C_{i(1)}, C_{i(2)}, ..., C_{i(n)}\}$, its adaptive values is $f(S_i) = \sum_{k=1}^{n-1} d(C_{i(k)}, C_{i(k+1)}) + d(C_{i(n)}, C_{i(1)})$.

The new sequence can be acquired by sequence generation mechanism. Algorithm is as follows:

BEGIN

1) Configuring the population size as N, the parameters as ψ_d, a, b, r_i, the number of initializing iterations as t, the position of each ant as $x_i(0)$, its corresponding sequence as S_i and fitness as $f_{i,0}(S_i)$;

2) To calculate the optimal positions $p_i(0)$ of the ants and their optimal adaptive value $f_{i,0}^{best}(S_i)$ at the next step $t=1$, $f_{i,0}^{best}(S_i)$ is the optimal adaptive value between adaptive value $f_{i,0}^{best}(S_i)$ of ant i and adaptive value $f_{k,0}(S_k)$ of its neighbor;

3) While (the number of iterations <= maximum number of iterations)

[a] Calculating the position $x_i(t)$ of each ant, reversing the sequence S_i to a sequence S_i', calculate its adaptation value to get $x_i(t) \to f_{i,t}(S_i')$;

[b] Calculating the optimal positions $p_i(t)$ of the ants and its optimal adaptive value $f_{i,(t-1)}^{best}(S_i')$, $f_{i,(t)}^{best}(S_i')$ is the adaptive value of ant i. $f_{i,0}^{best}(S_i)$ is the optimal adaptive value of ant i between the optimal adaptive value $f_{i,(t-1)}^{best}(S_i')$ in last step and adaptive value $f_{k,(t)}(S_k')$ of its neighbour (ant k and ant i are neighbors each other), (if $t=1$, the optimal adaptive value is $f_{i,0}^{best}(S_i)$ in last step);

[c] calculating $\Delta f_{i.t} = f_{i,t}(S_i') - f_{i,(t-1)}(S_i')$;

[d] If $\Delta f_{i.t} \le 0$. Then

Setting $S_i = S_i'$;

End if

[e] While (cross operation condition is met)

[i] Settings $p_i = S_i, f_i(p_i) = f_i(S_i)$;

[ii] Do crossover operation to get $p_i', f_i(p')$ and calculating $\Delta f_i^p = f_i(p_i') - f_i(p_i)$;

[iii] If $\Delta f_i^p \le 0$. Then

Setting $S_i = p_i'$;

End the if

End the While

End the While

4) To choose the optimal solution

END

5.3 THE SIMULATION OF ALGORITHM

In this section, Matlab7.0 was used as the simulation platform to verify the feasibility and performance of the improved algorithm of HACO. In this paper, there are only two instances of the simulation results, which are Eil50 and KroA100. Figure 2 and Figure 3 shows respectively the optimal solution of vehicle route.

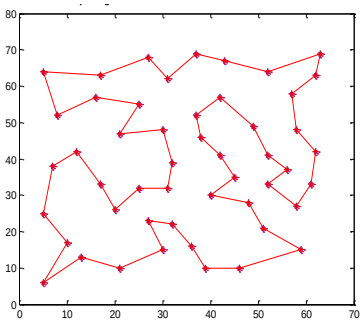

FIGURE2 Optimal solution 428.73 of Eil50

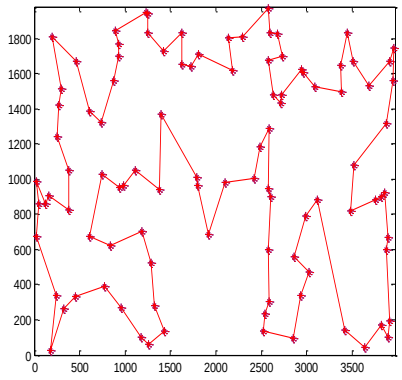

FIGURE 3 Optimal solution 21289.56 of KroA100

The convergence of HACO-TSP algorithm can be seen clearly and it is feasible that solved TSP problem together among ants exchange information each other from Figure 4 and Figure 5. Figure 4 and 5 show the convergence and the good performance of the improved HACO algorithm.

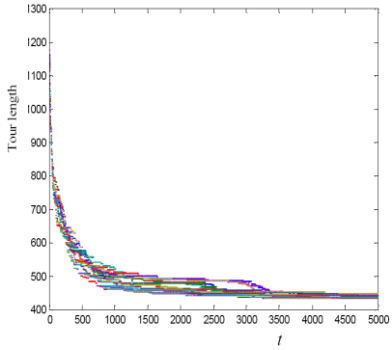

FIGURE 4 Eil50 the dynamic evolution over time of all ants over time

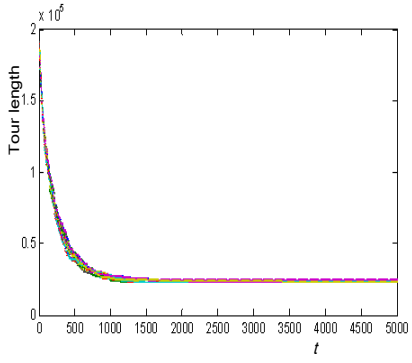

FIGURE 5 KroA100 the dynamic evolution of all ants over time

6 Analysis and implementation of designing

There are many factors to take into account in the process of designing. For instance, the locomotive operating rate, cycle and turnover rate of TPC, utilization of the railway line, the ability of level crossing, etc are analyzed.

It is viable to adopt programming languages such as C, Visual C++ to create model for rail transport of molten iron according to above pathway selection model based on design simulation system. Three-dimensional virtual simulation software Flexsim is used to achieve dynamic pathway selection and conflict-free driving.

Via regarding a simulation system of distributed intelligent hot metal scheduling as experiment platform and recording the raw data adopted to verify scheduling process of molten iron transportation. Intelligent control is applied before and after the key technology of hot metal scheduling, locomotive and TPC running are all got optimization to some degree.

7 Conclusions

Rail transport of molten iron is an important part in steel production. The scheduling simulation model and algorithm research also has important theoretical significance and practical value. This paper presents a simulation model of molten iron scheduling and strategy. Firstly, we propose input conditions of model and then the feasibility of scheme is proposed as complement through simulation studies. Finally, concluding the simulation results. This paper provides an effective and feasible method of simulation programs through research to optimize the in-depth study of intelligent scheduling of molten iron and practical application of the algorithm.

Abstract

The Alarm Processing System reference model for large-scale railway maintenance equipment diesel engine combustion control, which is based on multi-agent, is an important system for high speed and automation. Alarm Processing System are vital aspects in M large-scale railway maintenance equipment diesel engine combustion control, in this sense, alarm processing system should support decision-making tools as known as decision support system(DSS), new maintenance approaches and techniques, the enterprise thinking and flexibility. In this paper a Multi-agents based alarm processing System reference model for large-scale railway maintenance equipment diesel engine combustion control is presented which combines the existing models and multi-agents. This model is based on a generic framework using multi-agent systems for the diesel engine combustion control the diesel engine combustion control on-line monitoring system. In this sense, the alarm processing system is viewed like a feedback control process and the actions are related to the decision-making in the scheduling of the preventive maintenance task and the running of preventive and corrective specific maintenance tasks. The result of an evaluation of the Multi-agents based alarm processing system reference model for the diesel engine combustion control are presented. This new model is compared to some important existing models and applied to a real investigation.

Keywords: diesel engine combustion control, alarm processing systems, multi-agent system, automation

1 Diesel engine combustion control technology

In the innovation progress of diesel engine, new technology such as turbocharger technology, the three element catalytic processing, the lean combustion, homogeneous charge compression ignition (HCCI) comes out. In the conventional altitude conditions, the engine has reached a higher level of technology. But in the plateau and the special circumstances, the engine is still weak. In addition, with the requirements of increasingly stringent emission regulations, to explore a new combustion control method has become a necessity. Figure 1 shows the Schematic Structure of the diesel engine combustion.

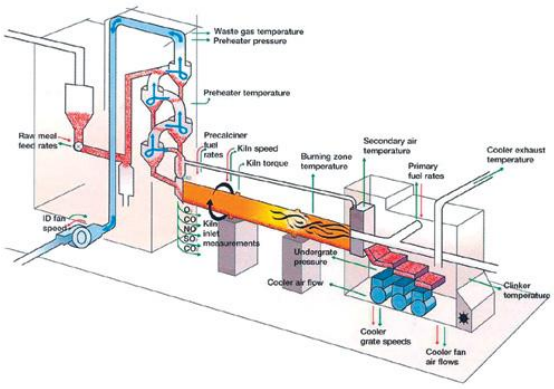

FIGURE 1 Schematic Structure of the diesel engine combustion.

With development of the catalytic converter processing technology, gasoline engine emissions are reduced, however, HC at starting stage is a major obstacle to achieve ultra-low emission [1]. To solve the problem of NO2 diesel engine emissions has been facing challenges; there are contradictions and difficulties in the trade-off between NO2 and particle. Although the existence of complex factors of engine combustion process, but the combustion is using oxygen as oxidant, controlling the share of air intake oxygen combustion control is the most fundamental way.

During combustion a control system must therefore maintain the following conditions:

1) Control of the O2 concentration in the flue gas to keep it at a constant figure.
2) Maintenance of a uniform thermal output.
3) Maintenance of optimum flow conditions in the furnace and the first boiler pass with as little variation as possible so that the desired conditions for attaining the lowest possible degree of emissions and thus preventing corrosion are always maintained [2].

These conditions can only be fulfilled by optimized combustion at a stable operation point. Conventional control systems are incapable of reacting to the inevitable local and intermit and inhomogeneity of the refuse fed to the grate, which are attributable to varying calorific values and

* ***Corresponding author's*** e-mail: sherly2001@sina.com

ignition properties. It is as a result impossible to avoid pronounced variations in the combustion process and such variations are always associated with unfavorable emission figures.

The engine combustion is mainly controlled by the contents of oxygen, nitrogen [3,4]. One is the intake combustion, the other is flame retardant, the two shares become the basic elements of the combustion process control. To implement the combustion and emission control is by the way of reforming the intake charge component. Oxygen Enriched Air (OEA) can significantly reduce the non-full combustion emissions (except NO2), can enhance the power performance and shorten the ignition delay period, which is conducive to low quality fuel [5,12]. Nitrogen Enriched Air (NEA) can inhibit the combustion process, can be beneficial to relieve the No emission, which is considered to be an effective method.

A possible method of automating this process is the registration of combustion by infrared thermography. This offers the immediate advantage that the plant operator is in a position to observe combustion directly from the control room [6,9]. Because of the geometry of the furnace in the plant under consideration the area which must be observed lies mainly in grate zone 3, but also to some extent in zones 2 and 4, which cannot be so completely observed.

This is however more than adequate in order to determine the position of the fire. Additionally it is possible, by statistical evaluation of the infrared picture, to determine the width of the combustion zone and derive from this information on asymmetric positions of the fire or secondary combustion zones.

Even if all the information given above is available it is still necessary to development an adequate mathematical model which will allow the information the information to be applied to a conventional control system. However combustion processes as a rule are of a highly non-linear nature and represent multi-variant problems. For conventional control system strategies the only feasible method is therefore to influence controllers by heuristic programming [8,10].

New solutions to problems of that kind are offered by the use of advanced control techniques. In particular fuzzy logic control has been applied to similar combustion processes [7,13]. Complex interactions between the various items of information evaluated require a methodology of structured information analysis.

Diesel engine combustion control is a capital intensive process due to increasingly severe environmental regulations. Complying with the environmental rules demands the adoption of new and expensive technologies for both the combustion process and treatment of the residues (gaseous, liquid). The investment and operation costs have to be regained through adoption of a number of measures, primarily more efficient combustion, which should minimize the residues and maximize the energy recovery.

With the advent of Diesel engine combustion control's facilities toward high speed and automation, the on-line monitoring becomes important [11]. Since a facility of the Diesel engine combustion control may break down unexpectedly, the unscheduled shutdown will cause the losses and deteriorate of the environment. The traditional time-based maintenance strategy does not take into account the practical machine condition and only performs the maintenance practice at a fixed time interval from local personnel. Therefore, accidental breakdowns will unavoidably happen, when the chosen time interval is too long. Otherwise, it will lead to over-maintenance, when the chosen time interval is too short.

In order to increase automation in Diesel engine combustion control, an on-line monitoring system for facilities based on computer's technology gains popularity. In general, facilities monitoring or supervision is carried out by measuring some parameters from some facilities of Diesel engine combustion control. The justification for on-line facility monitoring is prompted by the needs to achieve the availability of facilities and to protect facilities from some problems of running.

A five level's architecture is considered, in general, for MSW incineration automation schemes: process, local control, supervision, planning and administrative management, each one with specific tasks. In general, the couple model–control has constrained suppositions about the process' dynamic and its causes are not thoroughgoing modelled, thus, in case of not well working, the process performance should be deteriorated. These modelling suppositions put up with the development of Alarm processing system proposing fault detection, diagnosis and prediction tasks, and preventive maintenance plans; these tasks living together in the supervision and control levels. A multi-agent based automation model is proposed, taking into account the general objects of the production processes: production planning, production factors management, processes control, Alarm processing and abnormal situations management. The agents-based reference model for distributed control systems (DCS) has provided a generic conceptual framework permitting to see any system like a feedback control systems [14].

Alarm processing and maintenance are vital aspects in industrial process. They not only include the knowledge about the failure modes and their causes, but an awareness of the extent to which equipment failure affects safety, product quality, costs and plant availability. Changes in the maintenance approaches, recent knowledge, skills of maintenance people, and so on, must be incorporated into the maintenance systems in order to attain high performances. In this sense, maintenance systems should be developed in an open framework permitting to take into account the changes in the maintenance paradigms. In the maintenance framework, the challenges are related to the selection of the appropriate techniques for fault detection, isolation and diagnosis; the building of the appropriate models for detection, isolation, diagnosis and prediction; the decision-making in the design of feasible preventive maintenance plans; the decision-making in the emergency situations.

In this work, a multi-agents based Alarm Processing System (APS) reference model for MSW incineration process is proposed. This model outlines the management of the preventive maintenance plans permitting to perform detection, isolation and diagnosis tasks. This model takes

into account the following tasks: local or global abnormal behavior detection of the controlled process; fault isolation and diagnosis; fault causes identification; preventive and corrective maintenance task running; maintenance task planning; fault prediction models development.

The APS objectives are achieved by the coordinated interaction of the agents. Reasoning aspects as well as adaptive and learning aspects are incorporated into the multi-agent behavior, helping in the interpretation of available data from different sources and characteristics. This way, the agent-based APS provides the assistance in the detection-diagnosis-decision process, as well as in the planning and running of maintenance tasks.

Alarm processing refers to the interpretation of a large number of alarms in a computerized control system. It is one of the important functions of the computerized supervisory control and data acquisition (SCADA) systems. An alarm is a structured signal from the SCADA system which is used in distribution power substation control centers [15].

Alarm processing thus relies on status information or measurements gathered at a large number of points distributed throughout those substations. The advances in computer and communications technology in the last three decades have made it possible for a large SCADA system to scan 20,000 to 50,000 points every few seconds. Such a SCADA system will have the ability of displaying 500/1000 or even more alarm messages per minute.

The enormity of the system and rate at which messages are displayed on the console increases the complexity of the problem multifold. This complexity leaves an operator in the control center that has to analyze these alarm messages a highly constrained time frame suffering from high stress and cognitive overload. In early years, prioritizing the alarms and arranging alarm messages have been used to reduce the number of alarms listed to the operator's console [16]. However, the operator still needs to analyze the real-time messages to diagnose the system problem. In general, alarms can be caused by different events and an event can result in multiple alarms.

Uncontrollable events such as sudden load fluctuations, equipment failures and atmospheric perturbations can propel the system from a stable and secure state to an insecure and unstable state. The operator in these circumstances has to take immediate action in order to pull back the system into an acceptable state. Failure to respond quickly, can lead to catastrophic circumstances like the state of the system may continue to deteriorate with some loads getting disconnected or in extreme cases, and the entire system may collapse, leading to a blackout for hours. Under abnormal conditions, trigged alarms responsive to abnormal conditions will disturb the operator to take corrective actions in handling the fault. Therefore, alarm processing issues are worth studying and have received significant interests of many researchers.

In this paper, an agent-based alarm processing architecture is presented to solve the alarm problems inherent in computerized and centralized SCADA systems. For operations that require timely action, the proposed intelligent alarm processor is an ideal way to assist operators to take corrective actions.

The definition of an alarm is described as follows:

a. A measured analogue value exceeds the preset level.

b. A measured digital value changes the status.

2 The multi-agent technology

2.1 ORIGINS AND CONCEPTION OF MULTI-AGENT

The direct reason for MAS (Multi-Agent System) coming into being is that the ability of MAS in dealing with problems is better than that of single Agent, and MAS can communicate with current systems and software, it can enhance the efficiency and robustness of systems, and it is distributed. MAS are Agents that can work together or act autonomously in their environment to complete a set of goals. An Agent as well as a Multi-Agent system can be developed efficiently [17]. The study on Multi-Agents technology mainly lies in two fields: studying the architecture, communication and learning mechanism of MAS in theory, and studying scientific computing, computer network, robot and traffic controlling in application.

2.2 THE FRAME OF MULTI-AGENT SYSTEM

2.2.1 Centralized multi-agent system

The center is responsible for the control and cooperation of the system. This frame would keep the information coherent in the system; it can be managed, controlled and maneuvered easily. The disadvantage is that as every Agent becomes complicated and dynamic; the bottleneck in controlling becomes outstanding. The deadly shortcoming is that, once the Agent that controls the local part or all parts collapses, all parts will collapse.

2.2.2 Distributed multi-agent system.

This frame contains many service organizations, it offers services when Agents cooperate with others, and every Agent is equal. The virtue is to increase the flexibility and stability of the system, and thus the bottleneck in controlling is abated [18]. The shortcoming is that since every Agent is restricted by local and incomplete information, it is hard to implement the coincident behavior.

A multi-agent system is a system where multiple agents are acting in the same environment. Running in the same environment implies that they get the same inputs and that there actions affect the same environment. This automatically leads to more complex issues as soon as there are multiple agents in the same environment the action of one action affects all the other agents in the system as well. This clearly shows the need for some sort of communication between these agents. There are two basic modes of multi-agent systems: cooperation and competition. In a cooperative mode, agents cooperate to reach a common goal. Agents in such a system might for example each have a very specialized function so that they can only together achieve a goal that requires several of specialized functions. In competitive MAS, on the other hand, agents compete with each other for limited resources like computation

time [19]. MASIAP is designed as a cooperative one. Agents in MASIAP are specialized agents that are each pursuing their own goals. To reach these design objectives those agents most cooperate with other agents in the system because they can't achieve their goal without cooperation.

Traditional SCADA system attempts to monitor and control everything from a control center. Remote Terminal Units (RTUs) are widely used for centralized monitoring and control. A fixed communication channel has to be established for data exchange between control center and remote terminal units, and the failure of a remote terminal unit or of the centralized monitoring server could cause the whole system to fail. To conquer the limitations of centralized monitoring, a multi-agent approach is employed. The rationale and justification for the choice of multi-agents for distributed transformers on-site monitoring is the capability of an agent to respond to changes in its environment, act in anticipation of such changes, and interact with other agents to solve problems in a cooperative manner. Multi-agent systems are ideally suited to the characterization or design of distributed computing systems. With reference to the presentation of information and resource control in the distributed monitoring system, agents are appropriate because:

1) They are intelligent agents.
2) The autonomy of an agent enables it to encapsulate the identity of a particular user, and tailor its response to reflect the user's responsibilities, such as monitoring the state of relays.
3) Agents allow the integration of existing systems. Therefore agents can negotiate with each other to obtain required information.

2.3 THE FRAME OF MULTI-AGENT DECISION-MAKER

Agent Decision-Maker is used to hold the diesel engine combustion control of DSS, which is based on A-Team (asynchronous team) agent interaction structure. As shown in Figure 2, all of the diesel engine combustion control tasks which are need to process are store in a "Population". The sub-agents of the Decision-Maker are discussed as below:

1) Analyzer, which is used to analyze the diesel engine combustion control tasks and target the attributes of all the tasks.
2) Inquirer, which acquires the information from the system source database to support Analyzer for analyzing and targeting the attributes.
3) Updater, which updates the information changed by Analyzer to the system source database.
4) Specilizer, which constructs the rules of tasks from "Population".
5) Decomposer, which decomposes the tasks from Specilizer.

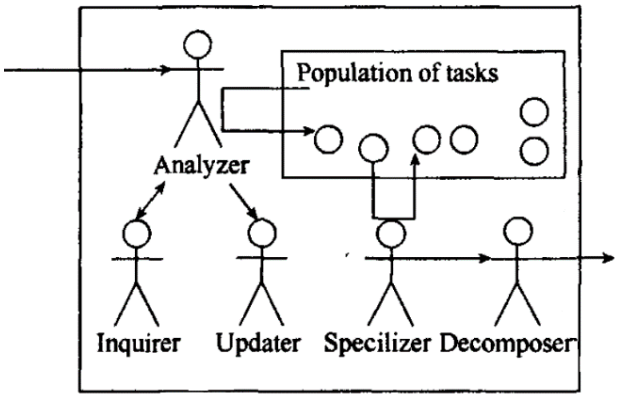

FIGURE 2 The frame of decision-maker

3 The proposed architecture of multi-agent based alarm processing system

This section will outline the general architecture of the multi-agent based alarm processing system (MASAPS). The architecture is presented from two perspectives: one is the software perspective and the other is the system perspective. The system perspective shows the relationship between different parts of the system and the physical location of the different software parts. The software perspective describes the way in which the system is embedded into different agents and the style in which they interact with each other [20]. The MASAPS mentioned above has been evaluated in the simulation experiment. The MASAPS is under development using the Java language and can run under any computational platform that supports Java byte code and GUI.

The system is under development using the Java language and can run under any computational platform that supports Java byte code and GUI (Graphic User Interface). The system architecture is depicted in Figure 3. It consists of five major components, Java-based human machine interface (HMI), data analysis agent, monitoring agent, control agent and database agent. We choose JADE (Java Agent Development framework) as development tools because it can provide an agent environment to communicate with each other and migrate from one substation to another. We will discuss the function of these components in the following sections.

In each substation, there exists database used for persistent storage of historical real-time data which connected to database agent. The real-time information is gathered from substation remote terminal units by monitor agent over serial RS232 or TCP/IP. The data analysis agent is not only responsible for analyzing the receiving measured values, but also can generate diagnosis information via its reasoning process. One of the advantages to detect data directly from each local remote terminal unit is the ability to suppress redundant alarms. After perceiving information from substation remote terminal units, the monitoring agent provides a copy of the receiving information to database agent for persistent data storage. Each user can access the system information through the Java-based HMI. In

order to effectively analysis system alarms, all agents are capable of communicating with other agents in different substations.

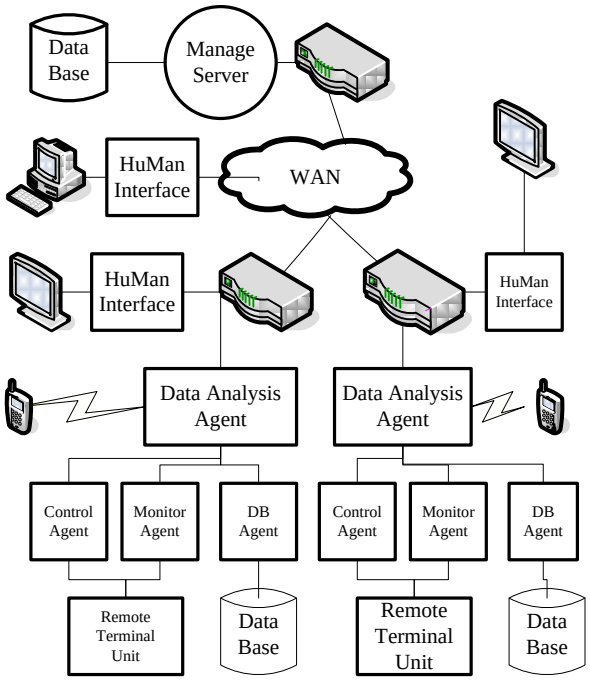

FIGURE 3 The proposed architecture multi-agent based alarm processing system

4 The function of the multi-agent

4.1 DATA ANALYSIS AGENT (DAA)

The Data Analysis Agent (DAA) plays an important role in the multi-agent systems. Hich task is to gather information from substation remote terminal unit and perform data analysis, and here the control task is executed by the control agent. Hile exist three software agents: messenger agent, fault analyzer agent, and learner agent. The messenger is an information centre that allows sending and receiving messages to other agents via FIPA compliant agent communication language. The incoming real-time data which come from monitoring agent is analyzed and fault sections using cause-effect networks to determine the relevant event is identified by the fault analyzer agent. The learner agent plays the role for enhancing accuracy of event identification by using the post experiences from interaction with user.

4.2 MONITORING AGENT (MA)

The main function of monitoring agent is to continuously monitor measured analogue values that exceed the preset limitation and/or digital values that change state from remote terminal unit. The collected data will be sent to data analysis and store in the database via database agent.

4.3 CONTROL AGENT (CA)

The control agent is responding to manages and performs a low-level control action in a secure way. By clicking a component for operation requests in the diagram window, a pop-up dialog box is displayed for confirming an executable operation. Through check before execution and software interlock functions to avoid critical operation process.

4.4 DATABASE AGENT (DA)

Several reasons lead us to make the decision that data about the activity in the substations, its environment and the systems activity should be logged.

These reasons were:

1) Requirement to make statistical tests about the behavior of the system.
2) To have a learning base, where the system could learn from experience.
3) An ability to plot charts about the behavior of the system.

4.5 USER INTERFACE AGENT (UIA)

The User Interface Agent is fully implemented by using Java, which provides a graphic operation interface with cross-platform feature that can run under different platforms with Java Virtual Machine (JVM).

4.6 MANAGEMENT SERVER

The management server, located in control center, contains a facilitator that provides with agent service lookup, user authentication, ontology database. The directory facilitator, connected to a recovery database, is designed for system recovery and migrate information from each substation. User authentication is the way of restricting access to database by asking for a username and password. Ontology is a description of a conceptualization and has properties for knowledge sharing. For pragmatic reasons, we choose to provide an ontology database as a set of definitions of formal vocabulary.

The proposed approach adopts a rational agent model as human practical reasoning and to represent human's mentalist attitudes. Belief, desire, and intention, representing the informative, motivational, and deliberative states of the agent, respectively, are the three attitudes of an agent.

When an event occurs, the goal of the proposed agent system will try to reach the event from overwhelming alarm messages by agent cooperation in related substations. The definition of events and their corresponding alarms, according to substation configuration, is used as the beliefs. The plan, which is deliberative attitude, is the way that agents achieve their goal. Each agent has to store the facts as beliefs that make up the agent's knowledge.

5 Conclusions

This Multi-agent based alarm processing system for MSW incineration could better realize heterogeneous enterprise data, application systems and business processes. Due to a distributed system, MAS modular design not only reduces the complexity of the system, but also is easy to expand, as well as has good robustness and reliability. It also can be integrated to the existing SCADA system. We have designned and implemented a multi-agent based alarm processing system framework, MASAPS, Which has cross-platform architecture, distributed computing capability, and intelligent inference mechanism. The system may be a suitable training simulator for system operators in the future.

Fault diagnosis expert system for large-scale railway maintenance equipment based on BP neural network

Ming Pu[1], Hairui Wang[2*]

School of information engineering and automation Kunming University of Science and Technology, No. 727, Jingming South Road, Kunming, China

Received 1 March 2014, www.cmnt.lv

Abstract

According to the characteristics of the neural network and expert system, a fault diagnosis method for large-scale railway maintenance equipment based on Back Propagation (BP) neural network and expert system is proposed. Fault diagnosis for large-scale railway maintenance equipment on BP neural network and expert system model are constructed. A weak of collection and expression of knowledge on traditional expert system is overcome. Availability of the method based on BP neural network system and expert system is verified by experimental results of large-scale railway maintenance equipment fault.

Keywords: BP neural network; neural network-knowledge base; expert system; fault diagnosis

1 Introduction

Tamping machine is a complex large-scale railway maintenance equipment, it often appears various faults inside and outside the tamping machine because tamping machine always work in field with influence of weather, temperature, humidity, dust, etc. [8]. Once a part of tamping machine fails, the whole system will cause malfunction, therefore the system performance will decline, serious faults will lead to a loss of most of the original features of system. Expert system and neural network methods both can be used in fault diagnosis, but single expert system and neural network fault diagnosis both have certain limitations. Theoretical analysis and experimental studies have shown that expert system based on symbolic logic specializes in reasoning work and artificial neural network based on practice specializes in information perception, both complement each other in function. A combination of expert system and neural network can make themselves mutually reinforcing. In order to make full use of the advantages of expert system and neural network, this paper will organically integrated diagnosis method based on rule-based reasoning of expert system and artificial neural network. Thus we can solve problems that existed in system such as "Knowledge Acquisition Bottleneck", "Match Conflict", "Combinatorial Explosion", "Infinite Recursion" and apply in fault diagnosis of tamping machine.

2 Principles and characteristics of expert system based on BP network

Since the system of tamping machine is very complex, working environment is very bad and the existence of other common phenomenon such as "high fault rate" and "hard to find fault reason" [10]. The system measures working parameters through monitoring status of tamping machine in real-time and uses these parameters to make a contrast with normal condition value [7]. When the measured working parameter does not match normal condition value, it can be shown that there exist at least one or more faults in tamping machine. We can consider using functions which conclude learning and memory in a neural network to replace the role of knowledge engineers. The main content is to learn from faults and complete automatic acquisition of fault diagnosis expert system and automatic updates. The reasoning process of building expert system in a neural network is actually a process of computing, it means that the neuron of neural network constantly parallels until convergence on solving space problems through the relationship among knowledge which are stored in a neural network. Because the parallel mathematical reasoning process in neural network replaces the matching search and backtracking problems in the processing of traditional artificial intelligence (AI) symbol, neural network has a higher efficiency of reasoning.

BP neural network will change diagnosis information into the weights and thresholds, and make them stored in network separately [12]. A combination of BP network and traditional expert system can overcome many defects in expert diagnosis system. BP network has a strong ability of adaption because diagnosis information which are distributed stored in the connected weights of the whole network, and each neuron stores various kinds of information, even though parts of neurons lost, the impact on BP network storage diagnosis information is not much, thus BP network can handle large disturbed input information, furthermore, BP network can solve problems about the bottleneck of knowledge acquisition in traditional expert system – self-learning [11].

3 Technical basis of BP neural network

In system based on neural networks, method of knowledge representation is completely different from method of traditional AI system. Traditional AI system uses the method of explicit knowledge representation, on the contrary, neural network uses implicit knowledge representation [9]. In Artificial Neural Network (ANN), knowledge is not expressed as a set of rules, unlike traditional methods, it is expressed a certain knowledge as the weights distribution in the same network. Figure 1 and 3-layer threshold BP network show the following 4 "XOR" logical formula rules:

IF x_1 =0 AND x_2=0 THEN y=0;
IF x_1 =0 AND x_2=1 THEN y=1;
IF x_1 =1 AND x_2=0 THEN y=1;
IF x_1 =1 AND x_2=1 THEN y=0

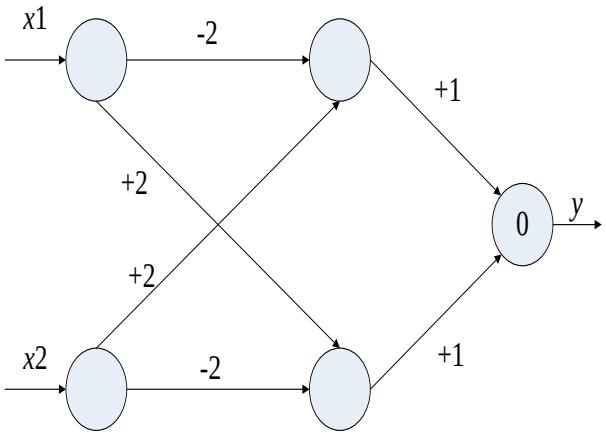

FIGURE 1 ANN representation of "XOR" logic

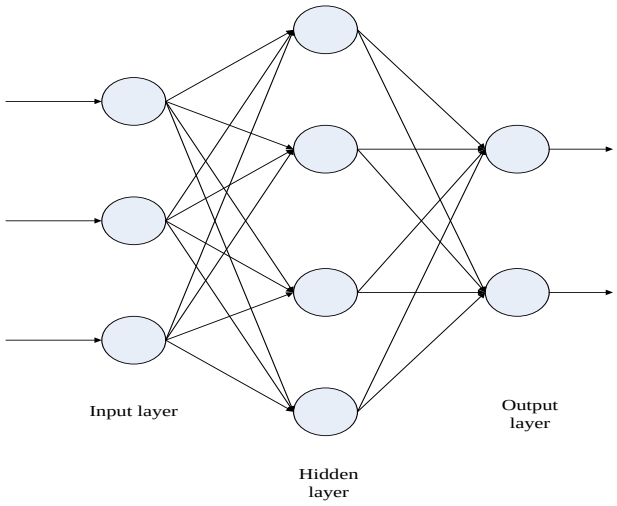

FIGURE 2 Network structure

Based on this network knowledge representation structure, its BP network structure is shown in Figure 2. Experts provide examples of problems and corresponding solution, BP network learns samples through learning network modules and modifies the weights until required learning through adaptive algorithm in network is accurate [12]. The learning process is as follows: Firstly, input fault symptoms and spread them forward to hidden nodes, secondly, spread the information of hidden nodes to the output nodes through output transfer function, thirdly, give results of output. Sigmoid function is chosen for the output transfer function. The learning process of this algorithm is composed of forward-propagation and back-propagation.

4 Corresponding formula

4.1 ORWARD-PROPAGATION STAGE

Set *k-th* sample of input vector x_k =(x_{k1}, x_{k2},…, x_{kl}), get the output of y_j of *j*-th nodes in the hidden layer:

$$y_j = f\left(\sum_{i=1}^{L} W_{ij} x_{ki} + \theta_j\right). \quad (1)$$

The output of O_r of *r-th* nodes in the output layer is:

$$Q_r = f\left(\sum_{j=1}^{M} W_{rj} y_j + \theta_r\right). \quad (2)$$

4.2 BACK-PROPAGATION STAGE

Set L pairs of learning samples (X_k, O_k) (K=1,2,…,l), the mean square error of actual output Y_k and required output O_k is:

$$E_k = \frac{1}{2}\sum_{p}^{m}\left(Y_{K,p} - O_{K,p}\right)^2. \quad (3)$$

The total error of sample set is:

$$\mathrm{E}=\sum_{k=1}^{l} E_k \ . \quad (4)$$

Modifying weights along negative gradient direction of error function so that network convergence, the weights in the output layer is modified as ΔW_{rj} :

$$\Delta W_{rj} = \frac{\partial \mathrm{E}(t)}{\partial W_{rj(y)}} = -\left[O_r'(t) - O_r(t)\right]\cdot\left[1 - O_r(t)\right] y_i(t). \quad (5)$$

Weighs in the output layer which is modified is:

$$W_{rj}(t+1) = W_{rj}(t) - \eta \Delta W_{rj} \quad (6)$$

Similarly, weights in the hidden layer which is modified is ΔW_{ji} :

$$\Delta W_{ji} = \frac{\partial \mathrm{E}(t)}{\partial W_{ji(t)}} = -\left[y_j(t)\left[1 - y_j(t)\right]\right]\cdot x_{ki}(t)\sum\nolimits_r \delta_r W_{rj} \ . \quad (7)$$

Weights in the hidden layer is modified as:

$$W_{ji}(t+1) = W_{ji}(t) - \eta \Delta W_{ji}. \quad (8)$$

Let us introduce the following terms:

f - sigmoid function;

L - numbers of neurons in the input layer;

W_{ij} - connection weights between input layer and hidden layer;

x_{ki} - the input of k-th sample;

k - the number of sample;

θ_j - thresholds of j-th neurons in the input layer;

M - numbers of neurons in the hidden layer;

W_{rj} - connection weights between hidden layer and output layer;

θ_r - thresholds of j-th neurons in the hidden layer;

m - numbers of units in the output layer;

E(t) - error function;

$O_r(t)$ - desired output;

η - steps, experience;

δ_r - sensitivity of r-th nodes correspond to output error function E(t);

5 Design of fault diagnosis expert system

Based on the analysis of fault diagnosis expert system and BP neural network technology above, expert system and neural network must be combined to play their strong point when problems can't be solved using expert system or neural network alone. So I design a fault diagnosis expert system. The basic structure of the process is shown in Figure 3.

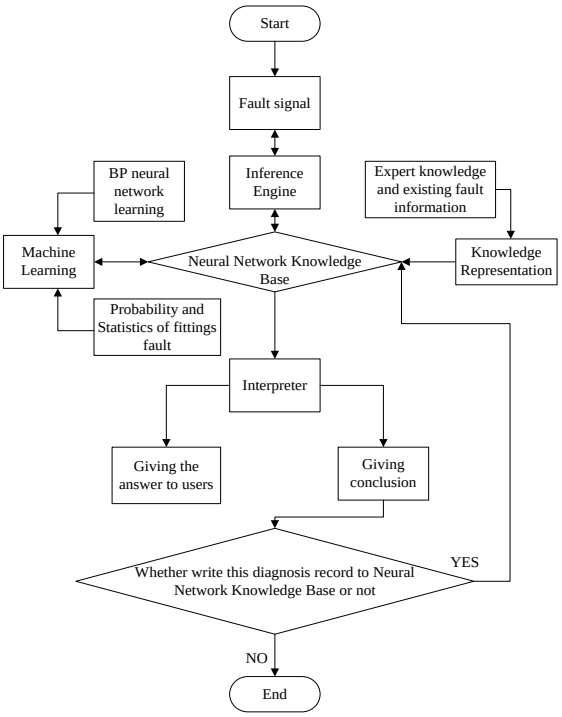

FIGURE 3 Fault diagnosis process of tamping machine

6 Simulation of tamping machine fault diagnosis expert system

The size of neural network is determined by need, the number of fault symptoms is corresponded to the number of input nodes; the number of fault is corresponded to the number of output nodes. The select of the number of hidden nodes in the hidden layer doesn't have theoretical guidance, the selected number is merely to meet capacity and requirements of certain learning speed.

This paper selects common engine fault diagnosis of 09-32 taming machine as the research object, illustrating the practice and diagnosis process of expert system and neural network fault diagnosis system [8].

Tamping machine mainly uses diesel engine, diesel engine often appears many faults such as electrical fault, mechanical fault and oil path fault [8]. Electrical fault shows mainly the line-to-ground fault, line empty pick up fault, damaged components fault and unreliable grounding fault. Line-to-ground fault is most common, as long as grounding can cause a short circuit and automatically cut off the power supply. Virtual connect circuit fault is mainly due to loose caused by vibrations in long-term work, effective way to avoid this is to strengthen the line inspection and tight of terminals. Mechanical faults are relatively less, but there are always several typical faults such as governor throttle trolley balance spring results in only idling, bolts of governor transmission shaft sheared causes failure of work, nozzle jammed results in a mass of diesel leaking into the machine and diluting the oil. The typical fault of oil path fault is diesel tank blocked, the main reason is that diesel tank not cleaned for a long time or some foreign matters get into the tank. When suction pipe appears loosen or the installation of filter element is unqualified, it will result in air suction, low back pressure of suction pipe, air into high-pressure oil pump.

The engine of this diagnosis system has 5 symptoms and 7 faults (Table 1). The 5 symptoms and 7 faults are designed for 5 input nodes and 7 output nodes, hidden nodes are calculated as 5. To calculate the answer, using the formula $h = \sqrt{n+m} + a$ (h is the number of neurons in the hidden layer; n is the number of input neurons; m is the number of output neurons; a is the network layer, which is a constant number between 1-10, here a is 2).

TABLE 1 Neural network output table

Input	Symptom	Output	Fault
x_1	DG08 charging current is high, table shows the maximum and the next to the diesel engine has screaming voice.	y_1	The ground wire of B13box is bad contact.
x_2	5e9 self-healing insurance will jump and can't start when the engine starts.	y_2	The damage of 317 lines in dryer working power supply results in grounding.
x_3	The diesel engine suddenly stalled when working.	y_3	5e9 and 5e7 self-healing are jumping.
x_4	Diesel tank is blocked.	y_4	Engine is damaged.
x_5	Throttle can't lift.	y_5	The damaged 81Re3 results in adjustment can't be passed to post - amplifier.
		y_6	The damaged Si1insurance of 81u1 results in power supply.
		y_7	Diesel tank is not cleaned for a long time.

In the Table 1, x_i represents fault symptom, x_i=0 (i=1,2,…,5) represents no symptom, x_i=1 (i=1,2,…,5) indicates the symptom, y_j =0 (j=1,2,…,7) represents a fault that doesn't exist, y_j =1 (j=1,2,…,7) represents a fault that existed. Based on the above, we selected 7 samples of examples to learn, when the network structure and learning sample are selected, you can train the neural network. First of Table 2 is trouble-free sample.

TABLE 2 Learning sample table

Sample	x_1	x_2	x_3	x_4	x_5	y_1	y_2	y_3	y_4	y_5	y_6	y_7
1	0	0	0	0	0	0	0	0	0	0	0	0
2	1	0	0	0	0	1	1	0	0	0	0	0
3	0	1	0	0	0	0	0	1	1	1	0	0
4	0	1	0	0	0	0	0	1	0	0	0	0

7	0	0	0	1	0	0	0	1	0	0	1	0

Table 3 shows the desired output and actual output through training.

TABLE 3 Desired output and Actual output

Desired output							Actual output						
y_1	y_2	y_3	y_4	y_5	y_6	y_7	y_1	y_2	y_3	y_4	y_5	y_6	y_7
0	0	0	0	0	0	0	0.0266	0.0268	0.0381	0.0038	0.0337	0.0093	0.0032
1	1	0	0	0	0	0	0.9663	0.9663	0.0042	0.0043	0.0027	0.0170	0.0152
0	0	1	1	1	0	0	0.0024	0.0037	0.9635	0.9342	0.9795	0.0068	0.0091
0	0	1	0	0	0	0	0.0023	0.0024	0.9923	0.0043	0.0199	0.0041	0.0108
0	0	0	0	0	0	1	0.0016	0.0160	0.0110	0.0073	0.0053	0.0233	0.9586
0	0	0	0	1	0	0	0.0027	0.0034	0.0087	0.0110	0.9694	0.0026	0.0152
0	0	1	0	0	1	0	0.0102	0.0093	0.9762	0.0046	0.0860	0.9508	0.0128

In fault diagnosis, according to the input fault symptom, we call the trained weights between the layers to calculate forward and display the results of diagnosis based on output of the output layer.

TABLE 4 Fault diagnosis example

Input					Output						
0	1	0	0	0	0.0019	0.9900	0.0152	0.0427	0.0025	0.0014	0.0

Table 4 shows that fault can be located in the damage of 317 lines in dryer working power supply results in grounding when 5e9 self-healing insurance jumps with diesel engine started. Table 3 also shows that the result of fault is consistent with the actual and this method is feasible in fault diagnosis application of tamping machine.

7 Conclusions

BP neural network has a feature of highly nonlinear function mapping, so it is very convenient for tamping machine fault diagnosis. It can not only improve the reliability of diagnosis, but also develop tamping machine fault diagnosis expert system by using BP neural network technology. This system has a self-learning function, with the growth of time investment, the system will automatically record the result of each test into knowledge base and update network weights constantly based on knowledge base, as a result, the system and the diagnosis accuracy will constantly growing and improving.

Innovation model for college ideological and political education in network environment

Jiahua Zhou*

Institute of Management Engineering, Su Zhou University, Anhui, 234000, China

Received 1 October 2014, www.cmnt.lv

Abstract

Ideological and political education is impacted by the rapid development of network technology, computer technology and high-speed communication technology, in aspects of concept, content, ways and means, and can not meet requirements of current network age development. Therefore, the ideological and political education is placed in network technology to form new pattern. This paper, first, made brief overview of the concept and characteristics of ideological and political education in network environment, then summarize college ideological and political education at home and abroad. Afterwards, it analyzed the challenges and opportunities after combined network technology and college ideological and political education, then proposed relative solutions in the perspectives of concept, content, means and position. At last, it put forward the construction of shared community pattern for ideological and political education in network environment, consisting of the organization structure and operation mechanism of shared community.

Keywords: network platform, college ideological and political education, teaching model research, innovation

1 Introduction

College is a place with high informatization degree in our country. The wide application of information technology and network technology brings not only rich resource and teaching platform for college ideological and political education, but also the unprecedented impact and challenge. Network, as the emerging fourth media after broadcast, newspaper and television, changes the idea and value orientation of leaders and students from college [1]. Under the network environment, the urgent task and efforts direction for current college ideological and political educator is to carry out ideological and political education work, innovate education model, and better perform the function of ideological and political education [1].

2 Overview of ideological and political education in network environment

The combination of information technology and communication technology promote the formation of network environment. Academic world defines network environment as the socialized visual environment. Ideological and political education is placed into network environment. With the principle of declaring idea and communication and the basis of stereo spatiality and interactive communication, ideological and political education relies on various newly-developing social tools and platforms supplemented with the behavior and ethics constraints of ideological concept, political concept and moral rule on network audience, thus promote the comprehensive development [2,3].

The combination of ideological education and network environment makes the emerging education model has the following characteristic:

1) Openness and timeliness. Resources in network environment can receive the information from various fields, then integrate, absorb and update it. Thus, ideological and political education excesses the boundary of time, space, nation and country in the open environment.
2) Subjectivity and anonymity. Ideological and political education transforms from single one-way knowledge transportation into bilateral interaction communication mode. Educates gradually become the other subject in education relationship. A new interpersonal model in ideological and political education based on network environment open under the effect of dual subjects. In the other hand, visual technology in network technology make the identity information and behavior purpose of netizen no longer transparent. It can bring unexpected effect for ideological and political educator as well as the troubles generated by anonymity of network.
3) Equality and interactivity. Ideological and political education in network environment ensures the equality of educator and educate. Meanwhile, the discussing mode between these two becomes more equal and domestic. Passiveness of traditional education will be replaced by two-way and multi-way communication means, which can provides conditions for the facticity, depth and effectiveness of communication.

* ***Corresponding author's*** e-mail:zjhzhoujiahua@163.com

4) Richness of content. Network can possess huge advantages, a large amount of information resource and various forms of expression through digital storage of information technology, thus further wide the ideological and political education in network environment.

Ideological and political education is extended and expanded under the network environment. Relatively, traditional ideological and political education is single. The media are most newspaper, television, etc. that is filtered by official media; in addition, it adopts inculcation education mode and political-centered education contents. It often neglects the individual difference of students. Ideological and political education in network environment is relatively complex, and has obvious diversification, openness and more frequent interactivity [4].

3 The research status at home and abroad

Ideological and political education is one of characteristics in our country. Corresponding subject does not exist abroad. However, network ideological education which has certain relevance to that is always in an important position for teenagers abroad. The research status of ideological and political education in network environment is shown in Table 1.

TABLE 1 Research status of ideological and political education at home and abroad

Country	Research status
At home	In 2000, Several Suggestions for Strengthening Network Work of College Ideological and Political Education pointed out to combine network technology with ideological and political education and emphasize education work situation IO In 2003, Information Network and Innovation of College Ideological and Political Education written by Hu Jue, Doctor of Law from Tsinghua University proposed that network has become thesis and basic method for new platform of ideological and political education innovation, and put forward feasible practical suggestions IO In 2004, Ministry of Education and The Central Committee of the Communist Young League proposed higher standard and requirements, in order to further enhance college campus network management to deeper combined ideological and political education with network technology IO In 2005, in order to further combined college ideological and political education with network technology, Beijing held national working conference for strengthening and improving ideological and political education of university students, and in the same year, Research on Network Ideological and Political Education edited by Dr. Wei Jifeng marked the initial construction of research on network ideological and political education in out country IO In 2013, Ministry of Education proposed to implement comprehensive deployment on network ideological and political education and campus network management in college.
Abroad	There is no relative subject abroad since ideological and political education is the product of Chinese characteristics. Foreign Countries mainly focus on the network ideological research that has certain relationship with ideological and political education in our country. Network ethics is a part that foreign countries emphasize, consisting of the specific problems generated in network application: definition of network behavior and norm, cross problem generated because of the mutual effect of visualized network and real society, etc.. It covers economy, culture, society, etc.

4 Challenges and opportunities faced by college ideological and political education in network environment

4.1 OPPORTUNITIES BROUGHT BY NETWORK TO COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION WORK

Ideological and political education with new media communication mode, overcomes the drawbacks of traditional media such as small amount of information, obvious time and space limitation and slow update of information. In addition, single one-way inculcation mode of "teacher teaching and student listening" has transformed into more vivid and charming teaching means consisting of words, voice, animation, image, etc. Meanwhile, time and space limitation of traditional education is improved; completely release the constraints of education coverage and education reception and form a global information system with broad region, large amount of information and convenient teaching communication. That is, college education space has not only been restricted within campus but also has realized the extension from internal campus to social open education space.

4.2 CHALLENGES PROPOSED BY NETWORK TO COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION

Every coin has two sides, so does network. Cross combination of network technology and education not only brings opportunities for college ideological and political education, but also put forward challenges in other aspects. Differing from senior school and junior school, teachers from college do not often restrict students, thus it proposes requirements for the self-discipline of students. The quality of education content will be affected by the time university students spent on network, the screening of network information, the restraint ability for bad information in network [6]. First, many university students probably neglect excise, since they are addicted in network. In addition, facing computer screen for long time may lead to diminution of vision. Irregular timetable can cause poor physical reaction such as chronobiology disorders,

insomnia and dreaminess, etc. On the other hand, students with weak self control and strong curiosity may be attracted by the junk information as well as wrong moral and notions in network, which will affect the physical and mental health of university students and lead to bad result; moreover, one of the characteristics of network is anonymity and concealment, thus university students can plays roles different from in daily life in network; this drawback is easy to corrupt the moral character of university students and make them to release speech violate morality and ethics; furthermore, the development of network brings huge changes for the interpersonal communication way, which impact the previous though of university students.

5 Exploration on innovation solution for college ideological and political education in network environment

5.1 INNOVATION OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION IDEA

Global and open network platform requires college ideological and political education to establish global and democratic education idea [7,8]. It should be improved in aspects of college and students. On the one hand, college ideological and political education should effectively apply network platform to make education promotion, widen education area and get rid of the constraints of regional consciousness; on the other hand, it requires university students to perform their subjective initiative, autonomously search, analyze, settle and screen network information, accept positive information, resist bad information and finally internalize the positive thought as the individual behavior and quality.

5.2 INNOVATION OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION CONTENT

The development of computer network technology can provide technical support for information circulation, update and communication, thus it covers various fields in people's life. Information resources of network become more comprehensive and rich. How college ideological and political education use rich network resources to innovate content should be considered by the reform for college ideological and political education content. Educator obtains the newest message, research achievement as well as the newest ideological and political education content from a large amount of network information resources, and presents them in form of words, music, image, etc. In addition, one of the disadvantages brought by students is that students are too easy to be addicted in network and away from right outlook of right and wrong and mortality; furthermore, university students should establish network legal system consciousness. Therefore, ideological and political education should strengthen students' network psychological education, guide right cultural value and culture good network mentality. Furthermore, university students should establish network legal system consciousness and restrict self behavior while strengthening self-protection.

5.3 INNOVATION OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION METHOD

In college ideological and political education, traditional duck-stuffing one-way teaching method is that teachers teach students and students accept teaching content passively, which will block the stimulation of students' enthusiasm and initiative to some extent [7]. Elicitation teaching of college ideological and political education is realized by network education platform. On the one hand, educator digitizes education resources and presents it in forms of words, music, image, animation, etc. Students no longer accept passively. Teaching students becomes more interesting in aspects of students' sense and acceptance mode, thus improve teaching quality and enhance the acceptance degree of students on information. On the other hand, educator can change his position by network platforms such as blog, BBS, etc., and interact with students with more equal means. Educator can understand the thought and opinion making use of anonymity of network. In addition, channel of ideological education can be further widened by network technology, for example, set psychological guidance and online employment guidance services in network platform.

5.4 INNOVATION OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION POSITION

Books, newspaper, broadcast and television are the main transmission ways. The development of network technology forms a new way of transmission, and replaces the traditional one to some extent. However, the popularity of network platform conforms to the requirements of age development and provides a new education position. The development of new position for ideological and political education need the extension of network space as well as the expansion and support from ideological and political education function of network mainstream media [7]. On the one hand, establishing ideological and political education website has become one of education approaches. College should strengthen establishment of red thematic website, and introduce rich red culture resource, historic culture, cultural relic of revolutionary spirit and revolutionary remains as teaching materials, in order to attract students, exert a subtle influence on students' character. By doing this, students can impressively feel the lofty ideal, attic faith and strong patriotic spirit, thus to awake their own patriotism and national spirit and better perform the function of ideological and political educa-

tion. On the other hand, establishing college mainstream network media becomes another approach. Currently, the main stream media includes government websites. Government spread and generalize their proposition and voice through mainstream media, thus to guide network consensus. Besides, business websites such as Baidu also has the function of spreading mainstream culture. College can generalize ideological and political education through the education function of mainstream media.

6 Construction of college ideological and political education shared community pattern in network environment

The word "society" first appeared in Community and Society written by the German sociologist Tnnies in 1887. Interpersonal relationship is the starting point of community. The same characteristics of societal community are to possess same value orientation, belief, custom and strong population homogeneity and indicate intimate state [9]. The formation and extension of visual community is realized with the support of network technology. No regional restriction is the biggest characteristics of visual community. Meanwhile, network provides a more convenient platform in the process of contributing and acquiring knowledge. Knowledge sharing is involved and generalized in network environment and form concept of share. Community sharing refers to community established based on common interests and hobbies. The important elements are shared resources, shared values, reciprocal behavior and shared rules. Shared community pattern for college ideological and political education should possess knowledge sharing, life sharing, resource sharing and process sharing.

6.1 ORGANIZATION STRUCTURE OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION SHARED COMMUNITY IN NETWORK ENVIRONMENT

Core leadership level, management executive's level and learning community level together form the college ideological and political education sharing community in network environment. Its organization structure is shown in Figure 1:

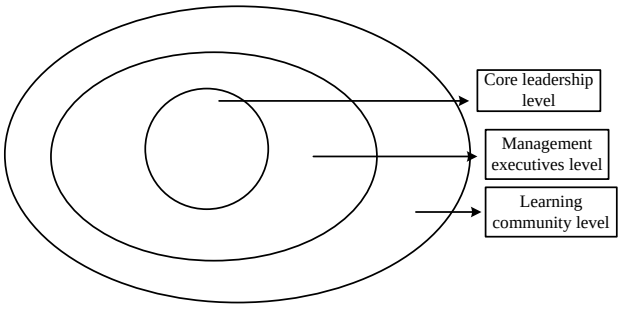

FIGURE 1 Three organization levels of college ideological and political education shared community in network environment

We can see from the Figure 1 that the core leadership level is located in the center, and meanwhile, also is person or organization for defining frontier problem in the whole community. Therefore, staffs in this level have rich experience, highly respected quality. The main function is to formulate the communication content and communication means of ideological and political education in network environment. Management executive's level is in the middle. It is the most important level in shared community, playing the maintenance function of community daily operation. It is composed of information coordinator and network support services staff. Learning community is the outermost. It is the relaying body and basis for shared community, consisting of members with same interests and professional background. They can autonomously discuss topics such as social hotspot, life fun, etc.

6.2 OPERATING MECHANISM OF COLLEGE IDEOLOGICAL AND POLITICAL EDUCATION SHARED COMMUNITY PATTERN IN NETWORK ENVIRONMENT

1) Leadership mechanism: college ideological and political education mechanism under the management, organization and implementation of party committee has certain defect when implementing ideological and political education teaching, management and logistics services, thus the overall efficiency can not be realized. Therefore, we should first innovate leadership mechanism. First, mechanism innovation should perfect party committee and government, school and students. Party committee of colleges and universities formulates overall planning after analyzing ideological and political education situation; schools further combine ideological and political education with other works and implements in various departments. Grassroots party and league organizations focus on organization work. Secondary, mechanism innovation should balance the relationship between organization structure of ideological and political education shared community in the perspective of network characteristics. At last, mechanism innovation should establish and improve level responsibility system, stabilize party cadres team, establish ideological and political education theoretical teacher team and improve structure of student cadre team.
2) Early warning mechanism: schools should understand thought dynamic of student group within the campus as well outside the campus, in order to ensure the successful operation of college ideological and political education shared community pattern and strengthen forward looking and pertinence of college ideological and political education. By doing that, the early warning mechanism for shared community is established.
3) Regulatory mechanism: regulatory mechanism of college ideological and political education shared community should insist the policy that combines heteronomy and self-discipline as well as the policy that pay equal attention to technical monitoring and personnel monitoring. Regulatory mechanism is a purposeful

education practice [9]. Regulation includes heteronomy and self-discipline. Heteronomy is to establish and perfect regulation and rules of shared community and form norm, thus to purify network space and monitor network content. Self-discipline is to culture self consciousness of legal system, sense of duty and network moral consciousness to achieve self-regulation. In addition, technology monitoring is combined with personnel monitoring to develop monitoring software for ideological and political education shared community, supporting with professional monitoring controller. Moreover, monitoring standard for network content should be formulated, and the plans and schemes for shared community should be properly revised, regulated, supplemented and improved combined with practice.

4) Security mechanism: establishment of ideological and political education shared community security should develop in aspects of content, technology, material and environment. The content of ideological and political education looks at the practice of college, and meanwhile, ensures the pertinence and attraction. For example, establish college ideological and political education in the perspective of ideal and faith, patriotism education, basic moral rule, quality-oriented education, etc., set up special ideological and political education channel and strengthen infectivity of college ideological and political education. College ideological and political education should make technical security on health of network content. In addition, certain material basis is needed for ensuring the normal operating of network education. Moreover, positive campus environment, scientific legal environment and effective moral environment are also the security of ideological and political education shared community.

7 Conclusions

Network society is characterized by openness, virtuality, universality, democracy and sharing compared with traditional society. In today's China, network forms complete social structure and function for its peculiarity, enters into fields such as education, industry, agriculture, information society, etc., and changes people's previous life style and thinking pattern in interactive process. Ideological and political education in network environment is a relatively new research field. We should remove the conventional part in traditional concepts, refer and innovate emerging technology, keep pace with the times, positively promote the innovation of college ideological and political education in aspects of concept, content, method and position, thus expand the space, channel and position of ideological and political education [7].

Abstract

With the constant intensification of market competition, manufacturing enterprises are racking their minds to lower the cost so as to obtain more profit. As the enterprise's third profit source, logistics has attached more and more enterprises' attention. According to the relevant data statistics, in the current production system, trucking expense accounts for 30% to 75% of total expense. However, after optimal management of logistics, it can save 15% to 30% of expense for enterprises. This paper discussed the current situation and research results of the workshop logistics of machine manufacturing, and analyzed the loopholes existed in the whole process of traditional logistics management of manufacturing. It also established a kind of manufacturing whole process logistics lean management operation model based on MES, which provided a kind of feasible management mode for machinery industry to lower the logistics cost of the whole manufacturing process.

Keywords: MES, manufacturing whole process, logistics lean management, operation model

1 Introduction

As we all know, the main aim of enterprise manufacturing is to make a profit, and one of the methods of obtaining profit is to lower production cost. However, with the continuous innovation of science and technology, and after the sufficient excavation of the first profit source and the second profit source, people gradually realized that the cost saving of materialized labor and direct labor seems to have come to the end [1]. Therefore, in recent years, not only the enterprise external logistics (supply chain management), but also the enterprise internal logistics (workshop logistics) have become research hotspots. In the article Research on the Operation Mode and Mechanism of Logistics Network System Based on Dissipative Network [2], Shan Lihui of Beijing Jiaotong University started from the entirety of logistics system and conducted recognition on logistics network from systematic and macro perspective. Through researches on the dissipative structure and entropy model of logistics network, she analyzed that resources integration, dynamic alliance and collaborative optimization are beneficial to the coordinated operation of logistics network. In addition, the operation mode of logistics network was established based on it, which optimally utilized the limited logistics resource and provided brand new exploration and theoretical security. In the article A Study on the Collaborative Operation of Logistics Service Supply Chain Based on Process Management [3], based on relevant theory commentaries, Li Yibin, Dong Qianli and Sun Haojie conducted research on the logistics service supply chain coordination with the idea of business process management and modeling approach of workflow for reference. They pointed out that the logistics service supply chain coordination should base on the perspective of process optimization and take the coordination of technology and management into consideration, thus to promote the performance of logistics service supply chain coordination. In the article Exploration and Analysis on the Logistics Process of Guangdong Donghong Metal Equipment Manufacturing Enterprise [4], Huang Yubin and Qian Yuanfang conducted field research on Guangdong Donghong Metal Equipment Manufacturing Company. Through the understanding of the company logistics operating process, they combined the theory of enterprise logistics management and found some problems existed in the company. They also combined the theory of logistics process reengineering, which provided a good referential experience for the remodeling of enterprise logistics process and the operation of other enterprise logistics management models in future.

This paper established a kind of manufacturing whole process logistics lean management operation model based on MES, which conducted redefinition on the department responsibility of manufacturing enterprise and recombination on the logistics operation process of the whole manufacturing process. In addition, this paper described the support of MES and other relevant information system to the logistics lean management operation mode of the whole manufacturing process. It also further perfected and managed enterprise logistics in technology level so as to promote the enterprise economic benefit, which has important economic and practical significance.

[*] ***Correponding author's*** e-mail: zjjuanz@163.com

2 Traditional logistics management problems

Manufacturing whole process logistics management refers that after the manufacturing enterprise accepts productive task execution instruction, the management on the dispatching, carrying, loading and unloading, and storing of materials and half-finished products during the process of starting from the recipient of raw materials, through the process and assembly of intermediate products and finally the production of qualified finished products.

With the increasingly fierce market competition, manufacturing enterprises in China are increasingly highlighting the optimal management of logistics. However, in recent years, most of manufacturing enterprises focus on the optimal management of enterprise external logistics (that is supply chain management), but neglect the enterprise internal logistics optimal management (that is manufacturing whole process logistics management). Therefore, manufacturing whole process logistics management has become the weak link among most of manufacturing enterprises in China. At present, under the circumstances of non-transparent workshop logistics information, the typical logistics management process of manufacturing enterprise is shown as follows:

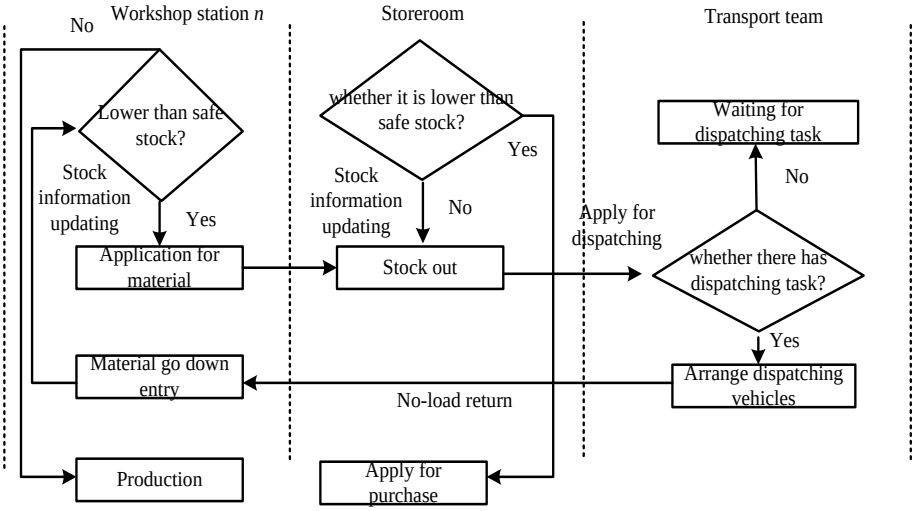

FIGURE 1 Manufacturing whole process traditional logistics management process

From the above Figure 1, the disadvantages of traditional logistical management can be summarized as follows: waste of space, large occupation of material capital; high no-load ratio of logistics transportation; repeated handling; unreasonable logistics path; untimely waste debris recycling.

3 Logistics lean management mode

3.1 MANUFACTURING EXECUTION SYSTEM (MES)

MES is the executive layer between the operation control system (SFC) of planning player (ERP) and workshop layer, which is mainly responsible for the production management and scheduling execution of production site. MES can transmit the management information in management layer like production plan, production instruction, etc and production instruction information like working diagram, process flow diagram, etc to lower levels of each station of production site. At the same time, MES also can real time collect and process the production data of production site, and submit them to ERP [5]. Therefore, manufacturing enterprises can realize the visual and digital management on the manufacturing whole process by implementing MES, which can provide timely and comprehensive information support for the manufacturing whole process logistics management.

3.2 LOGISTICS LEAN MANAGEMENT

As for manufacturing enterprise, in products total cost, the logistics cost of manufacturing whole process often occupies a large proportion. Therefore, the realization of manufacturing whole process logistics lean management is one of the core links of enterprise to reduce cost and improve market competitiveness. Manufacturing execution system can provide all static and dynamic data of manufacturing whole process for enterprises, a set of real time comprehensive logistics information and abundant data foundation for the logistics tracing, statistics, analysis and optimazation of manufacturing whole process [6,7]. At present, MES has obtained more good graces of Chinese manufacturing enterprises as well as enough reusing. Therefore, this paper proposed a kind of logistics lean management mode based on MES. The main content of manufacturing whole process logistics lean management based on MES is "material storage" and "material flow". Thus the purpose of manufacturing whole process logistics lean management based on MES is to realize the stock lean management and dispatching lean management.

4 Operation model

4.1 TOTAL FLOW DIAGRAM

Manufacturing whole process logistics lean management mode based on MES not only needs to realize the logistics lean management to manufacturing whole process, but also needs to perform recombination on traditional manufacturing whole process logistics management process. The recombined process will make full use of the powerful logistics real time information in MES, so as to maximize embody the value of real time logistics information in MES. The specific operation mode is shown as follows (Figure 2):

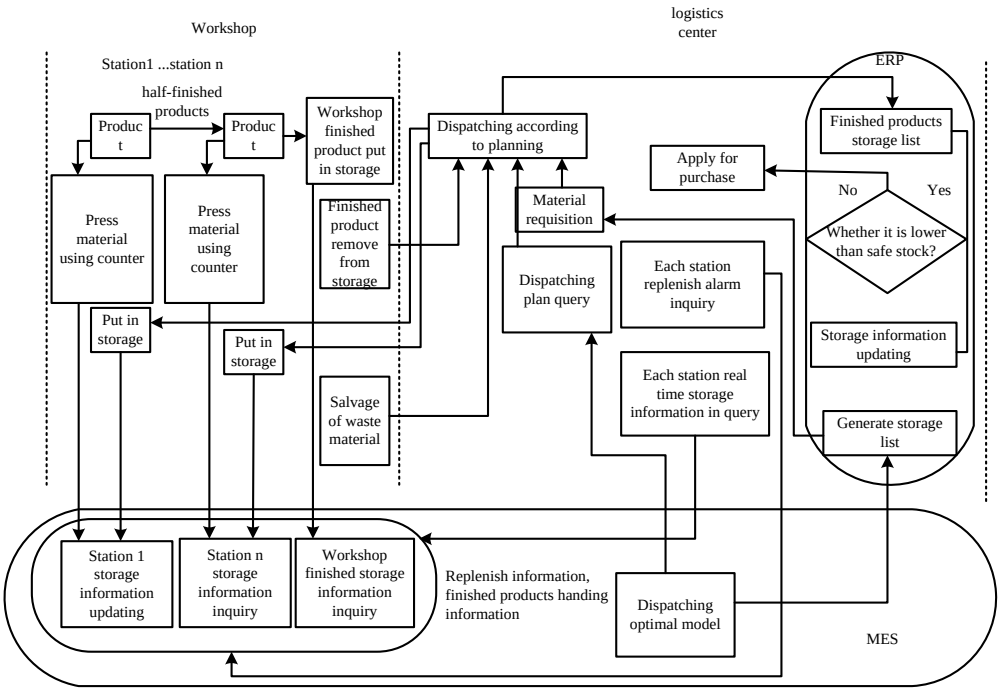

FIGURE 2 Logistics lean management operation mode based on MES

4.2 INFORMATION SUPPORT SYSTEM

Manufacturing whole process logistics lean management based on MES can not leave the enterprise informatization supporting environment. Besides MES system, it also needs ERP system of MES integration and SFC system of control layer. The information supporting system designed based on the above three systems are shown as follows in Figure 3:

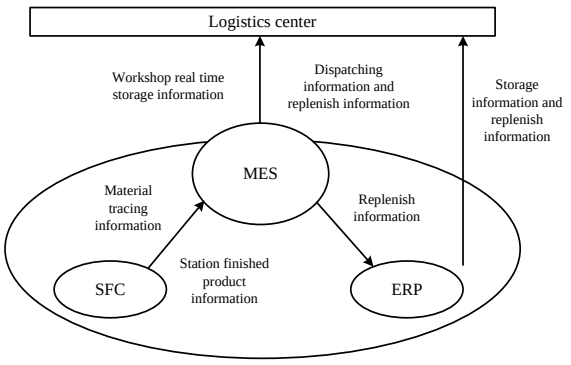

FIGURE 3 The informatization supporting environment of logistics lean management

Conclusion

Modern enterprise is a complex and large scale system. The generation of logistics is to meet the demand for purchase, production and sales departments, which is the inter communication bridge among various subsystems. It plays an important role in enhancing the quality of products and reducing production cost. Therefore, an increasing number of enterprises turn their attention to the enterprise logistics optimization. As a kind of advanced organization mode and management technology, modern logistics has become the third enterprise profit source of creation besides reducing material consumption, raising labor productivity. In terms of essence, the optimization of logistics management model is an important strategic decision for enterprises in coping with increasingly fierce market competition [8,9]. Base on the analysis of the shortages of traditional logistics model, this paper proposed the manufacturing whole process logistics lean management operation mode based on MES, thus to have the enterprise MES plays terrific value in logistics management. Its assistance in reducing production cost has better maintained enterprise profit, and created superior environment for further driving the economic development of society.

Design and construction of college English teaching model based on multi-dimensional integrated technology

Jingdong Hao*

Suzhou University, Anhui, 234000, China

Received 1 October 2014, www.cmnt.lv

Abstract

How to enhance language teaching efficiency, especially college English is always the focus of people. People pay more and more attention to the progress of the CAT with the development of linguistics and improvement of computer and network technology, at the same time, the combination of language teaching and computer science is also a major breakthrough in the history of the development of language teaching. This paper used the C3I-CAT integrated technology into college English curriculum design and research and development of independent study system, and developed more college English courseware and application methods that is matching to the need of teaching practice, thus to improve the learning efficiency of college English course.

Keywords: college English course, information technology, integration, design of model

1 Introduction

With more and more common application of information technology nowadays, education information technology represented by computer science and communications technology is playing an increasingly important role and influence on Chinese foreign language teaching [1]. Information technology and foreign language teaching are belonging to two different subject fields, and they have entirely different academic tradition and paradigm. On the other hand, interdisciplinary conformity is becoming a tendency of scientific development in 21st century. Under this macro-background, more and more scholars devote themselves into the study. Jiasheng Hu from Shanghai International Studies University used intelligent research [2] methods based on metatheory basis to prove some rationality and validity of microscopic view and infrastructure in Research on Construction of Foreign Language Education Technology Based on Paradigm Shift. He tentatively finished the structure of foreign language education technology based on normal form transformation. It became a subject rudiment in reality from an existence in theory. Thus the problem of disciplinary development and teaching actual effect of Chinese foreign language teaching were solved effectively. In the article of Integration of Information Technology and College English Course, Shengnan Zhang studied the significance of integration of modern information technology and college English teaching and discussed the strategy for the integration [3], which provides some feasibility idea for the further integration of college English teaching and modern information technology. Analysis of College Education in Network Times [4] wrote by Feng Cao discussed about the contradiction and countermeasure between network and college education and the opportunity of college given by network, centering on the theme of how the college education seize the opportunity and overcome the challenges in network times, which provides a reference for correctly handling the relationship between network and college education.

2 Significance of integration of college English course and information technology

With the development of Information technology and network technology, information technology provides more space for university English teaching. The combination of information technology and English lesson is not just a fixed model, but a concept. Teacher should catch the point of the lesson, and express it in efficient way. Same text book, different background and different teacher and student can give teaching and study different life [5,6]. The English teaching will become efficient, if combine the information technology and university English. In the aspect of information technology and college English course integration teaching, our country accumulate full of experience. However, in the process of teaching, many problems come out. The researchers should focus on the problem which appear in the combination and discuss the strategy in the combination of information technology and university English, to provide reference for the further development integration of information technology and college English course.

* ***Corresponding author's*** e-mail: hjdszxy@163.com

3 The application of C3i-Cat integrated technology in college English course

3.1 THE THEORETICAL FOUNDATION OF C3I-CAT INTEGRATED TECHNOLOGY

In the perspective of the cognitive psychology, learning about new knowledge should accord with the mechanism of human brain to accept and process information, and this mechanism tells us the way of information acquisition and storage in our human brain. The grasp of a new skill need three stages: acquisition, combination and spontaneous stage. The best way to get the declarative knowledge is to build relevance with past knowledge, but the best way to get procedural knowledge is to practice with systematic and suggestive. The cognitive theories show that, it is a proactive involvement process of people in a series of activities from incipient stage to enter a certain state and at last to get the new information.

We can use the C3I-CAT integrated technology in teaching and learning of college English based on this theory and regard the students as the subject and teachers as the leading. We should make full use of the practical type courses and the characters of general education class. This course assessment used the form of " PPT exhibition of research result in groups+ course work+ communication between 100 people about the note+ work+ classroom discussion+ final", that is, "3+2+1" appraisal mode, in order to encourage the students to proceed the course practice. The aim is to examine the master degree and application level of communication skill of students.

3.2 PATTERN DESIGN OF COLLEGE ENGLISH CURRICULUM BASED ON C3I-CAT INTEGRATED TECHNOLOGY

There have three ways to improve the college English teaching mode by using C3I-CAT integrated technology based on the study of cognitive theories, they are:

Strategy teaching model: this model thinks the objective is the core of learning. New information should establish relevance with the past knowledge, and learning needs the organization of knowledge. C3I-CAT integrated technology is to organize the effective resource of Computer-College-class and Internet, etc. The students are helped to gain new knowledge by the way of computer-assisted instruction, and they can make a correlation between new information and past knowledge.

Language study model of cognitive theories: the aim of this model is to gain procedural knowledge and use it to prompt the study of related discipline, and its applicative object is learners with middle rank of English. It contains three aspects, that is, theme and content, skills development and policy guidance, and they all can be realized by C3I-CAT integrated technology.

Cognitive strategy and society/ emotion strategies: modern multi-media and network communication tools such as MSN, QQ, BBS, E-mail and Blog can be used to improve the learning efficiency of students supported by C3I-CAT integrated technology.

3.3 DEVELOPMENT OF COLLEGE ENGLISH COURSE DESIGN AND AUTONOMOUS LEARNING SYSTEM BASED ON C3I-CAT INTEGRATED TECHNOLOGY

According to the spirit of College English Curriculum Requirements and Information of Launching College English Teaching Reform Pilot Work, we should train students' comprehensive proficiency in applying English, especially their listening and speaking abilities. It can make them perform effective verbal and written information exchange in English in the future work and social communication. At the same time, it can strengthen their autonomous learning ability, improve their comprehensive cultural literacy and make them adapt to the requirement of our social development and international communication. College English teaching reform of Henan University of Science and Technology implemented step by step according to phases like "beforehand pilot, gradual popularization, overall development", etc. Three experimental classes were established in class of 2010. According to experimental effect, they were gradually improved and promoted. At present, they have already developed overall among students of 2012 grade. The present new curriculum design is exactly based on C3I-CAT integrated technology and adopting new teaching mode. It has gradually improved the traditional teaching mode that centered on teaching, established the mode that centered on students' autonomous learning, which integrated the brand new teaching mode that the multimedia network teaching of C3I-CAT integrated technology combined with classroom teaching.

The realization of effective share among valid resources in various aspects between computer-college-class and Internet has effectively solved problems like failure of students' listening and speaking ability and "difficult to talk". Schools are trying their best to create learning time on the net for students. Students conduct self-study and discussion on the net, and teacher conducts mentoring, tutoring and correcting of students' homework on the net. In addition, teachers also guide students to carry out the preparation and representation of multimedia courseware work. It can realize online test, require students to finish the exercise and test prescribed online on time, and conduct duly record as curriculum evaluation basis.

4 Problems that C3i-Cat Integrated technology solve in college English course

English course teaching in colleges and universities in our country exists many problems because of the influence of Chinese traditional English teaching concept means. These problems seriously affect the development and progress of college English course teaching. Overall, the problems exists in college English course teaching in our country reflect on the following aspects. First, the concept and pattern of college English course falls behind. Many college English teachers have misunderstanding on English course teaching concept. They think that, English teaching is only limited within the class, thus neglect the importance

of English extracurricular teaching [7,8]. What's more, teachers may think that English teaching is only limited in teaching material, thus neglect the application of other English material. Second, students are lack of interest in English learning. Teaching forms adopted by college English teachers so far are always cramming education and duck-stuffing. This kind of teaching form neglects the individual difference of students, killing the enthusiasm and intuitive of English learning of students. Third, college English course teaching and evaluation system is not perfect. It is necessary to improve relative teaching evaluation system to improve college English course teaching quality, which can better promote teaching skills and level of teachers themselves. However, the establishment of English course teaching evaluation system is not perfect, thus the English course teaching quality and level of teachers is difficult to improve. It is also an important problem existing in college English course in our country.

However, this paper organically combined C3I-CAT integrated technology and college English teaching course and effectively solved the above problems. Therefore, students can learn college English more effectively under the help of C3I-CAT integrated technology, exchange in oral or written information by English in future job and social interaction, strengthen autonomous learning ability, enhance comprehensive cultural quality and adopt to the need of social development and international exchange in our country.

5 Conclusions

Bruner, American famous psychologist, said that leaning was an active process, and the best way to attract students is to let students actively and autonomously involve in study, and realize they are able to deal with the outer world. There is no doubt that language learning is a complex cognitive behavioral process. In addition, the control of all the knowledge and skills must depend on the psychological experience of the individual learner. The cognition assimilation theory can help the English teachers to achieve the individual guidance, and create an effective, close and fast contact with the English learners, thus to improve the efficiency of college English teaching.

Cognitive learning theory held that there is a thinking process behind human behavior, and based on this hypothesis, they thought that the behavior change was observable; meanwhile we can infer the learner's inner heart activities by the changing behavior. Good technology and new media means play an important role in human cognitive activities [9]. We used the latest research results in language teaching theory and cognitive science, and explored new approach of college English course design based on C3I-CAT integrated technology, autonomous learning system development, and manufacture and application research of college English courseware.

Comprehensive evaluation of education mode of university English model and swot analysis

Ying Bai*

Longdong University, Gansu, 745000, China

Received 1October 2014, www.cmnt.lv

Abstract

College English is a compulsory course for non-English majors, which is an important public class. The pros and cons of university English education are directly related to the improvement of comprehensive quality of college students. What the specific requirements of implementing quality education for college English education and how to further strengthen and improve the university English education are hot topics and have been widely concerned. This paper analyzes the traditional mode of university English education quality, and set up a comprehensive evaluation mode of education model, so as to provide some help for the university English reform.

Keywords: university English education, character building education, analysis of advantages and disadvantages, comprehensive evaluation

1 Introduction

Knowledge economy means knowledge producing, processing, dissemination and application which is based on modern science and technology, and determines the cultivation and development of people's innovative ability. It is very important to cultivate people to control and apply the information and knowledge. The coming of knowledge economy will promote the internationalization of Education. National power competition is becoming increasingly fierce shows that the strength of national will depend on the quality of workers, and depend on the quality and quantity of the talents [1]. The college English plays a decisive role in the knowledge economy. It is a basic course for the university personnel training, which is the premise to decide personnel quality; therefore, more and more scholars focus their attention on the university English educational model. In the article of the Research of University Curriculum Factors of Autonomous English Promotion Learning [2], Gu Shimin, from Shanghai International Studies, conducted a systematic research on the involved curriculum elements of Requirements of Teaching University English Curriculum, and reflected on the teaching principle of Requirements of Teaching University English Curriculum. He also put forward some suggestions on how to meet the individualized learning needs in the university English teaching and effectively promote the occurrence of autonomous learning. In [3], Kong Deliang Luan Shuwen constructed the structure model and the practical model of cross culture teaching university English, and aimed at enhancing cross-cultural differences in sensitivity, tolerance and flexibility of the treatment of culture in College English teaching, and expanding university cultural influence, and enhancing the cultural soft power in Universities. Wang Shouren Reflected on College English Teaching [4]. In the new era, college English teaching should stick to the right reform direction, and continue improve and enhance college English teaching; furthermore, it is the mission and task for college to construct university English curriculum system, and perfect the university CET4 CET6 test, and create high-quality professional university English teachers, and improve teaching quality. In addition, create a new situation in university English teaching.

In this paper, the author made a detail analysis of the advantages and disadvantages of the traditional mode of university English Education, and put forward the specific college English teaching requirements, mapped out the reform direction to some extent, and established a comprehensive evaluation model of comprehensive and objective assessment of the English education mode.

2 Analysis of the traditional model of English education quality

The traditional English teaching experienced variability for several decades and gradually formed a set of intrinsic mode. The long existence of this kind of education mode must have its advantages, but with the innovative reform of teaching mode, its malpractice also revealed beyond doubt.

The advantages of traditional education:

1) Pay attention to the students' knowledge and skills training.
2) The student fixed grouping according to teaching plan, clear learning objectives, schedule orderly and controllable.

* ***Corresponding author's*** e-mail: byyingb@163.com

3) The course of teacher's teaching, easy to play, good interactivity.

The disadvantages of traditional education:

1) Monotonous education environment and learning environment, dull, formulaic cramming education process, spoon feeding education
2) Teacher centered, more explanation, less language practicing, little chance for communication.
3) Focus on reading, ignoring the oral practicing.
4) The language is scattered grammar, vocabulary, idioms and other language points, contrast analysis.

3 The specific requirements for college English education after implementing quality education

The Decision on Deepening Education Reform and Advancing Quality Education by The CPC Central Committee and State Council pointed out the direction for the construction of socialist education system in twenty-first Century has China characteristics, and put forward principle requirements on implementing quality education. According to the "decision" requirement, there are at least four points on implementing the requirements for the university education of English quality education, the four points are as the following:

1) For all students.

As college English is a basic course in university and also a public course, each undergraduate has to learn it for a long time. It has a broad coverage and, far-reaching impact, which other subjects are not comparable [5]. The key is whether the education is truly for all students; whether all students can receive education and all the students' English level can be really improved.

2) Adding the moral education in college education.

The quality education must include aspects of education such as moral education, intellectual education, physical education and aesthetic education, and integrated them in the different parts in education activities. All types of schools at all levels should pay more attention to moral education, and strengthen the ability of moral education. We also need to carry forward the Chinese excellent traditions and combine it with all outstanding civilization achievement of the world. In order to enhance the student's education of strengthening the correct world outlook, life outlook education and ethics and civilization, we must study the world outstanding civilization achievements, and only do this can the students have a broad horizon and have a deep understanding of our country condition, in addition, they can strengthen the patriotism, collectivism and socialism feelings.

3) Emphasize the cultivation of students' quality and ability.

The implementation of quality education requires colleges to cultivate the students' professional quality, scientific and cultural quality and ability [6]. The college English includes intensive reading, extensive reading, fast reading, listening, grammar and exercises. Each course should emphasize the cultivation of the student's quality and ability, such as the structure of intensive reading exercises can improve the students' ability of expression. The reading exercises can improve the students' reading skills, and the extensive reading covers a range of subjects, new topics and genre diversity. It can improve students' scientific and cultural quality because of its knowledge and interest. Grammar exercises enable students to apply the grammar knowledge into language practice, and improve the ability to use grammar knowledge on discourse level. Listening can enhance the understanding and proficiency at discourse level and improve students' analysis, induction, and comprehensive and inference ability. Fast reading can improve reading ability and speed. The above part not only has its own system but complement each other, which can lay a wide, thick and solid foundation for students and constitute the comprehensive ability and quality of students.

4) Emphasize the cultivation of scientific spirit and innovation spirit.

There are a large number of relevant scientific and cultural knowledge article, and the teacher should explain these articles, which can enhance the dialectical materialism and historical materialism education, and cultivate science philosophy and spirit of exploration and innovation. In addition, it can integrate the scientific knowledge, scientific thinking, scientific method and scientific spirit, and become a kind of strength power.

4 A fuzzy comprehensive evaluation model of college English

4.1 CONSTRUCTION OF THE EVALUATION INDEX SYSTEM OF COLLEGE ENGLISH EDUCATION

This paper selected the learning attitude, the degree of interaction, resource use and test scores as the four evaluation model of university English education dimension according to the characteristics of autonomous learning university English education and university English. It adopted the analytic hierarchy process to determine the weight and used the current learning assessment commonly used in excellent, good, pass, fail these five grade evaluation to establish evaluation index system. The specific content is as following (Table 1):

TABLE 1 Evaluation index system of English education in a university

First class indexUi	Second class indexUij	The evaluation factors
Learning attitude	Complete the task of learning according to a predetermined course	Browse Webpage learning; courseware learning; complete homework etc.
	Actively participated in Online teaching activity organized by the teacher	Put forward the question; comment; watch video; listen to the audio; Participate in answering; taking the test;
	Willing to interact with other learning partner	Put forward questions; answer the question; asynchronous communication; send E-mail etc.
	Able to finish challenging task	The proposed scheme; works; teachers' evaluations of student; provide resources etc.
	Complete autonomy learning notes and class record	Electronic notes; record lectures etc.
	To actively participate in the course of the necessary counseling	The time of participating in counseling, participating times
	To submit coursework in a timely manner, do not do things carelessly	Submission time and the operation results
	No cheating in the homework exam and quiz	Results students comment;
Cooperation	In answering the students often ask questions to the teacher	Participate in answering questions; times; browsing answering database etc.
	Published course related comments and opinions in the discussion areas	Answer questions, such as the number of published articles
	To find out the important theme in the other people's point of view, to extract the useful information, form their own point of view	Published articles; BBS statement; teachers and students evaluation
	Often exchange learning problems with teachers or students	Chat room floor, E-mail communication
	Often put forward construction suggestions to teaching education work	The times of giving advice
	Timely response to the teacher's questions	Respond time and respond times
	Actively finish the task with other learning partners	Participate in the discussion of the number of proposed solutions etc.
Resource utilization	Make full use of system platform	Log on to the system platform for learning time
	Upload valuable resources on the system platform	Upload resources and provide the link address
	Do some learning records in a notebook	Electronic notes, notes, tag, summarize the study, reflection
	Effectively choose all kinds of resources for learning	Webpage, document browsing; the use of video, audio resources; information search
	To be able to use the knowledge to solve practical problems	Work, works; participate in the competition; problem solving etc.
Papers	Examination	Multiple choice questions 25%
		Word and phrase dictation 10%
		Grammar and structure 10%
		Sentence repetition 10%
		Essay writing 15%
		Fast reading 10%
		Deep reading 20%
	Homework	Teachers score for the job
	Test	Test results

4.2 A FUZZY COMPREHENSIVE EVALUATION MODEL OF UNIVERSITY ENGLISH EDUCATION

1) The establishment of evaluation index factor set and evaluation set.

Set the evaluation index for U, $U=(u_1,u_2,...,u_n)$, u_i is the evaluation index.

Define the first class index set $U=(u_1,u_2,u_3,u_4)$, which is equal to the utilization of resources, cooperation, learning attitude, learning achievement.

The corresponding weight set $A=(a_1,a_2,a_3,a_4)$. a_i (i = 1,2,3,4) indicates that the index weight in the total scores of the students in U, $\sum a_i=1$.

Define the second level of index set $U=(u_{i1},u_{i2},.....)$, which is equal to (complete the learning task according to a predetermined course).

The corresponding weight set $a_i=(a_{i1},a_{i2}.....)$. a_{ij} (i = 1,2,3,4), indicates the weight index in total score of the students.

Define the fuzzy evaluation set $V=(v_1,v_2,v_3,v_4,v_5)$, each parameter of the fuzzy sets is evaluated by the score level assessment.

2) Determination of membership function of fuzzy judgment matrix.

Students ranked hypothesis relation and the actual level of meet the normal distribution, and this normal distribution has been widely applied in practical application of education evaluation. In view of the entire university English class ranking, the student's ranked sequence is

divided into five: (0%~10%], (10%~30%], (30%~60%], (60%~90%], (90%~100%]. We use fuzzy membership concept and expert experience value to determine a student's ranking in the (possibility of localization of 10%~30%] 0.6, which falls on (0%~10%] and (the possibility of 30%~60%] each of them is o.2. Thus, the students in the real class ranking level of the available vector can be expressed by r = [0.2 0.6 0.2 0 0], while the fuzzy evaluation index of matrix U $R=[r_1,r_2,...,r_n]^T$. N is the number of the U evaluation index.

5 Conclusions

At present, college English education should be further strengthened and improved, and make it play a greater role in implementing quality education. Firstly, we need to improve our consciousness, transfer the concept, and eliminate obstacles of university English education, and establish the confidence of improving college English teaching. Secondly, we should solve university English education problems emphatically, and take effective measures so as to ensure the university English education along the healthy track [7-9]. This paper started from the traditional mode of university English education quality analysis and combined China's current education reform content as reference index, thus clear the improvement direction of education pattern. In addition, it constructed the reference for the further improvement of future English teaching mode which is based on the fuzzy theory and promotes comprehensive construction evaluation model and the English education career.

Research of golden week's tourism flow based on tourism system model visual

Yan Zhang*

Shangluo University, Shaanxi, 726000, China

Received 1 October 2014, www.cmnt.lv

Abstract

Travel system is a set of various travel issues; some negative effect of tourism factors in the overall tourism system will affect the tourists' decision. Since the "golden week" holiday, the growing numbers of residents traveller, form a tourist flow for a period of time, while promote domestic economic growth, accompanied by some negative effects, such as poor quality of "golden week" travel, poor tourist satisfaction, cause certain environmental pollution and so on, all aspects of the social concern is caused. This article make Huangshan scenic spot and the ancient villages in southern Anhui province as an example, based on tourism system vision, on the basis of the tourism golden week to explore, set up and analyze the "golden week" tourism flow system model. Classified tourism flow mobility factors by using the model, analyzing influence factor of golden week tourism, according to affect the positive and negative effects of tourism flows, come up with some suggestions and improvement measures, in order to improve the management and planning of tourism, meet the needs of the national holiday.

Keywords: travel system, golden week, tourist flow, Huangshan, villages in southern Anhui province

1 Introduction

Tourist flows are an important part of tourism geography research and left tourist's space behavior in time and space research to a level, become the focus of tourism management and development planning. Tourism development is vulnerable to outside influence, certain festivals, golden week, and all kinds of incidents are likely to cause fluctuations of tourism development, form a special tourism development period [1,2]. Since implementation of the golden week holiday system, it is to stimulate domestic demand, promoting consumption and major economic development initiatives, as well as to provide short periods of holidays [3]. From the practical standpoint, the golden week not only meets the needs of citizens tend to holiday getaway, to some extent, it fuelled the economy development of the consumer market.

Residents prefer to travel in the week holiday, for relieve work pressure, proper rest, family reunion, close to nature, a form of relaxing form of recreation. However, in reality, only to suffer road traffic congestion, tourist overload, unbalance of supply and demand, resulting in reduced quality of tourism services and other awkward situation. Exposed the imperfection of our holiday system design, especially Golden Week Holiday travel supply and demand contradiction is particularly acute. This paper will proposed recommendation based on tourism system models for study basis, analyses the impact of tourists, tourist routes and destinations tourism mobility factors, on how to improve our country's Golden Week travel, complete citizens leave systems, promote civic holiday recommenddations for the quality level.

2 Tourist flow influence factors analysis

2.1 LEIBOER TOURISM MODEL

Tourism flow refers to the subject of passenger flow, material flow, information flow, energy flow and cultural flow, etc, is by the tourists' need thrust, destination attraction and related external driving force, under the joint action of between tourists and destination, or multiple destinations of agglomeration and diffusion between flow collection [4,5]. In order to better demonstrate the characteristics of tourist flow and the influence of different factors on the tourist flow. This paper uses LeiBoEr tourism system models (see Figure 1), combine the travel demand, supply and affecting factors these related factors, research golden week tourism flow between the relationship of the destination, destination of tourists and tourism channel [6].

LeiBoEr tourist flow model system includes three parts: tourism, destination of tourists and channels between tourists and tourism destinations. In the tourist destination of tourists to travel from the process of forming the travel channel, namely, tourist flow, including the flow of tourists and the flow of tourism industry. The formation of tourist flow depends not only on the thrust of the tourists and the tensile strength of the tourist destination, the tourist flow's path and direction is influenced by political, economic,

* ***Corresponding author's*** e-mail: zylsjsa@163.com

cultural, personal hobby, tourist facilities and so on. So the tourist flow should not only study the tourist flow within the system of thrust and tension mechanism, and to study the effect of external factors on the tourism flow.

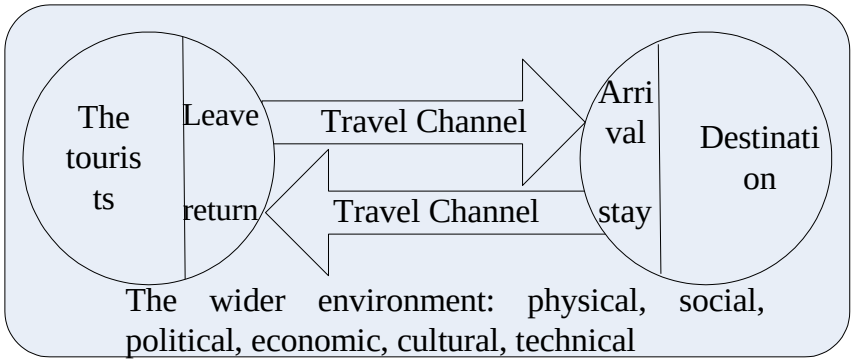

FIGURE 1 LeiBoEr tourism system models

2.2 TOURIST FLOW PATH AND ITS INFLUENCING FACTORS

According to Lei Boer tourist flow model, tourist flow path is a channel of tourist to destinations, from a different point of view, we can divided the tourist flow path into different types. From the economic needs, tourist flow is a research of supply and demand between tourist and tourist destination, calling it a "N-S", is an expression of needs are met by tourist destinations. Starting from the geo-spatial mobile is the study of space moves and layout of tourists and tourism industry, known as the "O-D".

From tourism demand factors, affecting people's Golden Week travel for many reasons and factors, including income, leisure time, and action and so on. Personal disposable income increased, tourism demand will increase. Travel spending is a time consuming, is the discretionary spending of tourists. Analyses pull factors of tourism demand, tourism flow influenced by product supply, pricing strategies, cultural similarities and differences between the source and destination and other factors "7" (see Figure 2)

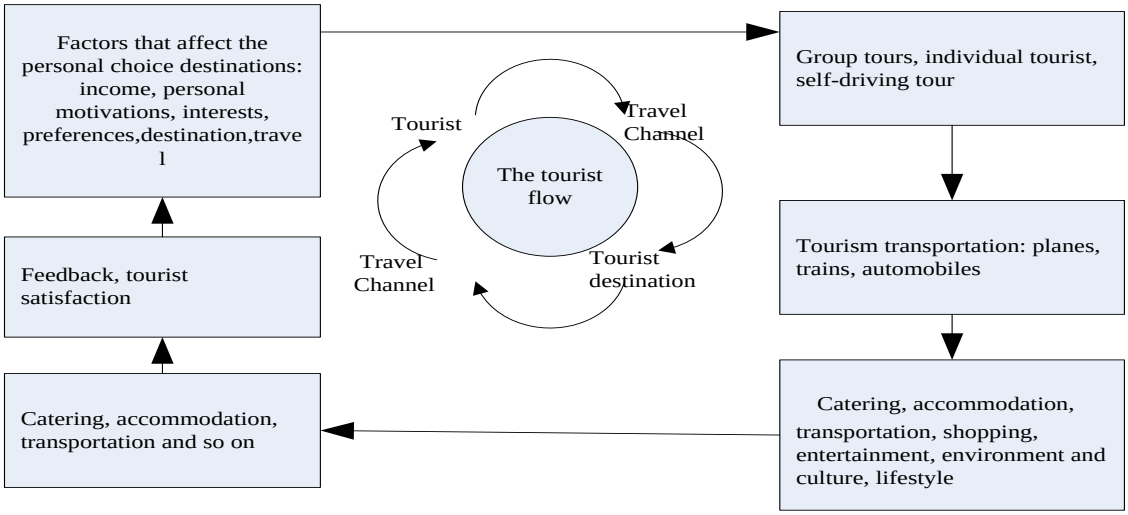

FIGURE2 Tourist flow path and its influencing factors

According to the research emphasis of this article, we analyzed the influence between tourism of tourists and tourist destination tourist flow and its influencing factors of tourist flow according to the economics point of view, that there is a travel demand supply (driver factor) and destination (pull factor), and the external factors influencing the tourist flow, such as government policy, social, economic and environmental status of destination is divided into four categories (see Table 1).

TABLE 1 Tourist influencing factors

First level categories	Second level categories	Influencing factors
Travel demand	Travel motivations	Willingness to travel
	Ability to pay	Disposable income, travel prices
	Leisure time	Length of holiday
Travel supply	Tourism resources	Types of cultural resources, natural resources
	Tourist facilities	Supply of food, lodging, travel shopping entertainment
	Tourist services	Ticket prices and traffic indicators, tourists streaming, information
	Tourism infrastructure	Infrastructure and public restrooms, visitor centers, hospitals
Policy and management	Policy support	Paid vacation, a small car-free tolls
	Government Regulation	Emergency plans, legislation, and other
	Scenic regulation	Swim smooth trails, parking and other
	Travel safety	Destination of the security situation
Destinations affection	economy	Focus consumer, price index
	Social cultural	Subject-object, custom merchandise
	environment	Eco-system

3 Golden week's effect on huangshan and ancient villages in Southern Anhui

3.1 TOURIST FLOW EVALUATION ON HUANGSHAN SCENIC AREA AND THE ANCIENT VILLAGE DURING GOLDEN WEEK

Huangshan scenic spots and ancient villages in southern Anhui are the world heritage site. Huangshan tourism system is top level tourism system in Huangshan city, systems of South Anhui ancient villages in Yixian County, is one of the five secondary tourist destination system of Huangshan [8]. The golden week period and different tourist tourists travel around the same time, prone to traffic concentration. According to tourist flows analysis from source to destination in the tourism model of flow paths and influence factors of tourist flow, this paper validated golden week affect tourists' satisfaction with the Huangshan scenic spots and ancient villages in southern Anhui (see Table 2). "+"expressed positive feedback, has no negative effect on the quality and experience, the government and the scenic no action, "-"indicates problems occurring in the tourism system, affect the satisfaction of tourists, have had some negative feedback, need ancient villages in southern Anhui and Huangshan scenic spots and local governments should take appropriate measures for improvement.

TABLE 2 Tourist flow evaluation table on Huangshan scenic area and the ancient village during golden week

First-class classification	Number	Second-class classification	Positive effects	Negative effects	Measures
Demand	1	Willingness to travel	+		
	2	Disposable income	+		
	3	Demand-oriented		-	Reasonable travel guide, control tourist flow
Supply	4	Humanities, natural resources	+		
	5	Food, lodging, travel shopping entertainment		-	Supply, increase the supply of temporary
	6	Tickets, of signs, tips, banners, etc		-	Appropriate increase in the ticket office, set the prompt
	7	Infrastructure such as hospitals, public toilets		-	Reasonable construction of temporary toilets and so on
Management	8	Small cars from tolls	+		
	9	Tourist trails, parking		-	Increasing the unimpeded protection counseling staff
	10	Crisis management		-	Timely and effective in resolving the crisis
Destination influence	11	Environmental impact		-	Strengthening education on environmental protection and appropriate penalties for the violators
	12	Travel experience			Increase the experiential tours, guided eco-tours
	13	Visitors and residents' consumption		-	Increase tourism supply, control prices
	14	Folk show		-	Strengthen management, proper guidance

3.2 ANALYSIS OF HUANGSHAN SCENIC SPOTS AND ANCIENT VILLAGES IN "GOLDEN WEEK" TRAVEL INFLUENCING FACTORS

Huangshan scenic area and ancient villages has geographical environment, rich in tourism resources. Among them, the Huangshan scenic area known as "the most fantastic mountain", with "pines, rocks, clouds, spring," four famous and ancient villages are outstanding representatives of China's Yangtze River residential villages in mountainous areas. Huangshan scenic spots on the surrounding area with strong radiative forcing [9], passénger flow in ancient villages in southern Anhui Huangshan obviously influence by the Huangshan passenger flow [10], due to the time and location of traffic restrictions, tourists are scheduled on the same day two scenic tours, tourists usually visit the resource levels and high visibility of Huangshan scenic area, followed by return, or continue down the Hill to visit ancient villages in southern Anhui.

Lei Boer tourism system models, travel demand is elastic, tourists can choose different tourist attractions according to their own needs,and tourism supply, especially the destination facility supply is rigid, maximum limits the pull of tourist destinations. Golden Week maximum release of tourists 'travel needs, increased tourism spending. But at the same time demand, appeared in Huangshan scenic area and the imbalances between supply and demand of the ancient villages, scenic overload, many negative consequences caused in Huangshan scenic spots and ancient villages. This paper analyses according to the main factor in Huangshan scenic spots and ancient villages, provide pertinent suggestions for scenic system improvement.

3.3 DEMAND FACTOR

Needs of tourists according to their capacity to pay, a form of willing and able to meet their own needs. Tourism demand has a point, driving tourists from source to destination and even tourism industry direction of the flow, accumulation. According to the research; we can find different tourist groups with social characteristics are different in selection of tourist attractions [11].

There are many factors that affect travel demand, including income, leisure time, and tourism and so on. When assessing item1-3 in evaluation table can find people's disposable income increases, travel demand is also growing; golden week was able to meet tourists on long-distance and trans-regional travel needs. Meanwhile, Huangshan scenic spots and ancient village with its famous attraction is so strong that tourism in the tourism system exerts a very strong cluster effect.

3.4 SUPPLY FACTORS

Implementation of the golden week, make the Huangshan tourist passenger demand and traffic congestion caused by the phenomenon, ancient village voice-belching, losing its origin color, does not know the atmosphere of the ancient village. Sparked conflicts between a tourist and scenic spots management, without tourists' safe and scenic spots of Huangshan scenic spots and ancient villages causing a negative impact.

From Table 2, item 4-7, one of the main factors that cause travellers dissatisfaction is area congestion, infrastructure is not complete. This scenic reception have been unable to meet the demand of tourist, demand and supply become imbalance. So although the Huangshan scenic area and the ancient village has the advantage of human, natural and landscape features, but due to inadequate supply, mismanagement, incomplete infrastructure during golden week, greatly reduced the tourists 'satisfaction.

3.4 MANAGEMENT FACTORS

In 2012, issued by the State Council on approving and departments such as the Ministry of transport on major holidays to exempt small passenger car tolls of notification of programmes should be implemented, greatly contributed to the drive travel and long distance tour. Meanwhile, caused heavy traffic, improper management and emergency measures of the problem in scenic. Travel safety is found to be the most fundamental requirements of tourist, destinations that security in tourist activities, prevent from physical and mental burden of injury or property damage, thereby increasing tourist satisfaction [12]. Huangshan scenic area to resolve risk management measures improper reduces the satisfaction of tourism.

3.5 DESTINATIONS AFFECTED

Passengers to destinations in their own needs can be met, have a pleasant and enjoyable travel. However, during the Golden Week travel, concentration of tourist information, as well as the demand of tourists, visitors make the Huangshan scenic area and the ancient village clashed with the management side, exposed the disadvantages of the reception capacity. Meanwhile, area admin area regardless of area of affordability, on the number of visitors without restrictions, results in crowded, ecological and environmental damage. Increased commercialization of ancient village tourism, loss of traditional culture of truth and simplicity, influences the attractiveness of destinations.

4 Suggestion

The "Golden Week" holidays in the form of travel, study it in the tourism system, are actually tourists demand and the impact of moving in space and time. "Golden Week" holidays of this centralized system, bringing" travel fashion" can easily lead to popular scenic spots heavily overloaded, causing similar problems of Huangshan scenic spots and ancient village tourist area. This paper asked on the study on ancient village tourism in Huangshan scenic area and analysis of influencing factors concerning the improvement of Golden week's tourism made the following recommendations:

1) Improve the holiday system and meet the diversifycation of tourism demand.

The rapid development of economy and technology, increasing residents' disposable income and time, enterprises can promote staggered holiday, tourism can be divided into time to travel, diversion of tourist flows play a role, alleviate the pressure of the golden week travel overcrowded, avoid crowded traffic, accommodation and tourism vacation problem such as poor quality.

2) Establish the perfect travel system and to divert divert visitors.

Travel system work, established vacation holiday travel forecast system based on prediction of golden week holiday tourism flows to help guide the management of scenic spots and providing visitors with useful travel information for their reference. Timely dissemination of early warning information to guide visitors through the broadcast or network, do an emergency plan to help tourist choice tourist attractions.

3) Limited tourist capacity, improving the quality of tourism.

Travel size must be in strict accordance with the scenic spot management system, develop scenic maximum carrying capacity of government violations of the scenic spots to take coercive measures, economic punishment as stipulated. Guaranteed quality of service, improve visitor satisfaction. Meanwhile, strengthening environmental education, increasing the visitor experience programs to prevent commercialization of scenic.

5 Conclusions

Passenger traffic is an important symbol of tourism development; passenger volume size can reflect the appeal to tourists. Implementation of the golden week, increasing passengers' chance to travel, has also led to generally lower quality of passenger travel experience. Implementation of the tourism law, area volume control to a certain extent, but the effect is not obvious. Hot scenic spot overload, poor tourism service quality, environment and resources has been disrupted, traffic and security issues highlighted, some people worried about congestion, safety and other factors delayed time to travel, that golden week can also delay a part of people's travel needs. This paper based on tourism system model, taking Huangshan scenic spots and ancient villages as case study, analysis of various factors of Golden Week affecting tourism flows and make recommendations, hope to implement new management measures, to solve problems arising during the golden week.

Establishment and implementation of network congestion control algorithm based on real-time streaming transmission

Pingping Xiao*

Changchun Guanghua University, Changchun, China

Received 1 October 2014, www.cmnt.lv

Abstract

In order to improve the network performance of computer and avoid the occurrence of network congestion better, this paper analyzed the problems faced by the integration of real-time streaming transport and network and their solutions in the perspective of the characteristics of real-time streaming transport. As to the congestion control of streaming media, TFRC algorithm was analyzed emphatically. Based on TFRC, network congestion was improved, monitored and predicted with parameter of real-time cache length; sending rate was corrected based on cache length when the network was saturate, in order to avoid congestion in time and improve fairness; at last, the test comparison proceeded by network simulation platform NS2. The result indicated that, the improved TFRC was fairer; meanwhile, it showed more friendliness to TCP.

Keywords: real-time streaming transport, congestion control, TFRC, cache length

1 Introduction

Network congestion is caused by the mismatching of network resources and data transmission, for example, the unreasonable network cache space, bandwidth capacity, processor performance, network structure; they detailed present as information packet reception delay, discard probability increasing, upper application system performance decreasing, etc. In the current stage, network protocol plan is widely applied in stream transmission [1,2]. Therefore, the research on network congestion control mainly focus on network TCP protocol, including improving TCP protocol, developing new congestion control protocol by simulating AIMD algorithm of TCP, or regulating transmission speed of media stream according to the TCP throughput capacity under stable state [3,4]. Wang Wenliang et al proposed a TCP congestion control method based on LwIP, detailed stated the implementation method of slow start algorithm, congestion avoidance algorithm, fast retransmission algorithm and restoring method, and optimized TCP congestion control method of LwIP according to correction of fast recovery algorithm of TCP. Lv Guanqiao [6] et al proved the effectiveness of TCP improvement as compared in the perspective of channel utilization, communication stability and fairness. Besides the above methods, TCP friendly congestion control mechanism is the most discussed and promising mechanism in recent years [7]. This paper first introduced TCP-friendly rate control protocol, then analyzed TFRC algorithm emphatically, adjust transmission speed through packet loss probability, round-trip time with the current formula. Meanwhile, smooth packet loss internal algorithm was introduced to precede weight average calculation on the newest eight packet loss rate to ensure smoothness of transmission speed. And then, based on TFRC, these papers introduced additional web cache parameters, proposed MulRFRC algorithm, estimate the behaviors of various TFRC data flow modify transmission speed and improved TCP friendliness and finally made experimental verifycation with network simulation platform NS2.

2 Real-time streaming transmission

2.1 DEFINITION OF STREAMING TRANSMISSION

Streaming transmission is process to transmit multimedia data from transmitting end to destination in the form of continuous data streaming and then play multimedia while receiving data in destination. It can be divided into real-time streaming transmission and progressive streaming transmission. Progressive streaming transmission refers to that, user only can visit the multimedia data that has been downloaded, moreover, the data is downloaded according to certain order. Real-time streaming transmission refers to transmit data into user side through certain network protocol, which is suitable for live event [8].

2.2 CHARACTERISTICS OF REAL-TIME STREAMING TRANSMISSION AND PROBLEM OF ITS INTEGRATING WITH INTERNET

The characteristics of real-time streaming transmission includes high bandwidth, burstiness, the same speed, voice frequency and video sampling rate while receiving end playing multimedia data in transmission.

In practical network, communication network is characterized by limited link bandwidth, unpredictable data packet delay, which is inconsistent with high bandwidth, real time and burstiness of real-time multimedia data strea-

* ***Corresponding author's*** e-mail:xpp163xpp@163.com

ming. Transmitting data by dedicated links is expensive and unpractical. As a resources-shared network system, some characteristics of internet is not suitable for multimedia data transmission. Normal transmission of multimedia data flow in internet should take some factors into account: internet has enough bandwidth, data packet can be transmitted to destination address of the same group at the same time, thus to reduce to burden of multicast; internet has relative mechanism and can meet the demand of enough bandwidth resources; internet transmission technology is based on data packet switching, and should ensure real-time data packet to reach receiving end in time according to certain order, thus play continuously and synchronously.

3 Research on network congestion control

3.1 NETWORK CONGESTION ANALYSIS

Network congestion mainly refers to that, the demand on network resources of user exceed the current volume, thus cause overload condition, decrease the communication of network and network throughput capacity, increase packet loss rate, data packet delay, and even cause network collapse. The main reason is that, link bandwidth, data packet processing capacity of network node and node cache cannot meet the demand of user [9]. Limitation of link bandwidth is because the channel capacity of transmission media is limited and the exceeding data volume capacity can cause loss or error of data packet; the limitation of data at node refers to the congestion when processor cannot process data packet, update of routing table and retrainsmission of data packet; node cache is induced by overflow of data packet and change of performance in buffer memory space caused by limited link bandwidth and insufficient processor. Moreover, complex network structure and unreasonable routing algorithm principle are also possible to induce network congestion.

3.2 TFRC ALGORITHM STUDY AND PROTOCOL

TCP protocol based on AIMD algorithm is not suitable for all internet application. New transport layer protocol is needed to meet multimedia application in order to meet the requirements of stable bandwidth, low delay and small shake. TFRC ensures the service quality of network in the premise of ensuring friendliness of TCP. TFRC is a kind of congestion control algorithm suitable for traditional and TCP data flow-dominated network environment. It can ensure data flow to have smooth transmit speed, reduce transmit speed through theoretical formula and is suitable for real-time multimedia data flow. The relative function is:

$$T=\frac{s}{R\sqrt{\frac{2p}{3}}+t_{RTO}\left(3\sqrt{\frac{3p}{8}}\right)p\left(1+32p^2\right)}. \tag{1}$$

In the Equation (1), T is the maximum of transmit rate of data flow, s is the size of data packet, R is the round-trip time of data packet, p is the packet loss rate in stable state, t_{RTO} is the retransmission time of TCP packet loss. If compared the different data flow effect in the same network environment, it is better to choose same response function to control transmission speed and fairly use network resources. Therefore, good use of TCP response function can ensure fair competition of TFRC and TCP as well as smooth of transmit rate. The flow of TFRC congestion control mechanism is as shown in Figure 1:

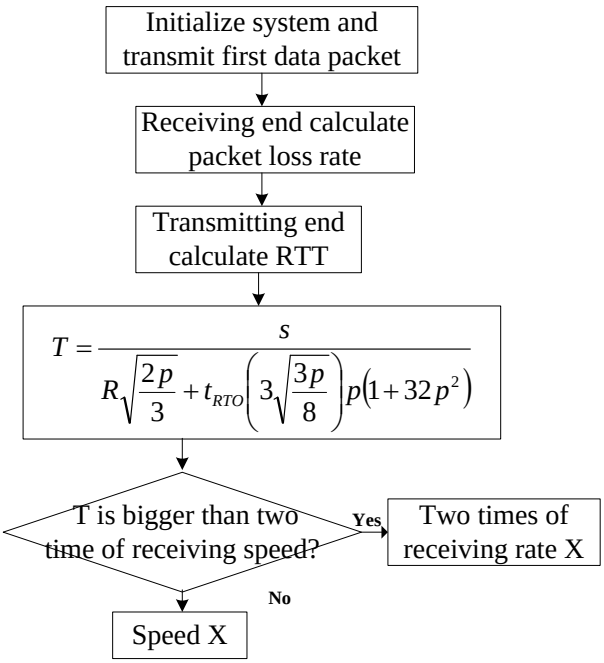

FIGURE 1 Flow chart of TFRC congestion control mechanism

Calculating packet loss rate is the most important part of TFRC algorithm. TFRC selects packet loss internal smooth algorithm to calculate the probability of packet loss event with weighted average, and can restrain some non-representative packet loss as well as reduce the shake of packet loss rate. Weighted average algorithm is as follows:

$$\hat{s}(1,n)=\frac{\sum_{i=1}^{n}w_i s_i}{\sum_{i=1}^{n}w_i}, \tag{2}$$

where is refers to the former number i packet loss event internal, which can be expressed as the number of data packets, $\hat{s}(1,n)$ refers to the smooth result of the former n packet loss event interval; the calculation of weight w_i is as follows:

$$\mathrm{w}_i=\begin{cases}1, & 1\le \mathrm{i}\le n/2\\ 1-\dfrac{i-n/2}{n/2+1} & n/2<i\le n\end{cases}. \tag{3}$$

When sample s_i take i=0, s_0 refers to the number of data packet received during the last packet loss event to the current time. The mean value of s_0, s_1,…,s_{n-1} is:

$$\hat{\mathrm{s}}(0,n-1)=\frac{\sum_{i=0}^{n-1}w_{i+1}s_i}{\sum_{i=0}^{n-1}w_{i+1}}. \tag{4}$$

Finally, it is obtained that the average interval $\hat{s} = \max(\hat{s}(1,n), \hat{s}(0,n-1))$, and the probability of packet loss event is:

$$p = \frac{1}{\hat{s}}. \tag{5}$$

The use of packet loss event probability can simulate "reduce transport protocol while coming across packet loss" [10]; meanwhile, use of TFRC algorithm can make transmit rate be smoother. However, TFRC responses slowly to packet loss, cannot be able to decrease transmit speed in time, thus occupy too much bandwidth. This paper aimed to improve based on this defect, thus enhance the fairness of TFRC.

3.3 TFRC IMPROVED ALGORITHM

Packet loss rate can be updates in a high speed through reduce sample number N, or increase weights of the newest samples, at the same time, shake of throughput rate increases and the redundant noise is introduced. This paper introduced extra network parameter - real-time cache length to correct packet loss interval, as shown in Equations (2)-(6):

$$s_m = \hat{s} \cdot f_{\text{RealTime}}, \tag{6}$$

where S_m is the packet loss interval after correction, f_{RealTime} is the introduced network parameter, which is not related to network condition, but can reflect and predict the congestion and saturation of network. In network with coexisting of TFRC and TCP, one-way delay of TFRC data packet can monotonically increase or decrease within a large range, emerging lots of peak value. Transformation process of network state: free network, transmit speed increases, use efficiency improves – data packet increases, one-way delay grows – network congestion – congestion control – free network, in dynamic balance. One-way delay of TFRC is monotonous. When the delay value increases, data packet is considered to be cached, and the amount of data packet is the network cache length; when the delay value remains the same, then network is free and the cache is 0; when the delay value decreases, then cache length decreases, as shown in Figure 2:

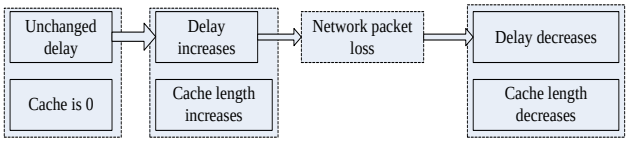

FIGURE 2 Change of cache length

When data packet reach receiving end, the one-way delay time of data packet is calculated. The equation is as follows:

$$\text{stt\_sample}_i = t\_\text{now-t\_send}_i. \tag{7}$$

In addition, instantaneous noise should be filtered, for example, the first sample takes $\text{stt}_{i-1} = 0$. The calculation method is:

$$\text{stt}_i = df * stt_{i-1} + (1-df) * stt\_sample_i \tag{8}$$

Smoothing factor can select the value same with RTT. When obtaining stt sequence, changes between samples are calculated, in order to deduce the current state of network. They are expressed by three parameters as follows:

Inc_count records the length of increased cache, indicating the network is in stage of gradual saturation. dec_count recorded the length of decreased cache, indicating the network is in stage of congestion control. equal_count records the amount of data packet when the cache is 0, indicating the network is free. Parameter zero_delay is used to filter the unnecessary delay shake, can be valued as 10-3ms. In addition, shake threshold value should be set to reduce shake and filter noise.

This paper mainly adopted RED [1] queue management mechanism, selected Minth as the shake threshold of parameter in gradual saturation state. For example, in free state, it is detected that inc_count is larger than Minth, then it is believed that network starts to enter gradual saturation state, that is, B_r =inc_count.

Real-time caches B_r can be used to correct transmit speed of TFRC. When B_r fluctuates near 0, it means network is free and do not need to correct speed; when B_r increase, network begins to saturate; before packet loss event and after some data, the bigger B_r is, the higher network saturation is, the more packet loss interval need to reduce. At this moment, a correction threshold value B_{th} should be set. The correction threshold value selected in this paper is the cache length when the first data packet is abandoned. When B_r is larder than B_{th}, algorithm can adjust packet loss interval. When B_r is larger than or equal to B_{th}, then the correction is not needed. The value of f_{RealTime} proceeds according to the following equation:

$$f_{\text{RealTime}} = \begin{cases} 1 & B_r < B_{th} \\ \sqrt{\dfrac{B_{th}}{B_r}} & B_r \geq B_{th} \end{cases} \tag{10}$$

Therefore, the Equation (10) for packet loss rate pm after improvement is as shown in Equations (2)-(11):

$$p_m = \frac{1}{s_m} = \frac{1}{\hat{s} * f_{\text{RealTime}}} \tag{11}$$

Detailed flow of improved TFRC is as shown in Figure 3:

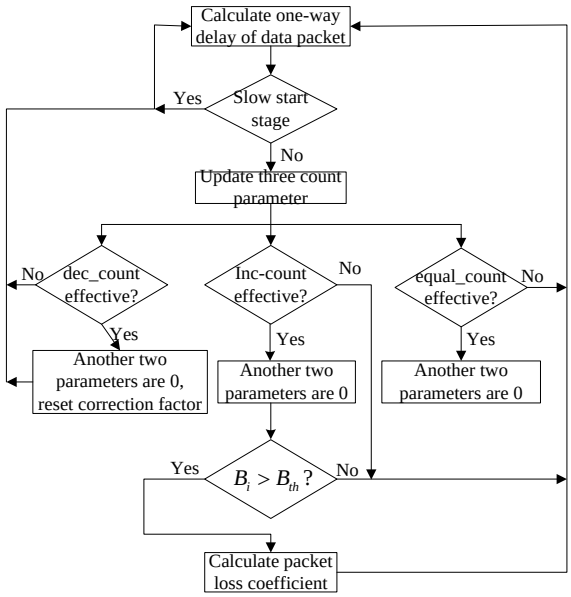

FIGURE 3 Algorithm flow figure

4 Performance analysis of algorithm

4.1 SET OF EXPERIMENTAL ENVIRONMENT

This paper selected NS-2 network simulation system as experimental environment. NS-2 is mainly used for solving problem of network research and simulates various network protocols such as TCP, routing and multicast in wireless or wire network. Network topological structure is this simulation is as shown in Figure 4:

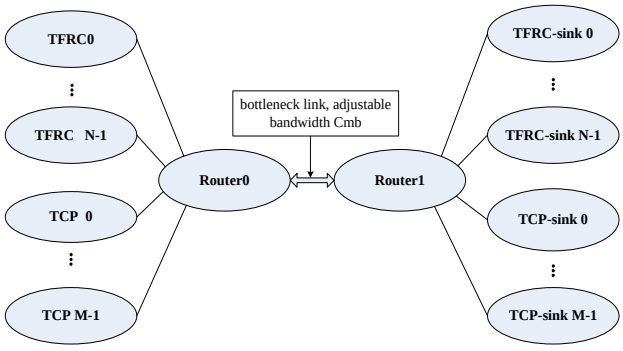

FIGURE 4 Simulation network protocol structures

R0 and R1 are two routers. Between them, it is the bottleneck of network. The delay is 15 ms. Queue scheduling adopts RED queue management. The minimum threshold of length is 5 packets and the maximum is 15 packets. Weight w is 0.002. The maximum temporary probability is 0.1. The link bandwidth between sending node and receiving node with router is 10Mb/s and the network delay is 0.

4.2 EXPERIMENTAL RESULT AND ANALYSIS

1) Analysis on fairness and throughput rate in network environment with different bottleneck bandwidth.

Set topology network according to the simulation scene of network environment with different bottleneck bandwidth. The fairness of simulation result is as shown in Figure 5 and the throughput rate of link is as shown in Figure 6. It can be found that, after the bottleneck bandwidth increases, packet loss event of TFRC data flow decreases, therefore, TFRC data flow tend to be more stable after bandwidth increasing. In addition, the improved TFRC can reduce resource occupation when congestion occurs, release more bandwidth for TCP data flow, improve the fairness; the average throughput rate of bottleneck is basically unchanged.

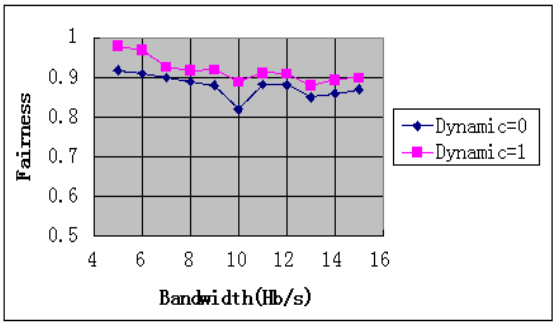

FIGURE 5 Fairness of TFRC in condition of different bandwidth

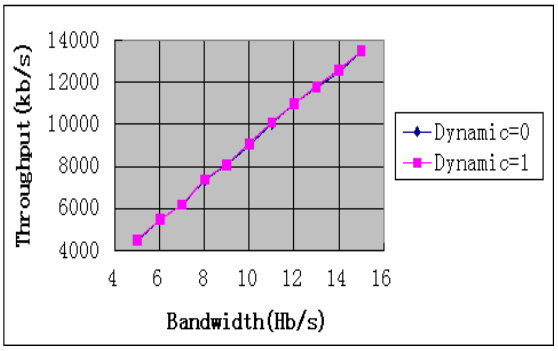

FIGURE 6 Throughput rate of TFRC in condition of different bandwidth

2) The analysis of fairness and throughput in network environment with different amount of TFRC data flow.

Set topology network according to the simulation scene of network environment with different amount of TFRC data flow. The fairness parameter of the simulation result is as shown in Figure 7 and the link throughput rate is as shown in Figure 8. It can be seen that the improved TFRC data flow cannot improve all sampling points because of the randomness of network; however, it can decrease sending rate in a high speed during network congestion, thus network resources can be released in time and its fairness also improves. With the increase of TFRC data flow, the improvement of TFRC algorithm improves fairness by sacrificing the average throughput rate of link.

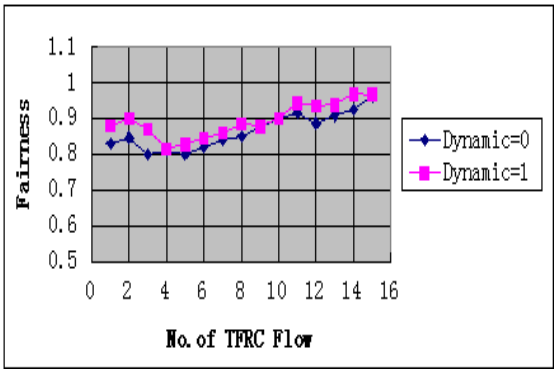

FIGURE 7 Fairness in the situation of different TFRC data flow

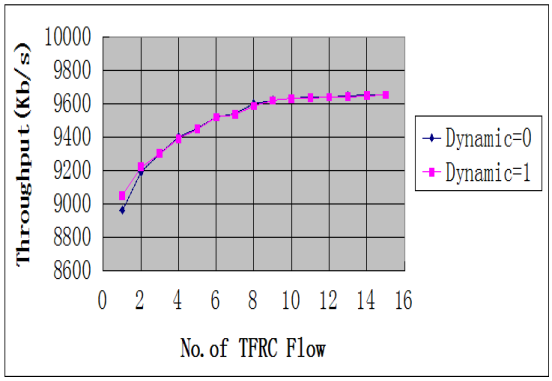

FIGURE 8 Throughput rates in the situation of different TFRC data flow

5 Conclusions

The key point of TFRC achieving good effect is to respond timely and accurately when the network occur congestion. TFRC algorithm can improve the quality of stream transmission service based on IP to some extent as well as the friendliness of TCP. This paper made improvement aiming at the insufficient fairness, introduced network parameter - real-time cache length to estimate network condition and improve the fairness of TFRC. In addition, it preceded test through network simulation platform, veryfying that the improved TFRC had higher fairness and showed good friendliness. Although real-time streaming transmission does not require the complete correction of data, proper packet loss retransmission can improve the transmission quality of multimedia. Therefore, the following research is to speculate network congestion degree according to real-time cache degree and precede retransmission of packet loss, in order to provide better transmission service for network.

Analysis evaluation and quantitative research on economic law behaviour cost and market efficiency

Jindong Chen*

Yuanpei College, Shaoxing University, Zhejiang, 312000, China

Received 1 October 2014, www.cmnt.lv

Abstract

Fiscal expenditure, as the material support of economic law behaviour, plays a critical function in regulating resource distribution, promoting economic development and guaranteeing social far equity. Analysis evaluation of fiscal expenditure is obtained through connotation of fiscal expenditure and investigation evaluation. This paper thought that, analysis evaluation of economic law behaviour cost referred to make comprehensive evaluation in aspects of economy, efficiency and benefits on fiscal expenditure process and result according to specific principles and using scientific and normative evaluation method and technology, with fiscal expenditure as management objectives. The results it obtained will be mostly reflected on market effect. Through the quantitative research on fiscal expenditure and economic benefits evaluation in our country, this paper made digitalization and objectification analysis on the comparison of economic law behaviour cost and market benefit, studied the relationship between fiscal expenditure scale and market economic, further estimated the optimal fiscal expenditure scale in our county, in order to provide basis and rule for the formulation of economic law behaviour cost based on quantitative analysis.

Keywords: economic law behaviour, fiscal expenditure, market benefits, quantitative analysis

1 Introduction

For a long time, the function of fiscal policy in economic growth is one of the core topics concerned by theoretical researchers and policy makers. Modern fiscal theory and practice proved that, fiscal expenditure and economic growth is closely related [1,2]. According to Keynesian fiscal theory, positive fiscal policy can promote economic growth by multiplier benefits, but meanwhile, it also can be decreased because of crowding-out effect [3]. At present, estimation of optimal fiscal expenditure scale are mainly based on two methods: one is to use natural efficiency condition – marginal output of public service is 1 under linear model framework to establish production function; the other one is to use the concave function relationship between economic growth and fiscal expenditure scale in the perspective of nonlinear to construct equation for estimation, taking Armey curve as example [4]. When Armey curve is expressed as small fiscal expenditure scale, the enhancement effect on output takes the leading role. At that moment, increasing fiscal expenditure can promote economic growth, when the scale reaches some critical point A (as shown in Figure 1), then the generated enhancement effect decreases progressively and further expansion of scale will inhibit output increase.

This paper analyzed the status of fiscal expenditure and market benefits in our country, made certain economic evaluation and confirmed the boundary of economic law behaviour based on quantitative analysis, thus to provide basis and rule for the relative research on economic law behaviour in our country.

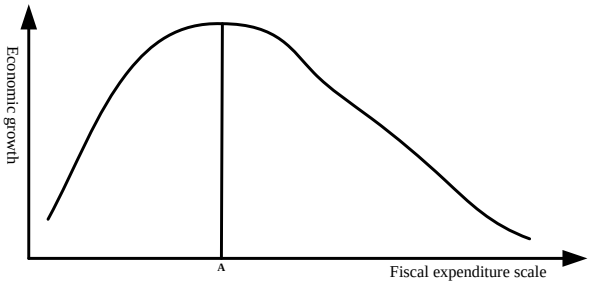

FIGURE 1 Armey curve

2 Analysis of fiscal expenditure status

2.1 FISCAL EXPENDITURE SCALE

Since the reform and opening-up policy, the scale of fiscal expenditure in our country showed change of down first and then rise. This change fully reflects the characteristics of economic transition period. In 1996, fiscal expenditure in our country decreased to the historical low point, accounted for 11.15% in GDP. It demonstrates that, market plays a leading role in resource distribution in the process of turning to market economic system. Year 1992 to 1996 is the stage of tight fiscal expenditure scale; year 1998 to 2002 is the stage of expanded fiscal expenditure scale; year

* ***Corresponding author's*** e-mail: cjdsxwl@163.com

2003 to 2007 is the stage of implementation of firm fiscal policy, and the fiscal expenditure scale remains between 17.8% and 18.7%; year 2008-2009 is the stage of expanded expenditure scale. In addition, calculated based on the current year's price, the total amount of Chinese fiscal expenditure from 1978 to 2012 grows as much as 111.03 times over the 34 years with an average annual growth of 3.27 times. We can found that, fiscal expenditure constantly increases with the development of modern society, and the expansion of fiscal expenditure scale is related to the fiscal policy and economic situation in that year [5]. For instance, in the second half of 2008, financial tsunami induced by subprime crisis spread around the world. As a result, the economic growth in our country slowed down and economic pressure became bigger. In order to resist the adverse effect of external environment on economy, our country proposed 4 trillion investment plan and a series of stimulus measures used for expanding domestic demand. The positive fiscal policy helped our country effectively resist financial crisis, made contribution for the early recovery of Chinese Economy but also aggravated fiscal deficit.

2.2 FISCAL EXPENDITURE RELATED TO ECONOMIC LAW BEHAVIOUR

2.2.1 Fiscal expenditure related to economic law behaviour in macroscopic view

Fiscal expenditure and fiscal revenue together constitute all steps of financial distribution, which detailed reflects on government's arrangement, supplement and utilization and management on the financial fund, indicating the scale, structure, flow direction and use of financial fund [6,7]. Fiscal expenditure can provide the financial resources needed by government, thus to ensure the normal operation of state machinery and realize function of the state; secondly, it can provide public goods and service for society; thirdly, fiscal expenditure can regulate the scale and structure of financial operation and make macro-adjustment on national economic policy, thus realize social equity and promote the healthy development of macro economy.

Public expenditure and government expenditure is also similar to the concept of fiscal expenditure. Fiscal expenditure contains all non-public expenditure used for investtment on competitive field such as economic construction as well as the public expenditure such as providing public products for non-competitive field; government expenditure is government-dominated and government duties-based financial expenditure activity. Public expenditure refers to in particular to the expenditure needed for providing public goods and service by public organization under market economy. It not only contains the main provider with government as core, but also contains lots of non-government public organization. The relationship between these three is as shown in Figure 2.

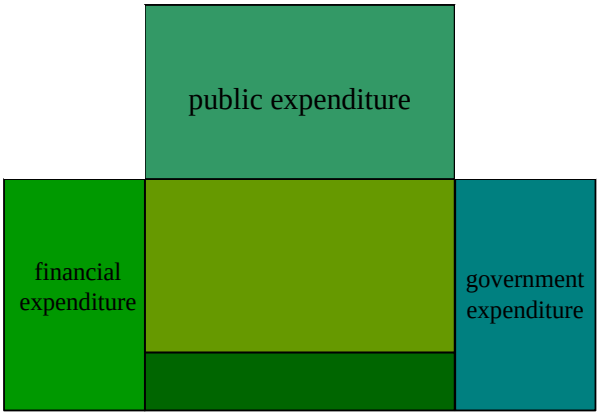

FIGURE 2 The relationship between financial expenditure, public expenditure and government expenditure

Fiscal expenditure project involves fields such as national defence, economy, education, social insurance. In recent years, the proportion of education expenditure in fiscal expenditure becomes higher and higher, increasing from 6.69% in 1978 to 15.10%. General public service and social insurance and employment take the second and third place, respectively. The development tendency of financial policy of our government is to carry out the people's livelihood finance and give way to the market. Therefore, the investment on people's livelihood projects such as education, social insurance and employment, medical care become more and more, while the expenditure proportion on grain and oil material management affairs and business service industry constantly decreases.

2.2.2 Fiscal expenditure related to economic law behaviour in microcosmic view

Analyzed from microcosmic view, the intervention of economic law behavior on economic life in aspect of fiscal expenditure roughly reflects on market control and economic services. Market control, in fact, is that, state use public power to correct and standardize deviation state in economic life from external market. Financial regulation accounts the most in market regulation. However, the foods and drugs regulatory affairs that affect the health of consumer has not greatly supported by finance. The regulatory efforts are not conforming to the impact strength needed for major food safety accidents such as swill-cocked dirty oil and red yolk eggs. In addition, the market regulatory strength on the retail price of goods cannot suppress the rapid growth of price. In the short term, the investment on market regulatory field is not perfect; meanwhile, missing merchant mortality and disordered economic operation also exist.

Economic service is the basis of normal economy operation, among which, the stand or fall of public transportation construction is related to the circulation and transaction of products in market. The normal supply of water and electricity is the security of normal operation of social

economy. For the past two years, our country mainly invested in transportation and infrastructure construction of small towns with large fund. For instance, in 2011, the expenditure on transportation is 749.78 billion, infrastructure of small towns 36.78 billion, total 786.56 billion, accounting for 7.2% in national fiscal expenditure.

3 Evaluations on the financial expenditure effect

3.1 FISCAL EXPENDITURE AND ECONOMIC GROWTH

Fiscal expenditure has multiplier effect and acceleration effect [8]. Fiscal expenditure is related to the national income to some extent. National income is increasing with the growth of fiscal expenditure. Then it feeds back to fiscal expenditure. As a result, fiscal expenditure increase promotes the increasing of national income, and then the income increasing stimulates the expenditure increasing.

Fiscal expenditure and GDP growth rate are all positive number (except 1980 and 1981), indicating GDP increases with the increase of fiscal expenditure. However, the fiscal expenditure growth rate does not have necessary correlation with GDP growth rate. Figure 3 shows the relationship between fiscal expenditure and GDP growth rate. It can be seen that, in 1979~1996, fiscal expenditure is basically consistent with the GDP growth rate curve, showing positive correlation. However, in 1996~2003, the curve moves towards the opposite direction, showing negative correlation. In 2003 to 2012, they become consistent again.

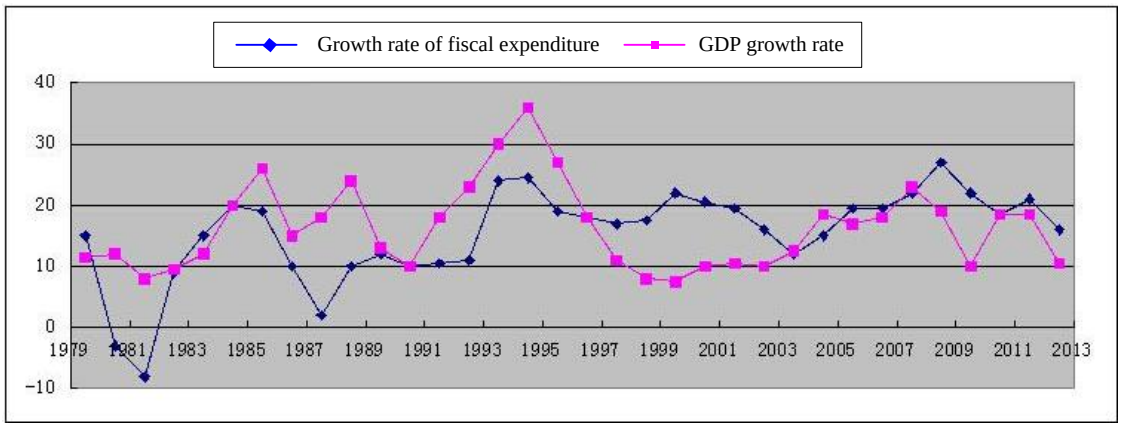

FIGURE 3 Growth rate of fiscal expenditure and GDP in 1979~ 2012(%)

Ratio of growth rate of fiscal expenditure and GDP fluctuates greatly over the 33 years. The ratio of growth rate of fiscal expenditure and GDP contains two information: the contribution rate of fiscal expenditure on GDP growth and the elastic coefficient of fiscal expenditure growth. As shown in Figure 3, 1996 is the turning point of the relationship between fiscal expenditure and GDP. 1996 can be regarded as the watershed of planned administrative intervention and market rules regulating. Negative financial policy and tight monetary policy is adopted to reply the increasingly serious inflation from 1993 to 1996; As the financial crisis broke out in 1997, our country began to carry out the positive financial policy that takes expanding domestic demand as basic approach, and enhance infrastructure construction and public investment. Before 1996, the promotion function of GDP comes from fiscal expenditure with pertinence and political orientation. After 1996, the state of GDP mainly relies on the development of market rule, and its relationship with fiscal expenditure decreeses.

3.2 ECONOMIC CONSTRUCTION EXPENDITURE AND ECONOMIC GROWTH

Figure 4 shows the curve relationship between economic construction cost and GDP growth rate. It can be seen that, from 1978 to 1997, the curve trend of economic construction expenditure and GDP growth rate is basically consistent. These two show obvious positive correlation while negative from 1997 to 2009. It demonstrates that, in the initial stage of market, the economic construction expenditure can significantly stimulate GDP. But with the economic development, economic construction cost is negatively correlated to economic growth. Therefore, in the meanwhile of economic development, economic construction expenditure should make structural adjustment.

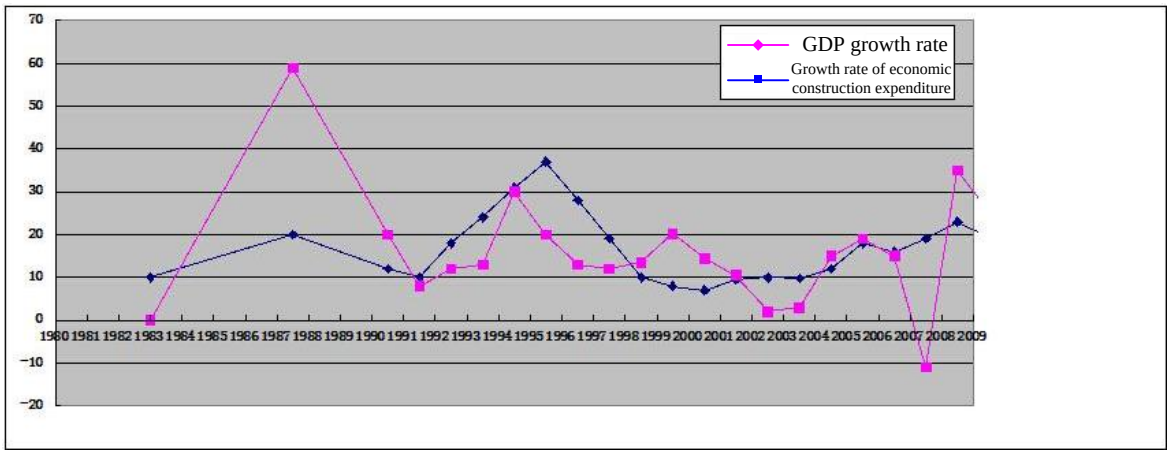

FIGURE 4 Growth rate of economic construction expenditure and GDP in our country from 1980 to 2009 (%)

4 Economic law behaviour based on quantitative analysis

It is of great significance of economic law behavioural norms to economic development. The boundary content of economic law behaviour contains intervention range, intervention object and intervention degree [9]. Accurate positioning of economic law behavioural norms can ensure market rule to have sufficient regulation space as well as providing probability for the defect intervention that is hard for market itself to overcome. In reality, macroscopic and idealized planning boundary has limited guidance on market intervention behaviour, and the objective and quantized reality boundary has stronger operability and adapts to market demand. According to quantitative information, government is regarded as rational economic man, and then the cost and benefits of governmental intervention behaviour is calculated, thus to be used to judge if the governmental intervention is necessary, feasible as well as how the effect is. To be specific, the confirmation of economic law behaviour norms can accord the following three points.

4.1 TIME AND SPACE DIMENSIONS

In practice of Chinese socio-economic transformation, concept of state intervention and market regulation both play functions, that is, market needs the economic intervention of state. Meanwhile, the concept and value orientation of state on economic intervention changes. That is, the state established intervention on the basis of respecting market rule. For instance, the state transforms the control method dominated in direct executive orders into the current control method dominated in market-oriented means; in different development stages, public power exertion will differ in range and strength as well as its functions and role positioning.

First, the national intervention boundary and economic development stage is closely related. In the initial stage of economy, government greatly increases the investment on environment and infrastructure in order to stimulate the rapid growth of economy. The total amount of governmental expenditure increases greatly, and the economic construction investment is dominated structurally; in medium term of economic development, the role of government slowly transforms to the extender of investment, the investment ratio may decreases and the direction transforms from economic construction to national education and health care. With the constant development of economy, the predominating direction of country will constantly improve to the development of market economy.

Secondly, the regional difference is also the content that should be considered by economic law behavioural norms. Regional difference not only reflects the disunion of economic development level and the different intervention function of government, but also requires economic law to adjust intervention range and degree according to different development.

4.2 TRANSFORMING FROM QUANTITATIVE CHANGE TO QUALITATIVE CHANGE

Market economy in our country from formation tom maturity experiences the process from administration dominating economy to full playing of market mechanism, meanwhile, reflects the transforming from quantity to quality of the intervention of economic law on economy. In the initial stage of market economy, government action shoulders productivity function, especially the fiscal expenditure even dominates the development of national economy; in economic mature stage, the dominant position of government should give way to market rule and retire after economic life, since too many government intervention will inhibit economic development rather than generate great function and significance on the regulation and development of market economy. In the real world, government should concern the transformation of the effect of fiscal expenditure on economic growth from quantity to quality, and then regulate economic law boundary norms relatively in order to make it adapt to the development of market economy.

4.3 OBSERVATION DATA AND FORECASTING DEVELOPMENT

Observation of cost of economic law behaviour is a key problem of economic law behaviour boundary. Economic law behaviour boundary, as one mean of state interfering market economy, affects the future economy, people's life and development and trend of social life. Its objective analysis and argument on economic performance is essential. Data can verify the stage that the economic development locates, market demand, situation of government demand and whether the intervention behaviour is conforming to expectation. Only by analyzing whether the norms of economic law behaviour is conforming to the development of market economy based on quantitative analysis can it be close to reality in accuracy.

Economy has certain predictability. In March, 2012, Prime Minister Wen announced that the economic growth objective in 2012 was 7.5%. Most analysts thought that, this conclusion was too cautious. However, it was proved when the growth of Chinese economy in the second quarter decreased from 8.1% in the first quarter to 7.6%. Economic prediction is made based on the full master of Chinese economic situation, economic rule and the current economic data. Through analyzing data and grasping rule, we predict the trend of economic development more accurately.

5 Conclusions

The research on the cost of economic law behavior is aimed at dynamics, those us, to look for the set factors of economic law behaviour norms in an absolute no balanced state. With the development of market economy, economical law behaviour norms with analysis of objective data constantly changes errors in it, which makes the market benefit and financial expenditure proceed in economic law behaviour that is conforming to market.

Received 1 July 2014, www.cmnt.lv

Abstract

As market competition gets increasingly fierce, the elastic way of employment arouses great concern among more and more enterprises, which results in rapid development of labour dispatch. Labour dispatch is different from the traditional way of employment and it involves the three parties of the employer, the accepting entity and the dispatched employee with the striking feature of asymmetric information. From the perspective of the employer, this paper analyses the incentives of the three parties in labour dispatch while taking the employer as the first principal and the accepting entity as the second principal in consideration of the factors that the intermediary agent's training will influence the quality of the employee. It verifies through models the sharing ratio paid by the accepting entity to the employer, the sharing ratio paid by the employer to the dispatched employee and the fixed wage paid by the accepting entity to the dispatched employee in expectation of offering concrete suggestions to the practice of enterprises.

Keywords: Labour Dispatch, Agent's Effort, Double Programming, Sharing Ratio

Introduction

With the development of global economy and the intensity of market competition, many enterprises endeavour to save business costs and enhance profit margins in order to keep and improve the core competitiveness. Different from the focus on the strict division of labour and centralization of functional authority under the background of industrialized production, the rapidly changing market requires that there should be more flexibility of the function and communication of the enterprise's various systems. Under such circumstances, flexible way of employment is widely adopted. On a global scale, although the elastic way of employment is of a small scale, it develops very rapidly.

Labour dispatch is that the dispatching unit signs the dispatching agreement with the accepting entity in accordance with the demands of the accepting entity and dispatch the employee with labour contract relations to the accepting entity so as to establish a special labour relation that the dispatched employee provides labour under the management of the accepting entity while the dispatching unit gets the dispatching payment from the accepting entity and pay the dispatched employees labour remuneration. Through the research on the situation of labour dispatch in Chicago, Peck and Theodore [1] find that this business is becoming divided, from which it derives the short-termed, low skilled and low-waged low-end service and the high-end service with a long-term cooperation and a close relation to the inner flow of the client's organization.

Labour dispatch is different from the traditional dual employment relationship, and it involves the three parties of the dispatching unit, the accepting entity and the dispatched employee. In general, the accepting entity does not know enough about the dispatching unit and the credit level and ability of the dispatched employee, which leads to the obvious asymmetric information. In the operation of labour dispatch, the training effort of the dispatching unit will influence the ability of the dispatched employee, and the ability and effort of the dispatched employee will directly influence the actual output of the accepting entity. Therefore, the double effort of the dispatching unit and the dispatched employee will influence the revenue of the accepting entity. This paper makes an analysis of the incentives of skill-oriented dispatched employees based on the bi-level program (i.e. when the work ability is stronger than the work effort) while taking the dispatching unit as the first principal and the accepting entity as the second principal under the circumstances of double moral hazard. The sharing revenues of the three parties are manifested through the models. The author wishes it a valuable reference to the practice of the enterprises.

Related literature

Labour dispatch involves the three parties of the dispatching unit, the accepting entity and the dispatched employee. The dispatching agreement is signed between the dispatching unit and the accepting entity and the employment contract is signed between the dispatching unit and the dispatched employee. Thus, the dispatching unit serves as the bridge in the business of labour dispatch. Literature from the perspective of the accepting entity mainly focuses on the motivation of choice of the accepting entity, such as literature [2] to [6] explaining the enterprise's motivation of the employment from the economic and social function. Literature from the perspective of the dispatched employee mainly focuses on the psychological contract and organization involvement, such as

* ***Corresponding author*** e-mail: yydouble@sohu.com

literature [7] to [9] discussing the relationship between psychological contract and attitude and action of the casual workers. Based on a study on 1091 dispatched workers and regular workers from 12 automobile factories in 6 provinces, Xie Yuhua et al. [10] analyses the difference of employee – organization relationship between the dispatched workers and regular workers. Based on a field survey of telecommunications in Jilin Province, Wang Hongyu [11] analyses the features of organizational justice of the dispatched employees in order to probe into the idea and effective ways to solve the organizational injustice. Most of the existing literature focuses on the practical experience of the labour dispatch unit instead of the theoretical research.

Moral hazard is a case of information asymmetry between the principal and the agent. Cooper [12] at first studies the problem of double moral hazard, proposing to encourage the two parties to reveal their actions by means of paying insurance money. Romano [13] makes a study on the double moral hazard model of linear contract. Al-Najjarz [14] expands the theory of linear contract in two-sided moral hazard to the situation of multiple agents. Under the background of the enterprise's incentives to the workers, considering that both the principal and the agent are risk averse, Agrawal [15] thinks that revenue-sharing contracts can make both parties' effort level reach the optimality. Tsoulouhas [16] applies the model of multiple agents' double moral hazard into the field of pricing the labour. De Janvry [17] makes a study on the sharing contract of labour revenue with moral hazard, manifesting those two-sided incentives of the employer and the employee can be obtained through making the sharing contract of labour revenue.

The existing research on double moral in the labour market focuses on the traditional dual relationship between the employer and the employee, while few focus on the study of the three parties of labour dispatch. Moreover, in the relationship of multiple agents, there is mainly paralleled competition or cooperation among the agents. However, there is no paralleled relationship among the multiple agents in labour dispatch. The effort of the dispatching unit will influence the working ability of the dispatched employees, and then the output level of the accepting entity. Therefore, the relationship among the multiple agents is the new principal-agent relationship.

3 Description of the models

This paper mainly discusses the incentives among the dispatching unit, the accepting entity and the dispatched employee in labour dispatch. The operation process in reality is that the accepting entity signs the agreement with the dispatching unit, and the dispatching unit signs the contract with the dispatched employee. The dispatching unit undertakes the training of the employees in expectation of improving their working ability, and then dispatches qualified employees to the accepting entity. The accepting entity pays some money to the employees and the dispatching unit according to the achievement of the dispatched employees. This paper mainly makes a study on the incentives of skill-oriented dispatched employees on the basis of double moral hazard (i.e. when the work ability is larger than the elastic coefficient work effort). For the convenience of research, following assumptions are made about the models:

1. Suppose that $f(\mathrm{e})$ is the output function of effort e, according to the actual situation, it should meet the requirement $f'(\mathrm{e}) \succ 0$, signifying that the more effort the dispatched employee and the dispatching unit make, the larger the output of the accepting entity. If the equation is $f''(\mathrm{e}) \le 0$, it signifies that the effort's marginal output is digressive (The equal sign signifies the marginal output is invariant). To simplify the assumption, here let the equation be $f_1(\mathrm{e}_1)=f_2(\mathrm{e}_2)=\mathrm{e}$.

2. Let $f_2(\mathrm{e}_2)$ be the function of the improvement of the dispatched employee's quality influenced by the effort e_2 of the dispatching unit. Let the coefficient of the dispatching unit's training ability be A_2, and its effort degree is e_2, both of which will directly influence the coefficient of the dispatched employee's working ability A_1. Moreover, A_1 will be influenced by the employee's original working ability d, that is, $A_1 = df_2(A_2, \mathrm{e}_2)$, thus $A_1 = dA_2 e_2$. The cost function of the dispatching unit's effort is $\mathrm{C}_2(\mathrm{e}_2) = \frac{b_2 \mathrm{e}_2^{\,2}}{2}$, and here b_2 is the cost coefficient of the dispatching unit's effort.

3. Suppose that the output function of the dispatched employee's effort for the accepting entity is $f_1(\mathrm{e}_1)$, and the cost function of the dispatched employee's effort is $\mathrm{C}_1(\mathrm{e}_1) = \frac{b_1 \mathrm{e}_1^{\,2}}{2}$, and here b_1 is the cost coefficient of the employee's effort.

4. The dispatching unit's training effort will influence the dispatched employee's working ability, and the working ability and working effort of the dispatched employee will directly influence the output level of the accepting entity. That is to say, the dispatching unit's training effort and the dispatched employee's working effort will directly influence the employee's output level. In this paper, let the output be based on the simplified Cobb-Douglas function, and the working ability and the working effort of the dispatched employee will exert different degrees of influence on the output. Let the dispatched employee's output be

$$Q = kA_1 e_1^{\alpha} + \varepsilon = kdA_2 \mathrm{e}_2 e_1^{\alpha} + \varepsilon . \quad (1)$$

Here, let the elastic coefficient of the dispatched employee's working ability be 1, and α is the elastic coefficient of the dispatched employee's effort for output, and also $0 < \alpha < 1$ (for details see the reduction of the

value range of α attached to this paper); ε is a random variable, and let it be accordant to the normal distribution $(0,\sigma^2)$, and suppose that the average revenue of the accepting entity's product is m, that is, the total revenue of the accepting entity is Qm;

5. In order to obtain the job opportunity provided by the dispatching unit, the dispatched employee needs to pay the fee v to the accepting entity while signing the employment contract with the dispatching unit.
6. The dispatching unit's revenue is directly connected with the dispatched employee's output level. The accepting entity pays the dispatching unit according to the proportion of the dispatched employee's output and income μ_1, therefore the dispatching unit's revenue is $\mu_1 Qm$. The income of the dispatched employee consists of regular wage and performance bonus. The accepting entity pays regular wage ω to the dispatched employee. The dispatching unit pays performance bonus to the dispatched employee according to its proportion of revenue μ_2. Thus the dispatched employee's income is $\omega+\mu_1\mu_2 Qm$.
7. Suppose that the accepting entity, the dispatching unit and the dispatched employee are all risk neutral.
8. This paper analyses the dispatching unit's function as the intermediary agent from the perspective of the dispatching unit, consequently taking the dispatching unit as the first principal and the accepting entity as the second principal.

Based on the above assumptions, the utility functions of the accepting entity, the dispatching unit and the dispatched employee can be concluded respectively as follows:

$$\pi_{the\ emplyer} = (1-\mu_1)kdA_2e_2e_1^{\alpha}m-\omega, \tag{2}$$

$$\pi_{the\ accepting} = \mu_1(1-\mu_2)\ kdA_2e_2e_1^{\alpha}m-\frac{1}{2}b_2e_2^{\ 2}+v, \tag{3}$$

$$\pi_{the\ dispatched} = \mu_1\mu_2 kdA_2e_2e_1^{\alpha}m+\omega-\frac{1}{2}b_1e_1^{\ 2}-v. \tag{4}$$

In the relationship of the three parties in labour dispatch, the accepting entity is the principal, the dispatching unit's training effort will influence the dispatched employee's working ability, and the working ability and effort of the dispatched employee will directly influence the accepting entity's actual output. Therefore, attention should be paid to the accepting entity's pursuit of maximizing its self-interest, the dispatched employee's incentive compatibility constraint and participation constraint, and also the maximizing interest of the dispatching unit. This paper carries on the research from the perspective of the dispatching unit, consequently taking the dispatching unit as the first principal and the accepting entity as the second principal. Thus, the following bi-level programming model is concluded:

$$\max_{\{\mu_2,e_2\}}\ \pi_{the\ employer}=\mu_1(1-\mu_2)kdA_2e_2e_1^{\alpha}m-\frac{1}{2}b_2e_2^{\ 2}+v, \tag{5}$$

$$s.t.\ \max_{\{\mu_1\}}\ \pi_{the\ accepting}=(1-\mu_1)kdA_2e_2e_1^{\alpha}m-\omega, \tag{6}$$

$$s.t.\ \ e_1\in \arg\max\ \mu_1\mu_2 kdA_2e_2e_1^{\alpha}m+\omega-\frac{1}{2}b_1e_1^{\ 2}-v, \tag{7}$$

$$\mu_1\mu_2 kdA_2e_2e_1^{\alpha}m+\omega-\frac{1}{2}b_1e_1^{\ 2}-v\geq s_1. \tag{8}$$

Let $R=kdA_2m$.

From equation (3) we get:

$$e_1^{o}=\left(\frac{\alpha\mu_1\mu_2\,\mathrm{Re}_2}{b_1}\right)^{\frac{1}{2-\alpha}}. \tag{9}$$

Substitute Eq. (9) and Eq. (8) into Eq. (6), we obtain:

$$\pi_{the\ accepting}=\frac{\mathrm{R}^{\frac{2}{2-\alpha}}e_2^{\frac{2}{2-\alpha}}\alpha^{\frac{\alpha}{2-\alpha}}\mu_1^{\frac{\alpha}{2-\alpha}}\mu_2^{\frac{\alpha}{2-\alpha}}}{2b_1^{\frac{\alpha}{2-\alpha}}}(2-2\mu_1+2\mu_1\mu_2-\alpha\mu_1\mu_2)-s_1-v. \tag{10}$$

From (10) we get

$$\frac{\partial\pi_{the\ accepting}}{\partial\mu_1}=\frac{\mathrm{R}^{\frac{2}{2-\alpha}}e_2^{\frac{2}{2-\alpha}}\alpha^{\frac{\alpha}{2-\alpha}}\mu_2^{\frac{\alpha}{2-\alpha}}}{2b_1^{\frac{\alpha}{2-\alpha}}}\cdot$$

$$\left[\frac{\alpha}{2-\alpha}\mu_1^{\frac{2\alpha-2}{2-\alpha}}(2-2\mu_1+2\mu_1\mu_2-\alpha\mu_1\mu_2)+\mu_1^{\frac{\alpha}{2-\alpha}}(2\mu_2-2-\alpha\mu_2)\right]$$

Let $\frac{\partial\pi_{the\ accepting}}{\partial\mu_1}=0$, then:

$$\mu_1^{o}=\frac{\alpha}{2+\alpha\mu_2-2\mu_2}. \tag{11}$$

Substitute Eq. (9) and Eq. (11) into Eq. (5), we obtain:

$$\pi_{the\ employer}=\frac{\alpha^{\frac{2+\alpha}{2-\alpha}}\mathrm{R}^{\frac{2}{2-\alpha}}e_2^{\frac{2}{2-\alpha}}(\mu_2^{\frac{\alpha}{2-\alpha}}-\mu_2^{\frac{2}{2-\alpha}})}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}}(2+\alpha\mu_2-2\mu_2)^{\frac{2}{2-\alpha}}}-\frac{1}{2}b_2e_2^2+v. \tag{12}$$

From (12) we get

$$\frac{\partial\pi_{the\ employer}}{\partial\mu_2}=\frac{\alpha^{\frac{4}{2-\alpha}}\mathrm{R}^{\frac{2}{2-\alpha}}e_2^{\frac{2}{2-\alpha}}\mu_2^{\frac{2\alpha-2}{2-\alpha}}}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}}(2+\alpha\mu_2-2\mu_2)^{\frac{4-\alpha}{2-\alpha}}(2-\alpha)}(2+\alpha\mu_2-4\mu_2). \tag{13}$$

Let $\frac{\partial\pi_{the\ employer}}{\partial\mu_2}=0$, then: $\mu_2^{o}=\frac{2}{4-\alpha}$. (14)

From (13) we get

$$\frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2^2} = \frac{\alpha^{\frac{4}{2-\alpha}} \mathrm{R}^{\frac{2}{2-\alpha}} e_2^{\frac{2}{2-\alpha}} \mu_2^{\frac{\alpha}{2-\alpha}}}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}} (2-\alpha)^2 (2+\alpha\mu_2-2\mu_2)^{\frac{4}{2-\alpha}}}$$
$$[(\frac{4\alpha-4}{\mu_2}+\alpha^2-4\alpha)(2+\alpha\mu_2-2\mu_2) \quad . \quad (15)$$
$$+(2+\alpha\mu_2-4\mu_2)(8-6\alpha+\alpha^2)]$$

From (14) and (15), we get

$$\frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2^2}\Big|_{\mu_2=\mu_2^o} = -\frac{\alpha^{\frac{4}{2-\alpha}} \mathrm{R}^{\frac{2}{2-\alpha}} e_2^{\frac{2}{2-\alpha}} (\frac{2}{4-\alpha})^{\frac{\alpha}{2-\alpha}}}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}} (2-\alpha)^2 (\frac{4}{4-\alpha})^{\frac{2+\alpha}{2-\alpha}}} (\alpha-2)(\alpha-4) \quad . \quad (16)$$

From (12) we get

$$\frac{\partial \pi_{the\ employer}}{\partial e_2} = \frac{\alpha^{\frac{2+\alpha}{2-\alpha}} R^{\frac{2}{2-\alpha}} \mu_2^{\frac{\alpha}{2-\alpha}} (1-\mu_2)}{b_1^{\frac{\alpha}{2-\alpha}} (2+\alpha\mu_2-2\mu_2)^{\frac{2}{2-\alpha}}} \cdot \frac{2}{2-\alpha} e_2^{\frac{\alpha}{2-\alpha}} - b_2 e_2 \quad . \quad (17)$$

Let $\frac{\partial \pi_{the\ employer}}{\partial e_2}=0$, then

$$e_2^o = \frac{\alpha^{\frac{2+\alpha}{2-2\alpha}} R^{\frac{2}{2-2\alpha}} \mu_2^{\frac{\alpha}{2-2\alpha}} (1-\mu_2)^{\frac{2-\alpha}{2-2\alpha}} (\frac{2}{2-\alpha})^{\frac{2-\alpha}{2-2\alpha}}}{b_2^{\frac{2-\alpha}{2-2\alpha}} b_1^{\frac{\alpha}{2-2\alpha}} (2+\alpha\mu_2-2\mu_2)^{\frac{2}{2-2\alpha}}} \quad . \quad (18)$$

From (17) we get

$$\frac{\partial^2 \pi_{the\ employer}}{\partial e_2^2} = \frac{\alpha^{\frac{2+\alpha}{2-\alpha}} R^{\frac{2}{2-\alpha}} \mu_2^{\frac{\alpha}{2-\alpha}} (1-\mu_2)}{b_1^{\frac{\alpha}{2-\alpha}} (2+\alpha\mu_2-2\mu_2)^{\frac{2}{2-\alpha}}} \cdot \frac{2}{2-\alpha} \cdot \frac{\alpha}{2-\alpha} e_2^{\frac{2\alpha-2}{2-\alpha}} - b_2 \quad . \quad (19)$$

From (18) and (19), we get

$$\frac{\partial^2 \pi_{the\ employer}}{\partial e_2^2}\Big|_{e_2=e_2^o} = b_2 \frac{2\alpha-2}{2-\alpha} \quad . \quad (20)$$

From (13) we get

$$\frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2 \partial e_2} = \frac{\alpha^{\frac{4}{2-\alpha}} \mathrm{R}^{\frac{2}{2-\alpha}} \mu_2^{\frac{2\alpha-2}{2-\alpha}} (2+\alpha\mu_2-4\mu_2)}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}} (2+\alpha\mu_2-2\mu_2)^{\frac{4-\alpha}{2-\alpha}} (2-\alpha)} \cdot \frac{2}{2-\alpha} e_2^{\frac{\alpha}{2-\alpha}} \quad . \quad (21)$$

From equation (14), (18) and (21) we get:

$$\frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2 \partial e_2}\Big|_{\mu_2=\mu_2^o, e_2=e_2^o} = 0 \quad . \quad (22)$$

From above we get: $A = \frac{\partial^2 \pi_{the\ employer}}{\partial e_2^2}\Big|_{e_2=e_2^o} = b_2 \frac{2\alpha-2}{2-\alpha}$;

$$B = \frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2 \partial e_2}\Big|_{\mu_2=\mu_2^o, e_2=e_2^o} = 0 \quad .$$

$$C = \frac{\partial^2 \pi_{the\ employer}}{\partial \mu_2^2}\Big|_{\mu_2=\mu_2^o} = -\frac{\alpha^{\frac{4}{2-\alpha}} \mathrm{R}^{\frac{2}{2-\alpha}} e_2^{\frac{2}{2-\alpha}} (\frac{2}{4-\alpha})^{\frac{\alpha}{2-\alpha}}}{\mathrm{b}_1^{\frac{\alpha}{2-\alpha}} (2-\alpha)^2 (\frac{4}{4-\alpha})^{\frac{2+\alpha}{2-\alpha}}} (\alpha-2)(\alpha-4) \quad . \quad (23)$$

According to the necessary and sufficient condition to determine the binary function's extremum, only when $AC-B^2>0$, the binary function has the extreme point; only when $A<0$, it has the maximum value

From $A<0$ we get: $\begin{cases}2\alpha-2>0\\2-\alpha<0\end{cases}$ or $\begin{cases}2\alpha-2<0\\2-\alpha>0\end{cases}$ that is:

$\alpha>2$ or $\alpha<1$. (24)

From $C<0$, we get: $\begin{cases}\alpha-2>0\\\alpha-4>0\end{cases}$ or $\begin{cases}\alpha-2<0\\\alpha-4<0\end{cases}$ that is:

$\alpha>4$ or $\alpha<2$. (25)

Simultaneous equations (24) and (25), then:

$\alpha>4$ or $\alpha<1$. (26)

Since μ_1 and μ_2 are the sharing ratios, then the ranging scope is $[0,1]$.

From (12) we get: $\mu_2^o = \frac{2}{4-\alpha}$, thus $\alpha<2$. (27)

From equations (9) and (12) we get:

$$\mu_1^{\ o} = \frac{\alpha}{2+\alpha(\frac{2}{4-\alpha})-2(\frac{2}{4-\alpha})} = \frac{\alpha(4-\alpha)}{4} \quad . \quad (28)$$

Thus $0<\alpha<4$. (29)

Consider equations (26), (27) and (29) at the same time we get:

If and only if $0<\alpha<1$, this model achieve it optimum.

Proposition 1:

Under the double moral hazard, the sharing ratios, optimal effort degree and revenues of the dispatching

unit, the accepting entity and the dispatched employee are respectively as follows:

$$\mu_2^o = \frac{2}{4-\alpha};\ \mu_1^o = \frac{\alpha(4-\alpha)}{4};\ e_2^o = \frac{\alpha^{\frac{2+\alpha}{2-2\alpha}} R^{\frac{2}{2-2\alpha}}}{2^{\frac{2}{2-2\alpha}} b_2^{\frac{2-\alpha}{2-2\alpha}} b_1^{\frac{\alpha}{2-2\alpha}}};$$

$$e_1^o = \frac{\alpha^{\frac{3}{2-2\alpha}} R^{\frac{2}{2-2\alpha}}}{2^{\frac{2}{2-2\alpha}} b_2^{\frac{1}{2-2\alpha}} b_1^{\frac{1}{2-2\alpha}}};$$

$$\omega^o = s_1 + v + \frac{\alpha^{\frac{4+2\alpha}{2-2\alpha}} R^{\frac{4}{2-2\alpha}}}{2^{\frac{6-2\alpha}{2-2\alpha}} b_2^{\frac{2}{2-2\alpha}} b_1^{\frac{2\alpha}{2-2\alpha}}}(\alpha-2);$$

$$\pi_{\text{the employer}} = \frac{\alpha^{\frac{4+2\alpha}{2-2\alpha}} R^{\frac{4}{2-2\alpha}}(1-\alpha)}{2^{\frac{6-2\alpha}{2-2\alpha}} b_2^{\frac{2}{2-2\alpha}} b_1^{\frac{2\alpha}{2-2\alpha}}} + v;$$

$$\pi_{\text{the accepting}} = \frac{\alpha^{\frac{4+2\alpha}{2-2\alpha}} R^{\frac{4}{2-2\alpha}}}{2^{\frac{6-2\alpha}{2-2\alpha}} b_2^{\frac{2}{2-2\alpha}} b_1^{\frac{2\alpha}{2-2\alpha}}} \cdot \frac{2(2-\alpha)}{\alpha} - s_1 - v \qquad (30)$$

Also, from the above we get:

$$\frac{\partial \mu_2^o}{\partial \alpha} = \frac{2}{(4-\alpha)^2} > 0\ ;\ \frac{\partial \mu_1^o}{\partial \alpha} = \frac{2-\alpha}{2} > 0\,. \qquad (31)$$

Proposition 2:

The sharing ratios paid by the accepting entity to the dispatching unit and paid by the dispatching unit to the dispatched employee will increase with the increase of the dispatched employee's effort degree.

4 Conclusion

This paper makes an analysis of the incentives of skill-oriented dispatched employees based on the bi-level program (i.e. when the work ability is stronger than the work effort) while taking the dispatching unit as the first principal and the accepting entity as the second principal under the circumstances of double moral hazard. The sharing revenues of the three parties are manifested through the models. The author wishes it a valuable reference to the practice of the enterprises.

Comparative study of personalizing recommender systems based on shopping system

Zhihang Tang, Zhonghua Wen

School of Computer and Communication, Hunan Institute of Engineering Xiangtan 411104, China

Abstract

Making choices is an integral part of everyday life; Recommender systems facilitate decision-making processes through informed assistance and enhanced user experience. To aid in the decision-making process, recommender systems use the available data on the items themselves, Personalized recommender systems subsequently use this input data, and convert it to an output in the form of ordered lists or scores of items in which a user might be interested. These lists or scores are the final result the user will be presented with, and their goal is to assist the user in the decision-making process. Recommender systems facilitate making choices, improve user experience, and increase revenue, therefore should be easily accessible for deployment to interested parties. The implementation of recommender systems in RapidMiner has been additionally simplified through the Recommender Extension.

Keywords: shopping system, personalized recommender systems, RapidMiner, decision-making

1 Introduction

Recommender systems have become extremely common in recent years, and are applied in a variety of applications. The most popular ones are probably movies, music, news, books, research articles, search queries, social tags, and products in general. However, there are also recommender systems for experts, jokes, restaurants, financial services, life insurance, persons (online dating), and twitter followers [1].

Recommender systems typically produce a list of recommendations in one of two ways – through collaborative or content-based filtering [2]. Collaborative filtering approaches build a model from a user's past behavior (items previously purchased or selected and/or numerical ratings given to those items) as well as similar decisions made by other users; then use that model to predict items (or ratings for items) that the user may have an interest in [3].

Content-based filtering approaches utilize a series of discrete characteristics of an item in order to recommend additional items with similar properties. These approaches are often combined (see Hybrid Recommender Systems).

Each type of system has its own strengths and weaknesses. In the above example, Last.fm requires a large amount of information on a user in order to make accurate recommendations. This is an example of the cold start problem, and is common in collaborative filtering systems. While Pandora needs very little information to get started, it is far more limited in scope (for example, it can only make recommendations that are similar to the original seed). Recommender systems are a useful alternative to search algorithms since they help users discover items they might not have found by themselves. Interestingly enough, recommender systems are often implemented using search engines indexing non-traditional data. Montaner provides the first overview of recommender systems, from an intelligent agents perspective [4]. Adomavicius provides a new overview of recommender systems [5]. Herlocker provides an additional overview of evaluation techniques for recommender systems [6]. They also provide a literature survey on research paper recommender systems [7].

Recommender system is an active research area in the data mining and machine learning areas. Some conferences such as RecSys, SIGIR, KDD have it as a topic.

2 Basic conception

2.1 RECOMMENDATION OPERATORS

The Recommender Extension has a total 26 recommendation operators. These operators are grouped in the following categories: Item Recommendation, Item Rating Prediction, and Recommender Performance.

Item recommendation operators operate over large matrices that contain information about which user consumed which item. These input matrices often contain large numbers of empty entries, and can thus be used in a more space-efficient way. We describe the appropriate format used for efficient data loading and storage in the next subsection.

2.2 DATA

Typical recommender systems, operating on user usage data, are built on top of large matrices called utility matrices. These matrices usually contain elements from a limited set of numbers, for example from 0, 1, 2, 3, 4, 5, where 0 typically denotes that the user had no interaction with the item, and the rest describes the level of that

interaction in a form of rating. Due to a large number of both users and items, these matrices are typically very large. In addition, since users mostly consume a very small portion of items out of the total number of items, these matrices tend to contain a lot of zeros-they tend to be very sparsely populated. This is why special data structures for handling sparse data need to be implemented. In RapidMiner, we can use AML reader operators to read such datasets. Input datasets used to learn a recommender system model must be formatted in two columns; for example, the first column can contain user IDs, while the second can contain item IDs. Attributes names, and their positioning can be arbitrary. Prior to applying recommenddation operators to input datasets, proper roles have to be set for these attributes. Any additional attributes will not be considered. An example of an AML, and a related DAT file for item recommendation operators is given in Fig. 1.

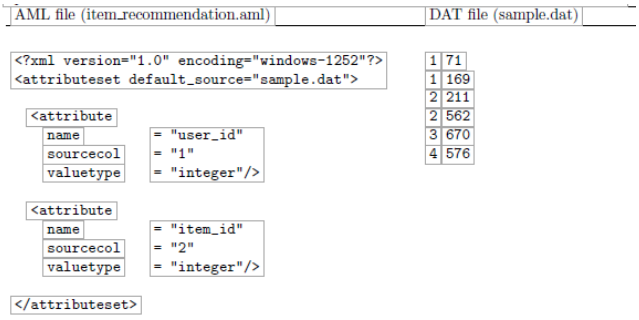

FIGURE 1 An example of an AML and a related DAT file for item recommendation operators

The recommender system datasets used throughout this paper consists of content and collaborative data. Content data was taken from the shopping system.

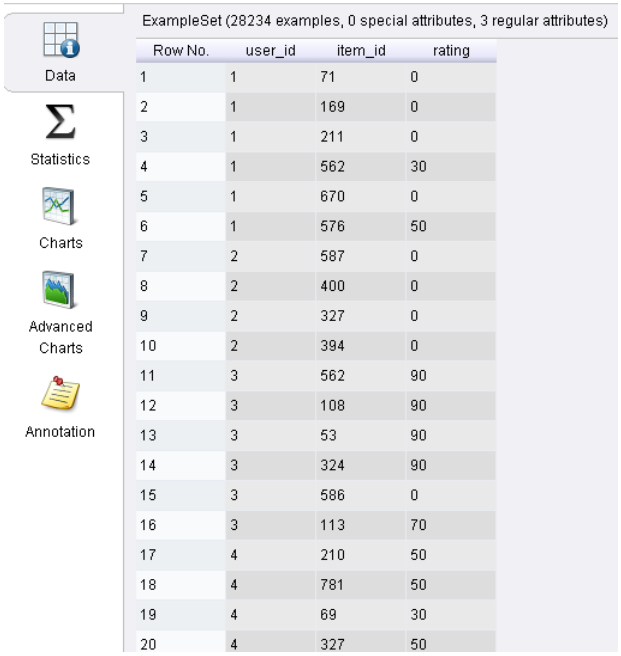
The content dataset described contains the following content attributes for each item:

brand ID: a unique integer that represents a lecture;

brand name: a text string containing a name of a particular lecture;

brand description: a text string denoting a description of a particular lecture.

A particular item identifier is denoted by the small letter i and the set of all items is denoted by the capital letter I. Collaborative data contains synthetic click streams of users, where each click stream is a sequence of items viewed by a particular user in some time interval. In the following text, we refer to the synthetic users as users. A particular user identifier is denoted by the small letter u and the set of all users is denoted by the capital letter U. Click streams are transformed into the sparse matrix A, which is called the usage matrix. The non-zero elements of the usage matrix (A (i, u)) tell us that the item i was consumed by the user u. Using this dataset, we construct collaborative and content recommender systems in the following sections. The collaborative recommender systems rely on the usage matrix A while the content recommender systems rely on items textual descriptions. We can get Fig. 2.



Row No.	user_id	item_id	rating
1	1	71	0
2	1	169	0
3	1	211	0

FIGURE 2 Initial data from shopping system

2.3 COLLABORATIVE-BASED SYSTEMS

The main idea of collaborative recommendation approaches is to use information about the past behavior of existing users of the system for predicting which item the current user will most probably like and thus might consume. Collaborative approaches take a matrix of given user-item ratings or viewings as an input and produce a numerical prediction indicating to what degree the current user will like or dislike a certain item, or a list of n recommended items. The created list should not contain items the current user has already consumed.

Neighborhood-based recommender systems work by counting common items two users have viewed for every pair of users in the system, or the number of common users that viewed the same pair of items. Using this count, similarity between two users or items is calculated. Neighborhood systems use intuition that two users who have viewed a large number of common items have similar tastes. That information can be used to recommend items that one user consumed and the other one did not. We are interested in finding pairs of users having the most similar taste, or pairs of items having the most users that viewed both items. Those pairs of users/items are called "the closest neighbors". We describe two main approaches of the neighborhood-based recommender systems: user and item-based nearest neighbor recommendation.

2.3.1 User-based nearest neighbor recommendation

Given a user-item viewing matrix and the ID of the current user as input, identify other users having similar past prefe-

rences to those of the active user. Subsequently, for every product the active user has not yet consumed, compute prediction based on the product usage of the selected user subset. These methods assume that users, who have previously shared similar tastes, will share similar tastes in the future, and that user preferences remain stable and constant over time.

To calculate similarity between users, two typical similarity measures are used: the Pear- son correlation and the Cosine correlation [6]. In our item recommendation problem we used cosine correlation as a similarity measure. Typically, we do not consider all users in the database when calculating user similarity, rather the k most similar ones.

2.3.2 Item-based nearest neighbor recommendation

When dealing with large problems, consisting of millions of users, user-based collaborative filtering approaches lead to increased memory usage and execution time. Since the system is required to calculate a large volume of potential neighbors, it becomes impossible to compute predictions in real time. In some cases, the number of users dominates the number of items in the system so it would be natural to try to use items for making recommendations. That is the reason for creating a second neighborhood-based recommender system based on items instead of users.

As opposed to the user-based approach, the item-based recommendation approach computes prediction using the similarity between items. We use a cosine similarity measure, as we did in the user-based approach. Likewise, as in the user-based approach, we use k-nearest neighbors, i.e. the k most similar items for prediction.

3 Personalizing Recommender Systems

Collaborative recommender operators use the user-item matrix to build a recommendation model. This user-item matrix is presented as an example set of user-item pairs describing user consumption history. The recommendation model built with this matrix is used to recommend items to users from a query set. The query set is an example set containing identification numbers of users for which we want to make recommendations. For each user in the query set we recommend only the items not consumed by this user. Figure 3 depicts a basic collaborative recommender operator workflow.

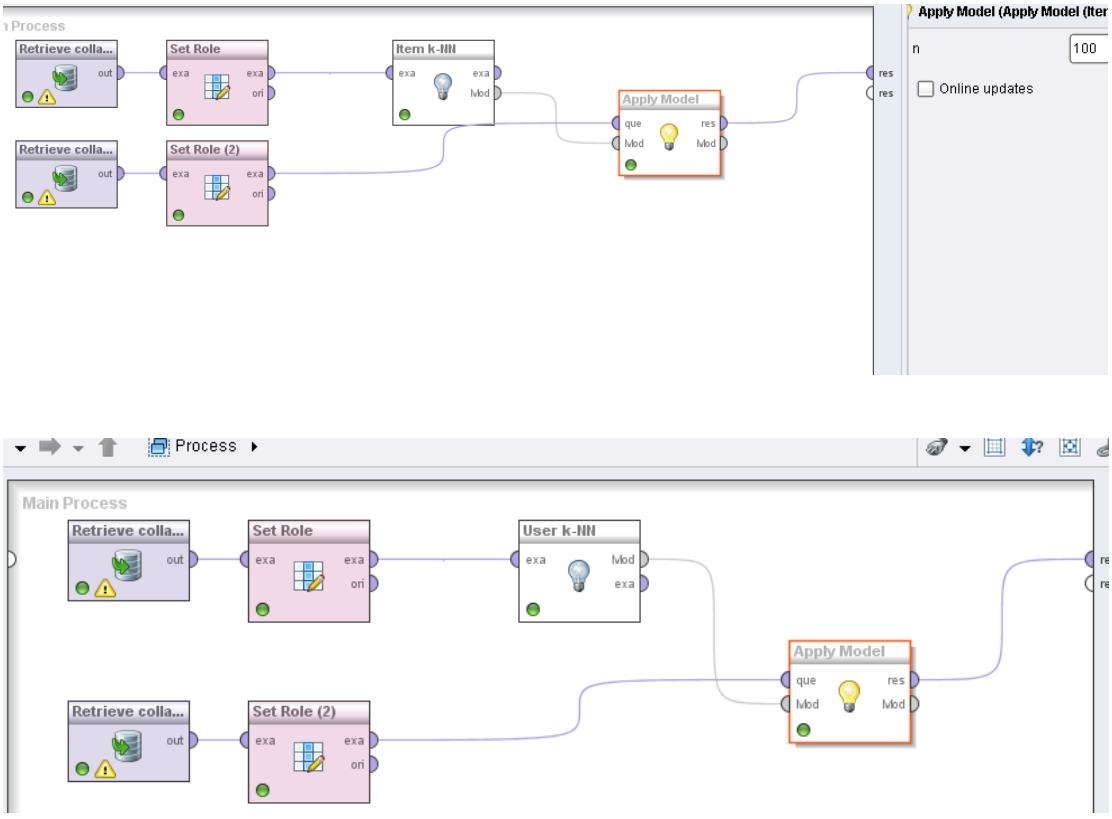

FIGURE 3 Two examples of an item recommendation workflow

The Recommended results shown in Figure 4.

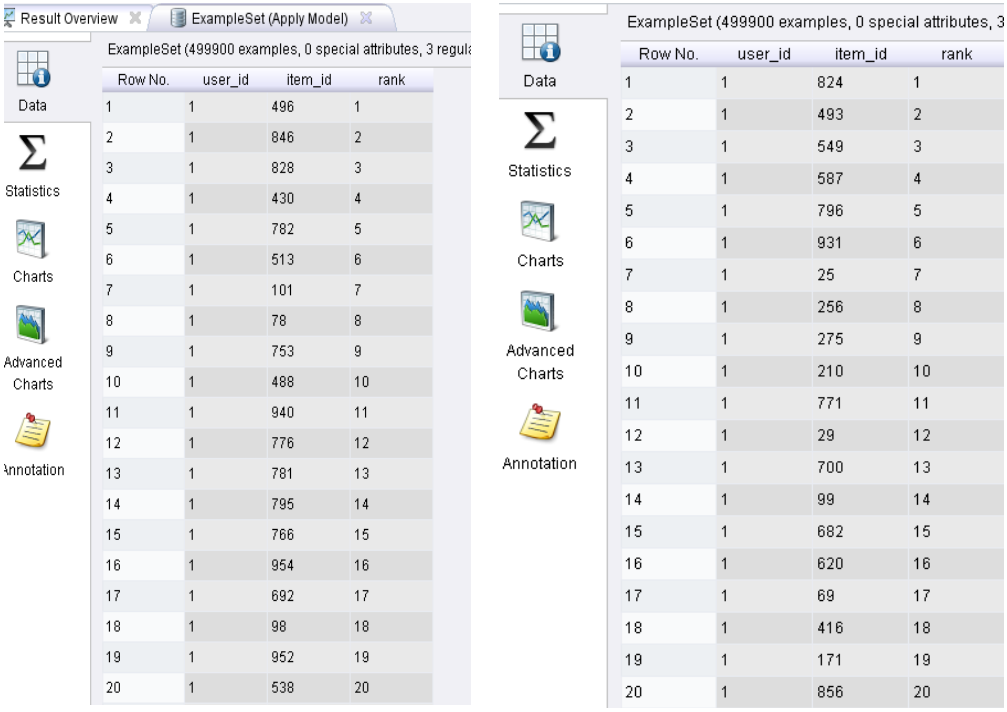

FIGURE 4 Comparative study of the recommended results

In the item recommendation workflow, the first two operators read the train and the query example sets using the Read AML operators (1,4). Following, the appropriate roles are set to attributes using the Set Role operator (2). The user identification role was set to user id attribute and item identification role to item id attribute. Data attributes can have arbitrary names but roles for those attributes must be set. Next, we use the train data with the appropriately set roles to train an Item k-NN model (3). At this point we can use our trained model to recommend new items to users in the query set using the Apply Model operator (6). Prior to model application, the user identification role was set for the query set (5). The Apply Model operator (6) returns an example set containing the first n ranked recommendations for every user in a query set. In Figure 3 we have seen how to make recommendations for particular users. In the following figure, Figure 4, we show how to measure performance of a recommendation model.

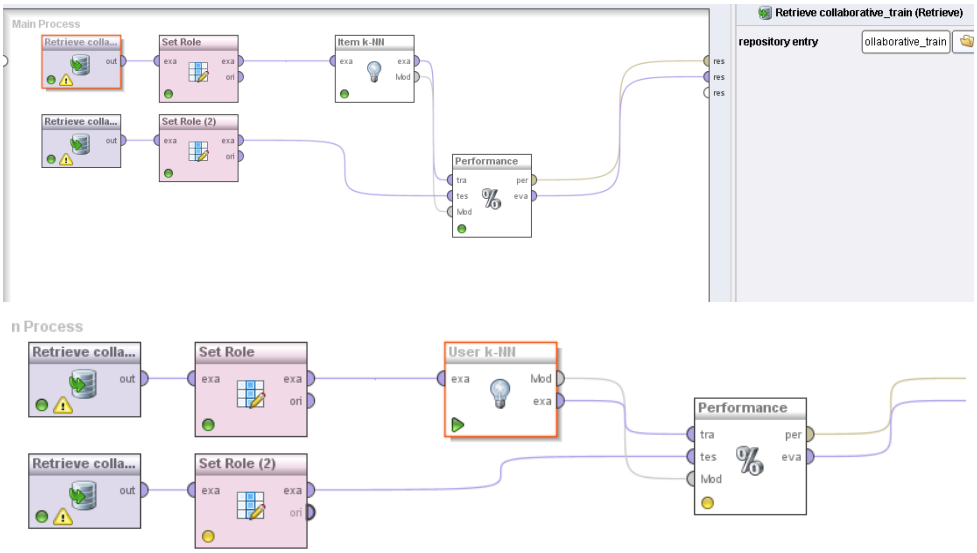

FIGURE 5 Comparative study of measuring performance of a recommendation model

The data management part of the workflow for measuring recommender model performance in Figure 5 is the same as in Figure 3. We use the Read AML operators (1,4) to load the data input, and the Set Role operators (2,5) to set the appropriate roles. In this workflow we use the test data (4) containing two attributes, the user id and the item id attribute and we set user identification and item identification roles to those at-tributes, respectively. The difference from the previous workflow is the need to calculate the performance of our built recommendation model (3). We use the Performance operator (6) to measure standard recommendation error measures we previously defined: AUC, Prec@k, NDCG, and MAP. The Performance operator (6) returns a performance vector and an example set containing performance measures. This enables a user to choose which format suits his or her needs. We can get Figure 6.

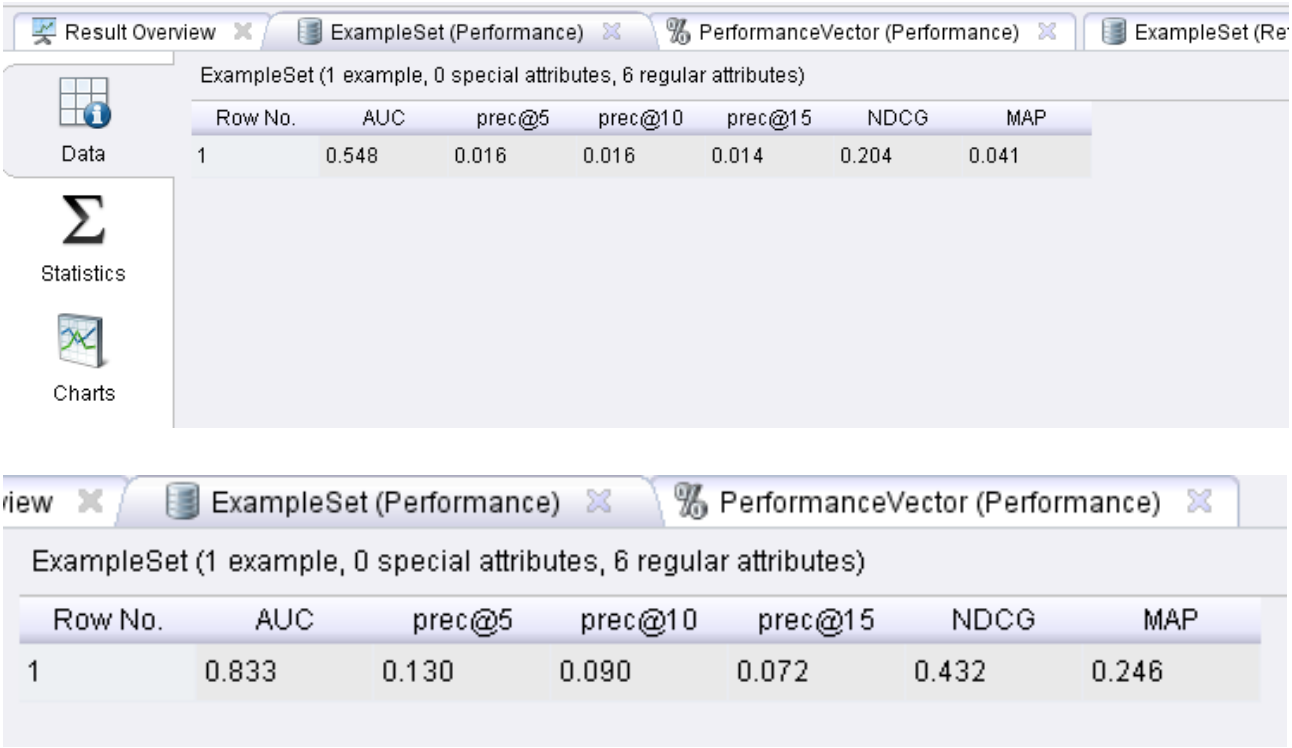

FIGURE 6 Comparative study of the performance of recommender systems

4 Conclusions

Recommender systems became essential in an information- and decision-overloaded world. They changed the way users make decisions, and helped their creators to increase revenue at the same time. Bringing recommender systems to a broader audience is essential in order to popularize them beyond the limits of scientific research and high technology entrepreneurship. The goal of the Recommender Extension for RapidMiner and this paper was to bring recommenders to a broad audience, in a theoretical, practical, and above all, application way.

In this paper we presented recommender systems and their different techniques: collaborative filtering, content-based recommender systems, and hybrid systems. We presented the advantages and disadvantages of each of those systems and demonstrated how they could be implemented easily in RapidMiner. The application of recommender systems outlined was just a small introduction to the possibilities of the extension. We hope you will use the knowledge obtained through this paper in your own applications, problems, and businesses, and that recommender systems will assist you in reaching quality, informed decisions.

Analysis on Ideological and Political Teaching Curriculum Design and Information Transfer Based on Complex Adaptive System Theory

Caihong Zhang*

Xi'an Physical Education University, Xi'an, 710068, China

Received x xx 2014, www.cmnt.lv

Abstract

In the field of technology, based on scholar's research results of instructional system design complexity, this paper discussed the development of instructional system design thought. It also analyzed the basic framework of ideological and political teaching curriculum design based on complex adaptive system.

Keywords: system, complexity, instructional design

1 Introduction

With the development of modern science and technology, informatization and networkization have become the trend of Chinese development. At the same time, with the development of Chinese higher education from elite to mass, the increased enrollment and building of colleges and universities, and running a school of multi-campus, teachers of ideological and political lessons have the reality of "mobile-mode of teaching" in teaching practices. The extracurricular contact time between political and ideological lesson teachers and students is lesser. Then students' consolidation and review of knowledge are total by themselves. However, such kind of way will cause lack of deep understanding on ideological and political lessons. In addition, students have strong material gaining attitude on learning, which causes students are to learn for examination. Therefore, as for how to utilize after class time in high efficiency has become another key point of teaching methods in ideological and political course of colleges and universities. Fro example, to strengthen the coaching of students to ideological and political course; to deepen students' understanding on knowledge of ideological and political course; to develop student's ability of logical thinking and to enhance the instruction effect of ideological and political course. With the help of researches of scholars in educational technology field on the complexity of instructional system design, this paper established ideological and political teaching curriculum design based on complex adaptive system.

2 Complex Adaptive System Theory

Complex adaptive system (CAS) theory put forward by Holland in 1994. CAS refers to the complex dynamical system of subjects improving their own behaviors through study in the process of evolution and development, and they are inter-coordinated, mutual adapted and inter active [1].

Its basic idea is that system is made up of subjects that have their own finality and initiative. Adaptive subject has connected micro and macro world together. In microcosmic aspect, subject can constantly learning in the interaction with environment and other subjects, and changing their own structure and behavioral pattern according to their learned experience, so as to better survival in objective environment, that is the subjective adaptive. In macrocosmic aspect, in interaction between subject and environment, the whole system shows complex evolutionary process. The initiative and adaptation expressed among subject, environment and other subjects are the basic agents of system development and evolution. The evolutions of whole system are all derived on this basis, including the generation, differentiation and appearance of diversity of new hierarchies, and the appearance of larger subjects that generated by new polymerization. This is the core idea of CAS theory-"adaptation creates complexity" [2].

3 Teaching System and Its Design

A. TEACHING SYSTEM AND ITS COMPLEXITY

According to the basic idea of system theory, we regard various educations and teaching organizational form that with the purpose of achieving certain education and teaching objectives and realizing certain education and teaching function as education system or teaching system. Teaching system is the subsystem of education system, which contains four basic elements: teacher, students, textbook and teaching media. It is the premise of system operation and forms the spatial structure of system. The mutual effect, interdependence and interaction among sys-

* ***Corresponding author's*** e-mail: zchongrainbow@163.com

tem elements have constituted the complex operational process between system input and output. American famous educational technical expert, B. H, Banathy thought that teaching system is the hierarchical system complexus. Teaching system is generally divided into four hierarchical systems, which are respectively system in institutional level, management level, teaching level and learning level from high to low [3].

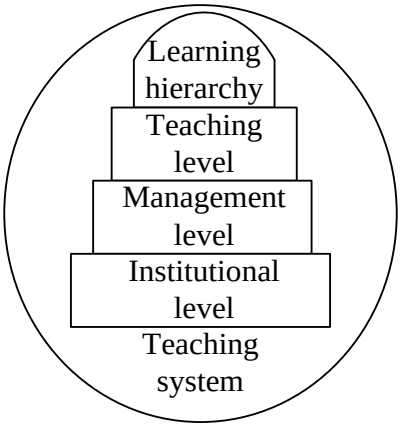

FIGURE.1 hierarchical structure of teaching system

Therefore, seeing from hierarchical structure and function, teaching system has the property and status of "complex".

B. INSTRUCTIONAL SYSTEM DESIGN AND THE COMPLEXITY OF ITS PROCEDURE SCHEMA

Instructional system design (ISD, which is also called teaching design), seeing from the history of the formation of its subject, is a subject that developed with the development of technology based on the integration of multiple theories. As for the definition of the concept of teaching design, different scholars have different opinions. Professor He Kekang [3] thought that teaching design mainly use system approach to convert the principle of learning theory and teaching theory into teaching objectives, teaching content, teaching method and strategy and teaching evaluation, so as to conduct specific planning and creation on the "process" or "procedure" of teaching and learning system. However, the fundamental objective of creating teaching and learning system is to promote students' learning. ISD has the following characteristics: the research object of ISD is learning and teaching system of different hierarchies, which includes the content, condition, resource, method and activity that promote students' learning; ISD refers to research and explore the essential contact among various elements, and element and whole using system method. It also comprehensively consider and coordinate their relations, which organically integrate elements so as to finish the function of teaching system; ISD aims to apply basic theories like learning theory and teaching theory to solve the practical problems of teaching, thus to form the teaching and learning system that has experienced verification and can realize intended functions.

The procedure schema of ISD is a set of programmed steps. The general procedure schema of ISD contains four basic elements: learner, objective, strategy and evaluation (Wu Meina, 1994). Currently, procedure schema of ISD has hundreds of types, of which the ISD schema with operability already has hundreds of types. It development is generally experienced four generations of evolutionary process (ISD1, ISD2, ISD3, ISD4). From the perspective of science of system, its evolutionary process also expresses as "linear cycle–flow chart–cycle in phase and linear out of phase–dynamic interaction network" [4]. We can induce the previous three phases of ISD procedure schema as linear teaching design. However, procedure schema of teaching design at the fourth generation is non-linear teaching design schema that based on the thought of complex adaptive system. There exist apparent differences between the two. We can compare the characteristics between them (as shown in Table 1[5]).

TABLE 1 Comparison of the main characteristics between linear ISD and nonlinear ISD

linear ISD	**nonlinear ISD**
linear, closed, static system	nonlinear, open, dynamic system
Teaching event presents linear causal relationship.	Teaching event presents interactive causal relationship.
Whole is the simple sum of each part.	Whole is not the simple sum of each part.
It can predict the change of learner's cognition and skill.	It can not conduct long-term prediction (butterfly effect). a tiny disturbance may produce unpredictable consequence. Integrate the unpredictable teaching event into the dynamic relation so as to increase its flexibility.
By decomposing the whole into the independent part to conduct analysis, and to simplify the complex teaching system	Part-whole-part…, constant cyclic and timely analysis, especially stress to use anthropological studies to understand the overall characteristics of complex teaching system.
Provide the predesigned teaching objectives and teaching sequence, until teaching is finished. There are seldom other alternative learning paths	Teaching objective is diversified and hierarchical with multiple alternatives of learning paths.
Factors like mistake and disturbance are corrected through negative feedback, which is an important means for maintaining the equilibrium state of teaching system.	Factors like mistake and disturbance are queries, explored and introspected in each level through positive feedback, which promote the constant evolution and development of teaching system and learners.

4 Development of ISD Thought

In long term of exploration, educational technology workers have confirmed the system theory thought as the guiding thought of ISD, considered teaching as system for study and defined system approach as the core method of teaching design. With the development of system theory and the constant deepening of cognition of teaching system, system thought and method used by ISD have successively experienced three phases: definitive linear system, definitive nonlinear system and indefinitive nonlinear sys-

tem. Currently it is developing in the direction of complex adaptive system [6].

The above three system thoughts have possessed the characteristics of some complex thoughts, but it cannot fundamentally solve the problems like the complexity of system, initiative adaptation of system elements and learning ability. Until the put forward of complex adaptive system (CAS), can these problems obtained better reply. CAS thinks that all subjects are in a common political and economic environment, but each part conducts adaptive learning and evolution concurrently and independently according to its surrounding partial microenvironment. Chen Liezun, et al tried to apply CAS thought for carrying out teaching design research and practice based on CAS theory, and also put forward the basic key points of ideological and political teaching curriculum design based on CAS thought [7], as shown in Table 2:

TABLE 2 Key points of ideological and political teaching curriculum design based on CAS

thought framework	**complex theory and CAS thought**
external relationship	It focuses on the social distant imagination. The designation is come forth with the purpose of conscious pursuing and adapting the uncertainty of future society. Its main aim is to culture future social citizens.
knowledge opinion	Knowledge is not only the reflection of objective and dynamic world. It also implicates the passion, faith, conscience and responsibility of human intelligence, which includes explicit knowledge and implicit knowledge. Among knowledge of different types and different subjects, they realize the mutual conversion, sharing, using and creation of knowledge though SECI* process.
Design focus	The creation strengthening of resource, rule, knowledge conversion (teaching platform) and mechanism, and the launch of activity. It attaches importance to practical teaching, extracurricular scientific activity and social practical activity
adaptivity	Subject automatically adapt to environment of indefinitive changes. It has strong environmental adaptability and forms mutual symbiosis with environment. It mainly relies on internal monitoring, automatic regulation and internal incentive.
internal relationship	System design experts provide design resource and conduct common design, interaction and collaborative operation with teachers. It will be much better if teaches are also system design experts. Cyclic, multi-causal relationship, nonlinear relationship and the coexistence of positive and negative feedback require to reform of system itself. The coexistence of self organization with other organization, and the harmonious coexistence of competition and cooperation.
procedure evolution	Teachers and students create together. Subject behavior or system behavior is unknown and cannot be totally predicted or controlled. All students design together and determine the orientation and process of teaching or spontaneously emerged. Keep open attitude to change, and guide by dynamic opinion of environment coordination evolution. Plan interacts with action.
Results assessment	individualized, polybasic, procedural and developed evaluation mode

Teaching system is considered as hierarchical complexus, instead of just staying in decomposing teaching system into teacher, student, teaching content and teaching media. This cognition has reached consensus in field of teaching design. Seeing from China's practical situation, there exist two design orientations: the ISD that defines teaching level as basic level and ISD that considers learning level as basic level. In China's teaching system of class teaching, teaching design with teaching level as basic level occupies leading role. However, in family education, social education, web education and school teaching that centered on student activities, teaching design with learning level as basic level has become the mainstream. At the same time, in other teaching forms, we can also consider institution level and management level as basic level for conducting teaching design.

According to the key points of ideological and political teaching curriculum design of CAS, this paper established the basic framework of ideological and political teaching design based on CAS, as shown in Figure 2.

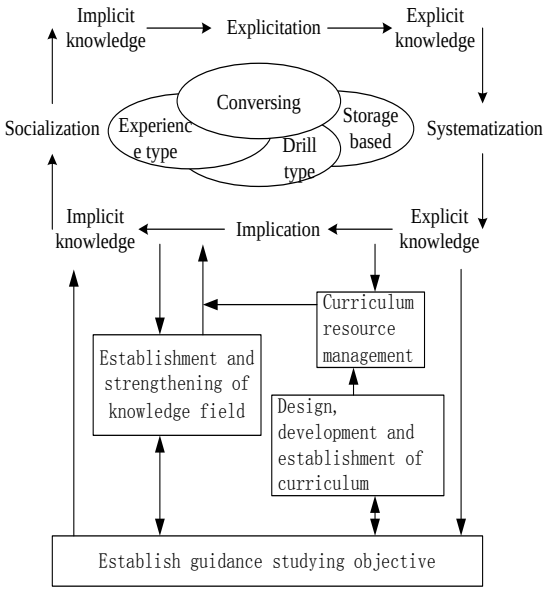

FIGURE. 2 basic framework of ideological and political teaching design based on CAS

Basic framework of ideological and political teaching design based on CAS has the following characteristics:

(1) Stimulate and intensify students' subject adaptation, which makes the inter coordination of demand between system objective and individual development;

(2) Respect the generative of teaching activity, advocate creative learning and culture student's innovation consciousness and ability;

(3) Competition and cooperation are harmoniously coexisted;

(4) Attach importance to the inter conversion and spiral upward of implicit knowledge and explicit knowledge.

5 Conclusion

Seeing from the development of ISD thought, the ideological and political teaching curriculum design based on CAS thought will certainly become the mainstream of ISD. Regard teaching system as hierarchical and stereo complexus, and ISD that respectively with teaching level as basic level and with learning level as basic level are the mainstream in the field of teaching design practice. It is believed that it can play tremendous effect in the future teaching practice, so as to improve the education quality of ideological and political curriculum. In addition, it also provides well reference for other subject educations.

The Attractiveness and Motivation of China's International Investment Based on Positive Investment Inertia

Liming Xiao*, Rui Jing

School of Economics and Management, Shanxi Normal University, Shanxi,, 041004, China

Received x xx 2014, www.cmnt.lv

Abstract

Nowadays, economic globalization is the main trend of world economic development. Each country takes the participation in international investment as a strategy. This paper analyzes China's international investment from the view of investment inertia. Though the attractiveness and motivation of China's investment keeps increasing, the integral development level is low which stays in the stage of zero inertia. The total amount of China's investment is increasing. But the invitation of investment is unreasonable; the short-term investment in foreign country prevails. We seek the strategic asset of developed country eagerly, and prefer to seek the market and resource of developing country.

Keywords: international investment; inertia; attractiveness; motivation

1 Introduction

International investment is the capital movement across the world. It is the investment in foreign country of enterprise, personage or government [1]. Since 21st century, the total amount of investment of each country is increasing rapidly as economic globalization enhancing. And it has become an important strategy to take part in international investment. By now, our international investment can be divided into invite investment and investment abroad. So, it means a lot to our international investment in the future to analyze the investment situation of our country based on the attractiveness, motivation and inertia of international investment which is already existed.

2 Relevant Content of International Investment

2.1 INTERNATIONAL INVESTMENT ATTRACTIVENESS

The international investment attractiveness is the host country's ability to attract and adsorb the capital of investment country. It is an objective economic power exists in the host country to regulate and dominate the orientation of the international capital [2]. The international investment attractiveness varies with the different GNP of each country. The higher GNP, the more powerful the attractiveness is [3]. Besides the GNP, there are some other factors that decide the international investment attractiveness of a country, such as, the country's capital demands condition, the accommodation power to foreign capital and the return on investment in the country.

2. 2 INTERNATIONLA INVESTMENT MOTIVATION

International investment motivation is the investment motivation and ability of one country or area to another [4]. Previous economist thought that investment abroad has direct relation with the situation of the country's economic development. That is to say, the motivation of a country depends directly on GNP, and GNP is the main factor that decides the motivation and attractiveness of investment abroad.

In China, someone put forward the Foreign Direct Investment theory – the theory of meeting each other's demand. They think the reason why international investment appears is both sides has different demands. An actual investment can be done only when both side that taking part in international investment must consider each other's demand [5].

2.3 INTERNATIONAL INVESTMENT INERTIA

International investment inertia is an objective economic phenomenon of international investment. The investment scale and speed of the country or area keeps the same while the international investment motivation, international investment attractiveness and the other economic and politic situation stays unchanged. It is divided into zero international investment inertia and positive international investment inertia. It can also be called the inertia of investment abroad [6]. The capital to invest abroad and continuous investment abroad are the two preconditions.

The international investment inertia theory depends mainly on the PLC (Product Life Cycle) model [7]. It has two basic points. Firstly, it is the original intention of international investment inertia to reduce the cost. Mostly, the investment country has the advantage of technology

* ***Corresponding author's*** e-mail: xlmxiaolm@163.com

and supervision while the host country has location advantage such as low price resource and labor. Secondly, transnational corporation eke out monopoly interest to bring out inertia from investment. The purpose of investment abroad is, to some extent, to prolong the monopoly advantage of the innovation country with the low cost of host country, and meanwhile to strike pirate.

3 Analysis of China's Investment Attractiveness and Motivation

3.1 ANALYSIS OF CHINA'S INVESTMENT ATTRACTIVENESS

We analyze international investment attractiveness with the model of international investment attractiveness, specifically as follow

$$E(a/b) = F(a/b) \cdot \frac{I(a/b) \cdot R(a/b)}{H(a/b)} \quad . \qquad (1)$$

Here: E(a/b) means China's general investment attractiveness coefficient to foreign country; F(a/b) means the ratio of national income per capital between China and target country; R(a/b) means the ratio of bank rate between China and foreign country; I(a/b)means the ratio of return on invest of certain industry between China and foreign country; H(a/b) means the ratio of investment density of certain industry between China and foreign country; Formula (1) shows that China's international investment attractiveness is proportional to the ratio of national income per capita, the return on invest of certain industry and invest density between China and foreign country.

When E (a/b)>1, capital flows into China; When E (a/b) <1, capital flows flow out from China. According to formula (1), we calculated China's international investment attractiveness during 1990 to 2009; the result is shown in Table1.

TABLE 1 Attrativeness coefficient of China's international investment

Year	**1990**	**1991**	**1992**	**1993**	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**
Coefficient	-17.44	NA	5.25	-17.78	-11.25	3.81	-8.38	1.33	-14.84	-13.94
Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009
Coefficient	-5.80	1.72	2.95	1.50	NA	4.45	NA	4.78	4.97	NA

Comment: NA means the data is lacked or the calculated result does not exist.

Table1 shows that in most years before 2001 the attractiveness coefficient is less than 1, which suggests China's lack of international investment attractiveness in those years. That is because, planned economic, the main part of China at that time, low opening degree and defective laws and regulations and policy and measure made economically advanced country not tend to favor China's investment situation. After 2001, the coefficient is more than 1. It suggests China's international investment attractiveness was gradually increasing. Mainly because China accelerated the market economy reform and opening degree, enacted lots of preferential policy to attract foreign capital, perfected investment climate further. That made foreign country looks good of the potential of China's market gradually and increased investment in China.

3.2 THE PROBLEM OF FOREIGN CAPITAL INTRODUCTION

1). The excessive speed of foreign capital introduction; the total amount of invite investment is 17.143billion during 1970-1996.After 1996, we make use of more than 10 billion each year. And we made use of more than 50 billion foreign capital each year after 2007; the invited projects were mostly foreign direct investment [8]. We estimated the relation of the foreign capital we used and GDP, using the ordinary least square method. During 1990-2008, the ratio of invited foreign capital and China's economic growth is 0.57.Every Yuan we invited increased 0.57yuan for GDP. The promotion of invited capital to the economic development was at average level. It suggests the large amount of foreign capital we utilized contributed a little to the economic growth.

2). The industrial structure of invited capital is unreasonable. **(1)** Foreign chose the unreasonable industry and the industry structure was imbalanced. Local administration department emphasized the scale of capital introduction, but they did not take China's industrial structure into consideration .Local government favored short-term benefit. Foreign capital was mostly invested to secondary industry, especially industry which needs less investment, has quick effect, brings high profit, and earns foreign exchange easily, such as manufacturing industry. As to the weak industry whose production cycle is long, such as science and technology, infrastructure, agriculture, etc., got poor investment. **(2)** The area selection of foreign investment is unreasonable either. The west area lags far behind the east area in making use of foreign capital. According to the statistics, at the end of 2008, the east and middle area absorbed 91.47% foreign capital of that year while his west area absorbed only 8.52%. And the development gap of east and west area is about to increase.

3). Capital invitation is in conflict with the development if local enterprise. Foreign investment values China's

preferential policy which make them in the advantageous position. But the local enterprise with less capital and backward technology do not have the preferential policy. They need equal preferential policy. So, the government has to considerate both sides and work out with suitable preferential policy.

4). The investment climate has to be improved; to attract foreign capital, we must have the laws to protect their rights and interests. So they have laws to abide during their operating. But China's laws and regulations are imperfect. And this make the transnational enterprise can't protect them when they get infringed illegally during their operation in China. What's more, though we have accelerated the infrastructure constructor and begin to pay attention to the environmental problem, we still have to perfect ourselves in many aspects.

3.3 ANALYSIS ON CHINA'S INTERNATIONAL INVESTMENT MOTIVATION

International investment motivation is a country's own motivation and ability to invest abroad. The coefficient the international investment motivation is the more investment abroad. So, the motivation coefficient is proportional to the height of the scale of investment abroad. We still use Wang Dongjin's international investment motivation model:

$$D't = \frac{H't(R't + I't)}{2} \quad . \tag{2}$$

Here: D, t stands for the coefficient of China's investment abroad, the bigger it is, the stronger investment motivation; H, t is the coefficient of China's civil investment density variation; R, t is the deposit interest rate of Chinese bank and variation index in a given period; I, t is the variation index of China's civil return of investment in a given period. Formula 2 shows that in a given period, China's motivation of investment abroad is proportional to investment density variation coefficient in the same term, and it is inversely proportional to the average index of return of investment and deposit interest rate. When D, t=1, the international investment motivation stays the same; When D, t>1, the motivation increases; When D, t<1, the motivation decreases. According to formula 2, w calculated the motivation coefficient of China's international investment during 1990 to 2009.See the result in Table 2.

TABLE 2 Motivation coefficient of China's international investment

Year	**1990**	**1991**	**1992**	**1993**	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**
Coefficient	39.40	4.95	0.51	-0.30	-0.59	-0.89	0.70	2.40	-3.60	1.25
Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009
Coefficient	0.93	0.08	2.01	0.21	0.04	0.36	0.68	1.04	1.17	2.35

The analysis of China's international investment motivation and inertia suggests that, though China's international investment motivation is gradually increasing, the motivation coefficient is low and stays at zero investment inertia period .That means China should increase the investment abroad.

3.4 THE PROBLEM OF CHINA'S INVESTMENT ABROAD

1). China's scale of investment abroad is small and scientific and technological investment is weak. It has a lot to do with the backward technology and small capital scale of most Chinese enterprise. What's more, the government attaches little importance to investment abroad. In fact, Chinese enterprise has realized the importance of investment abroad and expending of investment business. Though they have strong motivation to invest abroad, their investment scale was restrained by the limited capital and backward technology. Besides, China has few research institution or industry with advanced technology. Though Chinese university has some advantage on research and development, the research achievement can hardly be turned to productivity.

2). The problem of investment continuity. Abundant capital is needed to invest abroad. And the feasibility and profitability should consider. We should avoid blindness. In 2008, the acquisition of Gibson Iron Mine was strongly opposed by Australian and thus brought great financial lost to Shougang Corporation. In addition, to invest abroad, we should stick to the principal of win-win. Try to benefit our country's development and the host country in the same time. As the earning of investment abroad is not evident in the earlier stage, we should mind the chronicity.

3). The structure of the investment abroad is unreasonable. The investment in advanced country is based on service, as to developing country, it is resource. China's investment is indirect investment mostly. According to the experience of Multinational Corporation, we should transform our indirect investment to direct investment gradually. That will form stronger productive force, increase enterprise income and, as a whole, will promote our country's economic development.

4 Conclusion and Suggestion

The above shows, China is short of international investment attractiveness and motivation, international investment inertia is at zero investment inertia stage. To solve the problems that exist we should grounded on the actual situation and pay attention to the following problems.

1). To balance investment attraction and investment abroad. Investment attraction and investment abroad are the two main ways of China to take part in international investment. To confront the shock of economic globalization, we must develop introducing of foreign capital and investment equally. First, invited foreign capital can help to develop our economy and drive the innovation and development of enterprise, thus, laid foundation for investment abroad. Secondly, it can create condition for larger scale of capital invitation. If we simply import and output, we will probably rely on foreign capital and technology, lower the civil capital's rate of operation and the ability of technology innovation.

2). To create good investment climate. In order to get the initiative in the worldwide compete of using international investment, China should use the experience and lessons of other country's international investment for inference to perfect the rules and regulations and to better the investment climate to attract foreign investors.

3). Strive to develop domestic enterprise, enhance the competitiveness and encourage the investment abroad. To encourage those enterprises with advantages for development to invest abroad, to participate in world-wide competitiveness thus entirely elevate competitive force of China's investment abroad.

4). Maintain the appropriate scale of international investment. **(1)** Utilize foreign capital rationally and keep the reasonable scale of utilizing foreign capital. In practice, due to the limitation of reality, the theoretic best scale can not be achieved; therefore we should stick to the second-best principle [9]. And our foreign capital utilization is unreasonable in construction and source and area orientation. In view of this, we should, in the future, synthetically consider the speed and direction of utilizing foreign capital. **(2)** Maintain the appropriate scale of investment abroad. Properly balance the out flowed capital and net export of commodity.

Operation Path and Strategy of Logistics Enterprise Supply Chain Logistics Management under Horizontal Integration

Yue Zhang*

Shanxi Youth Vocational College, Taiyuan, 030032, China

Received x xx 2014, www.cmnt.lv

Abstract

This paper put forward the significance of horizontal integration service provided for society by logistics enterprise, and discussed in detail about how to realize horizontal integration service and what kind of operation model can be adopted by relevant sub-service. Researches on these contents not only have certain effect on correlated theoretical research, but also can provide certain guidance for logistics enterprise. This research aimed to promote the compound integrated service ability and international competiveness through horizontal integration management mode.

Keywords: Logistics, horizontal integration, operation and management mode.

1 Introduction

Logistics is an integrated service industry which involves numerous sub logistics business. With the increasing of market competition and refining of social division of labor, an in creasing number of clients well preparing core business for concentrating superior resources, outsourcing logistics business to professional logistics enterprises and wishing to obtain the "integration", "one-stop" or "point contact" comprehensive logistics service. However, most of logistics enterprises in China still rest on low side logistics market and provide single and low profit subsection logistics service, which lack of logistics resource integration competence. Logistics enterprises are obviously insufficient in aspect of providing horizontal integration service competence, for they center on providing subsection logistics service with single function. It will severely impede logistics enterprise to become bigger and stronger, and constantly widen its gap with international logistics tycoon. Therefore, the current logistics enterprise is badly in need of constantly promoting logistics comprehensive service competence through acquisition and reorganization and resource integration.

2 Overview of Logistics Enterprise Horizontal Integration Operation

Logistics enterprise horizontal integration strategy generally refers to the expansion aiming at same market or relevant market. In logistics industry, horizontal integration refers to that in order to realize providing comprehensive service for clients, logistics enterprise conduct joint operation on correlated business area of logistics business. The advantages of horizontal integration lie in that it can obtain faster enterprise development with lesser cost, decrease competitor in market, rapidly enhance market share and improve scale economy. Its main disadvantages are that enterprises will undertake risk of operation from larger scale, and the coordination difficulty within enterprises increase. The implementation of horizontal integration strategy mainly is "strong-weak" alliance. Large-scale enterprise is matrix of combined enterprises, and professional enterprises or middle and small-sized enterprises are joint enterprises. With the increasing of market competition and refining of social division of labor, an in creasing number of clients well preparing core business for concentrating superior resources, outsourcing logistics business to professional logistics enterprises and wishing to obtain the "integration", "one-stop-shopping" or "point contact" comprehensive logistics service. Customer's requirements are increasing, thus the third party logistics enterprise should change development conception, especially large-scale logistics enterprise, change the relatively single logistics business operation mode, increase logistics business type, expand network coverage and increase value-added cervices so as to provide comprehensive one-stop service for clients. Therefore, when providing logistics service for clients, logistics enterprises should not only provide basic transport service, warehouse service for clients, but also provide multimodal transport service, customs declaration and commodity inspection service, distribution processing service, distribution service, express service, changing or refunding service and order decision service for clients. Efficient and comprehensive one-stop logistics service models like logistics project formulation, supply chain fund settlement, etc are logistics enterprise horizontal integration operation service model. As shown in Figure 1.

* ***Corresponding author's*** e-mail: zyyuez@163.com

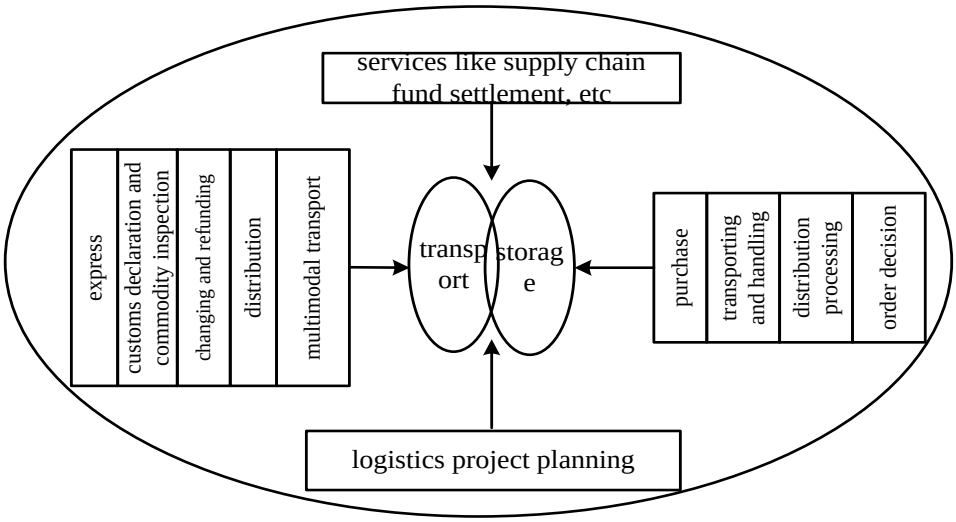

FIGURE 1: Operation model of logistics enterprise horizontal integration

3 Operation Path of Logistics Enterprise Horizontal Integration: Progressive Merger and Acquisition

When providing integration comprehensive service, as for how to obtain relevant resources that enterprise itself dose not possess is the primary problem enterprise will confronted, which also relate to the important decision of enterprise service quality. Besides the currently common merger and acquisition, investigation and reconstruction and outsourcing, paths of obtaining resources also include the newly emerged model-strategies alliance in recent years. Starting from bounded rationality and opportunism, the contemporary western economist Williamson [1] used the three properties (assets specificity, uncertainty and transaction frequency) that influence trade level and feature under incomplete contract to conduct further study on the nature of enterprise. He believed that there was a kind of governance structure in intermediate state based on transaction model between market and enterprise-alliance. Organization model of transaction is shown in Figure 2.

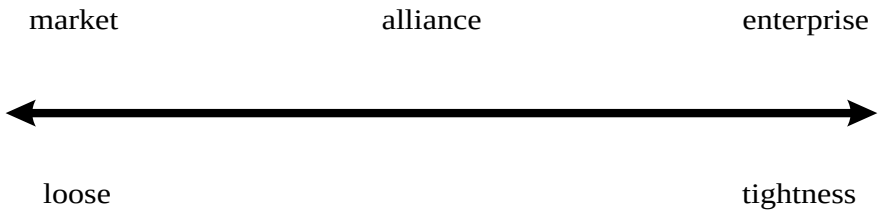

FIGURE 2: Williamson's alliance transaction organizational model

Alliance structure has both advantages of market and enterprise, is a kind of innovation and transition of transaction institution. This institutional arrangement can promote the mutual condition of market and enterprise under the limitation of protocol or property right, thus to play a role together. It also can overcome the malpractices of market and enterprise institution (information asymmetry in bureaucracy and enormous cost of one-time transaction in market) [2]. Based on Williamson's theory, enterprise integration operation can adopt market mode, enterprise mode and alliance mode. These three organizational modes have their own advantages and disadvantages in the operation process of enterprise integration.

"Progressive" is a kind of process gradually and slowly approach to objectives, which represent a kind of thought of quantitative change. Yi Chunguang [3] (2007) thought one of basic mode of expanding integrated logistics service is "break through", another is "progressive". He initially proposed to adopt progressive resources access path when providing integrated logistics service for clients. Progressive merger and acquisition on sub-business which logistics enterprise does not possess is an effective path for logistics enterprise to realize horizontal integration operation. Progressive merger and acquisition is divided in detail into six operation models, that is market-based outsourcing, customized service outsourcing, internal insourcing, contact type strategic alliances, share strategies alliances and merger and acquisition self-governance model. As shown in Figure 3, the advantages of applying progressive merger and acquisition are analyzed from two perspectives: small and medium-sized logistics enterprises and large-scale logistics enterprise.

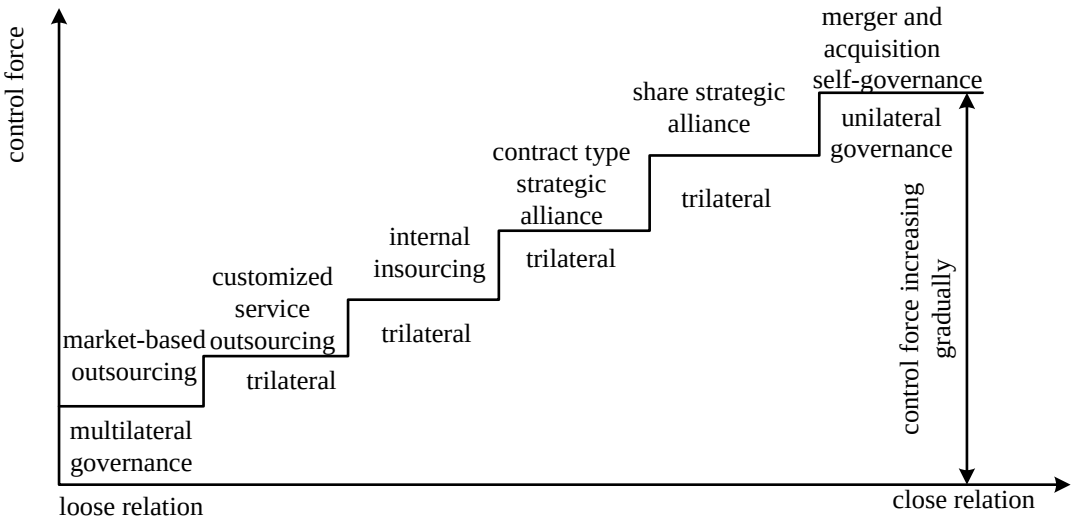

FIGURE 3: Six development stages of progressive horizontal merger and acquisition

Logistics enterprises can accumulate experience in process of constant try of integration operation by progressive horizontal merger and acquisition, for they adopt path of progressive resource access. As for current logistics development stage and developmental level, the accumulation is a kind of suitable development strategy for both small and medium-sized logistics enterprises and large-scale logistics enterprises. As for small and medium-sized logistics enterprises with limited capital capacity and in smaller scale, the adaptation of progressive merger and acquisition model is good for promoting the attempt of small and medium-sized enterprise providing comprehensive logistics service. Logistics industry is in developing phase with many features of "many, small, loose and weak". As for small and medium-sized logistics enterprises with limited resources, they start from outsourcing integration, and gradually grope the experience of integrated service, which avoid the overcrowding of many small and medium-sized enterprises in low-end market. It also guide middle and small-sized enterprises to attempt medium and high-end logistics market, thus to make them bigger and stronger until they have the strength to conduct horizontal mergers and acquisition. As for some large-scale enterprises with relatively abundant capital, progressive mergers and acquisition is good for avoiding enterprises make offensive mistakes. If not taking the practice of their self-development into consideration, and blindly study behaviors of international logistics tycoon and constantly conduct plenty of merger and acquisition, some enterprises especially those lack of integrated service experiences will have poor digestion. Moreover, they will suffer a lot because of lacking related sub-business operation experiences and merger and acquisition experiences [4-5]. As for logistics sub-business that has not yet involved in that, they should set down from low-end whether they are large or not. After they possess operation experiences, they can take the opportunity and implement merger and acquisition with self-support [6].

4 Logistics Enterprise Problems under Horizontal Integrated Operation Model and the Coping Strategy

There are three misunderstandings of logistics enterprises in the process of integrated operation, that is lack of horizontal integrated service awareness, excessively rely on outsourcing, blindly merger and acquisition and over expand.

4.1 LACK OF HORIZONTAL INTEGRATED SERVICE AWARENESS

Facing increasing number of market logistics comprehensive service needs, some logistics enterprises lack courage of enlarging range of logistics business, content with the status quo, fear to encounter risks and only provide simplified and segmented logistics service in low-end logistics market. They cannot meet customers needs, thus they lose middle and high-end market. The lack of horizontal integrated service awareness is one of vital reasons for logistics enterprise causing the fall behind of logistics horizontal integrated operation.

4.2 EXCESSIVELY RELY ON OUTSOURCING

Logistics enterprise horizontal operation model is to outsource sub-business. Although outsourcing can rapidly access resources, it has limitations. After logistics enterprises outsource sub-business, there exist not only transacttion cost, but the control on outsourcing business is also reduced, which lead to the decrease of client's satisfaction. Therefore, logistics enterprises should select the operation model of logistics sub-business according to the three-dimensional model established in this paper. Sub-business dose not suit for outsourcing can not outsource. Only in this way can logistics enterprises constantly enhance service quality in the process of integrated service, thus to realize the bigger and stronger of enterprises.

4.3 BLIND MERGER AND ACQUISITION AND EXPANSION

Some logistics enterprises adopt integrated operation model of over risk of expansion. In order to become bigger and stronger and reach to effect of horizontal integrated operation in short time, some logistics enterprises blindly implement merger and acquisition, of which the first bad results is rapture of capital chain and worse of financial condition. The second bad results are poor effect of merger and acquisition, and a series of troubles in the launce of business. Therefore, when implementing merger and acquisition, logistics enterprises should adopt progressive expansion style according to the enterprise strength and experience. As sown in Figure 4.

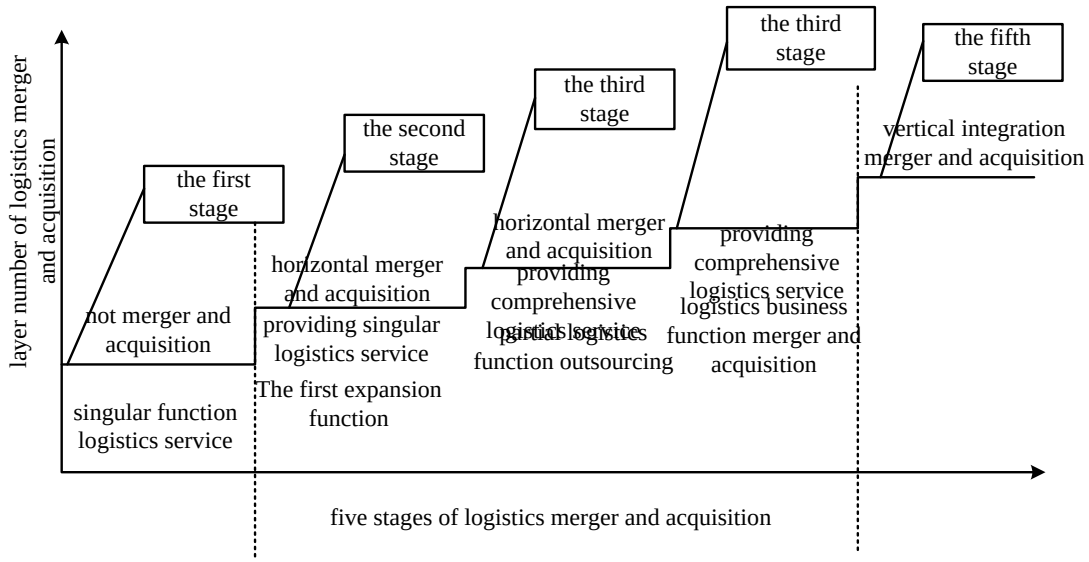

FIGURE 4: Progressive integrated merger and acquisition process of large-scale logistics enterprise

4. 4COPING STRATEGIES ON HORIZONTAL INTEGRATION OF VARIOUS LOGISTICS ENTERPRISES

Production enterprises' logistics department: the core business of production enterprises is not logistics business, thus it is difficult to realize large-scale. Logistics department also can meet the integration logistics service requirement of production enterprises thorough ways of outsourcing or alliance. Or they can cooperatively manage with the third part of logistics enterprise, and take advantages of each other so as to realize large-scale operation. It can both fully use the available resources and meet integration operation requirements [7].

Middle and small-sized logistics enterprise: outsourcing and alliance is very suitable operation model for vast middle and small-sized logistics enterprises in process of horizontal integrated operation, since their scale and resources are limited. However, in order to not reduce the effect of integration service, they should strengthen the control and management on outsourcing and alliance segment. In addition, middle and small-sized logistics enterprises also can adopt market-nicher strategy and depth appreciation model.

Large-scale logistics enterprise: enhance comprehensive degree of logistics service; adopt merger and acquisition means in good time; set up unified information platform; adopt horizontal networked organization structure.

5 Conclusion

Aiming at development status of logistics, logistics enterprises especially large-scale logistics enterprise should adopt horizontal integration operation model, which provide "one-stop" and "one-point-contact" comprehensive logistics service for clients so as to enhance their competiveness and shorten their gap with world logistics tycoon. The adoption of horizontal integrated operation model by logistics enterprises is good for improving the financial performance of logistics enterprises. Progressive merger and acquisition is an effective path to realize logistics enterprise horizontal integrated operation. Progressive merger and acquisition can be divided into six operation paths, that is market-based outsourcing, customized service, internal insourcing, contract type strategy alliance, share strategy alliance and merger and acquisition self governance model. According to the current situation of logistics enterprises in comprehensive integration service, there exist several misunderstanding of logistics enterprises in operation. The first is logistics enterprise lacks horizontal integration service awareness. The second is logistics enterprises are excessively rely on outsourcing operation model. The third is large-scale logistics enterprises are tending to blindly expand in process of horizontal integration. The participation or implementation of

logistics enterprise in supply chain logistics management is both serve for short-term objective and devote themselves to medium and long term objective. Logistics enterprise should orientate in customer value analysis and assessment, wholly enhance logistics management ability and service ability from supply chain level and height and timely and accurately find and recognize customer need and value point. At the same time, they should optimally configure the internal fine resources and external customer resources of supply chain, gather them in the business activity that can culture enterprise core competiveness and comprehensively optimize competiveness of supply chain logistics management of logistics enterprise.

Abstract

Basing on the previous research results, this study constructed an index system for the competiveness of the industrial cluster using analytic network process (ANP) method. Moreover, it employed the entropy method in objective assignment method to assign weights to the indexes and conducted empirical analysis by exampling the typical clusters in Zhejiang province. The results showed that the industrial concentration degree, specialization degree (location quotient), and Herfindahl-Hirschman index (HHI) took relatively high proportions in the indexes concerning the competitiveness of industrial clusters. This study also drawn an important conclusion, namely, high industrial concentration degree was conducive to improve cluster competitiveness and reduce cluster risk, while lower industrial concentration degree facilitated the formation of high overall cluster competitiveness.

Keywords: ANP, entropy method, Industrial cluster competitiveness

1 Introduction

In the context of economic globalization, industrial clusters have become remarkable regional trends, which have had a huge role in promoting economic development in both developed and developing countries. However, industrial clusters will likely lead to a recession or even crash of the entire regional economy if there are problems. So the correct evaluation of the competitiveness of industrial clusters has become an important issue. To comprehensively evaluate the competiveness of industrial cluster, it is needed to construct a scientific evaluation index system by treating industrial cluster as a network and comprehendsively analysing the competitiveness and relationships of all network layers.

2 The theoretical framework of the indexes for evaluating the industrial cluster competiveness

2.1 THE BASIS FOR CONSTRUCTING EVALUATION INDEXES FOR INDUSTRIAL CLUSTER COMPETIVENESS

This study built an evaluation index system for the industrial cluster competitiveness from the following aspects in reference with previous research results:

1) Using ANP method, index system was divided into the target layer, criterion layer, and index layer in turn. Meanwhile, in reference with related study results concerning industrial cluster network structure, the criterion layer of the index system was further decomposed into enterprise network, support network, and social network [1].
2) The core index for the competitiveness of enterprise network included five aggregation indexes, namely, industrial concentration, spatial Gini coefficient, EG index, location entropy, and two indexes reflecting the dynamic variations of cluster enterprises, namely, the derivation degree and innovation degree of enterprises.
3) The indexes for support network employed three indexes that were closely correlated with the cluster development, namely, public service platform construction, professional market perfection, and industry association service. The three indexes were scientifically evaluable using corresponding quantitative indexes through conversion [2].
4) Social network index was mainly selected according to the cluster embed ability of the social capital and social network in the social network structure of industrial cluster. The core indexes in the two factors, including entrepreneurship and social capital, were used for qualitative analysis. In real application, the two indexes could be subjectively analysed and evaluated using expert advice method and Delphi method [3].

2.2 THE INDEX SYSTEM FOR EVALUATING THE COMPETITIVENESS OF INDUSTRIAL CLUSTERS

According to the construction principle and basis above and the network structure characteristics of industrial cluster, this study constructed the index system for evaluating the competitiveness of industrial clusters, as shown in Table 1.

[*] ***Corresponding author's*** e-mail: *wwdn2002@aliyun.com*

TABLE 1 The index system for evaluating the competitiveness of industrial clusters

Target layer A	Criterion layer B	Index layer X		
		Index code	Index	Index connotation
The competiveness of industrial cluster A	The competiveness of enterprise network B1	X1	Industrial concentration	The total output of a cluster / the output of a industry in national level or in a high-level regional range
		X2	Spatial Gini coefficient	The distribution equilibrium degree of industrial space of cluster: G=∑N(si-xi) 2
		X3	EG index	Cluster scale and the cluster aggregation degree bearing regional differences γ=[Gi-(1-∑rxj2)Hi]/[(1-∑rxj2)(1- Hi)]
		X4	Cluster specialization degree (location quotient)	The ratio of cluster output in regional total output/ the ratio of provincial industrial output in total provincial output
		X5	The enterprise aggregation in a cluster(HHI)	The quadratic sum of ratio of the output of the leading enterprises in the cluster to the total output of the cluster
		X6	Derivation degree of cluster enterprises	The investment of fixed assets /the total output of cluster
		X7	The creative degree of cluster enterprises	The output of new products/ total output of cluster
	B2 The competiveness of supporting network B2	X8	Supporting degree of public service platform and	Total assets of service platform/the number of service enterprises
		X9	The perfection degree of professional market	Total market turnover/ number of market stands
		X10	The service level of industrial associations	Number of member enterprises/ number of industrial associations
	The competiveness of social network B3	X11	Entrepreneurship	The innovation consciousness of entrepreneur
		X12	Social relationship	The monopoly of social assets

3 The entropy method-based calculation method for index weight

At present, index weigh is mainly determined using subjective and objective assignment methods. In light of that the indexes of the competiveness of industrial cluster were constructed using the ANP in subjective assignment method, the weight of these indexes were determined using the entropy method in objective assignment method. Moreover, five typical clusters in Zhejiang Province was employed for empirical analysis.

3.1 INTRODUCTION OF THE PRINCIPLE OF ENTROPY METHOD

"Entropy" was sourced from the Greek and represents the variant capacity. Clausius pointed out that, since entropy was similar with energy and were both functions of state; the two concepts should also be similar in word form. In reference with the German expression of energy, namely, energy, Clausius noted the entropy as entropie. Chinese physicist Hu Gangfu firstly translated the entrpoie into Chinese word as "熵" by adding the word "商" with a "火" on the left in 1923 in view of the ratio of entropy energy variations to temperature [4].

In mathematics, entropy signifies the uncertainty of a situation or problem. In 1950s, American proposed the information theory. In this theory, entropy was directly treated as the uncertainty of the state of the signals sent from an information source and signified the information-sending ability of non-information source. Since then, entropy spread to non thermodynamic field in a new look. Subsequently, entropy was widely and rapidly applied into the fields of economy, city planning, decision analysis, artificial intelligence, and philosophy etc. In project evaluation, it is always needed to take account of the importance of each evaluation index. One of most direct and convenient methods to represent the importance is assigning weight to each index (weight coefficient). The research conclusion regarding the entropy theory above suggests that the accuracy and reliability of decision are dependent on the information amount grasped by decision maker in the decision process. Meanwhile, entropy serves as an ideal scale for the evaluation on different decision processes and case-handling effects [4,5].

3.2 THE BASIC STEPS FOR CALCULATING THE INDEX WEIGHTS USING ENTROPY METHOD

First, selecting positive or negative indexes as the evaluation indexes according to the research object and calculating y_{ij} according to standard equation, where, the treatment equation for positive index is calculated by (the larger the index, the better)

$$y_{ij} = \frac{x_{ij} - \min x_{ij}}{\max x_{ij} - \min x_{ij}} . \quad (1)$$

The treatment equation for the negative index is given by (the smaller the index, the better)

$$y_{ij} = \frac{\max x_{ij} - x_{ij}}{\max x_{ij} - \min x_{ij}}. \quad (2)$$

Secondly, calculating the entropy of evaluation indexes: in an evaluation issue containing m evaluation indexes and n evaluation objects, the entropy H_j of the *j*-th evaluation index is defined as:

$$H_j = -k\sum_{i=1}^{n} f_{ij} \ln f_{ij} \quad (j=1,2,...,m), \quad (3)$$

where, $f_{ij}=y_{ij}/\sum iy_{ij}$ (i=1,2,…,n), k=1/lnn. Moreover, it is assumed that when $f_{ij}=0$, $f_{ij}\ln f_{ij}=0$. The smaller the entropy of an index, the more useful the information provided by this index to the decision maker.

Thirdly, calculating the entropy weights of evaluation indexes: in the evaluation issue of (m,n), the entropy weight of the *j*-th index is defined as:

$$w(j) = \frac{1-H(j)}{m-\sum_{j=1}^{m} H(j)}. \quad (4)$$

4 An empirical analysis on the weights of the competiveness indexes of five typical clusters in Zhejiang Province

4.1 STANDARDIZATION OF THE ORIGINAL INDEXES FOR THE COMPETIVENESS OF INDUSTRIAL CLUSTERS

In this study, the original data of 5 typical industrial clusters in Zhejiang Province in 2011 were obtained from the data submitting platform for the key industrial clusters in Zhejiang province. Moreover, according to the data in the statistical yearbook of Zhejiang Province, the competitiveness indexes of the industrial clusters were calculated. In view of the competitiveness of support network showed little influences and was hard to be quantitatively analyzed as well, this study merely analyzed the weight of enterprise network competiveness of the industrial clusters using entropy method. The X1 to X5 of competiveness of enterprise network were calculated using the original data of the five industrial clusters on the "data submitting platform for the key industrial clusters in Zhejiang province" of the Zhejiang Province Economic and Information Commission in 2011. The calculation process was neglected in this study [6]. Table 2 shows the calculation results. Table 3 show the calculation results in Table 2 after being treated by the standardization equation of entropy method.

TABLE 2 The original data of the enterprise network competiveness of five industrial clusters in Zhejiang province

Criterion layer	Index code	Index	Typical industrial clusters				
			Shaoxing textile cluster	Haining leather cluster	Cixi household appliances cluster	Yongkang hardware cluster	Yueqing industrial electrical cluster
The competiveness enterprise network B1	X1	Industrial concentration	0.290	0.146	0.065	0.089	0.101
	X2	Spatial Gini coefficien	0.022	0.016	0.001	0.006	0.007
	X3	EG index	0.0210	0.0049	-0.0035	0.0036	0.0046
	X4	Location quotient	2.13	7.47	3.32	14.78	5.39
	X5	The aggregation degree of cluster enterprises (HHI)	0.0014	0.0112	0.0045	0.0024	0.0024
	X6	The derivation degree of cluster enterprises	0.038	0.022	0.050	0.067	0.124
	X7	The innovation degree of cluster enterprises	0.206	0.308	0.197	0.178	0.258

Data source: The "data submitting platform for the key industrial clusters in Zhejiang province" of the Zhejiang Province Economic and Information Commission.

TABLE 3 The standard data of the enterprise network competiveness of five industrial clusters in Zhejiang Province

Criterion layer	Index code	Index	Typical industrial clusters				
			Shaoxing textile cluster	Haining leather cluster	Cixi household appliances cluster	Yongkang hardware cluster	Yueqing industrial electrical cluster
The competiveness enterprise network B1	X1	Industrial concentration	1	0.36	0	0.107	0.16
	X2	Spatial Gini coefficien	1	0.762	0	0.238	0.286
	X3	EG index	1	0.343	0	0.290	0.331
	X4	Location quotient	0	0.422	0.094	1	0.258
	X5	The aggregation degree of cluster enterprises (HHI)	0	1	0.316	0.102	0.102
	X6	The derivation degree of cluster enterprises	0.157	0	0.275	0.441	1
	X7	The innovation degree of cluster enterprises	0.215	1	0.146	0	0.615

4.2 THE CALCULATION AND ANALYSIS ON THE COMPETIVENESS OF INDUSTRIAL CLUSTERS

Index weights were calculated according to the basic steps of entropy method, as shown in Table 4 (the calculation process is omitted).

TABLE 4 The index weight of the competiveness of the typical clusters in Zhejiang Provinces

Warning index X_J		Weight(W_J)
X_1	Industrial concentration	0.167
X_2	Spatial Gini coefficient	0.114
X_3	EG index	0.111
X_4	Location quotient	0.150
X_5	The aggregation degree of cluster enterprises (HHI)	0.190
X_6	The derivation degree of cluster enterprises	0.131
X_7	The innovation degree of cluster enterprises	0.138

According to weights, the indexes were sequenced as X5> X1> X4> X7> X6> X2> X3. This result suggests that the industrial concentration degree, specialization degree (location quotient), and HHI index take relatively high proportions in indexes of enterprise network competiveness. Moreover, industrial concentration, spatial Gini coefficient, and EG index are internally correlated. Gini coefficient and EG index take small proportions since they are used to detect the regional competiveness degree of a cluster.

By comparing the economic benefit indexes of the five typical clusters in Zhejiang Province in Table 5, it is found that Shaoxing textile cluster and Yueqing industrial cluster show higher economic benefits. Comparison on the network competiveness of the five clusters reveals that the two clusters above have high industrial concentration degree but low specification level and enterprise concentration degree. This result suggests that high industrial concentration degree is conductive to improve the cluster competiveness, while low industrial concentration degree means the low competiveness among enterprises and the high overall cluster competiveness formed thereby [7].

TABLE 5 The economic benefit indexes of the five typical clusters in Zhejiang Province

Indexes / Clusters	Labor Productivity(ten thousand Yuan per person)	Per capita profit rate (%)
Shaoxing textile cluster	76.38	2.96
Haining leather cluster	29.29	1.30
Cixi household appliances cluster	30.38	1.05
Yongkang hardware cluster	27.06	2.16
Yueqing industrial electrical cluster	42.1	2.89

Data source: The data submitting platform for the key industrial clusters in Zhejiang province

5 Conclusion and discussion

This study preliminarily attempts to quantitatively evaluate the competitiveness of industrial clusters. As for the large and complex industrial cluster network system, some factors are hard to be quantified and dynamic data are difficult to be collected [8]; limited by time, paper length, and objective conditions, this study merely empirically analyzed the typical industry clusters in Zhejiang Province. This determines the limitation of this study.

Wireless vehicle detection node based on tunnelling magneto resistance sensor

Wei Huang*

School of Automation, Hangzhou Dianzi University, Hangzhou, China

Received 15 September 2014, www.cmnt.lv

Abstract

A wireless node based on tunnelling magneto resistance sensor was designed for large scale vehicle detection in Intelligent Transport System. With regard to the sensor's characteristic of high resistance, rapid response and high linearity, the signal acquisition and regulation circuits were designed to meet the requirement of geomagnetic measure for three dimension axis of the sensor. A vehicle noise pre-detection unit was implemented to wake up the microcontroller from sleep state before vehicle enter the detection area. Low power chips were considered and the all sensor units were power supplied by MCU, cooperated with the improved power-efficient ATA algorithm, the power consumption was minimized. Experimental results showed that the designed node was capable of capturing the magnetic feature of different vehicle types and on line vehicle flow detecting for long time.

Keywords: tunnelling magneto resistance, geomagnetic induce, vehicle detection, ATA, WSN

1 Introduction

Vehicle detection and recognition is one of key technologies in Intelligent Transport System (ITS). From vehicle detection sensors, road traffic information are gathered, such as the vehicle occupying, driving in and departing, the vehicle speed and traffic flow. Currently, Surveillance technologies can be divided into two types, the Intrusive and Non-Intrusive [1]. Sensor used in the former are often embed under the surface of the pavement. Examples include inductive loop, pneumatic road tube, piezoelectric cable, and weigh-in-motion system. Drawbacks include the disruption of traffic for installation and repair, failures induced by poor road conditions, and system reinstallation caused by road repairs or resurfaces [2]. Non-Intrusive technology include microwave radar, infrared, Video Image Processing, etc. They are installed above the pavement or on roadside so that the installation and repair of such a system can be done without disrupting the traffic. However, the performance is greatly affected by the environment: confusing signal from sunlight, IR energy is absorbed or scattered by atmospheric particulates, fog, rain and snow. Besides, the devices listed above need auxiliary power supply circuit, which increase the costs and not suitable for distributed in a large scale space.

The increasing traffic congestion is a growing problem in many countries. Motivation for using Wireless Sensor Networks (WSN) to solve the problem needs searching for reliable and cost-effective devices, which can provide traffic data. Magneto Resistance Sensors have received lot of attentions. They are small size, flexibility in deployment configuration, and rarely affected by meteorological environment [3-5].

However, most of proposed research of magneto resistance were based on GMR or AMR, whose performance are limited by the Low-Frequency noise, nonlinear saturation field and low sensitivity for weak magnetic field measurement [6, 7]. There's serious magnetic hysteresis exists in the AMR, so that degaussing circuit are required in the sensor device, which restrict the technique applying widely in WSN apply [8, 9].

This paper presents the design and implementation of a brand new wireless sensor nodes for vehicle detection based on the Tunnelling Magneto Resistance (TMR), manufactured from CMOS-MEMS. The node was designed as an embed system with a microcontroller. The TMRs were used as the sensitive elements in three directions to measure the geomagnetic field of each dimension. Signal conditioning circuit were designed to ensure the analogue signal acquitted accurately. Secondly, An simple aural signal measuring circuit was realized to pre-detecting the vehicle from remote distance by the sound it emitted, so that the main system could in sleep mode for energy saving. Thirdly, an improved ATA detection algorithm was established. By the feature distance between the data series in sample window defined to observe magnetic field change, the algorithm counts the vehicles and schedules the state machine of the system. Outdoor experiments were conducted, the on road testing result shows the node have good performance and suitable for WSN application in ITS.

2 The measuring principle and TMR

2.1 GEOMAGNETIC DETECTION PRINCIPLE

The geomagnetic field is weak, ranged from 0.3 to 0.7Oe, but the magnitude is relative uniform and stable in a square

***Corresponding author** e-mail: hw@hdu.edu.cn

area. Since the Magneto conductivity of Iron is far larger than that of the air, ferromagnetic substance would cause a change in a magnetic field, distort the magnetic lines of flux. Since almost all vehicles have significant amounts of ferrous metals in their chassis the magnetic field disturbance created by a vehicle is sufficient to be detected by a magnetic sensor, which makes it a good candidate for detecting vehicles.

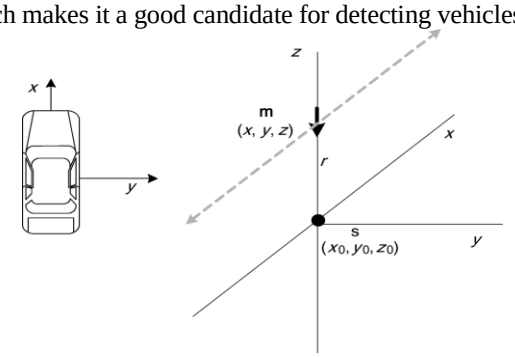

FIGURE 1 magnetic dipole of vehicle moves in x axis

The simplest mathematical model to describe the magnetic signature of a vehicle is a magnetic point dipole with a magnetic moment *m* cantered in the vehicle and parallel to the Earth's field (Figure 1). The field components B_x, B_y, B_z are

$$B_x = \frac{\mu_0}{4\pi}\frac{m_x(2x^2-y^2-z^2)+3m_y xy+3m_z xz}{r^5}, \quad (1)$$

$$B_y = \frac{\mu_0}{4\pi}\frac{m_y(2y^2-x^2-z^2)+3m_x xy+3m_z xz}{r^5}, \quad (2)$$

$$B_z = \frac{\mu_0}{4\pi}\frac{m_z(2z^2-x^2-y^2)+3m_x xy+3m_y xz}{r^5}, \quad (3)$$

where μ_0 is the permeability of free space, m_x, m_y, and m_z are the magnetic dipole moments in *X*, *Y* and *Z* direction, $s(x_0, y_0, z_0)$ and is the distance from the dipole to the observation point.

Suppose a vehicle moves in the x direction, m_x=m_y=0, the magnetic induction of magnetic dipole B_z is determin-ed by m_z and E_z, *where* E_z is the component of Earth's field in Z direction.

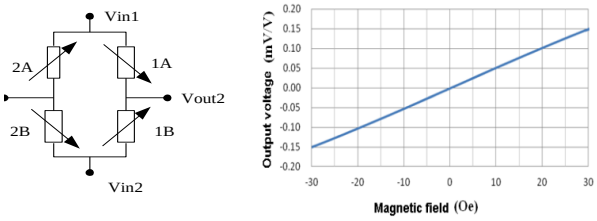
$$B_z = Z_E + \frac{\mu_0}{4\pi}\frac{m_z(2(z-z_0)^2-(x-x_0)^2)}{\left[(z-z_0)^2-(x-x_0)^2\right]^{\frac{5}{2}}}, \quad (4)$$

where B_Z can be used to judge whether a vehicle pass though the detection area. For each type vehicle may have their own ferrous metal distribution, distinct magnetic signature with multiple peaks they yield is benefit to vehicle recognition.

2.2 TMR SENSOR

TMR was first used in hard disk technology. With the change of external magnetic field, the Magnetic Tunnel Junction (MTJ) generates a change in resistance. Under the applied magnetic field, the magnetization direction of free layer will change, while the pinning layer keep still. So the relative orientation between the two layers is changed, resistance of the MTJ across the insulating layer is observed. Since this physical effect is based on the electron tunnelling effect in insulating layer, it is called as the Tunnelling magneto resistance effect [10].

This used the TMR chip MMLP57F with SOP8 packaging and a Wheatstone bridge inside consists of four pieces of TMR elements. The internal structure and output specific are shown in Figure 2.



a) b)

FIGURE 2 MMLP57F specification: a) Internal structure, b) Output feature in±30Oe

While the external magnetic field is changing, the resistance changing trend of 1A and 1B are opposite to that of 2A and 2B. Assume the four elements have equal resistance R when the detecting field is at zero. Output voltage is:

$$V_{out} = V_{-out1} - V_{-out2} = (V_{in1} - V_{in2})\frac{\Delta R}{R}, \quad (5)$$

where V_{in1} and V_{in2} are the bias, ΔR is the absolute value of changes in resistance. The output feature is shown in Figure 2b. Here, bias is 5V, from –30Oe to 30Oe, the sensitivity is 4.8 mV/V/Oe, the nonlinearity less than 1% and the hysteresis error is about 0.1%. That is sufficient to meet the requirement for geomagnetic field detection.

3 Hardwire design of the sensor

3.1 THE STRUCTURE OF NODE

The node is consists of five main units: the acoustic signal detection unit(ASD), the three axis magnetic detection and signal conditioning(MDSC), the wireless transport unit(WTU) and a microcontroller (MCU). The block diagram of the system is presented in Figure 3. The MCU is EFM32G, specially designed for low-power applying [11]. The core of chip is Cortex M3, highest working frequency 32MHz, supports five mode from EM0-EM4 and capable to wake up in 2 μS from sleep mode. Peripherals has the autonomous working ability in CPU sleep duration. The ADC is 8 channel, 12bit, rate at 500K/S with operating current 200μA, which is helpful for high speed data acquisition.

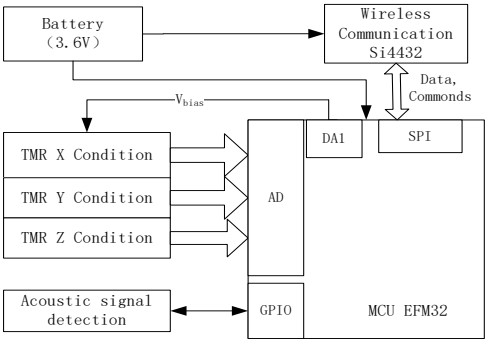


FIGURE 3 The block diagram of the system

Wireless chip Si4432 is used for communication, the bias 3.6V, transmission frequency 900 MHZ, the maximum data transfer rate 256 bps. The diversity antenna, power amplifier, digital modem and a 64B FIFO are internal integrated. External components are one 30MHZ crystal oscillator and a transceiver. The EFM32G communicates to the Si4432 through the SPI interface, the work mode settings and the data are transferred in packets.

3.2 THE MAGNETIC SIGNAL ACQUISITION AND CONDITION

The magnetic induction by vehicles is about -200uT to 200uT, and the responding output range of a single TMR is -32mV to 32mV. So, a power amplifier circuit is considered to conditioning the signal to 2.5V level to satisfy the AD sampling requirement. Since the equivalent internal resistance of TMR bridge is greater, and the magnetic signal to measure is weak, which require the amplifier has high CMRR. The Instrument amplifier chip INA332 can exercise its restraints upon the CMRR and reduce the disturbance from temperature drift and null shift. The chip has low power consumption that meets the system energy management. The conditioning circuit is shown in Figure 4.

The amplifier gain *G* is calculated from:

$$G = 5 + 5 \cdot \left(\frac{R5}{R6} \right), \tag{6}$$

where, R5=147K, R6=10K, G≈80. Vref=1.25 V. The common mode voltage(CMV) of TMR is 3.3V/2=1.65V. To ensure the input signal have maximized dynamic range, the ADC bias is set to 2.5V.

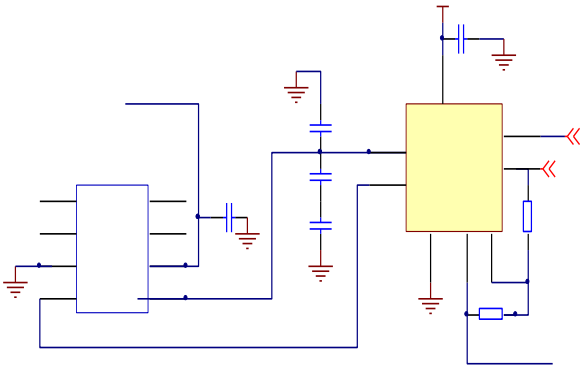

FIGURE 4 The circuit of a single TMR Sensor

Not like other MR chip that should designed with a special power circuit, the three dimension TMR chips are biased by the DA channel of the MCU directly, V_{bias}=3.3V. This is benefit from TMR extremely high input impedance, almost at MΩ level. Meanwhile, MCU provides the power in a intermittent way. The duty time span including the signal setup time and the analogue digital conversion time. For INA332, the AD time is 1μS. The designed circuit limited the amplifier gain under 100, so that operation bandwidth is about to 1MHZ, that minimizes the signal setup time.

3.3 THE ACOUSTIC SIGNAL DETECTION UNIT

To promote energy usage rate, the MCU and magnetic sensor should in speed mode or low power condition in spare time. The acoustic signal detection is used for pre-detecting the audio signals from vehicles, when the threshold is reached, an input is trigged to the MCU, and the system shift into vehicle detecting mode.

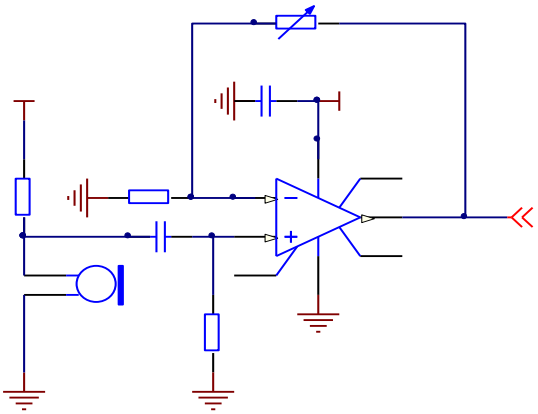

FIGURE 5 The acoustic signal detection circuit

In Figure 5, a two order active amplifier circuit is designed with high pass filtering. The GPIO of MCU have a high driving preferment of 20mA, 3V. External interrupt is supported to wake up the MCU from low power mode (EM1-EM3). The WM-034, an Omni directional electrets microphone has sensitivity of -44dB-36dB. With the in-phase proportion amplifying structure, Op07 magnification is A_{vf}=R4/R2. The range of sensitivity is adjusted by R4, the magnification changed in same way. Generally, the audio frequency the road vehicles emitted between 500HZ to 5KHZ, and that of the background noise is lower than 500HZ. Thus, let the cut-off frequency f_L=500HZ, C1=01.uF, R3=1/2πf_LC1=3.2KΩ.

4 Software design of the sensor

4.1 THE VEHICLE DETECTION ALGORITHM

Jiagen proposed the model of process sensor data in vehicle detection, and based on simple fix threshold value, the Adaptive threshold algorithm (ATA) is applied. But the ATA is not consider of the characteristics of vehicle magnetic signal (VMs), mathematics fault detection may lies in

the algorithm. Second, the algorithm require processing on each sample data, which would keep the MCU in busy mode with large emerge consumption [12].

Here, an improved ATA algorithm (IATA) is using in the sensor, the new algorithm can calculate the signal feature between the background window and the current window by separating vehicle coming and leaving events to realize vehicle detection. Based on the energy saving principle in WSN, Duty-cycling policy is applied to decrease energy consuming [13].

The signal characteristic function *I(K)* is used to distinguish the detecting signal from the background signal. Let:

$$I(k) = be^{ak} + c\,, \tag{7}$$

where $ab>0$. The factors may different for different vehicle type at different speed. For two real time signal sequences $X=\{x(1), x(2), \ldots, x(\mathrm{L})\}$, $Y=\{y(1), y(2), \ldots, y(\mathrm{L})\}$; the normalized power series for *I(K)* is:

$$\delta_f(k) = \frac{I(k)}{\sqrt{\sum_{i=1}^{L} I(K)^2}}\,. \tag{8}$$

The feature distance is defined as:

$$D_L(X,Y) = \sum_{i=1}^{L} \delta_f \cdot \left[y(k) - x(k) \right]^2. \tag{9}$$

4.2 THE IMPROVED ATA MODEL

The algorithm flow chart is shown in Figure 6. There are four basic status in IATA: No Vehicle sleep (NVS), High threshold enter (HTE), Middle threshold hold (MTH) and Low threshold leave (LTL). The feature distance used to detect the end point of VMS for HTE and LTL, while Duty-cycling for NVS and MTH.

Let $s(k)$ as current sample series, S_b is the average value of background, M is the background windows size.

$$S_b = \frac{S(k) + S(k-1) + \ldots + S(k-M+1)}{M}\,. \tag{10}$$

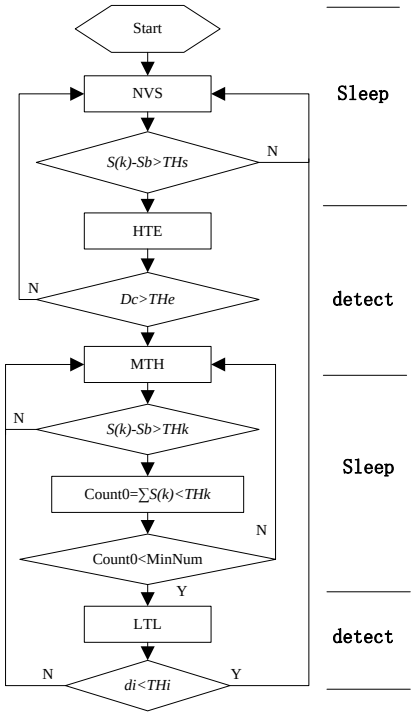

FIGURE 6 The IATA algorithm flow chart

5 Experimental Results and Discussion

The sensor node is in a compact structure, the size is 50mm*50mm, shown in Figure 7. A tiny WSN is built by a Ether2USB device connected to the laptop computer, act as the AP. When the SN is power on, the AP commands are processed in prior, ADC sample rate is set to 100HZ. SN sends a batch of data per second.

5.1 MAGNETIC SIGNATURE OF DIFFERENT PARKING CARS

In this experiment, the Acoustic Unit is Closed. We send AP commands to start the Recording function of SN, by which the SN will upload the raw sample data directly.

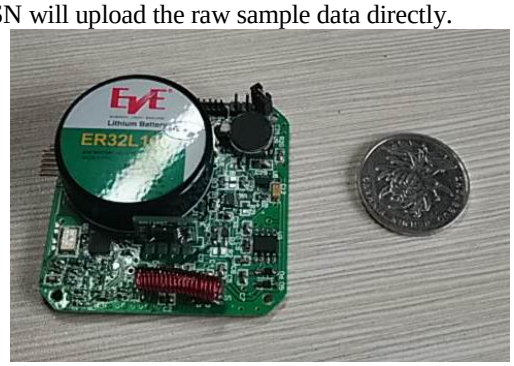

FIGURE 7 The picture of a real SN

We measured on parked vehicles and during parking maneuvers in an outdoor parking area. A compact vehicle (skoda Octavia), a subcompact compact (JinLong) and a truck (GreatWall) were involved. The sensor measured each vehicle on eleven positions along a line centred in the floor

of the vehicle (Figure 8d). D1, D2 are the effective detection area from the head and lap of vehicle respective.

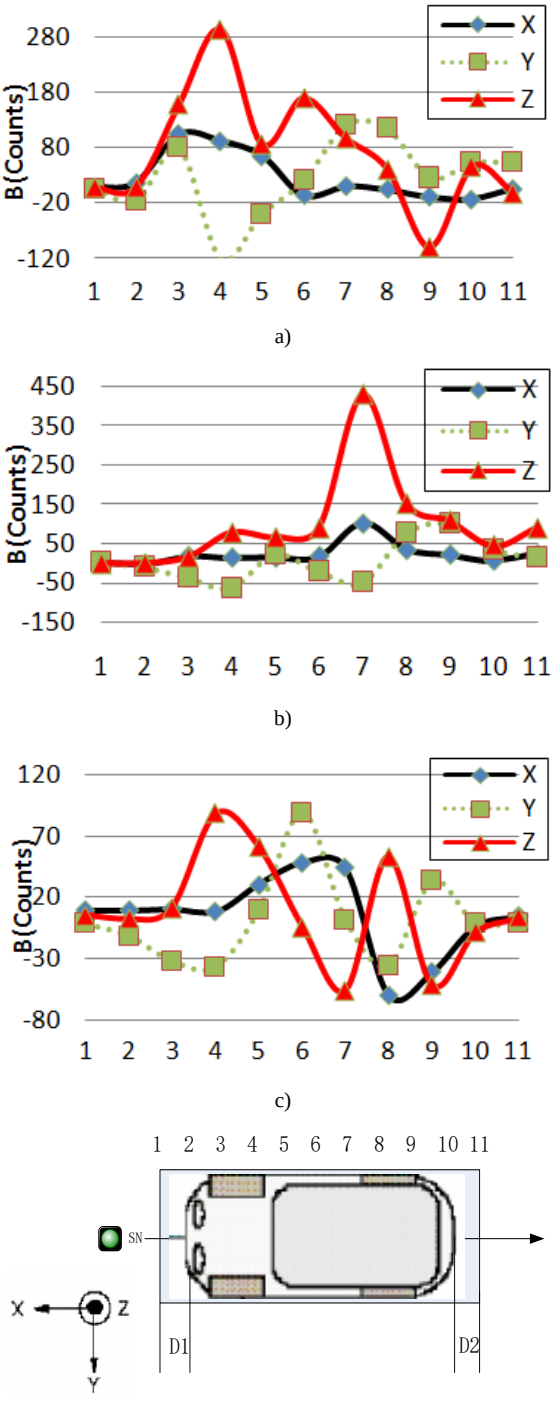

FIGURE 8 Magnetic signature of different parking cars: a) compact vehicle (D1=0.8m, D2=0.6m), b) subcompact vehicle (D1=0.4m, D2=0.3m), c) trunk (D1=0.7mm,D2=0.3mm), d) direction and position

Figure 8(a-c) shows the magnetic induction simultaneously measured by the sensor. Each value is averaged by ten raw data, and the resolution achieved was 36.7nT (12bit), the measurement time was 88mS.

The signatures suggest that compact cars can be roughly described by three magnetic dipoles: two larger dipoles for the engine and wheel axes and a smaller dipole between them. The trunk may have more dipoles with more wheel axes. As to B_Z, the peak counts, peak values and frequencies are distinguished from each type. The B_x and B_y also have distinct features to used for vehicle detecting and movement direction, i.e. the magnetic declination [14].

5.2 ON LINE DETECTING FOR MOVING CARS

The on line test was carried on in a campus lane and a main road to a logistic park. In Table 1, the false and missed count are produced by the IATA detection algorithm and the acoustic detection algorithm respectively. Experiments results shows the average accuracy is 95.8%.

TABLE 1 On line test results

Place	Actual counts	Detected counts	Wakeup times	False	Missed
Lane	86	83	84	1	6
Road	387	394	513	10	3

The magnetic background in campus lane is more stable than the main road, the IATA detection algorithm can had an accurate measurement output. But the missed count in campus is greater than the road, since there the vehicles are most compact type and low speed, if the acoustic threshold not set properly, the MCU would not be trigged when a car passed by slightly. The main road has large flow and through output, and vehicle move at high speed. The acoustic unit trigged about two times than the actual vehicle count because of the noise by adjacent vehicle.

5.3 CONTINUOUS WORKING TIME ESTIMATION

The power consumption of a node is:

$$P = \sum I_{ak} V_{DDK} , \tag{11}$$

were, I_{ak} and V_{DDk} is the average current and supply voltage of the unit *k*.

$$I_{ak} = \frac{t_k}{T} I_k + \left(1 - \frac{t_k}{T}\right) I_s , \tag{12}$$

I_s is current consumption in sleep mode, I_k is current consumption in active mode, T is the clock period, t_k is duty time on each cycle.

TABLE 2 Energy consumption of node units

Unit	Mode	V_{DD}	I_k(mA)
MCU	Active	3.6	0.18
	Sleep		9×10^{-4}
MDSC	Active	3.3	0.02
	Stop	0	0
ASD	Active	3	0.3
	Stop		0
WTU	Rx	3.6	18.5
	Tx		30
	adjust		8.5
	Sleep		1×10^{-3}

Assume the road lane vehicle flow is 220 per hour, and the node works autonomously, the nodes are distributed a long distance between each other, where communication channel collision is low probability. Duty cycle of ASD is 1%, miss trigger rate is 15%, a handshake package sent to AP every 5min and listen to the AP broadcasting per seconds. By Table 2, power consumption in 1 day is about 10.8mW. So the battery (9000mAh) would last about 1.5 years with the consideration of other battery loss of 30%.

6 Conclusion

A magnetic sensor node is proposed to detect the vehicles by measuring then changes of the geomagnetic field. When vehicles arrive or depart, the acoustic sensor detects the changes in illumination and wakes up the sensor node. The TMR sensor measure the magnetic field and IATA algorithm processes the data with energy saving policy of Duty-cycling is building in the control software. Experimental results showed the node can provide fast detection. The Node is compact, low-cost, and very low-power vehicle detector for WSN applications, and that is also reliable and easy to install and maintain.

Mechanical characteristics of multi-span concrete continuous girder oblique bridge based on ANSYS

Wan Ning*

Southwest Jiaotong University-Emei, Sichuan, China, 614202

Received 6 October 2014, www.cmnt.lv

Abstract

In order to adapt to environment and reduce the damage of construction for environment, the principle that environment adapts to construction is updated for bridge design, therefore lots special-shape bridges including oblique bridge emerge. However, there is no accurate and developed theory for computing the mechanical characteristics of oblique bridge. Generally, equivalent straight bridge is applied for computing. By performing finite element modelling, the internal force and displacement of oblique bridge and equivalent straight bridge with load were compared. The results showed that due to the special structure of oblique bridge, torque is generated under load, accompanying with coupling effect of bend-twist. Therefore, the mechanical characteristics analysis of straight bridge can not accurately explain that of oblique bridge.

Keywords: ANSYS, oblique bridge, computer simulations, finite element modelling

1 Introduction

Oblique bridge is a kind of special-shape bridges that different with straight bridge. Its normal line of bridge axis is not parallel to the support sides, between which the acute angle is called slope, which reflects the lean degree of the bridge. Benefited from high-grade highway, high-speed railway, urban three-dimensional traffic, etc. [1], oblique bridge develops continuously. With the development of economy, road network construction accelerates as well and new traffic lines are not always vertical to the existing lines and waterways in connection and crossing; considering the coordination with surrounding constructions and environment, the new traffic lines have to bring as little damage as possible to the environment; additionally, based on green building principle, the requirements for reducing water resistance ability of water piers and the navigation, and the change of design concept, the idea that traffic lines submit to bridges is not applicable any more. All these factors cause the existence of oblique bridge and its increasing proportion. To ensure quality of traffic lines, oblique bridges are mainly constructed in high-grade highways, such as urban three-dimensional traffic, expressway, and high-speed railway [2-5]. Regarding mechanical characteristics, there are large differences between oblique bridge and straight one. Compared with straight bridge, oblique bridge generates torque and complex internal forces with bend-twist coupling under loads. There are many factors influencing the internal forces of oblique bridge, including supporting stiffness, stiffness ratio of bending and torsion, and the angle between bearing line and axis line, that is, the slope. At present, research on oblique bridge in China and abroad is in the initial stage and there is lack of perfect design theory and method. Moreover, there are no definite stipulations for mechanical characters, construction features, and construction points of oblique bridge in related specifications [6].

2 Static finite element analysis principle

Figure 1 shows a skew girder element in horizontal plane, and there are three degrees of freedom for the node [7-11]. Slope is the angle between the oblique section of end point and *y*-axis (symbol description: it is positive when *y*-axis clockwise turns to the oblique section; otherwise, it is negative).

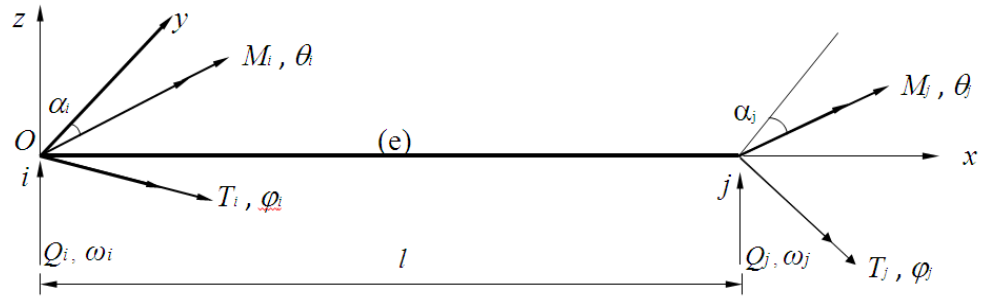

FIGURE 1 Skew girder element

***Corresponding author** e-mail: ningwan@163.com

Suppose the *i* end of the element (*e*) is fixed and the *j* end is free, when there are forces Q_j, M_j and T_j on the *j* end, each component of the internal force of *x* section are:

$$\left.\begin{aligned} Q(x) &= -Q_j \\ M(x) &= Q_j(l-x) - M_j\cos\alpha_j + T_j\sin\alpha_j \\ T(x) &= -\left(M_j\cos\alpha_j + T_j\sin\alpha_j\right) \end{aligned}\right\}. \tag{1}$$

The strain energy of the element is as follows without considering shear deformation:

$$U = \frac{1}{2}\int_0^l \frac{M^2(x)}{EI}dx + \frac{1}{2}\int_0^l \frac{T^2(x)}{GJ}dx. \tag{2}$$

According to Cass Tino theorem, we have:

$$\omega_j = \frac{\partial U}{\partial Q_j}, \theta_j = \frac{\partial U}{\partial M_j}, \varphi_j = \frac{\partial U}{\partial T_j}. \tag{3}$$

Therefore, the relationship of the node displacement and the nodal force of *j* end of the element is expressed by

$$\begin{bmatrix} \omega_j \\ \theta_j \\ \varphi_j \end{bmatrix} = \begin{bmatrix} \frac{l^3}{3EI} & -\frac{l^2\cos\alpha_j}{2EI} & \frac{l^2\sin\alpha_j}{2EI} \\ -\frac{l^2\cos\alpha_j}{2EI} & \frac{l\cos^2\alpha_j}{EI} + \frac{l\sin^2\alpha_j}{GJ} & \frac{l\sin 2\alpha_j}{2GJ} - \frac{l\sin 2\alpha_j}{2EI} \\ \frac{l^2\sin\alpha_j}{2EI} & \frac{l\sin 2\alpha_j}{2GJ} - \frac{l\sin 2\alpha_j}{2EI} & \frac{l\sin^2\alpha_j}{EI} + \frac{lcos^2\alpha_j}{GJ} \end{bmatrix} \begin{bmatrix} Q_j \\ M_j \\ T_j \end{bmatrix}. \tag{4}$$

That is:

$$\boldsymbol{\delta}_j = \boldsymbol{D}_{jj}\boldsymbol{F}_j. \tag{5}$$

The coefficient matrix $\boldsymbol{D}_{jj}$ is the flexibility matrix of the *j* end of the skew girder element. By performing inversion for the matrix, the stiffness matrix $\boldsymbol{K}_{jj}$ is:

$$\boldsymbol{K}_{jj} = \boldsymbol{D}_{jj}^{-1}, \tag{6}$$

where $\boldsymbol{D}_{jj}^{-1}$ is stiffness ratio of bending and torsion, namely:

$$\lambda = \frac{EI}{GJ}.$$

According to the equilibrium condition of the element, the relationship between force of *i* end and *j* end is:

$$\boldsymbol{F}_i = \boldsymbol{H}\boldsymbol{F}_j, \tag{7}$$

where $\boldsymbol{H}$ is stiffness transformation matrix.

The distal stiffness $\boldsymbol{K}_{ij}$ and proximal stiffness $\boldsymbol{K}_{ii}$ of *i* end of the element are:

$$\boldsymbol{K}_{ij} = \boldsymbol{H}\boldsymbol{K}_{jj}, \tag{8}$$

$$\boldsymbol{K}_{ii} = \boldsymbol{H}\boldsymbol{K}_{jj}\boldsymbol{H}^T. \tag{9}$$

Therefore, the stiffness matrix of the skew girder element is:

$$\boldsymbol{K} = \begin{bmatrix} \boldsymbol{H}\boldsymbol{K}_{jj}\boldsymbol{H}^T & \boldsymbol{H}\boldsymbol{K}_{jj} \\ \boldsymbol{K}_{jj}\boldsymbol{H}^T & \boldsymbol{K}_{jj} \end{bmatrix}. \tag{10}$$

Suppose that the torsion angle function and the vertical displacement function of the element are cubic linear functions, the displacement function of the element is:

$$\boldsymbol{\delta}(x) = \boldsymbol{N}(x)\boldsymbol{\Delta}, \tag{11}$$

where $\boldsymbol{\delta}(x)$ is the vector of the displacement function of the element.

$$\begin{aligned} \boldsymbol{\delta}(x) &= \left[\omega(x) \quad \theta(x) \quad \varphi(x)\right]^T, \\ \boldsymbol{\Delta} &= \left[\omega_i \quad \theta_i \quad \varphi_i \quad \omega_j \quad \theta_j \quad \varphi_j\right]^T. \end{aligned} \tag{12}$$

Furthermore, the shape function of the element is calculated. After obtaining the shape function matrix, the equivalent nodal forces of each load are calculated based on energy principle.

3 Experimental case

The example in the research is a concrete double-line railway bridge with continuous rigid frame and three spans. The slope of the bridge is 45°, and large general finite element software ANSYS14.0 is used [12, 13]. The span of the equivalent straight bridge is the diagonal of the oblique bridge. No. shell181 plate element is applied in the construction of the upper structure of the bridge and the bridge pier model. Solid modelling is constructed by defining nodes first, through which establishing elements, and then building the overall model based on the elements (Figure 2). The rigid connection of pier and girder is simulated by coupling all degrees of freedom using nodes, and the pier bottom is restrained by consolidation. Static load simulation is conducted when two trains cross the bridge at the same time and produce maximum load.

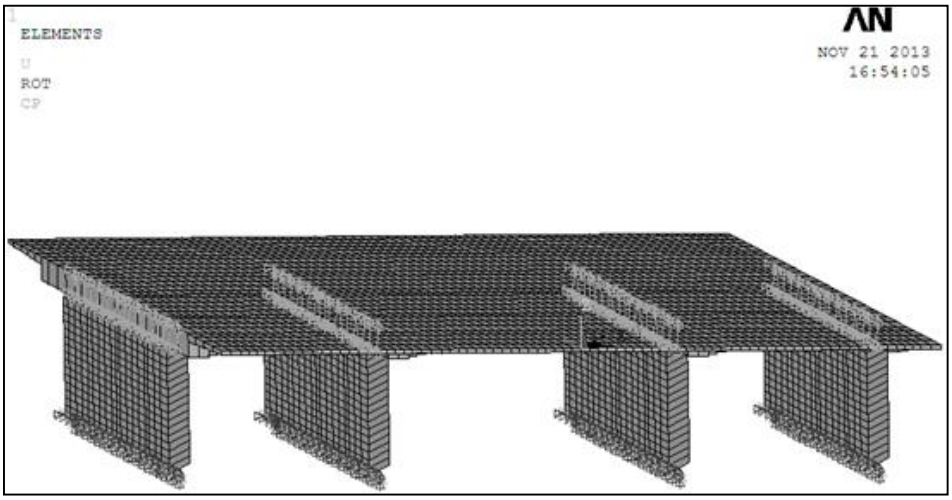

FIGURE 2 Whole oblique bridge model before the trains are loaded

3.1 DISPLACEMENT CALCULATION RESULTS

As there are lots nodes in the model, 21 key points in the oblique bridge and the straight bridge correspondingly are investigated to analyse their displacement, static force, and bending moment. The arrangement of the 21 points is demonstrated in Figure 3.

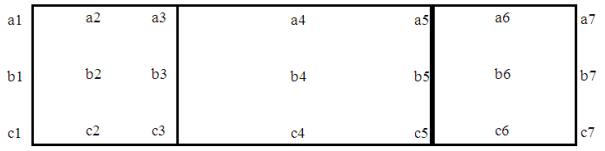

FIGURE 3 Distribution of 21 key points in the research

The static force calculation for vertical displacement of the 21 points of the oblique bridge and the straight bridge is illustrated in Figure 4. By turning the calculation results around y-axis (along the transverse direction), the results are displayed in Figure 5.

Figure 4 shows the calculation results of vertical displacement. It indicates that under common medium-live load of bi-direction, the vertical displacement of the straight bridge is regular. The midpoints of each span are the maximum vertical displacements of each span (with maximum deflection). When the bridge is divided by the central point and there are equal loads along the both sides, the vertical displacement of the bridge is symmetric for the central point of the span. The vertical displacement at flange plate is close to 0 without obvious warping deformation. While under common medium-live load of bi-direction, the oblique bridge shows significant irregular vertical deformation. The calculation results display that the maximum vertical displacements of each span are also at the midpoints of each span. While, besides this, different with the straight bridge, distinct vertical deformations are observed at flange plate and the angular points (a1, c7) of the long diagonal, which causes irregular deformation of the whole bridge.

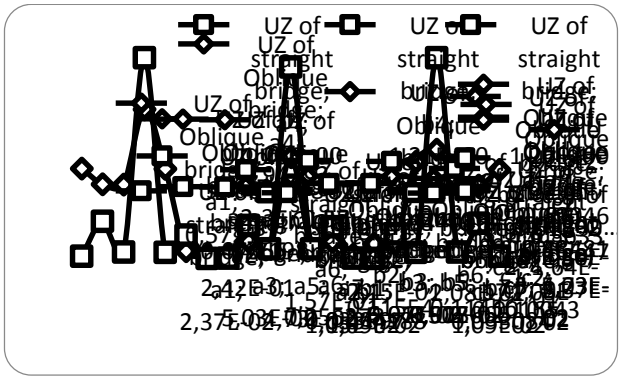

FIGURE 4 Calculation results of vertical displacements of the 21 points of oblique bridge and straight bridge (unit: mm)

The calculation results (Figure 5) demonstrates that the angular displacement of the straight bridge maintains dynamic equilibrium and fluctuates above and below zero alternatively. The displacement is regular without apparent change. Meanwhile, the angular displacement of the oblique bridge is irregular and shows peak values. For examples, there are large angular displacements at the angular point, bridge pier, and the centres of spans at both sides. Therefore, there is obvious twist deformation of the surface of the oblique bridge.

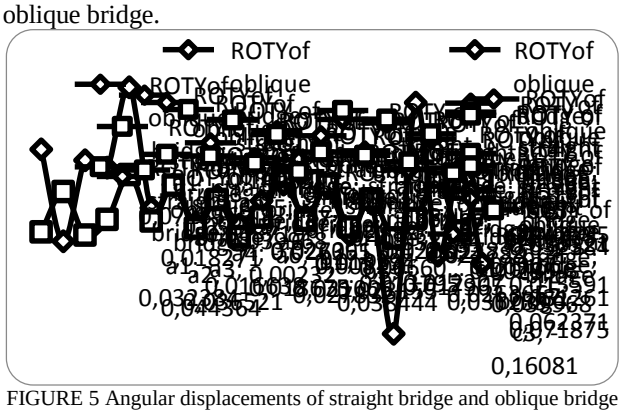

FIGURE 5 Angular displacements of straight bridge and oblique bridge by turning around *y*-axis (transverse direction) (unit: rad)

Merely specific points on each pier were analysed in the calculation of static internal forces, and the concrete positions of the points are demonstrated in the Figure below.

3.2 INTERNAL FORCE CALCULATION RESULTS

The static forces of the oblique bridge and the straight bridge are analysed and the comparison of calculation results of the axial force of the bridges is illustrated in Figure 6.

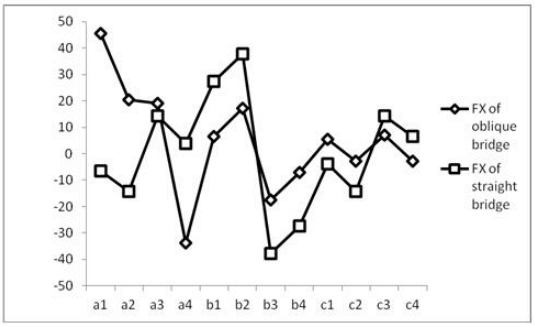

FIGURE 6 Calculation results of horizontal forces along the oblique bridge and the straight bridge (unit: kN)

It is observed in Figure 6 that among the selected points, the maximum axial horizontal force of the straight bridge is at the midpoint of the left central pier. The force is also positive. Maximum axial horizontal force difference (about 80 kN) is found between the midpoints of two central piers, where the directions of the two forces are opposite. For the oblique bridge, the variation of the axial horizontal force is mainly observed at two ends of the bridge, with a maximum difference of 90 kN around. Obviously, the mechanical character is different with that of the straight bridge.

Figure 7 shows that the maximum positive bending moment of the straight bridge is at the midpoint of the bridge surface and the maximum negative bending moment is at the left central pier. Considering the middle span, all the bending moments are large and positive and there is distinct variation of the bending moment along the axis. For the oblique bridge, the maximum positive bending moment is at point a3, which is near to the flange and the maximum negative bending moment is at the left bottom point a1. Meanwhile, the variation of bending moment along the axis is less than that of the straight bridge, with a maximum difference about 3 times. All these reveal that, for safety, it is better to calculate the bending moment along the axis using the data of straight bridge; while as the bending moments at side span and angular points of bridge surface are obviously different between the two bridges, the calculation of bending moments of oblique bridge using data of straight bridge can not ensure safety.

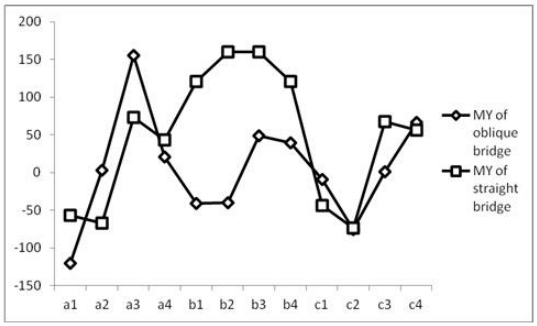

FIGURE 7 Bending moments of the oblique bridge and the straight bridge by turning around y-axis (unit: kN·m)

4 Conclusions and analysis

1) It is safe to calculate vertical displacement of oblique bridge using equivalent straight bridge at the midpoints of each span, where the vertical displacement of straight bridge are larger than that of oblique bridge. However, the vertical displacement of straight bridge is almost zero at flange and the oblique crossings of two ends; while oblique bridge generates coupling effect of bend-twist with load due to its special structure, and therefore leads to a larger internal force and large vertical displacements at the above positions. For example, obvious difference can be observed at the angular points (a1. c7), where there is no vertical displacement for straight bridge while about 0.6 mm of vertical displacement for oblique bridge. So, straight bridge cannot be applied in calculating vertical displacement of oblique bridge; otherwise, the safety of the oblique bridge cannot be guaranteed in usage.

2) The calculation of angular displacement by turning around y-axis shows that the angular displacement of straight bridge is stable without obvious variation; while owing to not completely symmetric structure, the oblique bridge generates torque under loads, accompanying with bend-twist coupling. This intensifies the local torsional deformation, for examples, the deformations at a5, c3, and c4. But the straight bridge is not influenced by the factor.

3) In the calculation of axial horizontal force, there is significant difference between the results of oblique bridge and the straight bridge. At some positions, the axial horizontal forces are in opposite directions, such as a1 and a4. There is about 50 Kn difference between the horizontal forces in the two computations, and the forces are in opposite indirections. Furthermore, the difference increases in dynamic calculation due to the movement of the loads. The inaccurate computation of horizontal force fails to accurately calculate and judge the stress and deformation of the bridge piers, and cannot provide valid data and reference for the design of lower structure. All these possibly cause transfinite deformation, even collapse of the bridge piers, therefore cannot guarantee the safety of the oblique bridge structure in usage.

4) Figure 7 demonstrates that, except several points are close to the straight bridge, the bending moments of oblique bridge around y-axis are significantly different with that of the straight bridge. This is clearly observed on the axis and angular points. On the axis, the maximum My difference reaches 200 Kn·m with opposite directions. When calculate bending moment using equivalent straight bridge, the tension and compression of girder and pier concrete of the oblique bridge cannot be accurately estimated. This probably causes that the tension of certain side of the concrete exceeds its tensile limit and therefore cracks. This inevitably threatens the safety of the bridge.

In summary, actual mechanical condition of oblique bridge cannot be accurately obtained in the computation of internal force and deformation using equivalent straight bridge, as the method fails to accurately consider or simulate the additional bending moment, coupling effect of bend-twist, non-uniform internal force and complex stress-strain

of the actual structure of oblique bridge. Presently, many scholars suggest that to improve the efficiency of the equivalent computing method by adding certain correction coefficient. However, with limited experience, specifications of each country have not provided accurate correction coefficients for each factor. Therefore, for safety, oblique bridges are generally designed with excessive bearing and cost vast manpower and material resources. The method for computing mechanical characteristics of oblique bridge using equivalent straight is not scientific and applicable. Further research is needed to provide more accurate computing method or correction coefficients for each factor apart from finite element simulation.

Design of new type biomass pellet forming machine with plunger roller and ring-die at room temperature

Xiangyue Yuan, Zhongjia Chen*

School of Technology, Beijing Forestry University, Beijing, 100083 China

Received 6 October 2014, www.cmnt.lv

Abstract

Bio-energy has become the fourth major energy resource after oil, coal, natural gas energy on account of the properties of green, clean, and renewable. And biomass densification is an important technology which makes the biomass resource be low cost and high value. But for current biomass forming equipment, there exist common shortcomings of high energy consumption, low efficiency, serious wear of forming parts, and etc. In this paper, a forming mechanism of a new type biomass pellet machine with plunger roller and ring-die was proposed, which using the mesh extrusion pressure between plungers and forming cavities (or called holes) to make the loose biomass material densification. It could avoid direct contact and intense friction of forming parts and biomass materials out of the holes. So the energy consumption of the materials in ineffective forming process was reduced and the wear of forming parts was effective alleviated. Then the new type biomass pellet forming machine was designed according to the requirements by Solidworks after force analysis and theoretical calculation, and a prototype was built with the whole power 22 kW and production capacity 450 kg/h. Compression experiments were done finally on the prototype. It was shown that the forming quality of solid pellet fuel tended to be stable after 30 minutes' running and the pellet density could reach more than 0.8 g/cm^3. So it represented that the designed pellet machine had a good practical operation and met the design demands.

Keywords: forming technology of biomass densification, pellet forming mechanism with plunger roller and ring-die, pellet fuel

1 Introduction

Energy shortage and environmental pollution are common serious problems currently restricting the development of world economy and the society. So it is the necessary way for the future to develop renewable and green energy, which means a low-carbon, sustainable and scientific development [1]. Although biomass materials are widely distributed with a good renewability and richness in natural resources, its greatest inadequacy lies in the scattered distribution, the low original density, and low energy density [2], which severely limits the direct utilization of biomass energy. So technologies should be developed to convert bio-materials into a new form fuel with high unit energy density.

Biomass densification is an important kind of technologies to achieve the target of the biomass resource utilization with low cost, high value and efficiency at present. The process of biomass densification is that compress biomass material (mainly residues of forest felling, thinning, processing and agriculture) physically at heating or room temperature into solid fuels shaped as columnar, cube, or pellet with high unit density after the pretreatment of drying, crushing and etc. [3]. The unit density and combustion value of the solid fuels after processing could respectively reach 0.8~1.4t/m^3 and 16~21MJ/kg in terms of kinds of biomass materials such as agricultural straws, grasses, woody resources like wood chips and sawdust. Combustion efficiency could be as high as 90%, and the conversion cost is low as well [4].

So far, there are many kinds of biomass forming machine, but an objective reality that the high power consumption (≥100kw/h per ton) and quick wear of main forming parts (≤1000h) still exists, which restricting the development of biomass solid fuels. To overcome shortcomings in traditional forming machines, a completely new type of biomass pellet forming mechanism with plunger roller and ring-die was designed after deeply studied the densification of biomass material in this paper, which effectively avoided the extrusion and friction of biomass material out of forming cavities. It would greatly reduce the power consumption of densification, and prolong the service life of forming molds.

2 Design of biomass pellet forming machine with plunger roller and ring-die at room temperature

2.1 THE WORKING PRINCIPLE OF THE FORMING MECHANISM

A new forming mechanism with plunger roller and ring-die was presented after deep study on compression and shaping process of many kinds of biomass forming machines, shown in Figure 1, which was similar to a pair of inner meshing gears. It depended on the mesh extrusion pressure between plungers circumferentially on the roller and forming cavities uniformly distributed in the ring-die to make the loose biomaterials densification. Compared with the traditional rolling ring-die forming mechanism, shown in Figure 2, it avoided direct contact between the ring-die and the roller,

***Corresponding author** e-mail: chenzhongjia@bjfu.edu.cn

reduced mutual extrusion and friction between the roller and bio-materials out of the forming cavities and alleviated the force of forming parts. Therefore, it could effectively reduce the power consumption of biomass forming and wear of forming parts to improve the service life [5].

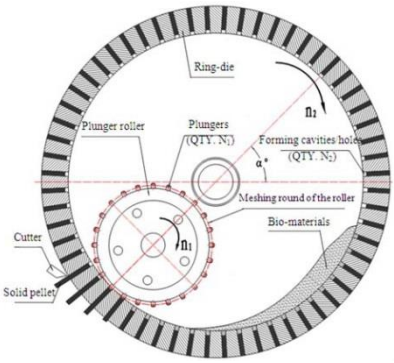

FIGURE 1 The working principle of biomass pellet molding mechanism plunger roller ring-die

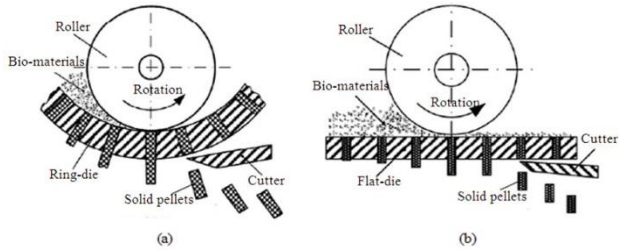

FIGURE 2 The traditional rolling ring-die forming mechanism

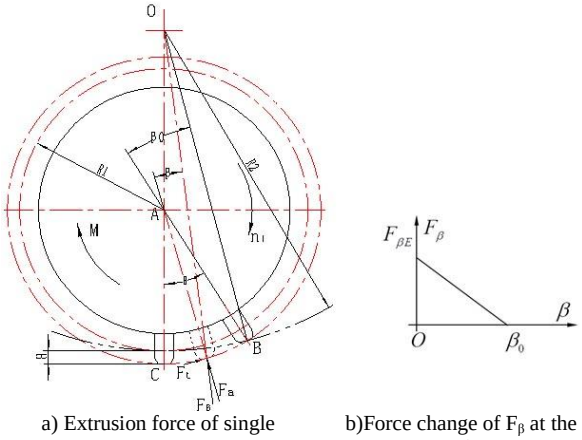
All of the plungers and forming cavities were uniformly distributed along circumference in the Figure 1. Let the quantity of plungers and forming cavities of each row separately be N_1 and N_2, the revolving speed of plunger roller and ring-die be n_1 and n_2 in turn. Then when the four parameters matched the following equation, the movement between the plungers and forming cavities was similar to the meshing motion of the gear: $\frac{N_2}{N_1}=\frac{n_2}{n_1}=\left(\frac{Z_2}{Z_1}:gear\right)$.

2.2 FORCE ANALYSIS OF PLUNGER RING-DIE FORMING PARTS

Figure 3 was the force schematic of plunger roller. In the Figure 3a, the plunger roller was rotated at speed of n_1 driven by torque (M) after bio-materials filling into the forming holes in the ring-die. The plunger began to mesh with forming hole at the position of B, that is to say, bio-materials in the hole were squeezed by the plunger. When rotated to the position C, the plunger reached a maximum depth of engagement with H mm, and it would gradually withdraw from the hole with the continual rotation of roller. It was thought that the top end of the plunger was subject to the action of force F_β to the centre of the ring-die O when the materials was squeezed because of the larger radius of ring-die compared with roller. The angle between F_β and the centre line of the roller was β. F_β could be decomposed into the radial force of the roller F_a and the tangential force F_t, so F_t would be the resistance to the rotation of roller. It could be simplified to a static force process due to the short residence time in the meshing zone BC of the plunger and higher rotating speed of the roller.



a) Extrusion force of single plunger

b)Force change of F_β at the top end of plunger

FIGURE 3 The force schematic of the plunger roller

O and A were the rotation centre of the ring-die and roller respectively. Point B and C were the entry and exit points of engagement separately. R_1 and R_2 were radius of roller circle and ring-die inner circle in turn. M was the driving torque, and n_1 was the rotating speed of the roller. θ was the central angle of the roller at the mesh zone of plunger and forming hole. β was the angle between axes of plunger and hole and the maximum was β_0 (i.e. at the position of B). F_β was the force of the plunger, and F_a and F_t were the radial and tangential force of the roller respectively, while the maximum was $F_{\beta E}$ at the position of C. H was the maximum insert depth of plunger.)

For ease of calculation and analysis, F_β was simplified as a linear growth in the Figure 3b, and the following Equations could be obtained.

$$F_{\beta E}=P_0\frac{\pi D^2}{4},\ \beta_0=\cos^{-1}\frac{R_2^2+(R_1+H)^2-OA^2}{2R_2(R_1+H)}, \quad (1)$$

where, P_0 was the maximum extrusion pressure per unit (MPa), D was the diameter of the forming hole.

Equation (2) can be calculated from Equation (1).

$$F_\beta=F_{\beta E}-\frac{F_{\beta E}}{\beta_0}\beta. \quad (2)$$

Decompose F_β into radial force F_a and tangential force F_t, and Equation (3) can be received:

$$F_t=\sin\beta F_\beta,\ F_a=\cos\beta F_\beta, \quad (3)$$

where resistance torque produced by the tangential force to the roller is:

$$T=\sum_{\beta=\beta_0}^{0}F_t\cdot(R_1+H)=(R_1+H)\sum_{\beta=\beta_0}^{0}\sin\beta\left(F_{\beta E}-\frac{F_{\beta E}}{\beta_0}\beta\right)= \quad (4)$$
$$(R_1+H)F_{\beta E}\left(\frac{\sin\beta_0}{\beta_0}-1\right).$$

The resultant of all radial force to the roller was R_a:

$$R_a = \sum_{\beta=\beta_0}^{0} F_a = \sum_{\beta=\beta_0}^{0} \cos\beta F_\beta = F_{\beta E}\left(\frac{\cos\beta_0 - 1}{\beta_0}\right). \quad (5)$$

Plungers would squeeze the bio-materials in the range of angle θ, and θ was received through the geometric relationship in the Figure 3a:

$$\theta = \cos^{-1}\frac{OA^2 + (R_1 + H)^2 - R_2^2}{2OA\cdot(R_1 + H)}. \quad (6)$$

Bio-materials were extruded by more than one plunger when the roller rotating because several ones were circumferential distributed per row on the roller. So let the number of meshing pair between plunger and forming hole which took part in squeezing simultaneously be ω:

$$\omega = \frac{\theta}{2\pi / N_1}, \quad (7)$$

where, N_1 was the number of plungers per row on the roller and ω should be an integer.

So the resistance torque and the resultant radial force are:

$$T^{total} = \omega Ts,\ R_a^{Total} = \omega R_a. \quad (8)$$

Equation (9) can be obtained integrating Equations (4), (5) and (8).

$$\begin{aligned} T^{Total} &= \frac{\theta}{2\pi / N_1}(R_1 + H)P_0\frac{\pi D^2}{4}\left(\frac{\sin\beta_0}{\beta_0} - 1\right), \\ R_a^{Total} &= \frac{\theta}{2\pi / N_1}P_0\frac{\pi D^2}{4}(\cos\beta_0 - 1)\frac{1}{\beta_0}. \end{aligned} \quad (9)$$

Bio-materials in each forming hole were extruded by appropriate plunger from the position *B*, and it reached the maximum depth *H* when at the position *C*. During the process, extrusion force increased gradually from 0 to maximum P_0 with the degree of the materials compression. Curve 2 in the Figure 4 showed the actual force change. To measure the complicated friction resistance between bio-materials and hole wall in compression process, relationship of extrusion force and deformation was simplified as a positive correlation, shown in curve 1 of the Figure 4.

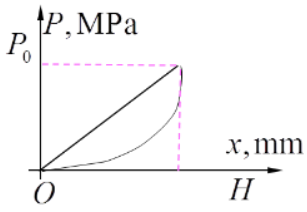


FIGURE 4 The relationship between deformation and pressure of bio-materials in one forming hole

Curve 1 and 2 were the linear simplified and actual relationship respectively between deformation and pressure of bio-materials in straight forming hole.

According to the forming theory of open straight hole [6, 7], it was known that the radial force generated by bio-materials in the mould, friction per unit length of straight hole wall, and the total friction are:

$$P_r = \varepsilon P, \quad (10)$$

$$dF_f = fP_r ds = 2\pi Df\varepsilon P dx, \quad (11)$$

$$F_f = \int_0^H dF_f = 2\pi f\varepsilon D\int_0^H P dx = \pi Df\varepsilon P_0 H. \quad (12)$$

The value of the total friction F_f based on curve 1 in Figure 4 was slightly larger than the actual friction of the straight hole for more safe and reliable.

Similarly, the total friction of the ring-die was expressed in the Equation (13) because there were several (the number was ω) forming holes working for extrusion simultaneously at forming zone *BC*:

$$F_f^{total} = \omega F_f = \omega\pi Df\varepsilon P_0 H. \quad (13)$$

In Equations (10)-(13), ε is a side pressure coefficient and *f* was friction coefficient of materials and forming hole (usually to be 0.1-0.7) [8].

Equations (1)-(13) are the approximate static calculation results for pressure of plunger and forming hole per row. If the row number of plunger and forming hole was *N*, the force of forming mould should be *N* times.

2.3 GENERAL DESIGN OF THE FORMING MECHANISM WITH PLUNGER ROLLER AND RING-DIE

The pellet forming machine was mainly composed of transmission system, forming parts, enclosure bodies and frames, and so on, where, the key points of the design were the transmission system and size of the roller and the ring-die.

2.3.1 Design of the transmission system

Figure 5 was the design of the transmission system. It was known that the ring-die spur gear 2 and the roller spur gear 1 with their shafts were in rigid connections respectively. The ring-die and the roller were mounted on the frame by the bearings, and the idle gear with its shaft was mounted on the frame as well.

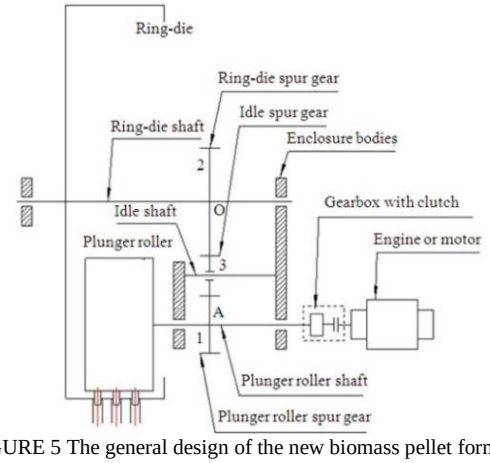

FIGURE 5 The general design of the new biomass pellet forming mechanism

The engine power was transported to the roller shaft through the clutch, which driving the roller rotation. Then the ring-die parts rotated by the gear transmission system 1-3-2, and finally turned round together with the plunger roller at a certain ratio. The running speed of the forming mould could be changed by gearbox in real time according to the actual forming conditions of the materials' characteristics to improve the forming fuel quality and productivity.

Considering the transmission system and design demands, spur gears parameters of the roller and the ring-die could be determined finally referred to size of the same type of pellet forming equipment existing on the market, shown in Table 1.

TABLE 1 The spur gears' design parameters of the plunger roller and the ring-die

Z_1	Z_2	Z_3	m/mm	i	R_1/mm	R_2/mm	OA/mm
24	60	24	3	2.5	132	330	198

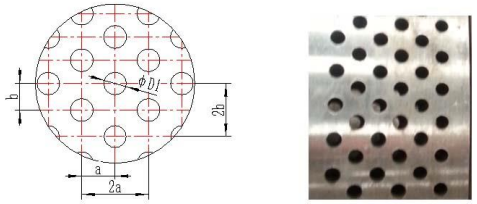
2.3.2 The design of the key forming parts

1) Design of the ring-die parts: according to the design requirements, the productivity (Q) of the new type forming machine was greater than or equal to 450 kg/h. The rotation speed of the ring-die was elected to be n_2, which was equal to 240r/min, to ensure the forming mould working under lower shock load. The layout of the forming straight hole in the ring-die was shown in Figure 6. In the figure, two adjacent rows of straight holes were symmetrical and staggered distribution, which could increase the hole wall thickness and its strength. And the pressure of the roller and the ring-die could be relatively more dispersion at the same time when the bio-materials in the forming holes were squeezed in turn by each row of plungers on the roller. So it was benefit to the smooth operation of the mould. As the diameter of pellet fuel was already determined (D was 8mm according to the design demands), the diameter of the forming hole (D_1) should be 8.5 mm in order to ensure the enough buckling strength of the extrusion plunger body in the same size, and offset the transmission error caused by gear backlash and machining error.

The number of holes per row would be determined based on the productivity of design requirement:

$$N_2 = \frac{4\times10^6 Q}{60\pi N D^2 H \rho n_2 \zeta} \approx 114.9\,, \tag{14}$$

where, Q=500kg/h, N=6, D=8mm, H=6mm, ρ=0.9g/cm^3 (density of pellet), n_2=240r/min, ζ=0.167.



a) Layout of forming holes in the ring-die b)Actual forming holes

FIGURE 6 The straight forming hole layout of the ring-die

Let the number of holes per row (N_2) be 120, and the design parameters of the ring-die was listed in Table 2.

TABLE 2 The structure parameters and dimensions of the ring-die

Inside Diameter/mm	Outside Diameter/mm	Number of Rows/N	Number of holes per row/N2	Hole Diameter D1/mm	Space in rows/mm
φ660	φ760	6	120	φ8.5	12.5

2) Design of the plunger roller parts: the number ratio of plungers and holes per row must be equal to the speed ratio of the roller and the ring-die because all the plungers on the roller and the corresponding straight holes in the ring-die needed precision engagement. Based on the data in the Tables 1 and 2, the number of plungers (N_1) per row on the roller should be 48 (N_1=N_2/i). Like the layout of forming hole in the ring-die, the plungers were circumferential uniform distributed. The position and space of the two adjacent rows were same as the forming holes. The design parameters of the plunger roller parts were expressed in Table 3 and the structure was in Figure 7.

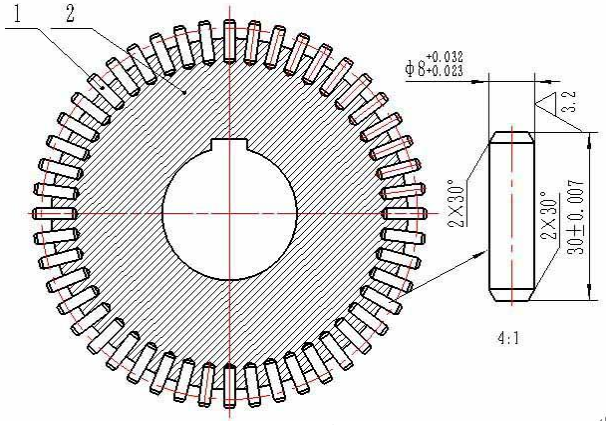


FIGURE 7 The structure schematic of plunger roller. 1) The plunger body 2) The roller body

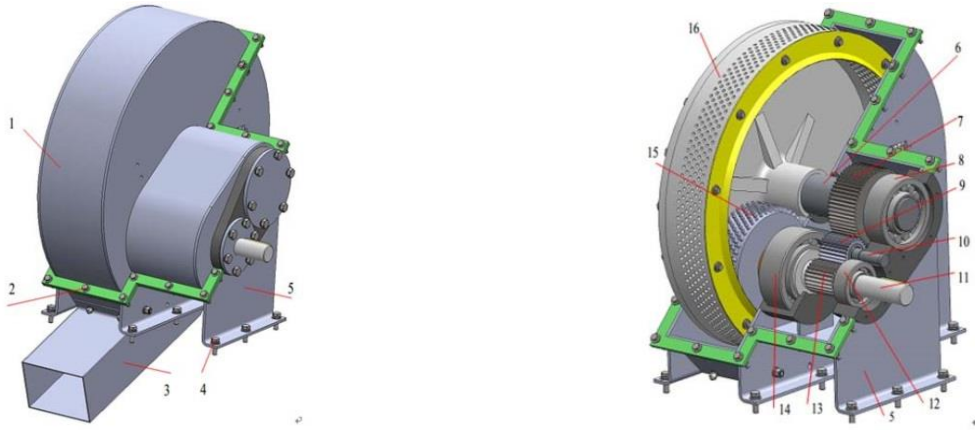
TABLE 3 The structure parameters and dimensions of the plunger roller parts

Mesh Circle Diameter of the Roller /mm	Mesh Depth of the Plunger /H/mm	Row of the Plunger /N	Number per Row/N_1	Diameter of Plunger/D/mm
φ264	6	6	48	φ8

According to the above design of several parts and reference of similar equipment on the market, the new biomass pellet forming machine with plunger roller and ring-die was designed completely, shown in Figure 8.



a) Appearance of the forming machine b) The internal structure of the forming machine

FIGURE 8 Complete design of the new type biomass pellet forming machine 1) Upper enclosure body. 2) Enclosure body connecting bolts. 3) Outlet hopper. 4)Forming machine fixing bolts. 5) Lower enclosure body. 6) Ring-die shaft. 7) Ring-die spur gear. 8) Ring-die bearings. 9) Idle spur gear. 10) Idle shaft. 11) Plunger roller shaft. 12) Right plunger roller bearings. 13) Plunger roller spur gear. 14) Left plunger roller bearings. 15)Plunger roller 16) Ring-die

2.4 POWER CALCULATION FOR THE FORMING MACHINE

The other parameters of angle and force could be calculated based on the Equations (1)-(13) and the design parameters of the forming parts. And the total weight of the plunger roller parts and the ring-die parts could be obtained as well on the foundation of design, listed in Table 4.

TABLE 4 The other parameters of angle and force for forming parts

θ/°	β_0/°	T^{total}/N·m	R_a^{total}/N	F_f^{total}/N	G_P/N	G_R/N
22.05°	13.02	119.7533	11258.133	21191.5	592.7435	1977.64

Note: β was the angle between axes of plunger and hole and the maximum was β_0.

Table 5 shows the bearing types for both side support of ring-die and plunger roller respectively.

TABLE 5 Bearing types

Right side of ring-die	Left side of ring-die	Right side of plunger roller	Left side of plunger roller
NJ2316E	NJ2316E	NJ2310E	NJ2319E

Let frictional coefficient μ and friction arm d_m of the rolling bearing to be 0.006 and $(d_i+D_0)/2$ apart, then the rolling friction torque of the couple forming parts would be get in the Equation (15), and the power consumption of the friction torque in Equation (16) below:

$$T_1 = \mu(G_1 + R_a^{total})d_{m1},\ T_2 = \mu(G_2 + F_f^{total})d_{m2}, \tag{15}$$

$$P = \frac{Tn}{9550}, \tag{16}$$

where, P – power consumption (kw); T - torque (N·m); n - rotation speed (r/min); d_i - inner ring diameter of bearing (mm), D_0 - outer ring diameter of bearing (mm).

The calculations of resistant torque and power consumption for the couple forming parts were listed in Table 6.

For probably fieldwork, a chipping equipment (power was P_2=3 kW) was installed at the feed inlet to improve the application performance of the forming machine. So the total power consumption of the whole machine was calculated below.

TABLE 6 The resistant torque value and power consumption of forming parts

	Resistant torque / $N \cdot m$			n/rpm	P/kW
	T^{total}	$T_{1,2}$	$\sum T$		
Roller part	119.753	10.488	130.241	600	8.1827
Idler part	–	–	–	240	–
Ring-die part	–	17.376	17.377	240	0.4367
				$P_1=\sum P$	8.6194

Note: Speed of forming mould n was calculated according to the theoretical productivity Q=450 kg/h

$$P_0 = k\frac{P_1 + P_2}{\eta} = 1.3\frac{3 + 8.6149}{0.85} = 17.8 \text{ kW}, \tag{17}$$

where, P_0 was the power of the whole forming system with unit kw, k was the power factor (k=1~1.1 when $P_0 \leq 5$kW, k=1.1~1.2 when P_0=5~10kW and k =1.2~1.4 when P_0>10kW), and was selected to be 1.3 according to the power calculation. η was the total efficiency of the transmission system (η=0.80~0.90), and was selected to be 0.85.

It could be known from Equation (17) that total power consumption of the new pellet machine with productivity 450 kg/h was about 39.6 kW/t theoretically, much less than that of traditional forming equipment on the market (about 80~100 kW/t) [9].

A multi-cylinder diesel engine with type of ChangChai ZN3850Q, was chosen finally in the light of lighter weight at the same power to make the machine with enough power reserve. And the main parameters were listed in the Table 7.

TABLE 7 The main parameters of ChangChai ZN385Q diesel engine

Number of cylinders	Engine displacement	Rated power	Idle speed	Maximum torque	Fuel consumption	Cooling	Shape size	Weight
Unit	L	kw/ rpm	r/min	N.m /rpm	g/kw.h	–	mm	kg
3	1.617	22/2400	800	91 /1800	≤220	Water cooling	614×492×628	185

3 Forming test on the prototype of the new biomass pellet forming machine

A prototype of the new biomass pellet forming machine was assembled completely after design and machining, shown in the Figure 9, which included a drum chipper directly mounted on the side panel of lower enclosure body for integration fieldwork operation. And the machine and engine were fixed on the frame by bolts.

FIGURE 9 The biomass forming system with plunger roller and ring-die at room temperature 1) Frame. 2) Forming mechanism. 3) Drum chipper. 4) Clutch lever. 5) Gearbox lever. 6) Changchai ZN845Q diesel engine. 7) NJ130 Gearbox. 8) Clutch

3.1 UNLOAD TEST

Unload test must to be done before the actual operation to keep normal meshing of each couple of plungers and forming holes. The test was conducted according to the following steps.

Firstly, started the forming machine by hand. The transmission must be in "neutral", and turned the roller shaft slowly by manually to run the forming mechanism. Any sound like metal friction and knocking must be noticed during the rotation. After several times of manual rotation, friction between plunger and entrance to forming hole would be well fit.

Then, started the diesel engine, and unload test with multi-speed running would be done.

1) The forming machine was idle run driven by the engine at the speed of about 1000 r/min with the first gear engagement, and maintained the speed of 10 minutes to make the forming pairs mesh fully at high speed.

2) Adjusted the engine to the speed of 1800 r/min with maximum torque and the second gear engagement, the ring-die parts would be run at fastest speed of the design about 240 r/min. Kept the state for 10 minutes to observe the actual operation situation, and the results showed well run.

3) Increased slowly the speed of the engine to the maximum 2400 r/min, namely, the ring-die parts would be run at speed of about 320 r/min. Kept the state for 10 minutes to observe the actual operation situation, and the results showed normal working.

It was known from the above unload test results that the designed forming machine could run well at different speeds after low speed running.

3.2 COMPRESSION TEST

At the beginning of work, the state of the new and traditional forming machine was similar. Loose bio-materials entering into the forming parts would directly drop out with the centrifugal force of rotation due to the open end of the forming hole. With the continuous supplement, bio-materials were gradually compacted to densification under the combined action between the friction produced by hole wall and the extrusion pressure of plunger. The larger density of the pellet, the greater of friction and extrusion pressure. After stable run for a period of time, steady-state balance was developed of the friction and extrusion, when the forming density of bio-materials tended to be stable, and reached the maximum. Then the solid pellets were constantly squeezed out.

Compression tests were done with sawdust and paper scraps at the condition of 12% moisture content and ≤2mm granularity as test materials [10, 11]. Adjusted the speed of engine at about 1600 r/min with the first gear engagement, that is, the ring-die part was run at 100 r/min. After 10 minutes feeding, bio-materials (sawdust) in forming holes would be dense gradually and begin to be squeezed from the holes, seen in Figures 10a and 10b. The pellet density was lower (about 0.4-0.5g/cm^3) for the poor particle binding force at the moment in Figure 10c. With the growth of work time, the pellet production quality had been improved greatly and tended to be stable, when the pellets density could reach 0.8-0.9 g/cm^3 finally shown in Figures 10d and 10e. Figure 10f was the paper pellets produced at the engine speed of 1000 r/min, the density of which was measured to be 0.85 g/cm^3.

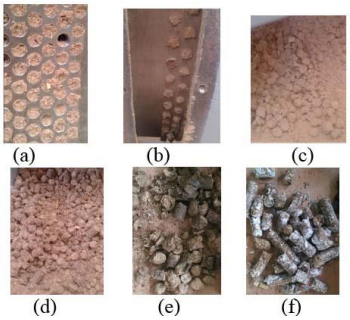


FIGURE 10 The compression experiments of the new biomass pellet forming machine a) Material extrusion condition at the entrance end of forming holes after 10 minute sawdust feed. b) Discharge condition at the outlet end of forming holes after 10 minute sawdust feed. c) Biomass pellet product after 10 minute sawdust feed. d) Biomass pellet product after 20 minute sawdust feed. e) Pellet fuel made by sawdust after 30 minute operation. f) Pellet fuel made by paper scraps after 40 minute operation

4 Conclusion

At present, there exist common shortcomings of low efficiency, high energy consumption, serious wear of forming mould, and etc., general existing in current biomass forming equipment's. In this paper a forming mechanism of a new type pellet machine with plunger roller and ring-die was proposed, which using the extrusion force of mesh between plungers circumferentially on the roller and forming cavities uniformly distributed in the ring-die to make the loose biomaterials densification. It could avoid direct contact and intense friction of forming parts and materials out of the holes. So the energy consumption of the materials in ineffective forming process was reduced and the wear of forming parts was effective alleviated. Then the new type biomass pellet forming machine was designed according to the requirements by CAD/CAE system (SolidWorks), and a prototype was built with the power 22 kW and production capacity 450 kg/h. Unload and compression test were done finally on the prototype. It was shown that the machine could run well at different speeds when idle load, the forming quality of solid pellet fuel would tend to be stable after 30 minutes' continuous operation and the pellet density could reach more than 0.8 g/cm^3. So it represented that the new pellet machine had a good practical operation and met the design demands. The test results ensured feasibility and practicability on the mechanism of plunger roller and ring-die forming machine.

Reaction mechanism of carboxymethyl starch-based wood adhesive

Yong Zhang, Lixia Li*

Faculty of Modern Agricultural Engineering, Kunming University of Science and Technology, Kunming, China

Received 5 November 2014, www.cmnt.lv

Abstract

The technology involved in manufacturing carboxymethyl starch-based adhesive was studied with the aim of enhancing its water-resistance. The optimum formula was based on previous research using a quadratic orthogonal rotation combination design to synthesise the carboxymethyl starch-based wood adhesive. Compared with the original starch, carboxymethyl starch improves the performance of starch adhesive due to its advantageous properties such as hydrophilicity and stability during freezing and thawing etc. Infrared spectroscopy and scanning electron microscopy were used to analyse the synthesis of the carboxymethyl starch-based adhesive. Many functional groups could be identified by their characteristic Fourier transformation infrared vibration frequency and this was used to explain the structural changes. At the same time, the microstructure of the adhesive was analysed by scanning electron microscopy (SEM), and porous, round or elliptical granules in the carboxymethyl starch were observed. An SEM of the main starch agent revealed a network structure; the granules did not aggregate together to form large groups due to the polyvinyl alcohol that prevented granule agglomeration. However, the SEM of the starch adhesive showed a smoother and more compact network structure, due to the large number of strong chemical bonds that were formed by the association of isocyanate with the main starch agent.

Keywords: carboxymethyl starch, wood adhesive, optimisation, mechanism

1 Introduction

In recent years, sustainability has gained greater attention due to the world's heavy dependence on petroleum and natural gas for energy and various products; the development of alternatives to petrochemical-based products from renewable materials improves sustainability [1]. At present, urea-formaldehyde resin, phenolic resin and melamine formaldehyde resin are still widely used to synthesise wood adhesives; however, these are not sustainable in the long run. Furthermore, the emission of carcinogenic formaldehyde during their production has been a serious concern in recent years [2-4]. Natural resources have unique properties and advantages. Starch is an abundant natural polymer that is excellent for use in the manufacture of wood adhesives. For a long time, starch has been used as an additive in conventional adhesives [5-7] because it is easily obtained, the process is simple, it is easy to operate, it is low cost, gives good adhesion and is environmentally friendly; it is therefore potentially a useful product to investigate [8]. Li Lixia [9] achieved the best operating parameters of wet strength adhesive after bonding wood materials and analysed the effects of the formula and synthesis technology using a quadratic orthogonal rotation combination design. Shi Junyou [10] investigated the bonding mechanism of the starch-based aqueous polymer isocyanate and birch wood using Fourier transformation infrared (FTIR) and electron spectroscopy for chemical analysis (ESCA). Wang Zhenjiong [11] analysed starch-based wood adhesive by FTIR, nuclear magnetic resonance (NMR) and SEM.

These studies on starch wood adhesive led to significant progress, but there are still some issues such as problems of low starch content and poor water resistance. Compared with the original starch, carboxymethyl starch can improve the performance of starch adhesive due to its advantages, including hydrophilicity and good stability during freezing and thawing etc. Therefore, in this paper we investigated the optimal formula for the preparation of carboxymethyl starch-based wood adhesive [9]. We aimed to reveal the reaction mechanism of the starch-based adhesive through comparative analysis using infrared spectroscopy and SEM to analyse the starch, the main agents of starch and the starch-based adhesive. The ability to enhance the water resistance of starch-based adhesives is of great importance.

2 Material

Material: carboxymethyl starch (Heilongjiang Longfeng Modified Corn Starch Factory); polyvinyl alcohol (1788, Tianjin Kemiou Chemical Reagent Development Centre); two-component polyisocyanate emulsion adhesiv Prefere. 6150 (Taier Chemical (Shanghai) Co., Ltd.); carboxylic butadiene-styrene latex Nipol LX473D (Shanghai Lishen Chemical Co., Ltd, Shanghai, China).

Instruments: HH.SY11-Ni electric-heated thermostatic water bath (Beijing Changfeng Instrument Company), JJ-1 type power basic stirrer (Jintan City, Jiangsu Province Medical Instrument Factory), three-necked flask (250 ml; Sichuan Shubo Co., Ltd.), thermometer (100 °C), measuring cylinder (100 ml), pipetting device (20~200 L; Shanghai Dragon Medical Equipment Co., Ltd.), JM1102 electronic

balance (Yuyao Jiming Weighing Electronic Balance and Check Equipment Co., Ltd.), VECTOR22 Fourier transform infrared spectrometer (Swiss Bruker company), Scanning electron microscope and E-1010 ion sputtering apparatus (Japan Hitachi company).

3 Methods

3.1 PREPARATION OF THE ADHESIVE

The optimum formula for carboxymethyl starch adhesive was based on previous research using a quadratic orthogonal rotation combination design to synthesise the starch-based wood adhesive [9].

3.2 FOURIER TRANSFORMATION INFRARED (FTIR)

The starch and the samples of carboxymethyl starch adhesive were fully milled in an agate mortar, and samples were prepared by grinding the finely powdered starch with potassium bromide. The mixture was then pressed into tablets before measurement. The IR spectra were obtained using a VECTOR22 IR Spectra Scanner, and they were recorded over a wave range of 400–4000 cm^{-1}.

3.3 SCANNING ELECTRON MICROSCOPY (SEM)

The carboxymethyl starch-based wood adhesive was synthesised using the optimal parameters from the above-mentioned experiment. A sample was placed on the carrier using a pipette, then it was solidified in a drying vessel. The dehydrated samples were coated with gold powder to avoid charging the sample under the electron beam. Finally, the microstructure was observed using a scanning electron microscope.

4 Results and discussion

4.1 ANALYSIS OF FTIR

Infrared spectroscopy was used to analyse carboxymethyl starch, carboxymethyl starch main agent and carboxymethyl starch-based adhesive; the results of IR spectra are shown in Figure 1 (Figure 1a, Figure 1b and Figure 1c).

The information on chemical structure from FTIR spectroscopy in Figure 1a shows a broad band at 3400 cm^{-1} attributed to O-H stretching [12-14]. This is due to the hydroxyl groups present in the starch molecules, and indicates that these hydroxyl groups are not free; they form large amounts of intramolecular and intermolecular hydrogen bonds [5]. Meanwhile, the C-H stretching vibration gave a strong signal at 2890–2940 cm^{-1} [15-17]. The peak at 1650 cm^{-1} was attributed to C=O stretching [18-20], and the peaks at 1350–1450 cm^{-1} were related to the C–H bending of CH_2 [21-23], this indicated that the hydroxyl groups of starch molecules were carboxymethylated. The results were consistent with previous reports concerning different kinds of carboxymethyl starch. The peaks at around 1160 cm^{-1} and 1090 cm^{-1} were characteristic of C–O–H in starch [24-26], while the peak between 990 cm^{-1} and 1050 cm^{-1} was attributed to C-O bond stretching in the C-O-C group [27-29]. A similar phenomenon was observed in the absorption peaks present at 928 cm^{-1} for skeletal mode vibrations of glycosidic linkages (C–O–C) [30]. Bands at 850 cm^{-1} were due to the C(1)-H deformation of CH_2 in the glucose unit, and the bands at 575 cm^{-1} and 750 cm^{-1} related to the C–C stretching of skeletal modes in the glucose unit, this observation is similar to the results of Joshi et al. [23, 30].

Compared with Figure 1a, the information of chemical structure from FTIR spectroscopy in Figure 1b shows a smaller peak at 3740 cm^{-1}; this was attributed to the free O-H stretching. The band, which was displaced at 3600 cm^{-1} as a sharper and smaller peak in carboxymethyl starch main agent was the characteristic absorption peak for the stretching vibration of O-H groups because of the complex vibrational stretching associated with intramolecular and intermolecular bound hydroxyl groups. In addition, this peak had a high transmittance in the spectrum of carboxymethyl starch main agent attributed to the introduction of polyvinyl alcohol and carboxylic butadiene-styrene latex. The results indicated that the reaction of the hydroxyl and carboxyl weakened the peak intensity and wave number of hydroxyl absorption, and hydroxyl groups were blocked to proper lever in the carboxymethyl starch main agent. The band occurring at 2350 cm^{-1} was most probably due to the presence of carbon dioxide in test samples. The absorption bands at 1680 cm^{-1} were attributed to C=O stretching and this is consistent with the results of Machová et al. [31, 32], indicating the presence of carboxyl in the samples. It was also observed that the absorption peak present at 1525 cm^{-1} was characteristic for benzene [33-35], and the peaks at 1800–1950 cm^{-1} indicated the vibrating property of mono-substituted benzene derivate, suggesting the presence of carboxylic butadiene-styrene latex. The presence of the carboxyl group and phenyls made significant improvements in the viscosity and adhesive strength of the polymer and thus improved the property of the adhesive.

The absorption bands between 2310 and 2350 cm^{-1} were ascribed to - NCO antisymmetric stretching vibration (see, Figure 1c) and a large number of strong chemical bonds were formed by the association of –NCO groups and carboxymethyl starch main agent, which improved the wet strength of the adhesive. It was also observed that absorption peaks were present at 1550 cm^{-1} for N-H bending deformation and C-N antisymmetric stretching vibration [36, 37]. The peaks at 1700 cm-1 and 1650 cm^{-1} were attributed to the C=O stretching vibration [38, 39]. Moreover, the broad band at 1250 cm^{-1} was attributed to N-CO-O asymmetric stretching vibration, indicating the introduction of isocyanate. This significantly increased the viscosity and wet strength of the adhesive.

4.2 ANALYSIS OF SEM

The microstructure of starch-based adhesive that was analysed by scanning electron microscope is shown in Figure 2. As can be seen in Figure 2a, round or elliptic shaped granules were present in the cornstarch [40-43] and the surface of the cornstarch had a smooth, full and compact structure [44-46]. The starch granules appeared to agglomerate due to the strong interaction of intermolecular and intramolecular hydrogen bonds in the starch molecules [47]. Compared with Figure 2a, carboxymethyl starch (see, Figure 2b) was still present in a granular form and it was similar in shape to the corn starch. However, holes were apparent on the surface of granules that increased the surface area thus improving solubility and adsorption. This observation suggests that the starch crystallinity was altered, thus allowing the etherifying

agents to have more access to the starch molecules for the carboxymethylation processes [48, 49]. The changes observed on the modified starch granules were also due to the breakage of chemical bonds in starch molecules affected by the strong alkaline environment together with heat treatment, this means that the carboxymethyl reaction took place both on the surface and within the starch granules [50]. The network structure following the introduction of a carboxyl group, benzene and polyvinyl alcohol can be seen in Figure 2c. This significantly improved the viscosity and adhesive strength of the polymer and improved adhesive properties. Each granule still maintained its individual entity but the granules did not agglomerate to form large groups (see, Figure 2c). This was due to the polyvinyl alcohol, which prevented granules agglomerating and accelerated the emulsifying process. When compared with Figure 2c, the much smoother and more compact network structure can be seen in Figure 2d. The starch adhesive was highly compatible because the uptake of isocyanate greatly improved the adhesive strength. The isocyanate was uniformly distributed in the water-soluble solvent of emulsifying by polyvinyl alcohol as long as it was reacting with the main agent and then forming solid amine fat keys, urea key chemical bonds and so on. Subsequently, these chemical bonds reacted with hydrogen, forming a network of structural molecules that increased the wet strength.

5 Conclusions

1) FTIR of carboxymethyl starch revealed a broader band at 3400 cm^{-1} attributed to the large number of hydrogen bonds that were formed by the association of hydroxyl and carboxyl. The C-H stretching vibration gave a strong signal at 2890-2940 cm^{-1} and the primary and secondary alcohols of the bands at 990-1160 cm^{-1} indicated C-O stretching. The FTIR of carboxymethyl starch main agent showed absorption bands at 1680 cm^{-1} attributed to C=O stretching, thereby indicating the introduction of carboxyls. It was also observed that the absorption peaks present at 1525 cm^{-1} were characteristic of benzene, and the peaks at 1800–1950 cm^{-1} had the vibrating property of monosubstituted benzene derivate; this indicated the introduction of phenyl of carboxylic butadiene-styrene latex. The introduction of polyvinyl alcohol and carboxylic butadiene-styrene latex made the viscosity and adhesive strength of the polymer increase significantly and thus improved the adhesive property. The FTIR of carboxymethyl starch adhesive absorption bands at 2310 -2350 cm^{-1} were ascribed to the - NCO antisymmetric stretching vibration, and isocyanate was introduced into the carboxymethyl starch adhesive.

2) Round or elliptic shaped granules appeared in the carboxymethyl starch and the granule surfaces became pocked with a number of holes. The carboxymethyl starch granules appeared to become agglomerated due to the strong interaction of the intermolecular and intramolecular hydrogen bonds of the starch molecules. The SEM of carboxymethyl starch main agent presented a network structure; however, each granule maintained its individual entity while the granules did not bind together to form large groups as compared with Figure 1b. This was due to the polyvinyl alcohol that prevented granule agglomeration and improved stability. In addition, the SEM of the carboxymethyl starch adhesive displayed a smoother and more compact network structure, due to the large number of strong chemical bonds that were formed by the association of isocyanate and the starch main agent.

Acknowledgements

The authors gratefully acknowledge all the scientific members of the research team. This study was supported by research project of the Heilongjiang (GB06B501-2-2). Also we are grateful to the Heilongjiang Longfeng Modified Corn Starch Factory for kindly supplying the carboxymethyl starch, and the Shanghai Lishen Chemical Co., Ltd for the carboxylic butadiene-styrene latex.

Abstract

In this paper, a new energy-saving-and-environmental-protection heat-preservation wall material is studied. This material is mainly made by waste foam, cement and sand in the structure of "sandwich" - cement foamed plastic is in the middle of cement mortar. Experimental study reveals that the heat-preservation block of this material has lighter self-weight and higher compressive strength and better performance in heat preservation, sound insulation and frost resistance, that is to say, its overall property is obviously superior to that of others such as aerated concrete block. This block consumes a large amount of waste foam that is difficult to dispose, which conducive to environmental protection and energy is saving. It can bring favourable social, economic and environmental benefit. Besides, less energy is consumed in the production of this material and it is easy to realize volume production, so this material is a new wall material of energy saving and environment protection.

Keywords: waste foam, heat preservation, wall material, new technologies

1 Introduction

With heavy self-weight and high energy consumption, the traditional wall materials in China waste lots of land resources, so it is to the disadvantage of environment protection and energy saving. Heat preservation property of the building envelope is a major factor influencing energy consumption of a building and different envelope materials need different energy costs. In China the insulating layer is generally not built in the outer wall of house by tradition, resulting in poor heat preservation and deafening effect as well as more energy consumption [1]. There is one important aspect in the architectural idea of "sustainable development": laying emphasis on energy conservation [2]. Currently the development priority in wall materials is to develop the new wall material, which needs low energy consumption and causes less pollution local resources by utilizing local resources [3]. Meanwhile, the waste foam is difficult to resolve in natural environment, causing serious pollution in modern times. With the development of social economy and rapid improvement of living standard, the demand for foamed plastic is increasing and waste foam is bringing more serious pollution and some experts have listed this pollution on the top three public pollution following water pollution and air pollution. As the aggregate of concrete heat presservation block, recycled polyphony l granule cannot only avoid "white pollution", but has many advantages such as good particle size gradation, being easy to be coated by size, good property and low price. The concrete heat preservation block in this paper is produced through simple technique, consumes less energy and has many advantages including light self-weight, good heat preservation property and high strength. This block consumes a large amount of waste polystyrene foam, opening up a way of removing white pollution and helping to environmental protection and energy saving, so it is a new green wall material with broad prospect.

2 Experiment materials

Cement: PO 32.5, PO 42.5 and PO 52.5 ordinary Portland cement from Luoyang Yellow River Cement Plant.

Foamed plastics particles: waste polystyrene foam is broken into particles of 0.4 mm~5 mm.

Sand: medium sand with the fineness modulus of 2.6 and qualified grain size gradation.

Tackifier: new environment-friendly II glue from Luoyang Kelong Coating Co. Limited.

Water: drinking water.

3 Experimental study

3.1 MAKING BUILDING BLOCK

1) To make the test mould in size of $150mm \times 150mm \times 150mm$ and its size and structure are shown in Figure 1. Steel plates with the thickness of 5mm are selected to make the test mould in the net size of $150mm \times 150mm \times 150mm$; the plates can be disassembly and place together flexibly and no gap is allowed after the assembly. 2 scale marks which are 20mm to the upper and lower surfaces are drawn on the side wall of the test mould in order to control the thickness of screed and that of cement foam layer. Waste engine oil is painted on inwalls for easy mold release.

***Corresponding author** e-mail: cai-lipeng@163.com

2) Cement:Sand:Water = 1 : 2 : 0.6 and cement mortar is mixed mechanically. Put the cement mortar on the bottom of test mould as thick as 10mm.

3) Cement:Sand:Tackifier=1:10:0.10 to make the cement paste; fully mix the paste with recycled polyphony l granule; after the paste attaché evenly to polyphony l granules, to put the mixture in the test mould about 5mm to the top edge of the block.

4) To spread the cement mortar to the top edge and smooth it over with a spatula.

5) To cover the surface of the test mould immediately once it shapes up to prevent evaporation of water. After 24 hours standing at the temperature of 20°C±5°C, to mark serial numbers and remove the block from the mould.

6) To put the test block in a standard curing room with the temperature of 20°C±1°C and working humidity above 95%. After the test block is maintained for 28d, the cement heat preservation block can be formed.

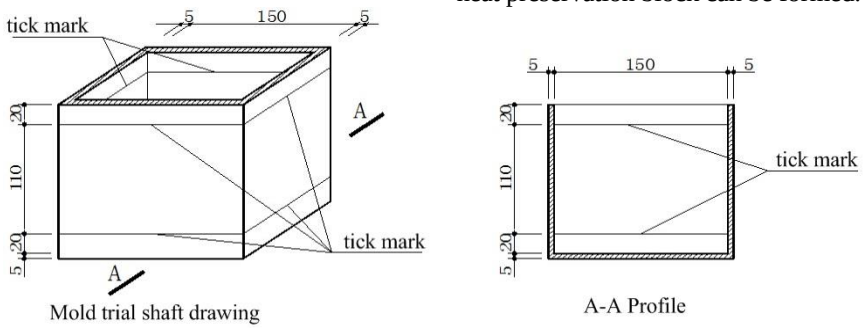

FIGURE 1 Test mould dimension drawing

3.2 PERFORMANCE DENSITY TEST

There are 18 test blocks in 6 groups for this test. The performance density is tested in the following steps:

1) To bake the test block in a 105~110°C baking oven until it has constant weight and to cool it to room temperature in a dryer.

2) To measure the size of the block with a straightedge (mm). Since it is a cube, the arithmetic mean value of 3 extents on all surfaces is used as the test value. Note down the value and calculate the volume (V_0).

3) To weight the mass with a balance and calculate its performance density ρ_0 according to the Equation - $\rho_0 = m/V_0$. Table 1 displays the test data.

TABLE 1 Performance density test data

Groups	No	Test block size/ cm			Test block volume V_0/cm³	Test block mass m/ g	ρ_0/(g/cm³)	Mean value/(g/cm³)
		Side length	*Side length*	*Side length*				
Group 1	1	15.0	15.1	15.2	3442.80	2065.7	0.600	0.610
	2	15.0	14.9	15.1	3441.90	2109.9	0.613	
	3	14.9	15.0	14.9	3330.15	2054.7	0.617	
Group2	1	15.0	15.0	15.2	3420.00	2072.5	0.606	0.607
	2	14.9	14.9	15.0	3330.15	2034.8	0.611	
	3	15.0	15.1	15.2	3442.80	2082.9	0.605	
Group3	1	14.9	15.0	15.1	3374.85	2058.3	0.610	0.606
	2	15.0	15.1	15.2	3442.80	2093.2	0.608	
	3	14.9	15.1	15.2	3419.85	2047.8	0.599	
Group4	1	15.0	14.9	15.0	3452.50	2106.0	0.610	0.612
	2	15.1	15.0	15.2	3442.80	2107.3	0.612	
	3	15.0	14.9	15.0	3352.50	2061.2	0.615	
Group5	1	15.1	15.0	15.2	3442.80	2105.4	0.612	0.611
	2	15.0	14.9	14.8	3307.80	2040.5	0.617	
	3	15.0	15.0	15.1	3374.85	2042.3	0.605	
Group6	1	15.0	15.0	14.9	3352.50	2038.3	0.608	0.613
	2	15.1	15.0	15.1	3442.80	2110.3	0.613	
	3	15.0	15.0	14.9	3352.50	2071.4	0.618	

According to Table 1, the performance density is: $\frac{0.610+0.607+0.606+0.612+0.611+0.613}{6} = 0.61$.

The performance density is 0.61g/cm³, that is 610 kg/m³.

3.3 COMPRESSIVE STRENTH TEST

There are 18 test blocks (used in the above test) in 6 groups for the compressive strength test. The compressive strength is tested in the following steps:

1) To wipe and measure the size of the test block (1mm) as soon as it is taken out from the curing room and to calculate its compression area A (mm2).

2) To place the test block on the bearing plate according to Illustration 2: the pressure-bearing surface of the block should be perpendicular to the top surface when it shapes up and its centre should align with the centre of the tester. To start the tester and adjust the ball seat for balanced contact between the top and bottom platens and the top and bottom surfaces of the test block.

3) In this test, loading should be increased constantly and uniformly with the speed of 0.3MPa/s. When the test block begins to deform, stop to adjust the accelerator of the tester until the block is destroyed. Note down the collapse load $P(N)$.

4) To calculate the compressive strength according to $f_{cu} = P/A$. 3 arithmetic mean value of the strength is used as the compressive strength value of their group (0.1MPa). If $\min imun\ value - mediam > 15\%$ median or $maximun\ value - mediam > 15\%$ median, the minimum value and the maximum value should be removed in the calculation; that is the median is the compressive strength value. If $\min imun\ value - mediam > 15\%$ median and $maximun\ value - mediam > 15\%$ median, the test results are invalid.

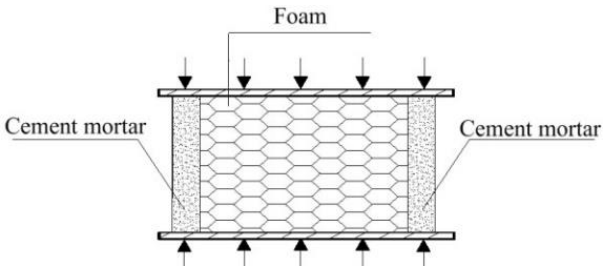

FIGURE 2 Compressive Strength Test

Table 2 presents the compressive strength test data.

TABLE 2 Compressive Strength Test Data

Groups	NO.	Size(mm)		A(mm^2)	P (N)	CS(MPa)	
		a	*b*				
	1	150	151	22650	90250	3.98	
1	2	150	149	22350	85250	3.81	3.81
	3	149	150	22350	80850	3.62	
	1	150	150	22500	78400	3.48	
2	2	149	149	22201	72550	3.27	3.41
	3	150	151	22650	78750	3.48	
	1	149	150	22350	84000	3.76	
3	2	150	151	22650	81200	3.58	3.63
	3	149	151	22499	79550	3.54	
	1	150	149	22350	85500	3.83	
4	2	151	150	22650	91500	4.04	3.84
	3	150	149	22350	81550	3.65	
	1	151	150	22650	82500	3.64	
5	2	150	149	22350	77800	3.48	3.57
	3	150	150	22500	80550	3.58	
	1	150	150	22500	84000	3.73	
6	2	151	150	22650	89500	3.95	3.75
	3	150	150	22500	80500	3.58	

According to Table 2, the compressive strength is: $\frac{3.81+3.41+3.63+3.84+3.57+3.75}{6} = 3.67$.

The average value of compressive strength is 3.67MPa and the minimum value is 3.27MPa.

3.4 HEAT PRESERVATION PROPERTY TEST

This test is a comparison test. The property of heat preservation is compared between heat-preservation concrete block, aerated concrete block and common brick to conclude the heat preservation property and heat conductivity of this block.

3 sealed experiment rooms of the same size are built up with common bricks, aerated concrete block and the concrete block studied in this paper [7]. Place an electric stove (power: 2500w) in each room to heat the experiment rooms. Stop the heating when the temperature reaches 95°C and observe how the temperature changes in each room at the interval of 30m for 9 times. Note down the temperatures observed.

Do this test for 3 times. The temperature-time variation curves in the 3 experiment rooms are shown in Figures 3, 4 and 5.

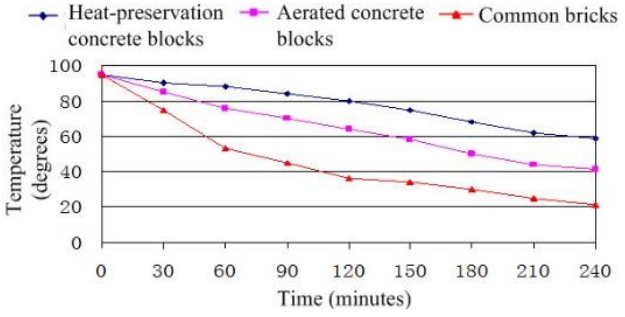

FIGURE 3 Temperature variation curve in rooms (1st time)

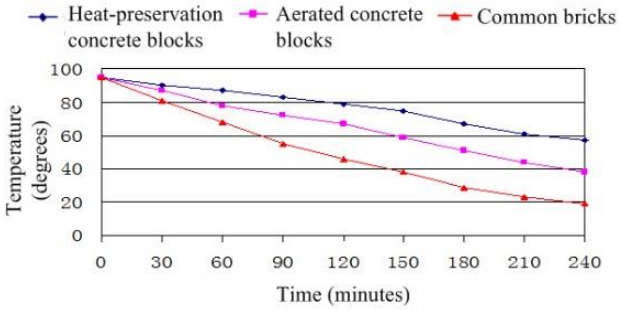

FIGURE 4 Temperature variation curve in rooms (2nd time)

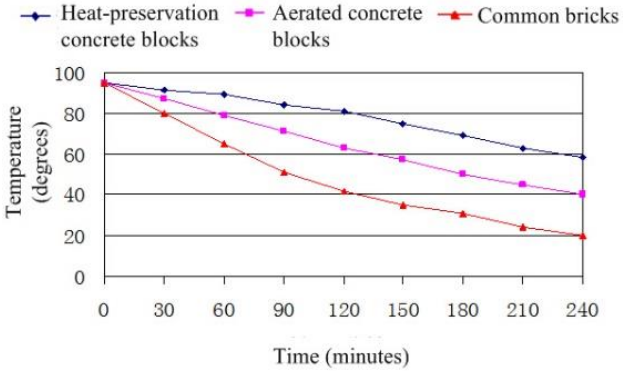

FIGURE 5 Temperature variation curve in rooms (3rd time)

Test results show that the temperature drops slowest in the room made by heat-preservation concrete blocks followed by the room made by aerated concrete blocks and common bricks. Thus, it can be inferred that the heat preservation property of the block studied in this paper is obviously superior to aerated concrete block and common brick, and that its heat conductivity is smaller than that of aerated concrete block, that is its heat conductivity $\lambda < 0.12 \ \ w/m.k$.

4 Conclusions

1) The concrete block studied in this paper can fully meet the requirement of new wall materials in properties such as performance density, compressive strength and heat presservation. Compared with the autoclaved aerated concrete blocks, this block has obvious advantages.

2) In engineering practice, the cement mortar layer on the outer coat of block is the main framework and the polystyrene granule in the block can bears little external force, so cement mortar of high strength can produce the heat-preservation concrete block of higher strength.

3) The technique in this paper is quite simple and easy and consumes less energy. Large equipment is not needed; small investment requires; desired results are produced rapidly and it is easy to realize volume production.

4) Blocks of various specifications can be produced according to the thickness of wall for different environment. For example, the $190*190*H$ (the mortar layer is as thick as 15mm) and $240*240*H$ (the mortar layer is as thick as 20mm).

5) This concrete blocks have digested a lot of waste polystyrene plastics, protecting the environment and steering the building materials in the direction of saving resources, utilizing wastes and protecting environment.

6) To carry out the studies on heat-preservation concrete blocks made from recycled polyphony l granules can acelerate the progress of wall material innovation in China and the greenization of building materials industry and is conducive to the popularization of energy saving construction. To build houses with high-quality new wall materials has obvious building energy efficiency and improves comfort level of living and can meet the requirement of economic and social development and upturn living standarts. To launch the studies plays a positive role in propelling the progress of wall material innovation and the greenization of building materials industry and the popularization of energy saving building in China.

Abstract

During the previous decade, several offshore wind-farms were constructed for offshore wind energy generation showed promise as a source of green energy. However, there are several challenges to be met in the design and construction of the foundations for offshore wind turbines. The fatigue load plays an important and crucial role in the design of the supporting structures. In this paper, the vortex-induced vibrations of the tension leg platform were studied. Two types of structures namely; cylindrical Tension Leg Platform (TLP) and variable cross-section TLP were designed and studies on them were conducted to compare the advantages and drawbacks resulting from vortex-induced vibrations. Both uniform and shear flow were considered to simulate water flow through the structures. The variable cross-section TLP, which possesses outstanding mechanical properties, gave lower vortex shedding frequency compared to the cylindrical TLP for the same velocity. This is the objective desired in vortex-induced vibration.

Keywords: vortex-induced, tension leg platform, variation section

1 Introduction

With increasing population and economy, many countries began to exploit the natural ocean resources such as offshore oil and wind energy. The foundation of the wind turbine is the most important component. For its operation at increasing depths the traditional foundation fails to meet the necessary requirements. At 60m-100m, the TLP is not only economical but also stable [1].

The TLP is the vertical basis of mooring and compliant structure, similar to the combination of rigid and flexible systems. It is a complex nonlinear dynamic system. Its structural principle is producing a greater weight than force of buoyancy for offsetting the gravity and preload. Besides, the flexibility of TLP can realize the plane movement conforming to the external load. As a result the structural internal load is not needed [2, 3].

The TLP works in a complex environment. One of its serious operational problems is vortex-induced vibration. When there is an ocean current flow over a flexible cylinder, there will be a shedding vortex behind the structure because of the non-uniform pressure distribution. The vibrations in the structure will be produced by the shedding vortex because of the cross-flow and in-line flow pulse pressure. The vibration is the main factor for the fatigue of the structure [4].

Three methods are employed to study the vortex-induced vibrations. These are experimental empirical modelling and numerical simulation. Feng [5] conducted experiments on the vibrations of one-degree-of-freedom of a circular cylinder in air flow. In his study, the vibration of the cylinder was confined to the cross-flow direction where only typical lock-in phenomenon was presented. In general, when a cylinder is subjected to a flow at a high mass ratio, only two amplitude response branches exist. These are initial and lower branches. If the cylinder is placed in a flow at low mass ratios, the third branch (i.e., upper branch) is also observed. The mostly known empirical model includes the VIVA, VIVANA, SHEAR7 and VICoMo. Along with the advances in computers, the science of Computational Fluid Dynamics (CFD) developed rapidly. Anagnostopoulos and Iliadis [6] carried the out numerical studies on the 1 DOF VIV of a circular cylinder in the stream direction and found that the response of the cylinder was amplified significantly, if the oscillatory flow frequency was close to the natural frequency of the cylinder. Zhao and Cheng [7], Zhao et al [8] simulated 1 DOF VIV of a cylinder in oscillatory flows at KC=10 and 20 and found that the response of the cylinder included more than one frequency as the reduced velocity exceeded KC=8. Ding [9] studied two-dimensional vortex-induced vibration with numerical simulation method and found that the lift coefficient and drag coefficient transformation laws were functions of the Reynolds number. Willden [10] researched on the vortex-induced vibration under the shear flow and observed a new locus for the movement of the structure.

The entire published research focused on the vortex-induced vibration of cylinder. The effect of varying section did not receive the attention of the researchers. Yanqiu Dong proposed the structure of non-uniform cross section for the oil platform, without analysing the mechanical characteristics for the structure. In this paper wake pattern lift and drag were compared for the cylindrical and cylindrical-conical structures at different stream velocities.

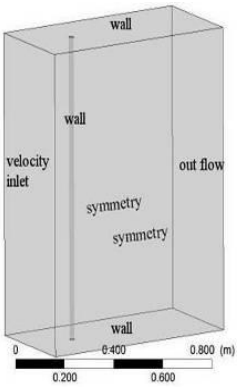
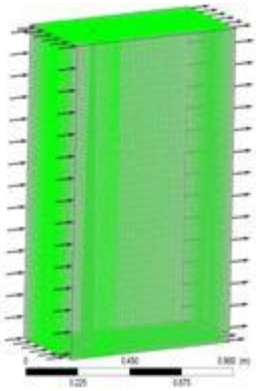
2 Numerical methods

The material of the TLP was steel, with ρ=7850 kg/m^3, E=2.06E+11, and Poisson ratio of 0.3. The dimensions of the TLP were: 100min length, and 2m in diameter. For the variable cross-section of TLP, the diameter was 1m-3m. There was a preload of 100N at top of the TLP. The top of TLP was fixed to the floating structure with hinged joint and the bottom was fixed with the seabed foundation. The software ICEM was used to generate the mesh. The dimensions of the domain were 80m×40m×100m. The distance from the inlet and side face to the TLP was 20m. The grid elements around the TLP were encrypted because the subdomain was complicated and not only included fluid breakdown, but also vortex shed. All of the grid elements were in form of a structured grid. The geometrical and mesh models are shown in Figure 1a and Figure 1b respectively.



a) The geometric model



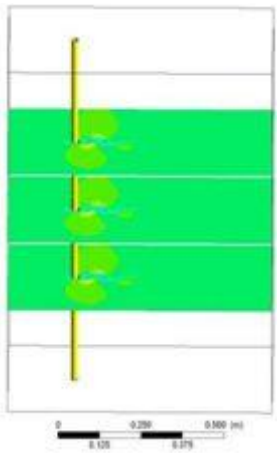
b) The mesh model

FIGURE 1 The geometric and mesh models

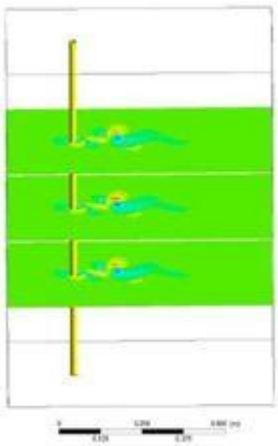
The initial and boundary conditions were set in CFX-pro, the TLP was non-slipping boundary, the top and bottom sides were walls, the left and right sides were in symmetry. In this paper, discretization format was Second-order central difference and k-ε was chosen as the turbulent model. All of the residuals were limited to 10E-4, the time step was chosen as 0.05s and the terminating time was 40s.

3 Results

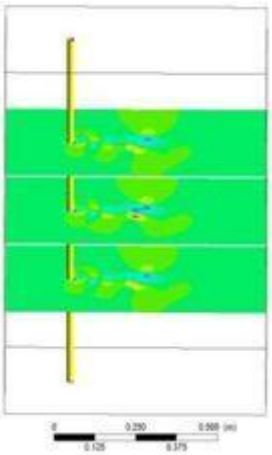
In this section, three velocities 0.2m/s, 0.4m/s and 0.2y+0.2 [0<y<1] (m/s) were chosen. The results for cylinder section and the cone section were obtained. Figure 2 shows the process of cylinder section vortex shedding. The corresponding times are 1.5s, 3s and 5s, the left column of figures is for the velocity 0.2m/s and the right column of figures is for 0.4 m/s. The results obtained from the velocity contour are that Reynolds number has a significant effect on the wake. Higher the Reynolds number sooner is the vortex generation and higher is the amount of energy is stored in the vortex. Besides, the linear distance between adjacent vortexes is less at 0.4m/s than that at 0.2m/s.



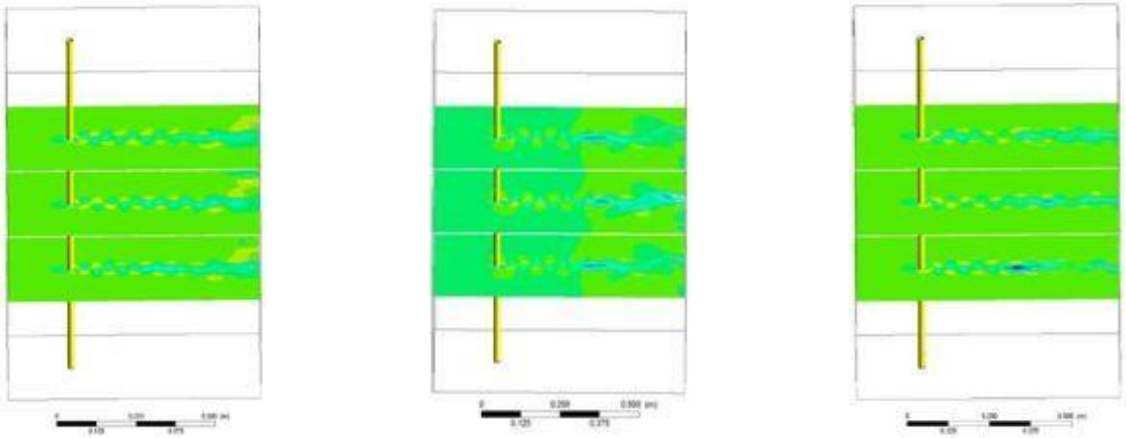
a) 1.5s at 0.2m/s



b) 1.5s at 0.4m/s



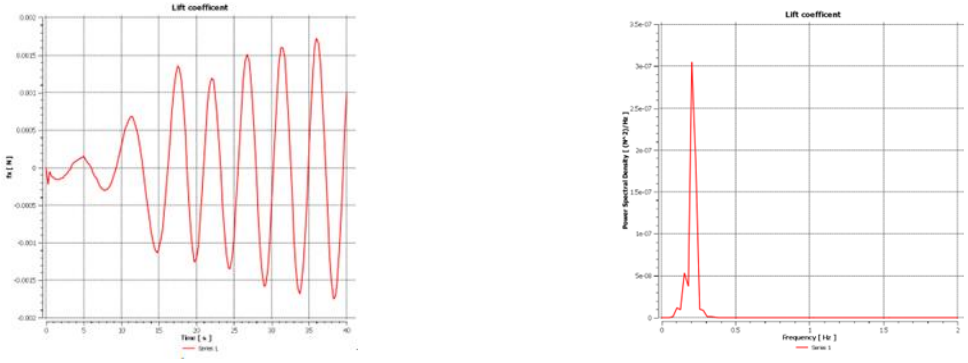
c) 3s at 0.2m/s



d) 3s at 0.4m/s e) 5s at 0.2m/s f) 5s at 0.4m/s

FIGURE 2 The velocity contours of cylinder TLP at different instants of time

The lift force, drag force time history curve and frequency spectrum for cylinder TLP and variable cross section TLP result are shown in Figure 3 to 10. It can be seen from these figures that when the velocity increases, the amplitude of lift force and the frequency increases. This means that the frequency of vortex shedding is accelerated. The lift force frequency is 0.251Hz at 0.2 m/s and the corresponding Strouhal number S_t is 0.23. When the velocity is 0.4 m/s, the lift force frequency is 0.498Hz and the S_t is 0.21. The above simulation results are in agreement with those in literature in which S_t was reported as about 0.2 when $300 < R_e < 1.5\times10^5$.



a) The time history curve of lift force b) The spectrum

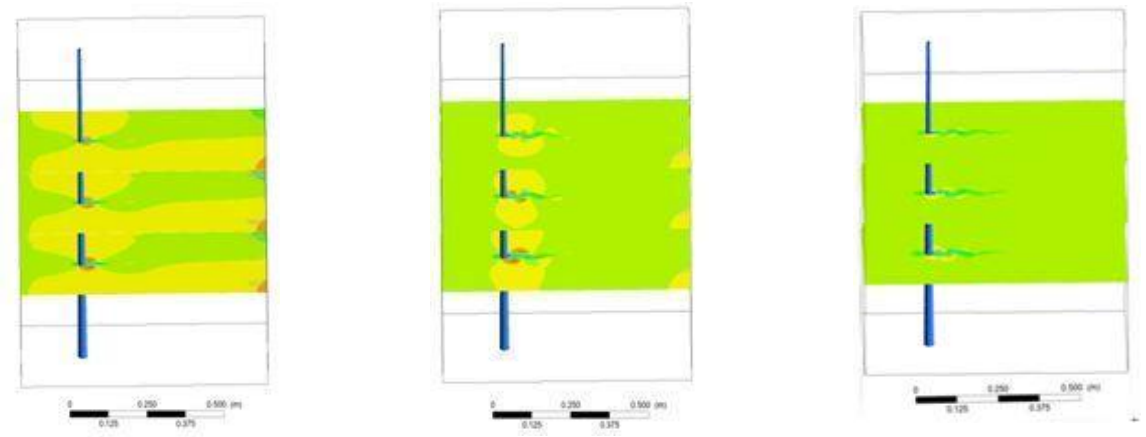
FIGURE 4 The time history curve of lift force and its spectrum at 0.4m/s for cylinder TLP

The contours shown in Figure 5 below illustrate the variation of vortex at different times and positions. The effect of velocity is similar for the cylinder TLP, but vortex changes with the altitude and size of the section also has influence on the vortex. The diameter of the vortex is larger and the distance in-line between adjacent vertexes is more at bottom than at the top.

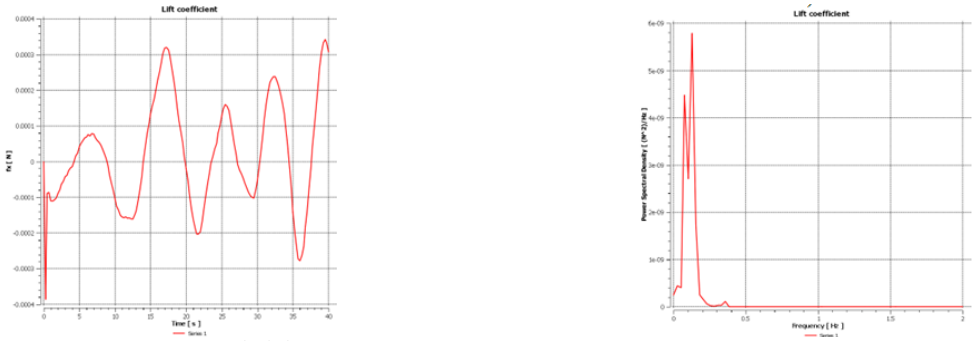


a) 1.5s at 0.2m/s, b) 1.5s at 0.4m/s c) 3s at 0.2m/s

d) 3s at 0.4m/s e) 5s at 0.2m/s f) 5s at 0.4m/s

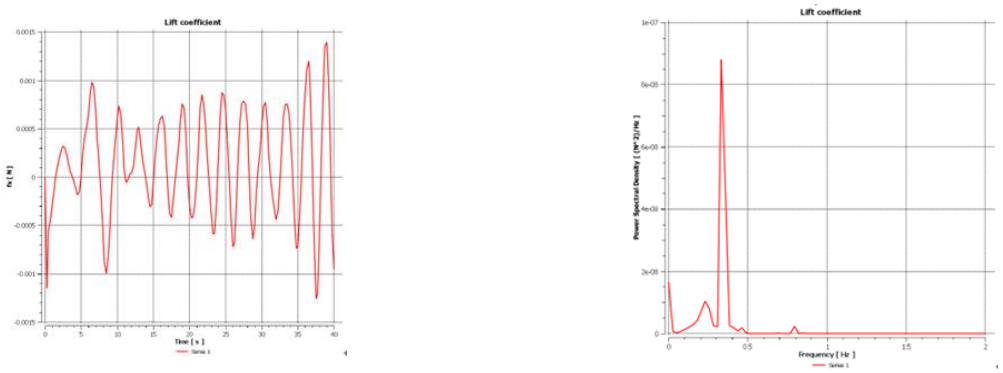
FIGURE 5The velocity contours at different instants of time for variable cross-section TLP

The time history curve of lift force in Figure 6 below shows the period of variable cross-section TLP is larger than of the cylinder TLP for the same velocity. Their frequencies are 0.11-0.198Hz at 0.2 m/s and 0.352Hz at 0.4 m/s. The stiffness of variable cross-section TLP is larger than that of the cylinder TLP. In fact, the stiffness has significant effect on the frequency of the vortex shedding. The trend of the time history curve for variable cross-section TLP is similar to that of cylinder TLP at different velocities.



a) The time history curve of lift force b) The spectrum

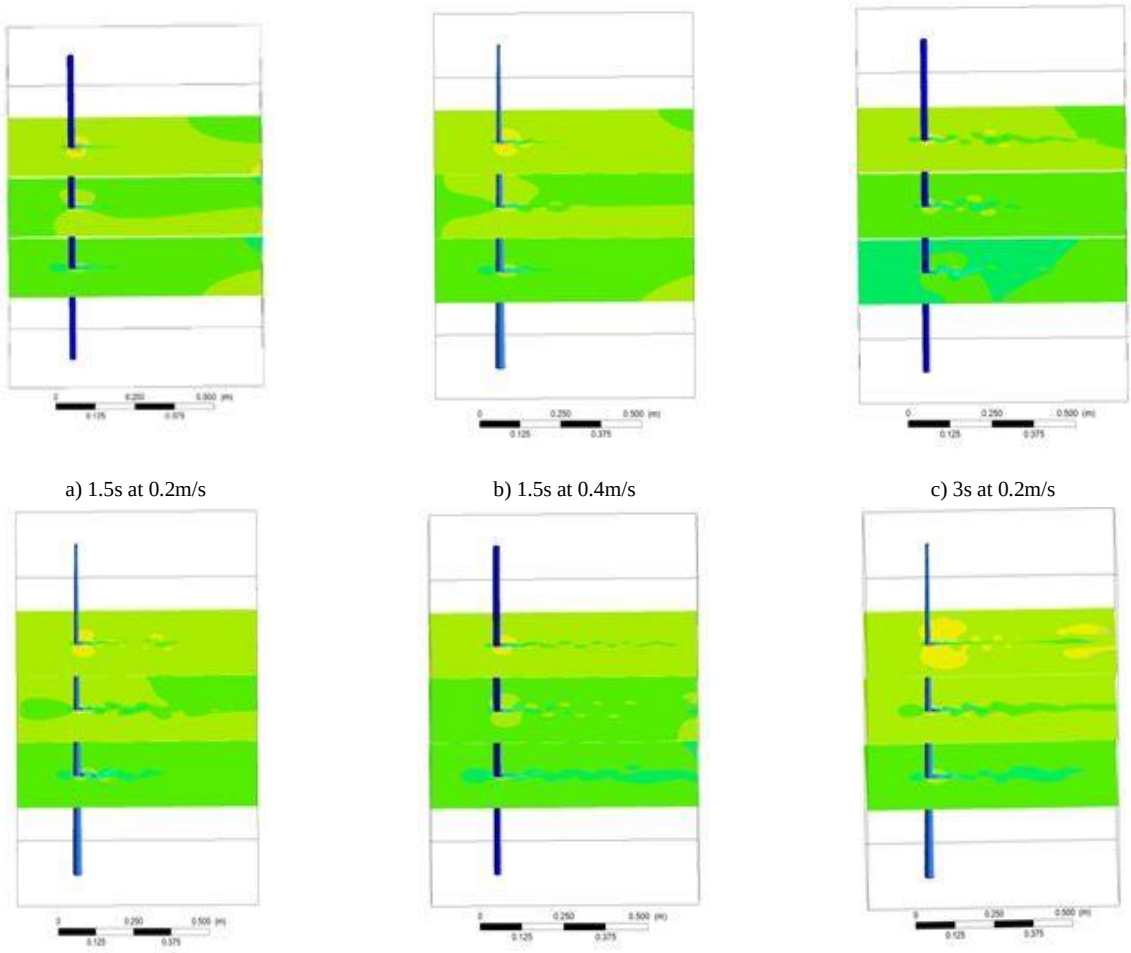
FIGURE 6 The time history curve of lift force and its spectrum at 0.2m/s for variable cross-section TLP



a) The time history curve of lift force b) The spectrum

FIGURE 7 The time history curve of lift force and its spectrum at 0.4m/s for variable cross-section TLP

As uniform flow cannot simulate the true environment of the TLP, shear flow is considered in this section. Firstly, the velocity contours of the variable cross-section TLP (Figure 8 b), d), f)) and the cylinder TLP (Figure 8 a), c), e)) are displayed below. For the cylinder TLP, the vortexes are different at different positions. The bottom of variable cross-section TLP does not show visible vortex, but it does not affect the top. There is vortex shedding at the top.



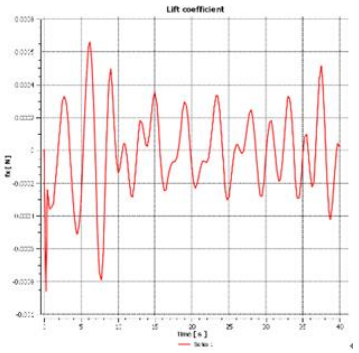
a) 1.5s at 0.2m/s b) 1.5s at 0.4m/s c) 3s at 0.2m/s

d) 3s at 0.4m/s e) 5s at 0.2m/s f) 5s at 0.4m/s

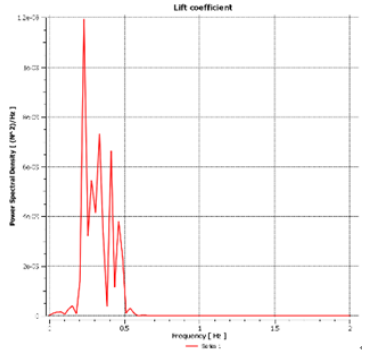
FIGURE 8 The velocity contours at different instants of time for cylinder TLP and variable cross-section TLP

In comparison to the uniform flow, for shear flow the time history curves of lift force for cylinder TLP and variable cross-section TLP change appreciably. For cylinder TLP, small oscillations are noticeable in every

period. The interval of frequency for vortex shedding is wider than before. The vortex shedding is in the range of 0.2Hz-0.5Hz. For the variable cross-section TLP, there are two types of oscillations. The trend of large oscillations is the same as that of the cylinder TLP, but the frequency of every small oscillation is larger than that of cylinder TLP. Though the frequency of vortex shedding for variable cross section TLP is smaller than that of the cylinder TLP, the vortex shedding begins from 0.157Hz. The shedding is also found at a high frequency of 0.697Hz.

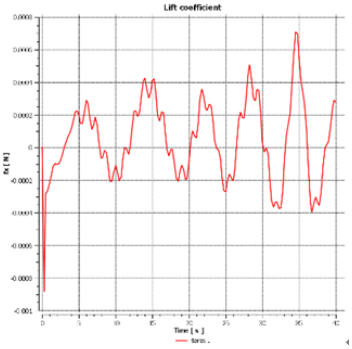


a) The time history curve of lift force

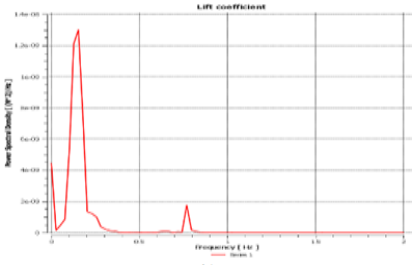


b) The spectrum

FIGURE 9 The time history curve of lift force and its spectrum for cylinder TLP at 0.2y+0.2[0<y<1] (m/s)



a) The time history curve of lift force



b) The spectrum

FIGURE 10 The time history curve of lift force and its spectrum for variable

From the Table 1 below, it can be seen that the frequency of variable cross-section TLP is always smaller than that of the cylinder TLP, although their average cross sections are equal and the volume of variable cross-section TLP is smaller than that of the cylinder TLP.

TABLE 1 The frequencies of TLP and variable cross section TLP at different velocities

	0.2(m/s)	**0.4(m/s)**	**0.2y+0.2[0<y<1] (m/s)**
Uniform cross-section (*D*=2m)	0.251Hz	0.498Hz	0.2Hz, 0.31Hz, 0.42Hz, 0.5Hz
Variable cross-section (*D*=1m-3m)	0.11Hz, 0.198Hz	0.352Hz	0.157Hz

4 Conclusions

This paper reports design of two types of TLP structures for simulation with uniform flow and shear flow. The velocity contours, lift force and drag force are illustrated to explain the results obtained. Following is the summary of final results:

1) For the two types of TLP structures studied, higher Reynolds number resulted in earlier vortex generation and higher energy storage in the vortex. Besides, the distance in-line between the adjacent vortexes is smaller at 0.4m/s than that at 0.2m/s. when velocity increases, the amplitude of lift force and also the frequency increase, which means that the frequency of vortex shedding is accelerated.

2) There are also several differences between the effects of the two types of TLP. The vortex is influenced by size of the section, that is the diameter of the vortex at the bottom is larger and the distance in-line between adjacent vortexes is more for the variable cross-section TLP than that for the cylinder TLP. Besides, a wider wake of variable cross-section is shown for the TLP. The time history curve of lift force shows that the frequency of variable cross-section TLP is smaller than that of the cylinder TLP for the same velocity though their average diameters are the same. In addition, low frequency vibration is observed in variable cross-section TLP.

3) When both types of TLP are subjected to shear flow, wake is different from the top to the bottom, and the vortex is generated earlier at the top. There are four peaks for cylinder TLP. The distribution of the peak value is amongst the uniform flow of 0.2m/s and 0.4m/s. Small oscillations arise in every period when variable cross-section TLP is subjected to shear flow. In the frequency spectrum curve, high frequency of lift force is found, but the main peak value is smaller than that of cylinder TLP.

This paper demonstrated that performance of variable cross-section TLP is better than the cylinder TLP with regard to the vortex-induced vibration. On the basis of results obtained in this study the variable cross-section TLP is recommended in engineering practice.

Study on the device of multipath household heat metering

Zhongguo Yang*

Collage of Engineering, Hei Longjiang Bayi Agricultural University, 2 Xin Yang Road, Daqing, China

Received 30 August 2014, www.cmnt.lv

Abstract

One of the most important contents of reforming heating system is that more attention will be paid to residential energy conservation and improvement of heating facilities in order to charge heating fee by heat consumption. But the out-dated technology prohibits the widespread use of multipath household heat metering. Since the heating system in China is still confronted by the substantial energy waste, the jumble of pipelines and difficult management of the system etc, a company in Liao Ning has developed a new kind of water supply system on multipath household heat metering. The new system blazes new trails on household heat metering, solving the problem of traditional pipelines. The paper uses the computational method of hydrodynamics and provides the experimental platform of pipe resistance measurement and its theoretical parameter for the system. The study shows that resistance coefficient of the experimental pipeline corresponds with the theory, and multipath household heat metering has favourable prospects.

Keywords: converter multipath, household heat metering, pipe resistance measurement

1 Introduction

The consumption of energy resources is one of the core problems for the "Scientific Concept of Development". How to effectively save energy and reduce consumption has become an important strategic task for the future of a country. According to statistics, heating energy consumption on the building accounts for about 30% of total energy consumption of the national economy and 52% of China's total building energy. Therefore, the heating control is the biggest and most potential way of energy conservation in China, a top priority in energy-saving work. [1] Urban central heating is mainly used in the northern area of China, an important urban infrastructure meeting the requirements of basic living quality of urban residents. At present, China's heating fee is charged according to the area, traditional, unreasonable, more importantly, wasting energy; so many experts put forward the concept of household heat metering.

2 System introduction

Household heat metering not only saves energy, but also charges fairly and manages easily [2]. It changes the heating pipes from the initial series or parallel operation into a set of system of each family, solving the problem that now if individual users do not pay, other users would be involved in real trouble. At the same time, it truly realizes the heating commercialization since it charges by the actual use of heating instead of the housing area. In view of that, a company in Province Liaoning developed a new type of water supply system of multipath household heat metering. The centralized control of the household heat metering spreads among seven floors, and it is shown in Figure 1. For the system, porous pipes and accessories of pipelines are mainly made of polyvinyl chloride resin (PVC-U) and polypropylene (PP-R) respectively, lastly centralized control system on water supply system of the household metering comes into being. Floor one and floor two share pipes with seven channels, and the interior of the pipe is divided evenly into small seven fan-shaped paths, which correspondingly suply one house. And water separator with seven holes turns into those with five holes between the second and third floor, so floor three and floor four use pipes with five channels. In Figure 2, since the interior of the pipe was divided into small five fan-shaped paths, water separator with five holes turns into those with three holes between floor four and floor five. So pipes with three channels are used between floor five and floor six, and between floor six and floor seven is three steering connector. The pipes between the floors uses flange to connect together, sealed by the sealing rubber ring. This system adopts mechanical circulatory system of single up-supply and down-circle pipe in practice, and the main water supply pipe for heating reaches the top of floor seven. Put the main water supply pipe and water separator of seven holes together and meanwhile water separator of seven holes connect pipes of seven channels through output of seven paths. Heating each floor, output of one path among output of seven hot water paths connects with heating equipment, and blocking pad with seven channels will seal firmly the hole of the bottom, so this part becomes empty, preparing backwater of heating for the user. The heating backwater of floor seven is directed into the original pipes of seven empty holes, finally achieving a heating return around floor seven. By this way, the heating shunt realizes household heating of floor seven to floor one by different paths. Completing the seven loop heating, the system extends to the underground and then into heating well or heating box through right-angle connector of seven holes, so in such condition is heating

***Corresponding author** e-mail: yzg111402@163.com

system of household metering developed through multi-channel self circulation. It charges heating fee by central heating metering, suitable for every house of new buildings, and also applicable to reconstruction of the old building. There is profound basis for heating household metering. Central heating, the infrastructure of the city, saves energy and reduces environment pollution, improving people's quality of life, and so on.

3 Calculation on heat transfer between different pipes

Now China is gradually charging fees by household metering of central heating. On the one hand, the method saves energy; on the other hand, it brings a lot of trouble. First, different users are located in the different places of the buildings, so each room has different face with various external and internal walls, and each user has different heating load caused by different circumstances of transferring the heat. Secondly, when temperature of one room is higher than its adjacent room, the room would transfer heat to the adjacent room, increasing heat load of the other room and meanwhile users do not need genuinely this part of increased load. Although this system is newly developed, there still exist some problems, such as heat transferring between the pipes. Take the pipe of seven channels as an example, temperature of indoor water is 85°C and backwater temperature 60°C in this system. Since the water still goes back to the duct, six hot channels and one cold path appear among the pipes of floor six (it is only relatively said that 85°C is hot, 60°C cold), and in the pipes of five floor occur five hot channels and two cold, and so on. Therefore, we carried out the calculation and measurement, thermal conductivity of PVC tube was 0.16w/m2 K, return pipe of the heating system in floor seven have six hot channels and one cold, and that of floor six five, hot channels and two cold.

Return pipe of the second floor is six cold channels and one hot, so conductive heating during the passage between the return water in the second floor to inlet supply pipe in the first floor accounts for the largest amount of heat conduction, and heat conduction is:

$$q = \frac{\Delta t}{\delta} = 666.67 w / m^2 . \quad (1)$$

The most unfavourable heat loss:

$$Q = 2.5 \times 0.25 \times q = 416.66875 w . \quad (2)$$

Heat loss rate:

$$416.66875/7200=5.787\%. \quad (3)$$

Heat transfer in every hole does exist, and the heat loss accounts for about 6% of total calories. To meet the needs

of users, the provision in calculation of the heating is that calculation of heat load increase to 6%-10%. Although this only takes pipes of seven channels as an example, in other cases, the heat loss and the heat load of the room is not different for the same housing.

4 The principle of resistance measurement

Since water resistance in multipath household metering has both pipe frictional drag and local resistance, while measuring the resistance, pipes with seven channels, those of five paths, those of three channels or their accessories are respectively supposed to measure both frictional drag and local resistance.

4.1 A SUBSECTION THE PRINCIPLE OF PIPE FRICIONAL DRAG

According to Bernoulli equation [4]

$$z_1+\frac{p_1}{\gamma}+\frac{v_1}{2g}=z_2+\frac{p_2}{\gamma}+\frac{v_2}{2g}+h_f. \tag{4}$$

By continuity Equation, when the diameter is constant, flow velocity is [5]

$$v_1=v_2=v=\frac{Q}{A}, \tag{5}$$

frictional resistance is [6]

$$h_f=(z_1+\frac{p_1}{\gamma})-(z_2+\frac{p_2}{\gamma}). \tag{6}$$

Then by the Equation, [7]

$$h_f=\lambda\cdot\frac{l}{d_e}\cdot\frac{v^2}{2g}. \tag{7}$$

friction coefficient λ can be calculated, meanwhile, also according to the Equation [8]

$$R_e=\frac{vd_e}{v}. \tag{8}$$

Reynolds number R_e is obtained and the diagram $R_e-\lambda$ with different Reynolds numbers drawn.

4.2 THE DETERMINATION PRINCIPLE OF LOCAL RESISTANCE

From the Equation

$$h_\xi=\xi\frac{v^2}{2g}, \tag{9}$$

$$\xi=\frac{2gh_\xi}{v^2} \tag{10}$$

is available.

Then the measurement of local resistance loss can be read by the piezometric tube, that is, the actual local resistance loss should be equal to the measurement of the local resistance loss minus loss of the two measurement points along the path.

5 The result of measurement

According to requirements of actual heating velocity, design velocity for the experimental pipeline is 0.8~1.2m/s and the corresponding Reynolds number about 14500~21000. In this range, regardless pipes with seven channels, those of five channels or those of three channels, the corresponding region in diagram Mo Di are smooth region of turbulent flow and transitional rough area of turbulent flow. Roughness of the pipe has been determined (about 0.0008 mm), so the curve $\mathrm{Re}-\lambda$ presents the downtrend. By using the method of curve regression, the paper shows the working system under the non-design condition. Figure 3 is a diagram $\mathrm{Re}-\lambda$ of pipes with seven channels.

In order to verify accuracy of the experimental results, in the same diagram can be drawn and compared theoretical curve of the regression for pipes with seven channels, those of five paths, those of three channels and cast iron pipe with the same roughness, as is shown in Figure 4. In Table 1 is local resistance coefficient.

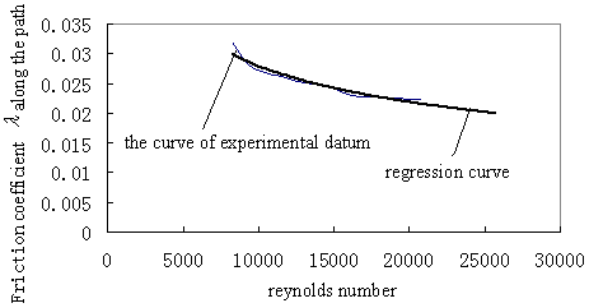

FIGURE 3 The diagram of pipes with seven channels

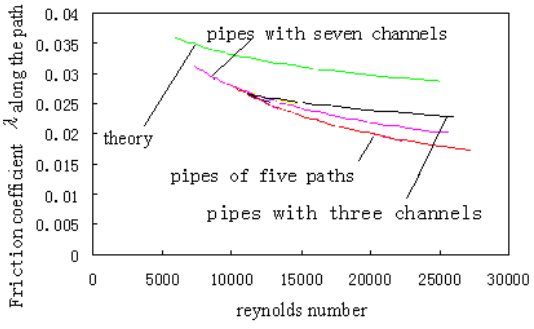

FIGURE 4 Regression curve $\mathrm{Re}-\lambda$

TABLE 1 The local resistance coefficient

Project	system of floor7	system of floor6	system of loor5	system of loor4	system of loor3	system of loor2	system of loor1
resistance coefficient of merging device of seven holes							1.54363
resistance coefficient of connector of seven holes	0.949072	1.700191	1.09999	1.41039	1.16111	1.88151	1.35818
resistance coefficient of water separator with seven holes	1.037447	1.127317	1.61171	1.06657	1.82916	1.56194	1.65768
resistance coefficient of water separator with five holes changed by those with seven holes	1.271711	1.226959	1.33825	1.16806	1.85618	1.72526	
resistance coefficient of water separator with five holes	1.569386	1.11457	1.1921	1.06456	1.88297		
resistance coefficient of water separator with three holes changed by those with five holes	1.496716	1.634158	1.49962	1.61476			
resistance coefficient of water separator with three holes	1.147256	1.511206	1.48419				
resistance coefficient of head cover of three channels	0.798686	4.812194					
20 connectors	0.441452						
mat of seven apertures							1.03224
mat of seven apertures							0.72685
mat of three apertures							1.35128

6 Conclusion

Seen from Figure 3, resistance coefficient of pipes with three channels is biggest, followed by that of pipes with seven channels, then is that of pipes with five channels, and resistance coefficient of cast iron pipe with the same roughness is obviously higher than the other three pipelines. For pipes with seven channels, those with five paths and those with three paths, is the same the friction coefficient of Reynolds number before about 11000, which is located in the smooth region of turbulent flow. Afterwards, is different the roughness of each kind of pipe, and so the turbulent transition region appears, which correspond to actual situation very well.

Error of friction coefficient is smaller, because there is no "instability" in the experimental process, and the graph $R_e - \lambda$ and theory also match very well, so the results can be directly applied to engineering practice. But the local resistance coefficient has relatively poor reliability, there are several reasons:

1) Unavoidable errors read by the man.

2) For flange mat of seven apertures, that of five apertures and that of three apertures, deformation exits greatly. When installing the system, tightening bolts leads directly to the flange deformation. Then large deformation appears in the channels, which deviates directly the test result of the local resistance coefficient greatly from the actual results. This is the reason why only water separator with seven channels on floor one is much higher than that of the other floors.

3) Do house-installed pipe, water separator with five holes changed by those with seven holes, water separator with three holes changed by those with five holes and head cover of three channels fuse poorly. The main problem is that house-installed pipe is not in the same height as the central line of the system, and there exits an angel, which directly causes the local loss of this place.

4) Water pump work longer, water tank is smaller, and the cooling effect is relatively not good. Consequently vapor contained in the water increases and easily collects in the plastic hose connecting with piezometric tube, which leads the water column astray.

Research on the relationship between moisture content and the dielectric constant of the tree trunk by the radar wave

Jingxia Lv, Lin Gao*, Jian Wen

School of Technology Beijing Forestry University, Beijing, China, 100083

Received 6 September 2014, www.cmtn.lv

Abstract

Radar wave technology offers a noninvasive, quick determination technique and has potential for the applications of the non-destructive detection (NDT) for the trees trunk and wood based materials. The precision of NDT determination by radar wave is influenced the wood dielectric constant which is closely related to the moisture content of the trees trunk. For our investigations we used TRU trees radar wave to detect the trees trunk. Four typical trees trunks were selected: polar, willow, pine, eucalyptus. Different trees trunks moisture content and dielectric constant were tested under the radar wave frequency respectively. Models of the relationship between moisture content and dielectric constant of the trees trunks were established for improving the accurate of radar wave NDT.

Keywords: radar wave, dielectric constant, moisture content, tree trunk, non-destructive detection

1 Introduction

As a new detection technology, Radar wave NDT has been widely applied in geological exploration. Electromagnetic wave signal was first used in detection of underground metal body by German Hulsmeyer. In 1910, Leimback and Lowy proposed radar's principles to ground-penetrating in the form of patents, it was the first time that the concept of ground penetrating radar (GPR) was put forward formally [1, 2]. In the early 1970 s, Domestic began the study of ground penetrating radar (GPR) and gradually applied to engineering application [2, 3]. In the early 1990 s, the technology was gradually widely used in many fields such as engineering geology exploration, quality inspection, mine detection, disaster geology survey, archaeological investigation, exploration, non-destructive evaluation [4]. In 2009, J R Butnor [5] etc. applied GPR technology to pinaceae standing timber, and the detection result was compared with hardwood. The TRU trees radar was developed by Tree Radar Company in the USA for wood internal defects detection. It was the first time the Radar wave was applied in the tree trunk NDT commercial application. Due to the fixed electric constant value of the TRU radar system, limited precision and poor suitability have limited its development and application in tree trunk NDT. Many experiment results showed that the detect result of wood internal defects changed by selected dielectric constants. And the moisture content has a great influence on the dielectric constant [6, 7]. Thus, it can be seen that the detecting precision of the defects is closely related to the dielectric constant of the measured wood, and wood moisture content is the key factor of dielectric constant of the wood. Therefore, in this paper, the different relationship of four typical woods such as poplar, willow, pine and eucalyptus between dielectric constant and moisture content were studied respectively.

2 Material and methods

The four kinds of typical wood adopted in this study are newly felled. It is reported that the dielectric properties of wood are related to wood structure, grain direction, moisture content, temperature, magnetic field frequency [8-10]. So, the radar detection system with a constant frequency of 900 MHz was used to investigate the dielectric properties at room temperature. Wood samples were in the form of cylinders with a diameter of 32 mm and a height of 3.0-3.5mm, in addition, the two main directions of wood samples were considered – parallel to grain and perpendicular to grain.

The dielectric constants were carried out by a Precision Impedance Analyser (Agilent 4294A) shown in Figure 1. Tree Radar Company's TRU radar equipment was used in this study shown in Figure 2.

FIGURE 1 Precision Impedance Analyser

* ***Corresponding author*** e-mail: gaolin0215@163.com

FIGURE 2 Field data manager and the radar antenna

Samples were placed under different moisture conditions for 96 hours.

The weight of the samples were measured respectively before and after each measurement of dielectric constant, denoted as w1 and w2. Dielectric constant values were measured at room temperature under the frequency of 900 MHz, denoted as ε.

After the test, samples were placed in the air.

Repeated step 1~2 until the weight had no significant change.

Finally the oven dried weight of the specimens was taken by drying in an electronic oven at 100 ± 3°C for 24 hours.

PASW Statistics software was carried out on the test data processing [11].

3 Results and discussion

First of all, the significance level of four groups' data was analysed respectively, the all result: sig. = 0.000. It shows there is a significant difference in moisture content and dielectric constant. Therefore, the data could be processed through curve fitting method.

R^2 is the curve fitting degree. That is how many percent of your sample curve similar. *F* value indicates a significant degree of R^2. *Sig*. is significant, the closer to 0.000, the better. Parameter estimation of b_0, b_1, b_2, b_3 is equation coefficient respectively:

$$y = b_0 + b_1 x + b_2 x^2 + b_3 x^3 . \quad (1)$$

Equation's inspection level α is 0.001, the value of sig. was 0.000. Four equations of poplar are significant. The highest fitting (R^2) is cubic curve, R^2 is 0.973. Therefore, cubic curve's fitting level is the best. The relationship between the dielectric constant and moisture content of poplar equation is:

$$\varepsilon = -0.351 + 14.994\omega - 19.475\omega^2 + 9.543\omega^3 , \quad (2)$$

where ε is the dielectric constant, ω is the moisture content.

The cubic curve in the Figure 3 indicates that the dielectric constant increases as the moisture content increases from 0 to 25%. The moisture content from 25% to 100% does not have much effect on the dielectric constant. The abrupt change of the dielectric properties is observed at very high moisture content and the curve becomes concave upward.

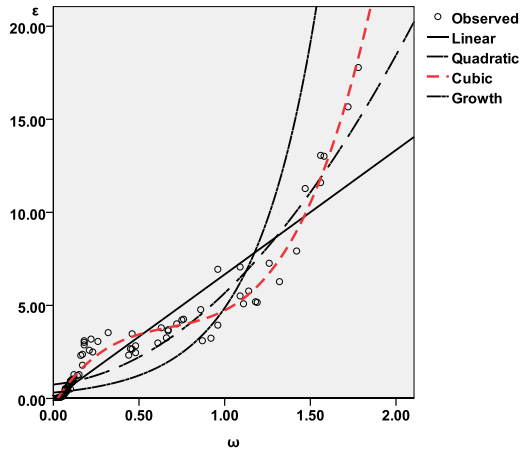

FIGURE 3 Curve fitting poplar moisture and dielectric constant

The various parameters in Tables 2 and 1 are the same. Equation's inspection level α is 0.001, the value of *Sig*. is 0.000. Four equations of willow are significant. The highest fitting (R^2) is cubic curve, R^2 is 0.964. Therefore, cubic curve's fitting level is the best. The relationship equation between the dielectric constant and moisture content of willow is:

$$\varepsilon = -0.132 + 13.738\omega - 22.307\omega^2 + 11.638\omega^3 , \quad (3)$$

where ε is the dielectric constant, ω is the moisture content.

TABLE 1 Popular model and parameter estimation

growth	.428	61.370	1	82	.000	–.715	2.228		

ω is the independent variables, ε is the dependent variable.

From cubic curve in the Figure 4 we can see, the dielectric constant increases as the moisture content increases from 0 to 20% the moisture content from 20% to 100% does not have much effect on the dielectric constant. The abrupt change of the dielectric properties are observed at very high moisture content and the curve becomes concave upward.

The various parameters in Tables 3 and 1 are the same. Equation's inspection level α is 0.001, the value of *Sig.* is 0.000. Four equations of pine are significant. But the curve fitting is not very good. R^2 is only 0.803, according to the law of the scatter distribution, piecewise fitting, depending on the moisture content of pine, is divided into below 25% and above 25%.

growth	.738	211.522	1	75	.000	–1.108	5.957		

ω is the independent variables, ε is the dependent variable.

Pine overall fitting curve is shown in Figure 7. By the fitting degree of R^2, the piecewise fitting degree of pine is larger than the whole. So we choose the sub-fitting equation.

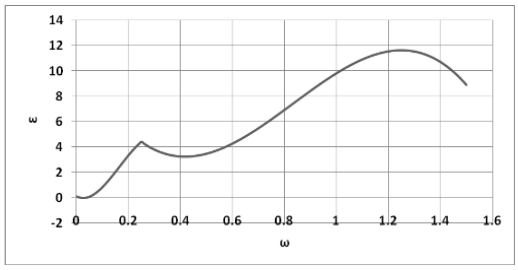

FIGURE 7 Curve fitting pine moisture and dielectric constant

From cubic curve in the Figure 8 we can see, the dielectric constant increases as the moisture content increases from 0 to 65%.

The main work of this paper is to use the TRU trees radar system to achieve accurate measurement of timber internal defects. Because in the measurement process of intermediary the radar system's electric constant value is fixed, the system exists accuracy defects. The results show that if different dielectric constants can be chosen, the location of detected wood internal defects is different. And as the moisture content of lumber changes, its dielectric constant changes.

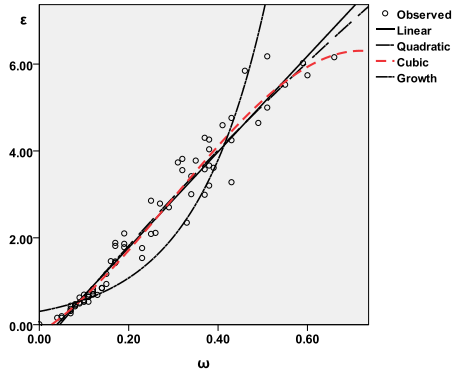

FIGURE 8 Curve fitting eucalyptus moisture and dielectric constant

According to the dielectric constant values of wood at different moisture content obtained in this paper, taking pine as an example, the results of analysis are applied. A piece of pine whose moisture content is 100% was chosen. A hole is measured in 10.5 cm from the bark. The defect position was gotten with TRU trees radar system, as shown in Figure 8. When the moisture content is over 25%, the pine's dielectric constant is obtained by this article. The relationship equation:

$$\varepsilon = 11.727 - 45.725\omega + 72.995\omega^2 - 29.178\omega^3. \quad (7)$$

If the moisture content is 100%, the dielectric constant is 9.819. The permittivity of TRU trees radar detection system was corrected to 9.819, measured defect location again, as shown in Figure 9. Compare Figure 8 to Figure 9, defect location in Figure 8 is 9.5 cm, error is about 9.5%. But defect location in Figure 10 is 10.7 cm, error is about 1.9%. Therefore, the measurement position using the model was closer to the actual position of a defect. It was found that application of the model has improved the accuracy of the TRU trees radar system.

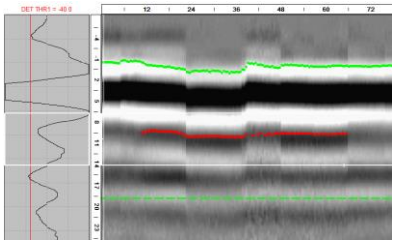

FIGURE 9 defect locations of pine

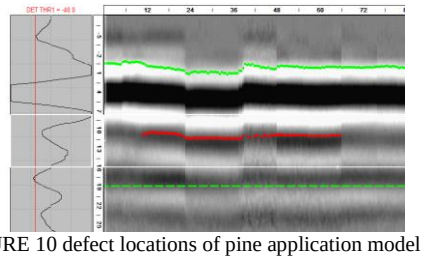

FIGURE 10 defect locations of pine application model

4 Conclusions

Relational models of four typical wood moisture content and dielectric constant were obtained, by the dielectric constant measuring instrument and the weighing method. The result shows that, for poplar, willow, eucalyptus, distribution curves of the relation between moisture content and dielectric constant were cubic, but for Pine, distribution curve was piecewise fitted with two different cubic. The dielectric constant increases exponentially with increasing the moisture content from 0 to Fiber saturation point (FSP), while it does not have much effect within the range of FSP to 100%, the concussion of measurement point was caused by measurement errors. When the moisture content is over 100%, the dielectric constant increases a bit linear upward trend.

Therefore, based on the relational model of moisture content and dielectric constant obtained, the accuracy of measurement instrument has been improved, meanwhile, experimental results showed that the model can improve the accuracy of the instrument effectively.

Abstract

According to total compensation composite inversion algorithm, physical parameter identification and inversion of wave time interval are done under the condition of input information of isolated pier in wave force part being unknown. Based on the characteristics of large-diameter piers in shallow water which are affected by wave force and combining with "statistical average method" in probability theory, structural physical parameter identification and wave inversion calculation are done under the condition of unknown wave force. Analysis of numerical values shows that results of structural physical parameter identification cater for accuracy requirements which is feasible for inversion method of parameter identification of large-diameter piers in shallow water with unknown input information thus providing a new method for structural physical parameter identification research of river-spanning and sea-crossing piers affected by wave force and providing references for engineering application.

Keywords: bridge pier structure, parameter identification, unknown input, load inversion, time domain correlation

1 Introduction

Performance of river-spanning and sea-crossing bridges in service gradually degenerates under the effect of load and environment. Although degeneration process is slow, structural damage is sudden and fragile which keeps high randomness and unpredictability giving considerable difficulties to safety forecasting. Therefore bridges' health monitoring and preservation including detecting the current condition of bridges in service and judging their damage condition are essential. Correctness of bridge structural health monitoring results mainly depends on whether recognition algorithm could accurately and effectively identify the real form of structure from the actual recorded signal.

At present most recognition algorithms are established on the basis of recorded information being complete which is not suitable for damage detection of river-spanning and sea-crossing bridge structures. The reason is that environmental excitation is generally taken as vibrating load in physical testing. However, interaction positions of these vibrating loads are uncertain which brings difficulties for measurement and is difficult to guarantee the completeness of recorded information. Moreover limited by testing cost, not enough number of sensor could be used to record the response messages at all positions with independent freedom degree in the structure, which is also difficult to guarantee the completeness of response. Therefore, how to identify the structural dynamic properties under the condition of testing information being incomplete or unknown is a difficult problem in the research of bridge dynamic detection technology theory at present. According to this, this paper takes irregular wave excitation simulated by linear amplitude superposition method as example and utilizes total compensation composite inversion algorithm to do identification on isolated piers under the following two input conditions:

1) When wind power is low, only underwater part of isolated bridge pier is affected by wave. While force on the part above the water is approximate to 0. Identification is done on it under the condition of input information being unknown.

2) Large-diameter piers in shallow. water are totally submerged. They are done with unknown input information system identification affected by wave force. Identification results show that total compensation composite inversion algorithm, in which wave excitation is manually simulated could better invert wave effect, do large-diameter unknown input system identification and wave force inversion.

2 Numerical simulation of random wave force of isolated piers

2.1 NUMERICAL SIMULATION OF IRREGULAR WAVE OF LINEAR SUPERPOSITION METHOD

Suppose that the known input wave force $f(t)$ is Gaussian random process whose average value i=0 and wave spectrum density function $S(\omega)$ is known. Then numerical simulation could be done on manual wave through three methods of constant amplitude superposition method, various amplitude superposition method and autoregressive method. This paper utilizes various amplitude superposition method, in which Fourier rapidly transforms helping to greatly save

***Corresponding author** e-mail: 121687678@qq.com

computation time. Comparing with constant amplitude superposition method, it presents certain improvement and keeps unconditionally stable. Specific derivation and simulation process is as follows [1]:

One random wave process could be described as:

$$\eta(t)=\sum_{n=1}^{\infty}a_n\cos(k_n x-\omega_n t-\varepsilon_n). \quad (1)$$

In terms of a fixed point, it is advisable that x=0, then:

$$\eta(t)=\sum_{n=1}^{\infty}a_n\cos(\omega_n t+\varepsilon_n). \quad (2)$$

In order to determine the of each a_n,ω_n component wave, wave spectrum $S_{\eta\eta}(\omega)$ may be used to make it in which ε_n is the evenly random distribution number in the range of $0\sim 2\pi$. Take wave spectrum $s_{\eta\eta}(\omega)$ as target spectrum whose energy covers the vast majority in the range $\omega_1\sim\omega_{m+1}$ and other parts are rejected. It is defined that $\Delta\omega_i=\omega_{i+1}-\omega_i$ and $\varpi_i=\frac{1}{2}(\omega_i+\omega_{i+1})$. Superpose m cosine waves of wave energies in m sections whose wavefront equation is:

$$\eta(t)=\sum_{t=1}^{m}\sqrt{2S_{\eta\eta}\varpi_i\Delta\omega_i}\cos(\omega_i t+\varepsilon_i). \quad (3)$$

According to [2], fluctuate horizontal velocity and accelerated velocity of water particle to acquire the following equations:

$$\mu(t)=\sum_{t=1}^{m}\sqrt{2S_{\eta\eta}(\omega_i)\Delta\omega_i}\,\omega_i\frac{\cosh(k_i z)}{\sinh(k_i d)}\cos(\omega_i t+\varepsilon_i), \quad (4)$$

$$\mu(t)=-\sum_{t=1}^{m}\sqrt{2S_{\eta\eta}(\omega_i)\Delta\omega_i}\,\omega_i^2\frac{\cosh(k_i z)}{\sinh(k_i d)}\cos(\omega_i t+\varepsilon_i). \quad (5)$$

Wave force Equation (6) is affected on piles of per unit length deduced according to Morison.

$$f(t)=f_D(t)+f_I(t)=\frac{\pi}{4}\rho C_m D^2\dot{u}(t)+\frac{1}{2}\rho C_m D^2 u(t)|u(t)|. \quad (6)$$

Suppose that the total height of this pier is *l*, height of the below-surface part is *d*, weight is concentrated on the single-degree-of - freedom system of z_0 height centre. Then time-varying Equations (7)-(9) of the simplified total inertia force of single degree of freedom, total drag force item and total wave force are shown as Equation (9):

$$P_I(t)=\frac{\pi}{4}\rho C_m D^2\dot{\mu}(t)d, \quad (7)$$

$$P_D(t)=\frac{1}{2}\rho C_D D\mu(t)|\mu(t)|d, \quad (8)$$

$$F_l(t)=\frac{1}{2}\rho C_D D f(z_0)\sum_{i=1}^{m}2S_{\eta\eta}(\omega_i)\Delta\omega_i\omega_i^2\frac{\cosh(k_i z)}{\sinh(k_i d)}\cos(\omega_i t+\varepsilon_i)\left|\frac{\cosh(k_i z)}{\sinh(k_i d)}\cos(\omega_i t+\varepsilon_i)\right|-\frac{\pi}{4}\rho C_m D^2 d f(z_0)\sum_{t=1}^{m}\sqrt{2S_{\eta\eta}(\omega_i)\Delta\omega_i}\,\omega_i^2\frac{\cosh(k_i z)}{\sinh(k_i d)}\sin(\omega_i t+\varepsilon_i), \quad (9)$$

$$F_j(t)=\frac{\pi}{4}\rho C_m D^2\frac{\cosh(k_i z)}{\sinh(k_i d)}\sum_{i=1}^{m}\sqrt{2S_{\eta\eta}(\omega_i)\Delta\omega_i}\,\omega_i^2\sin(\omega_i t+\varepsilon_i)dz,\ j=1,2,\ldots. \quad (10)$$

Total wave force $F_l(t)$ in Equation (9) is the wave force vibration equation, which is acquired after wave is transformed to the top of pier. Substitute this wave force vibration equation into dynamic equation, in which response spectrums of displacement, velocity and acceleration of this pier structure could be acquired through calculating this differential equation.

2.2 SIMPLIFIED CALCULATION OF WAVE FORCE OF LARGE-DIAMETER PILE IN SHALLOW WATER

2.2.1 Water Depth Keeping Great Influence on Wave Motion

Wave in deep water (*d*≥*0.5L*), *d* means water depth, *L* is wave length, the same below.) is called deep-water wave. Wave in shallow water (*0.05L*≤*d*<*0.5L*) is called shallow-water wave. Wave in extra-shallow water (*d*<*0.5L*) is called extra-shallow wave. According to [3], suppose that wave period *T* or wave number *K* in shallow water do not change with water depth namely $K=\frac{2\pi}{L}$.

2.2.2 Large-Diameter Components

Aiming at large-diameter components, the influences of diameter of pier on wave force usually utilize diffraction theory proposed by MacCamy and Fuchs from USACE in 1954. In terms of relatively big-size structures (*D*≥0.2*L*, *D* is the diameter of the structure), viscosity effect could be neglected. Wave force is main the inertia force [3].Thereby formula of simplified wave force of large-diameter piers in shallow water taking *dz* height as unit is as Equation (10). Here *dz* is the height of pier which is divided into single degree of freedom.

j is the dividing segments taking dz as height and $j = d / dz$. z_j is the height from centre of j to the bottom of pier. Other parameters are the same as the above.

It is deduced from the simplified Equation (10) that wave force ratio affected on any adjacent unit is determined only by $\cosh(kz_j)$:

$$\alpha_j = \frac{F_{j+1}(t)}{F_j(t)} = \frac{\cosh\left(kz_{j+1}\right)}{\cosh\left(kz_j\right)}. \tag{11}$$

3 Algorithm theory and identification steps

3.1 PART OF UNKNOWN EXTERNAL EXCITATION MATRIX

Electrical Dynamic equation of multiple-degree-of-freedom system is:

$$M\ddot{u} + C\dot{u} + Ku = F(t), \tag{12}$$

where M, C, K are respectively weight, damping and stiffness matrix. $F(t)$ is the external excitation vector. u, $\dot{u}$ and $\ddot{u}$ are respectively structural displacement, speed and acceleration response vector.

Suppose that M is the known diagonal moment. Transpose the Equation (12) to acquire that:

$$C\dot{u} + Ku = F(t) - M\ddot{u} = P. \tag{13}$$

Lead P to become system input vector.

1) Part of unknown input external excitation matrix could be shown as:

$$F(t) = \left[F_k(t) \;\; F_u(t)\right]^{'}. \tag{14}$$

where $F_k(t)$ is external excitation of known time interval information. $F_u(t)$ is external excitation of unknown time interval information. According to Reference [4], Equation (13) could be transformed as:

$$H\theta = P, \tag{15}$$

where H is system response matrix namely the response of system under excitation of external system $F(t)$. θ is the system physical parameter vector waiting for being identified. According to Equations (13) and (14), system input vector of P is acquired:

$$P = \left[P_k \;\; P_u\right]^{'}. \tag{16}$$

Total compensation inversion algorithm identifies system parameter θ according to Equation (15) and inverts unknown input vector P_u under the condition of system response matrix H and part of input P_k being known. Inversion algorithm is done on the part of unknown input according to [5] whose main steps are:

Artificially define initial value of any structural parameter vector to be $\hat{\theta}_0$;

Substitute the given initial value $\hat{\theta}_0$ into Equation (15) to calculate out that:

$$\tilde{P}_0 = H\hat{\theta}_0, \tag{17}$$

where $\tilde{P}_0$ could be expressed as:

$$\tilde{P}_0 = \left[\tilde{P}_k \;\; \tilde{P}_u\right]^{'}. \tag{18}$$

Replace the estimated $\tilde{P}_k$ in Equation (21) with known excitation time interval P_k to acquire the revised system input vector:

$$\hat{P}_0 = \left[P_k \;\; \tilde{P}_u\right]^{'}. \tag{19}$$

According to Equation (18) perform the calculations on the revised $\hat{P}_0$ vector based on least squares criterion to acquire the new estimated value of structural parameter:

$$\hat{\theta}_1 = \left(H^{'}H\right)^{-1} H^{'}\hat{P}_0. \tag{20}$$

Determine whether $\hat{\theta}_1$ caters for all convergence conditions. All parameters cater for the following formula:

$$\left|\frac{\hat{\theta}^i_n - \hat{\theta}^i_{n-1}}{\hat{\theta}_{i-1}}\right| \le \varepsilon, \tag{21}$$

where $\hat{\theta}^i_n$ is the i system parameter estimated value of the n iteration. ε is the artificially given precision value. If all conditions cater for Equation (21), calculation finishes, in which the current system parameter identification result is the final calculation result. If not, new $\hat{\theta}_1$ is taken as initial value, in which Equations (16)-(21) are repeated.

3.2 UNKNOWN EXTERNAL EXCITATION MATRIX

$$F(t) = \left[F_u(t) \;\; \alpha F_u(t)\right]^{'}, \tag{22}$$

where $F_u(t)$ is wave force of the unknown input unit. $\alpha F_u(t)$ is the wave force of adjacent unknown input unit. α is the ratio of wave forces between two adjacent units. They are calculated through Equation (11).

Similarly it could be transformed as follows according to Equation (15):

$$H\theta = P. \tag{23}$$

According to Equation (18), system input vector is acquired:

$$\tilde{P}_0 = \left[\tilde{P}_{ui} \;\; \tilde{P}_{u(i+1)}\right]^{'}, \tag{24}$$

where $\tilde{P}_{ui}$ and $\tilde{P}_{u(i+1)}$ are respectively the unknown input vectors of i and i+1 degrees of freedom or units.

Main steps of inversion algorithm under similar part of unknown input are:

Initial value of artificially given any structural parameter vector is $\hat{\theta}_0$.

Substitute the given initial value $\hat{\theta}_0$ into Equation (16) to calculate out that:

$$\tilde{P}_0 = H\hat{\theta}_0, \tag{25}$$

where $\tilde{P}_0$ can be expressed as:

$$\tilde{P}_0 = \left[\tilde{P}_{ui} \quad \tilde{P}_{u(i+1)}\right]^{'}. \tag{26}$$

After $\tilde{P}_0$ is calculated, $F(t)$ in Equation (22) becomes known, through which estimated values of $\tilde{F}_u(t)$ and $\alpha\tilde{F}_u(t)$ could be acquired according to Equation (22). Generally values of $\tilde{F}_u(t)$ in estimated $\tilde{F}_u(t)$ and $\alpha\tilde{F}_u(t)$ are unequal which does not cater for the equal result deduced in Equation (11). At this moment statistical average method in probability is done on $\tilde{F}_u(t)$, in which the average $\bar{F}_u(t)$ is utilized to acquire the new estimated input force $\hat{P}$ process [6] of each unit.

$$\bar{F}_u(t_i) = \frac{1}{N}\sum_{l}^{N}\tilde{F}_{u.l}(t_i), i = 1,2,...,M; l = 1,2,...,N, \tag{27}$$

where N is degree of freedom or unit number. M is sampling points.

Utilize the new $\bar{F}_u(t)$ to acquire the revised vector $\hat{P}_0$. Then new parameter estimated value could be acquired under least squares criterion according to Equation (20).

Determine whether the new calculated $\hat{\theta}_1$ and the original $\hat{\theta}_0$ cater for the convergence condition of the given precision ε. Suppose that $\hat{\theta}_1^i$ is the i identification value of structural parameter. If all parameters cater for the following equation:

$$\left|\frac{\hat{\theta}_1^i - \hat{\theta}_0^i}{\hat{\theta}_0^i}\right| \le \varepsilon. \tag{28}$$

Then parameter estimated value of this step $\hat{\theta}_1$ is taken as the final calculation result. Otherwise it would be taken as new parameter initial value to repeat steps 2~5 up to convergence.

Utilize the finally identified parameter $\hat{\theta}_1$ to invert the practical wave force excitation according to Equation (16).

Calculation steps under the above-mentioned two input conditions could be expressed more directly by Figure 1.

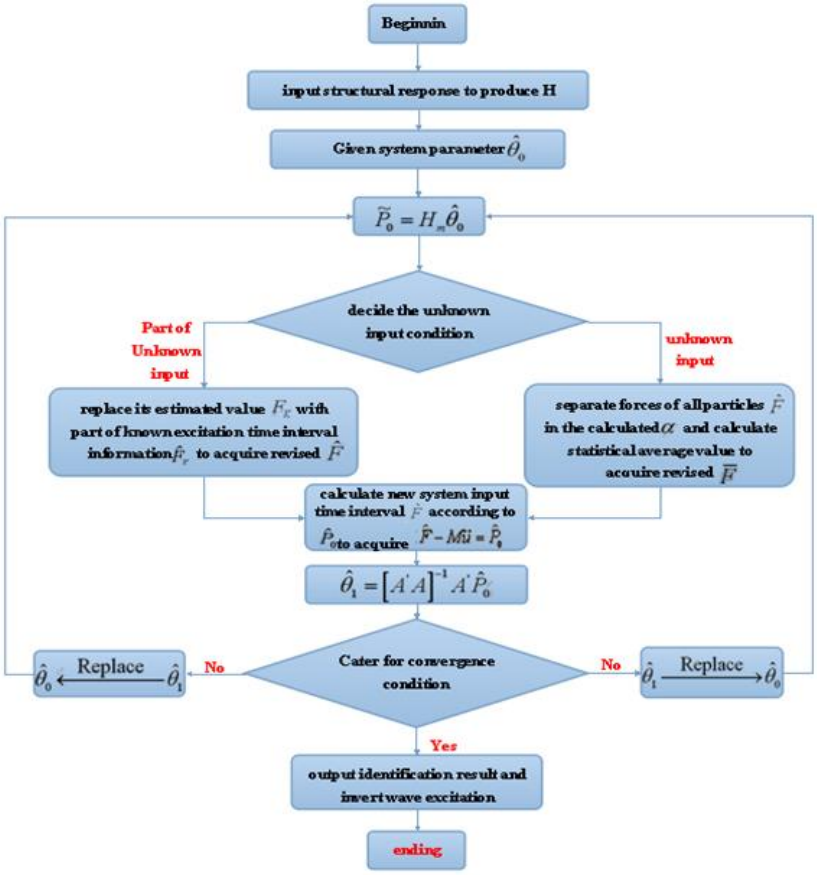

FIGURE 1 Flow diagram of inversion calculation

It is seen from a series of algorithm steps above that physical parameter identifications of pier structure under condition of part of wave input being unknown and of large-diameter piers in shallow water under the condition of wave input being unknown according to total compensation composite algorithm are done whose concept is clear. Thought is of clarity and identification steps are easy for programming realization.

4 Example analysis

4.1 EXAMPLE ENGINEERING PROFILE

Establish the simplified model of isolated pierstructure Figure 2.

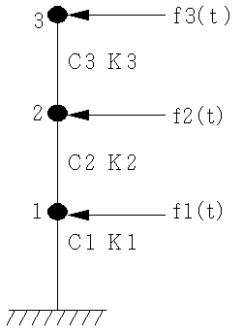

FIGURE 2 Simplified model of isolated pier structure

Suppose that concentrated masses M1 = 18840 kg, M2 = 18000 kg, M3 = 15840 kg, stiffnesses between units K1 = 1.623×10^7 N/m, K2 = 1.082×10^7 N/m, K3 = 0.952×10^7N/m and proportional dampings among units are respectively C1 = 138693 Ns/m, C2 = 108462 Ns/m and C3 = 75786 NS/m. Diameter of the bridge pier is Dm whose heighth is 24m. Here the designed wave height $H = H_{1\%} \approx 1.51H_{1/3} = 9.0m$ and designed wave length $L = \bar{L}$(average wavelength) $= 135.0$m. According to characteristics of wave method, it is acquired that $P_D \le 0.5P_I$. Neglect drag force and only take effects of inertial wave force into consideration. Wave spectrum uses P-M Spectrum. Suppose that displacement, speed and acceleration response of each node are all known. It is required to identify all dampings and stiffness parameters and invert the input wave force. Utilizing $Newark-\beta$ Method to calculate dynamic response, in which sampling point M is 1000 and sampling time interval $dt = 1.0s$. Suppose that all mass parameters in calculation process are known and real parameters of structure are shown in Table 1. Physical parameter identification and effect load inversion are done under the following conditions.

TABLE 1 Parameter list of each node of bridge pier

Node	Weight(kg)	Damping(kg/ms)	Stiffness(N/m)
1	0.1298e+07	0.7788e+06	0.2384e+06
2	0.1400e+07	0.8400e+06	0.2540e+06
3	0.1584e+07	0.9504e+06	0.3010e+06

4.2 PHYSICAL IDENTIFICATION AND WAVE FORCE INVERSION UNDER PART OF INPUT UNKNOWN AND UNKNOWN INPUT

When diameter of pier d is 9.0m and water depth is 20m, wave time intervals of node1 and node2 affected by irregular wave force which is simulated by variable amplitude superposition method are shown in Figure 3 in which correlation coefficient $\alpha_1 = 1.14$ of $f1(t)$ and $f2(t)$. It is known through numerical calculation that after response, the assumed input wave forces $f1(t)$ and $f2(t)$ are unknown. At this moment known force of pile segment above water surface $\alpha_1 = 1.14$. Thereby a problem of parameter identification under part of input being unknown and input load inversion comes into being.

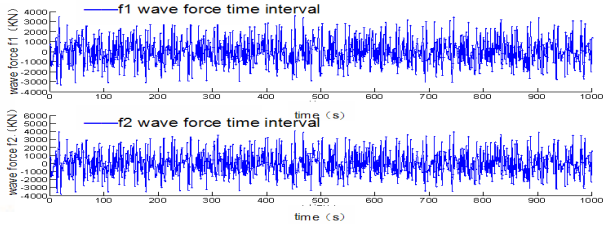

FIGURE 3 Time interval curve of wave force exerted on nodes

Stiffness and damping matrix of bridge pier structure in this case are shown as (29):

$$K = \begin{bmatrix} k_1+k_2 & -k_2 & 0 \\ -k_2 & k_2+k_3 & -k_3 \\ 0 & -k_3 & k_3 \end{bmatrix}, \quad C = \begin{bmatrix} c_1+c_2 & -c_2 & 0 \\ -c_2 & c_2+c_3 & -c_3 \\ 0 & -c_3 & c_3 \end{bmatrix}. \tag{29}$$

Concrete matrix expressions of H, θ and P deduced by Equation (16) are shown as Equation (30):

$$H(t_i) = \begin{bmatrix} x_1(t_i) & x_1(t_i)-x_2(t_i) & 0 & \dot{x}_1(t_i) & \dot{x}_1(t_i)-\dot{x}_2(t_i) & 0 \\ 0 & x_2(t_i)-x_1(t_i) & x_2(t_i)-x_3(t_i) & 0 & \dot{x}_2(t_i)-\dot{x}_1(t_i) & \dot{x}_2(t_i)-\dot{x}_3(t_i) \\ 0 & 0 & x_3(t_i)-x_2(t_i) & 0 & 0 & \dot{x}_3(t_i)-\dot{x}_2(t_i) \end{bmatrix}, \tag{30}$$

$$P(t) = [P(t_1), P(t_2), P(t_3), ..., P(t_M)]', \tag{31}$$

$$P(t_i) = \begin{bmatrix} f_1(t_i) - m_1\ddot{x}_1(t_i) \\ f_2(t_i) - m_2\ddot{x}_2(t_i) \\ 0 \end{bmatrix}, \tag{32}$$

$$\theta = [k_1, k_2, k_3, c_1, c_2, c_3]', \tag{33}$$

According to the above-mentioned conditions, responses of displacement u, speed $\dot{u}$ and acceleration $\ddot{u}$ of structure affected by $f2(t)$ and $f3(t)$ are acquired utilizing Nemark Method. Meanwhile Node 3 not affected by wave load is taken as known part of input information of input load $f3(t) = 0$. Without regard to noise, parameter results identified by the method of this paper are shown in Table 2. Taking the influence of noise on the actually acquired data into consideration, influence of white noise is added into the response acquired by structure to simulate the actually measured results, in which added noise level is determined by percentage between response peak value and noise peak value [7] in order to test the sensitive degree of this algorithm on the influence of noise. Here parameter identification and load inversion are considered under two conditions of 1% and 6%. Parameter identification results under the condition of noise are shown in Table 3 and Table 4.

It is seen from Table 3 and 4, and Figures 4-7 that under condition of part of unknown input wave force being time domain related, method of this paper could not only identify physical parameter of pier but also accurately invert input load of each node. In terms of 6% of noise level, identified parameters are utilized to do inversion on the input wave forces on Nodes 1 and 2. Comparing with actually input wave force, the maximum error is 6.6149% whose results are shown in Figures 4-7. Obviously, its inversion results are ideal.

When diameter of pier D is 9.0m and water depth is 24m, wave time intervals of Nodes 1, 2 and Node 3, affected by irregular wave force, which is simulated by variable amplitude superposition method are shown in Figure 4, among

which correlation coefficient of $f1(t)$ and $f2(t)$ is $\alpha_1 = 1.14$ and the one of $f1(t)$ and $f3(t)$ is $\alpha_2 = 1.44$. Through numerical calculation it is acquired that input wave forces $f1(t)$, $f2(t)$ and $f3(t)$ are unknown after response. Thereby a typical problem of parameter identifycation and load inversion under unknown load input comes into being. Input wave time intervals on pier nodes are shown in Figure 8.

Similar with the condition above, parameter result identified by the method in this paper are shown in Table 5 without taking noise into consideration. Similarly parameter identification and load inversion under 1% and 6% percentage of noise are considered. Parameter identification results with noise are shown in Table 6 and Table 7.

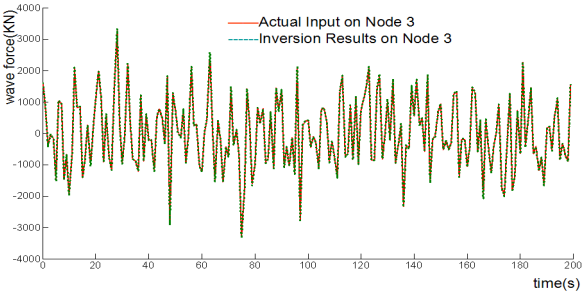

FIGURE 15 Comparison of actual input inversion results on node 3 under 6% noise

It is seen from Tables 2-7 and Figures 13-15 that under the condition of unknown input wave force being time domain related, method of this paper could not only identify physical parameter of pier but also accurately invert input load of each node. In terms of 6% of noise level, identified parameters are utilized to do inversion on the input wave forces on Node 1 and Node 2. Comparing with actually input wave force, the maximum error is 5.7087%. Obviously its inversion results are ideal.

5 Conclusions

Under condition of input wave load being known and unknown input wave load being time domain totally related, this paper does researches on physical parameter identification and load inversion of cantilever bridge pier structure. Suitable node units on piers are chosen to establish simplified computation model, in which characteristic parameters of damping and stiffness chosen from each node unit are taken as targets waiting for being identified. Numerical analysis is done utilizing numerical analysis software MALTAB through specific examples whose analysis conclusions are as follows:

Utilize total compensation method to do physical parameter identification and unknown wave force inversion on bridge piers under condition of part of unknown wave input. Its identification and inversion results present good stability.

In terms of circular piers without considering wave drag force, statistical average method of probability and improved total compensation method are combined together to do physical parameter identification and load inversion under unknown wave force input when wave force time intervals affected on each node are almost totally time domain related and correlation coefficient is α_i. For cantilever bridge pier structure, this algorithm keeps good applicability and accuracy on parameter identifications of damping and stiffness of each node under the influences of different noise signals when shear is out of shape.

Different initial values of physical parameters waiting for being identified keep little influence on identification result. Whether chosen initial values are near to the true values is just related to convergence time and convergence steps.

Without influences of noise, identification precision of physical parameter on each node of bridge pier structure is higher than that with noise existing whose reason is that there exists big difference between order of magnitude of stiffness parameter and the one of damping parameter. This leads identification result of stiffness parameter to be obviously lower than that of damping parameter. Small scope of noise influence keeps both being within the range of precision requirements.

This paper only takes researches of physical parameter identification and load inversion of cantilever bridge piers affected by wave load into consideration. It does not consider influences of bridge superstructure, cross-section shape

of pier, water velocity, wind load, etc. Necessary experiments and actual monitoring are still needed to test or correct the inversion calculation method in order to understand applicability and universality of the proposed method in this paper more clearly.

Abstract

Acrylic plastic, polymethylmethacrylate (PMMA), are widely employed as the material for the viewports of human occupied vehicle (HOV) which usually dives into deep sea. The service life of viewport is critical to the reliability and safety of HOV. In order to predict life of viewport in design stage, mathematical statistics method is applied to establish the load spectrum for viewport. It is found that ALVIN (America) HOV's dive-depth data is in a skewed distribution, and a piecewise function combined Gumbel and Weibull distributions is proposed for data fitting. HOV undertakes long-term and cyclic load in service, which will cause damage on viewport, so a creep-fatigue load spectrum is established and applied for JIAOLONG (China) HOV's viewport, which integrates both the dive-frequency of each depth range and the duration that maximum stress acts. The proposed method for determination of creep-fatigue load spectrum could thus be considered to be employed for failure analysis and life prediction of modern HOV's viewport.

Keywords: viewport, human occupied vehicle, distribution function, creep and fatigue failure, load spectrum

1 Introduction

Viewport is the main tool to observe and investigate underwater world for scientists and engineers occupied in a HOV. A crucial evaluation standard of a HOV is the number and vision of its viewport. The manned spherical shell of ALVIN HOV (America) has a main viewport and four auxiliary viewports, which can ensure a broad vision in deep sea [1].

Acrylic plastic, PMMA, is the choice material of underwater window rated for depths to 11000m [2]. It is widely employed as the viewport's material due to its optical property, corrosion-resistance, and great strength-weight ratio [3]. The viewport configurations mainly include flat disc, conical frustum, spherical sector, hemisphere, and hyper-hemisphere [4, 5]. HOV need dive to different depths during its service life to finish different scientific investigations, which generates alternating stress and creep strain on viewport due to cyclic and long-term external load [6]. So creep and fatigue are the main failure forms of HOV's viewport [7]. In order to predict its life, a load spectrum for both creep and fatigue analyses should be built at first.

PMMA is a typical viscoelastic material whose fatigue properties are strongly influenced by temperature and cyclic frequency. The creep of PMMA may occur when exposed to the long-term and high load. The creep behaviour of PMMA was theoretically and experimentally investigated by lots of researchers for the characterization, predictive models, and temperature effect [8-10]. Also its fatigue property is studied for the crack propagation, frequency effect, and life prediction [11-13]. Creep damage accumulates in every cycle with a long time, so the fatigue life is affected by creep. The models for life predicting considering both fatigue and creep effects have been proposed [14, 15]. These works are instructive to future research on life prediction of HOV's viewport. But they cannot be used directly due to the simple structure of PMMA specimen and load spectrum. A comprehensive analysis of creep and fatigue behaviours of PMMA viewport is still lacking. The first step for life prediction is to build a real load spectrum for the viewport.

The dive depth of a HOV for different scientific investigations is a random process about time, so the external load on viewport is also a group of random loads with time span. Mathematical statistics method is applied to analyse dive data to determine the load spectrum of viewport because of the random character of external load.

Professor Sasaki, a Japanese scholar, has made a data statistics on dive frequency of Yomiuri submersible whose maximum dive depth is 300m. Chen [16] has also analysed Yomiuri's data and found an obvious bimodal distribution of dive frequency and depth. Li [17] proposed that Gumbel distribution function can be used to determine fatigue load spectrum of spherical shell used in HOV. Although some studies have been made on load spectrums of submarine and submersible, there are still several problems to be solved. First, a more suitable distribution function should be propo-

***Corresponding author** e-mail: kangyiting@sina.com

sed for HOV, which works in deep sea. Second, a load spectrum concerning both time and frequency should be determined for HOV's viewport because its failure behaviour is not only fatigue but also creep.

In this paper, a load spectrum for life prediction of HOV's viewport is determined. Firstly, ALVIN's dive-depth data is collected for analysis and statistics at first. Moreover, Gumbel and Weibull distribution functions are applied for data statistics, and two fitting curves are compared to propose a more suitable function. Finally, the load spectrum for JIAOLONG HOV's viewport is determined based on the new function where both time and frequency are considered.

2 Collection of dive data

The maximum dive-depth of 7 HOVs are more than 4500m, namely MIR I/II and RUS (6000m, Russia), SHINKAI 6500(6500m, Japan), NAUTILE (6000m, France), ALVIN (4500m, America), and JIAOLONG (7000m, China).

The dive-depth data of ALVIN is selected to analyse (Table 1) because it is relatively more comprehensive compared to the others mentioned above. Only total numbers and maximum dive-depth of the others can be found, which is not enough to build a reliable load spectrum.

TABLE 1 Dive data of ALVIN HOV

Depth range (m)	Frequency	Proportion (%)	Accumulative proportion (%)
0-300	161	3.8	3.8
300-600	99	2.4	6.2
600-900	227	5.4	11.6
900-1200	141	3.4	15
1200-1500	202	4.8	19.8
1500-1800	169	4.0	23.8
1800-2100	377	9.0	32.8
2400-2700	1311	31.2	78.2
2700-3000	209	5.0	83.2
3000-3300	153	3.6	86.8
3300-3600	137	3.3	90.1
3600-3900	256	6.1	96.2
3900-4200	122	2.9	99.1
4200-4500	38	0.9	100

3 Data fitting of dive-depth

ALVIN's dive data is in an asymmetric and skewed distribution (Figure 1), so Weibull and Gumbel distribution functions are selected for data fitting. The fitting degrees of the two curves are compared to find out a proper function to establish load spectrum of ALVIN.

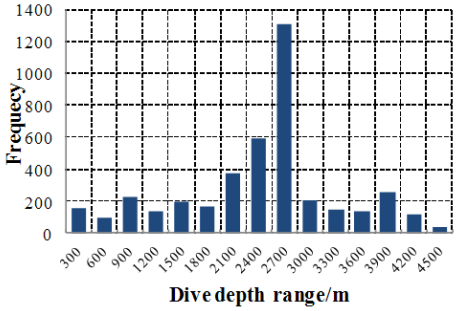

FIGURE 1 Histogram of ALVIN's dive data

3.1 WEIBULL DISTRIBUTION

The frequency distribution with different shapes can be described well by Weibull function with three parameters whose probability density and distribution functions respectively are:

$$f(x)=\frac{\beta}{\eta-\gamma}\left(\frac{x-\gamma}{\eta-\gamma}\right)^{\beta-1}\cdot\exp\left[-\left(\frac{x-\gamma}{\eta-\gamma}\right)^{\beta}\right], \quad (1)$$

$$F(x)=1-\exp\left[-\left(\frac{x-\gamma}{\eta-\gamma}\right)^{\beta}\right], \quad (2)$$

where γ is location parameter, β is shape parameter ($\beta > 0$), and η is scale parameter ($\eta > 0$).

It is obvious that location parameter γ of ALVIN's data distribution is 0 according to Figure 1, so only the shape and scale parameters, β and η, are required to be solved. Equations (1) and (2) can be simplified to

$$f(x)=\frac{\beta}{\eta}\left(\frac{x}{\eta}\right)^{\beta-1}\exp\left[-\left(\frac{x}{\eta}\right)^{\beta}\right], \quad (3)$$

$$F(x)=1-\exp\left[-(\frac{x}{\eta})^{\beta}\right]. \quad (4)$$

The shape and scale parameters could be estimated by graphic method. Firstly, Equation (4) should be transformed by taking the logarithm twice of both the left and right-part:

$$\ln\ln\left(\frac{1}{1-F(x)}\right)=\beta(\ln x-\ln\eta). \quad (5)$$

Assuming $Y=\ln\ln(1/(1-F(x)))$, $X=\ln x$ and $B=\beta(\ln\eta)$, Equation (5) can be expressed as:

$$Y=\beta X-B. \quad (6)$$

Obviously, Equation (6) is a line equation, so shape and scale parameters of Weibull distribution, β and η could be obtained from its gradient and intercept.

The confidence intervals of β and B under the confidence level of 1-α are respectively:

$$Q_{\beta}=[\beta-t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_{\beta},\beta+t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_{\beta}], \quad (7)$$

$$Q_{B}=[B-t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_{B},B+t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_{B}]. \quad (8)$$

3.2 GUMBEL DISTRIBUTION

Gumbel function is a theoretical model whose extreme value is in asymptotic distribution, and its probability density function and distribution function respectively are:

$$f(x)=\frac{1}{\varphi}\cdot\exp\left[\frac{x-\lambda}{\varphi}-\exp(\varphi)\right], \quad (9)$$

$$F(x)=1-\exp\left[-\exp\left(\frac{x-\lambda}{\varphi}\right)\right], \quad (10)$$

where φ is shape parameter (φ>0), and λ is scale parameter.

The shape and scale parameters of Gumbel distribution can also be obtained by transforming Equation (10) to:

$$\ln\ln\left(\frac{1}{1-F(x)}\right)=\frac{1}{\varphi}(x-\lambda). \quad (11)$$

Assuming $Z=\ln\ln(1/(1-F(x)))$, $C=1/\varphi$ and $D=\lambda/\varphi$, Equation (11) can be also transformed to a line equation:

$$Z=Cx+D. \quad (12)$$

So the shape and scale parameters of Gumbel distribution, φ and λ, could be solved from the gradients and intercept of Equation (12).

The confidence intervals of C and D under the confidence level of $1-\alpha$ are respectively:

$$Q_C=[C-t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_C, C+t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_C], \quad (13)$$

$$Q_D=[D-t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_D, D+t_{1-\frac{\alpha}{2}}(n-2)\cdot\sigma_D]. \quad (14)$$

3.3 COMPARISION OF CURVES FITTED USING WEIBULL AND GUMBEL DISTRIBUTION

Curve of ALVIN's dive data fitted employing Weibull distribution is shown in Figure 2, which indicates that the fitting degree is much higher when the dive-depth is over 2700m. β and η are solved (β=3.1059, and η=2599.2), so the distribution function can be obtained

$$f(x)=\frac{3.1059}{2599.2}\left(\frac{x}{2599.2}\right)^{2.1059}\cdot\exp\left[-\left(\frac{x}{2599.2}\right)^{3.1059}\right], \quad (15)$$

$$F(x)=1-\exp\left[-\left(\frac{x}{2599.2}\right)^{3.1059}\right]. \quad (16)$$

The curve fitted by Gumbel distribution is also shown in Figure 2, which suggests it agrees well with the origin data when the dive depth is less than 2700m. φ and λ are solved (φ = 725.42, and λ = 2634.6), so the distribution function can be obtained:

$$f(x)=\frac{1}{725.42}\exp\left[\frac{x-2634.6}{725.42}-\exp\left(\frac{x-2634.6}{725.42}\right)\right], \quad (17)$$

$$F(x)=1-\exp\left[-\exp\left(\frac{x-2634.6}{725.42}\right)\right]. \quad (18)$$

Q_β and Q_B in Weilbull distribution under the confidence level of 80% are [1.2985, 1.7366] and [8.5725, 12.9942]. Q_C and Q_D in Gumbel distribution under the confidence level of 95% are [0.0009, 0.0011] and [-2.9553, -2.5156].

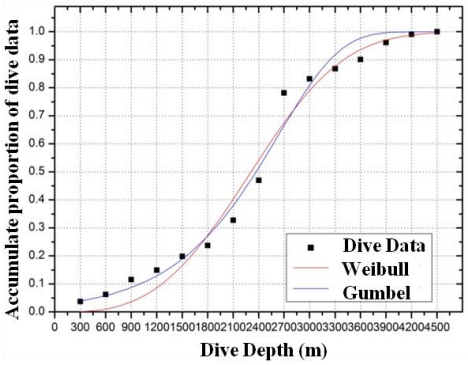

FIGURE 2 Comparison of two curves fitted by Weibull and Gumbel

When dive depth (x) is less than 2700m, fitting degree of the curve "Gumbel" is much better, while that of "Weibull" is superior when x is more than 2700m. So distribution function can be expressed with the combination of Gumbel and Weibull:

$$F(x)=\begin{cases}1-\exp\left[-\exp\left(\frac{x-2634.6}{725.42}\right)\right], x<2700\\ 1-\exp\left[-\left(\frac{x}{2599.2}\right)^{3.1059}\right], x\geq 2700\end{cases}. \quad (19)$$

Dive frequency (n) of ALVIN in the depth-range [d_1, d_2] can be solved by:

$$n=\begin{cases}N\left\{\exp\left[-\exp(\varsigma_1)\right]-\exp\left[-\exp(\varsigma_2)\right]\right\}, x<x_p\\ N\left\{\exp\left[-(\xi_1)^{3.1059}\right]-\exp\left[-(\xi_2)^{3.1059}\right]\right\}, x\geq x_p\end{cases}, \quad (20)$$

where N is the total dive frequency, $\varsigma_i=\frac{d_i-2634.6}{725.42}$, $\xi_1=\frac{d_i}{2599.2}$, $i=1,2$ and $x_p=2700$.

Result of n solved by Equation (20) is shown in Table 2, which clearly demonstrates Weibull and Gumbel are respectively applicable for data fitting in different depth-ranges. And it is necessary to develop a new function with the combination of Weibull and Gumbel.

TABLE 2 Dive data of ALVIN solved by Weibull and Gumbel functions

No.	Depth-range (m)	Frequency	Proportion (%)		
			Real	Weibull	Gumbel
1	0-300	161	3.8	0.1	3.9
2	300-600	99	2.4	0.9	1.9
3	600-900	227	5.4	2.6	2.9
4	900-1200	141	3.4	5.0	4.2
5	1200-1500	202	4.8	7.9	6.0
6	1500-1800	169	4.0	10.8	8.2
7	1800-2100	377	9.0	12.9	10.9
8	2100-2400	595	14.2	13.9	13.5
9	2400-2700	1311	31.2	13.4	15.0
10	2700-3000	209	5.0	11.5	14.4
11	3000-3300	153	3.6	8.7	10.9
12	3300-3600	137	3.3	5.9	5.9
13	3600-3900	256	6.1	3.5	1.9
14	3900-4200	122	2.9	1.8	0.3
15	4200-4500	38	0.9	0.8	0.0

The sum of squares of the difference between fitting results and real data are:

$$E_j = \sum_{i=1}^{15} (P_{ji} - P_i)^2 , \quad j = W, G, P , \tag{21}$$

where P_{ji} and P_i are respectively the fitting result and real value in No. i depth-range, and subscript j indicates the different fitting curves: W (Weibull distribution), G (Gumbel distribution), and P (combined both W and G). E_W, E_G and E_P are listed in Table 3. Values of E_W and E_G are almost equal, however that of E_P is much smaller comparing to E_W and E_G. The distribution equations combined both Weibull and Gumbel is more effective for data fitting of dive-depth.

TABLE 3 Sum of squares of difference between fitting result and real data

Parameter	E_W	E_G	E_P
Value	0.049733	0.046639	0.037577

4 Load spectrum for viewport of JIAOLONG HOV

Based on the above analysis of ALVIN's dive data, a piecewise function, which combines Gumbel and Weibull distributions is selected to determine the load spectrum of viewports used in JIAOLONG HOV for creep and fatigue analysis.

Maximum dive-depth of JIAOLONG is 7000m, which is greater than that of ALVIN, so the independent variable in Equation (11) should be transformed to get the new distribution function:

$$F(x) = \begin{cases} 1 - \exp\left[-\exp\left(\dfrac{4.5x/7 - 2634.6}{725.42} \right) \right], x < 4200 \\ 1 - \exp\left[-\left(\dfrac{4.5x/7}{2599.2} \right)^{3.1059} \right], x \geq 4200 \end{cases} , \tag{22}$$

Dive frequency n of JIAOLONG in the depth-range [d_1, d_2] can be calculated by:

$$n = \begin{cases} N\left\{ \exp\left[-\exp(\varsigma_1) \right] - \exp\left[-\exp(\varsigma_2) \right] \right\}, x < x_p \\ N\left\{ \exp\left[-(\xi_1)^{3.1059} \right] - \exp\left[-(\xi_2)^{3.1059} \right] \right\}, x \geq x_p \end{cases} , \tag{23}$$

where $\varsigma_i = \dfrac{4.5d_i/7 - 2634.6}{725.42}$, $i = 1, 2$, $\xi_i = \dfrac{4.5d_1/7}{2599.2}$, $x_p = 4200$, and d_1 and d_2 are between 0 and 7000m.

The data of JIAOLONG's viewport in every depth-range solved by Equation (23) are listed in Table 4.

The fatigue load spectrum of JIAOLONG when it finishes a dive to 7000m is shown in Figure 3.

When JIAOLONG HOV serves, both creep and fatigue damages may occur on its viewports because of the effect of alternating load and long-term load. Creep is a time dependent structural behaviour of acrylic. As a result, the duration of external load should be taken into account in the establishment of its load spectrum. In normal conditions, underwater time of HOV does not exceed 8 hours, and diving and floating speed are about 40m/min. So the duration that maximum stress acts is:

$$t = 8 - \frac{x}{1200} . \tag{24}$$

TABLE 4 Dive data of JIAOLONG HOV (a depth-range: 500m)

No.	**Depth-range (m)**	**Frequency**	**Proportion (%)**
1	0-500	5	3.9
2	500-1000	2	1.9
3	1000-1500	4	2.9
4	1500-2000	5	4.2
5	2000-2500	8	6
6	2500-3000	10	8.2
7	3000-3500	14	10.9
8	3500-4000	17	13.5
9	4000-4500	19	15
10	4500-5000	11	8.7
11	5000-5500	7	5.9
12	5500-6000	4	3.5
13	6000-6500	2	1.8
14	6500-7000	1	0.8

Load spectrum considering both the dive frequency and duration that maximum stress acts for creep and fatigue analysis and life prediction of JIAOLONG HOV's viewports is illustrated in Figure 4 and Table 5.

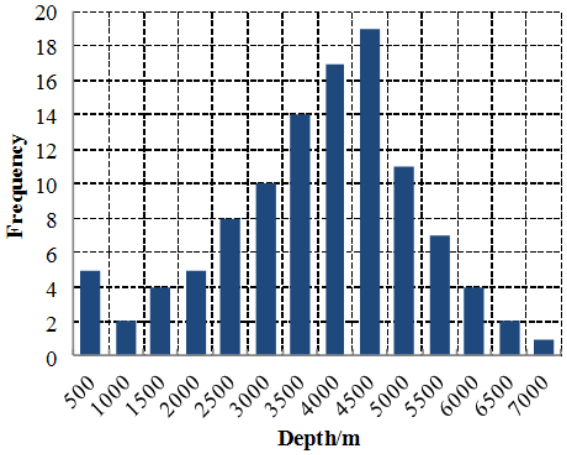

FIGURE 3 Fatigue load spectrum of JIAOLONG HOV

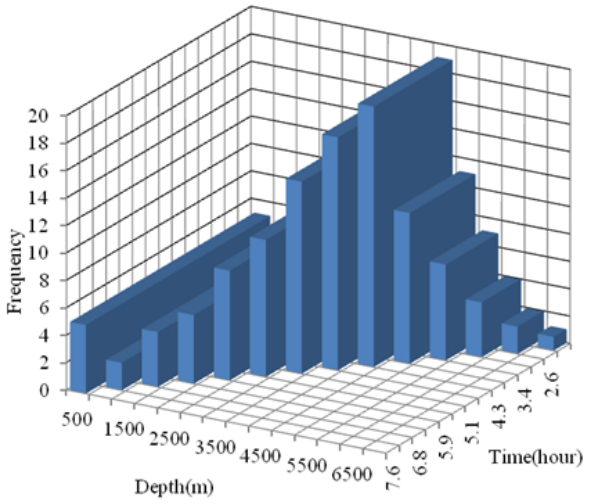

FIGURE 4 Creep and fatigue load spectrum of JIAOLONG HOV

TABLE 5 Data in creep-fatigue load spectrum of JIAOLONG HOV

Depth-range (m)	Frequency	Proportion (%)	Duration (h)
0-500	5	3.9	7.6
500-1000	2	1.9	7.2
1000-1500	4	2.9	6.8
1500-2000	5	4.2	6.3
2000-2500	8	6	5.9

4000-4500	19	15	4.3
4500-5000	11	8.7	3.8
5000-5500	7	5.9	3.4
5500-6000	4	3.5	3.0
6000-6500	2	1.8	2.6
6500-7000	1	0.8	2.2

5 Conclusions

In order to determine a load spectrum for failure analysis of viewport used in JIAOLONG HOV, dive data of ALVIN HOV (America) is collected for analysis and statistics due to its completeness and comparability. It has been found that the dive data has a skewed distribution feature, so both Weibull and Gumbel distributions are selected and compared for ALVIN's data fitting. The results indicate that Weibull and Gumbel function are respectively suitable for fitting data of different depth-ranges, so a piecewise distribution function is proposed to determine the load spectrum with the combination of two distribution functions. Both creep and fatigue are the main failure forms for HOV's viewport made by PMMA, so a load spectrum concerning dive time and frequency, which can be used for, creep and fatigue analysis is determined for JIAOLONG's viewport at last.

Abstract

In this paper, we propose to recognize the Acoustic Emission (AE) signal, by using a Gaussian Mixture Model-Universal Background Model (GMM-UBW) with an embedded AANN. The AANN based GMM-UBW combines the learning ability of neural network and strong distribution capabilities of GMM. And, it trains the model parameters alternatively in order to approach the maximum likelihood. For illustrating the effectiveness of the proposed recognition method for the AE signal, an experiment is conducted. In the experiment, three cases of AE signal are considered, namely with no rub impact, slight rub impact and serious rub impact. The experimental results reveal that the AANN based GMM-UBW outperforms the GMM, with respect to the recognition rate, for any case of AE signal. For the case of slight rub impact, the GMM-UBW and that with embedded AANN both have the worst recognition performance, among the three cases. And, the proposed method has the biggest improvement for this case.

Keywords: acoustic emission; Auto-Associative Neural Network; Gaussian Mixture-Universal Background Model

1 Introduction

The acoustic signal processing has always been a hot topic in the world [1-4]. The acoustic emission is a typical application. The rub-impact between rotor and stator is a common fault in rotating machines [5]. Effective recognition of the rub-impact plays an important role in safe and stable running of the rotating machines [5]. The AE recognition can realize the fault recognition of the AE source by using the AE signal [6-9]. And, it is a non-destructive detection method [6-9]. By employing the tool of pattern recognition [10], the AE signal can be properly classified. The AE recognition can realize the effective fault recognition and the evaluation of the safety performance of the correspondding material.

Gaussian Mixture Model-Universal Background Model (GMM-UBM) plays an important part in the field of pattern recognition (e.g., speech recognition) [11-16]. It can approach the AE data correctly in AE recognition and decrease the total difference between various signals. The artificial neural network (ANN) can simulate the human brains' structure and faculty using parallel processing technology [10]. It can approximate almost any non-linear mapping. And thus, in the AE recognition, it plays an important role where the model construction cannot be reached and in the comprehensive recognition. ANN is an effective tool in analysing the AE signal [10]. Auto-Associative Neural Network (AANN) possesses a special symmetric structure, and is proven to be a successful algorithm in signal detection [15-16].

In order to improve the performance of the AE signal recognition, the AANN is embedded into the GMM-UBM. Firstly, the feature vectors are input into GMM-UBM after being processed by AANN transfer. The output results are used to modify the AANN model through error back propagation. As two models are trained alternatively, the maximum likelihood can be approximated and a superior recognition rate can be achieved.

2 AE recognition based on GMM-UBM with an embedded AANN

2.1 APPLICATION OF AANN IN THE AE RECOGNITION

AANN, proposed by Kramer in 1990s, is a special forward neural network, where the identity mapping is adopted. The topology structure of the AANN is illustrated in the following Figure 1.

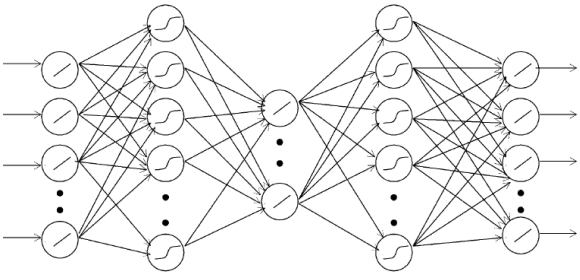

FIGURE 1 Auto-Associative Neural Network

The topology space of the AANN is set through associative learning. Then, the data coding and compression are implemented in the network bottleneck. Afterwards, the characteristic information of the process is obtained and the

* ***Corresponding author*** e-mail: chengxinmin@hutc.zj.cn

noise is filtered. Finally, the output (approximately) identical to the input is obtained. After the model training, the signal with noise being cancelled can be obtained by inputting the original signal with noise into the model. In the compression process, the characteristic dimension is reduced and the signal in higher-dimension space is projected into lower-dimension space. The linear combination of the principle components is utilized to represent the signal's high-order statistical property. And thus, the AANN can be taken as a non-linear principal component analysis (PCA) model.

In the field of pattern recognition, the data in the feature space generally has a complex distribution. However, as for the GMM, the data in the feature space are represented by statistical quantities of first and second orders and the mixture weights, and number of mixture is generally confined. So, the AANN, which is a non-linear model possessing multi-layer perceptron, is considered to be a practical model suitable for processing complex sound signal. It can obtain the error curve of the feature space, which matches the distribution of the training data. The approximation ability of the network to data can be observed, by training the error curve.

In the following, we will deduce the rule for training the model parameters of the AANN model. The basic idea of the training rule of the neural network is gradient descent method. Let $\vec{w}$, D and d be the weights, the training set and an instance in the set, respectively. The error E is defined as follows:

$$E(\vec{w}) = \frac{1}{2}\sum_{d\in D}(t_d - o_d)^2 , \tag{1}$$

where t_d and o_d are the expected and true outputs. Starting from some set of initial coefficients, the gradient descent method can be utilized to modify the coefficients of the model.

$$\Delta w_i = -\eta\frac{\partial E}{\partial w_i} = \eta\sum_{d\in D}(t_d - o_d)x_{id} . \tag{2}$$

For each layer of a neural network, the weights of the input vector $net_j = \sum w_{ji}x_{ji}$ is transformed through the sigmoid function. The training process from i th hidden layer to the j th output layer is illustrated as follows:

$$\begin{aligned}\frac{\partial E_d}{\partial w_{ji}} &= \frac{\partial E_d}{\partial net_j}\cdot\frac{\partial net_j}{\partial w_{ji}} = \frac{\partial E_d}{\partial net_j}\cdot x_{ji} \\ &= \frac{\partial E_d}{\partial o_j}\cdot\frac{\partial o_j}{\partial net_j}\cdot x_{ji} = -(t_j - o_j)\cdot o_j(1-o_j)\cdot x_{ji}\end{aligned} . \tag{3}$$

Thus, the weight update quantity is:

$$\Delta w_{ji} = -\eta\frac{\partial E_d}{\partial w_{ji}} = \eta(t_j - o_j)\cdot o_j(1-o_j)\cdot x_{ji} = \eta\delta_j x_{ji} , \tag{4}$$

where $\delta_j = -\dfrac{\partial E_d}{\partial net_j} = (t_j - o_j)\cdot o_j(1-o_j)$ is the error term.

Similarly, for the k th output layer, the training process from the i th input layer to the j th hidden layer is illustrated as follows:

$$\begin{aligned}\frac{\partial E_d}{\partial net_j} &= \sum\frac{\partial E_d}{\partial net_k}\cdot\frac{\partial net_k}{\partial net_j} \\ &= \sum(-\delta_k)\frac{\partial net_k}{\partial o_j}\cdot\frac{\partial o_j}{\partial net_j} \\ &= \sum(-\delta_k)w_{kj}\cdot o_j(1-o_j) = \eta\delta_j x_{ji}\end{aligned} . \tag{5}$$

Thus, the weight update quantity is

$$\Delta w_{ji} = -\eta\frac{\partial E_d}{\partial w_{ji}} = \sum\eta\delta_k w_{kj}\cdot o_j(1-o_j)x_{ji} = \eta\delta_j x_{ji} , \tag{6}$$

where $\delta_j = -\dfrac{\partial E_d}{\partial net_j} = \sum\delta_k w_{kj}\cdot o_j(1-o_j)$ is the error term.

Summing up the above deduction, the weight update process of the AANN is provided as follows:

Step 1. Set the numbers of layers and nodes for each layer, and the initial weight coefficients.

Step 2. For the output o_k of the training instance $(k \quad t_k)$, calculate the error term from hidden layer to output layer $\delta_k = -(t_k - o_k)\cdot o_k(1-o_k)$.

Step 3. Calculate the weight update quantity $\Delta w_{kj} = \eta\delta_k x_{kj}$ from hidden layer to output layer and update the weight value w_{kj}.

Step 4. Calculate the error term from input layer to hidden layer $\delta_j = \sum\delta_k w_{kj}\cdot o_j(1-o_j)$ according to δ_k.

Step 5. Calculate the weight update quantity from input layer to hidden layer $\Delta w_{ji} = \eta\delta_j x_{ji}$ and update w_{ji}.

Step 6. If the convergence conditions are satisfied, then terminate the iteration. Otherwise, go to step 2.

2.2 IMPLEMENT GMM-UBM IN THE AE RECOGNITION

GMM is a linear combination of multiple Gaussian probability density functions. Any continuous distribution can be approximated with desired precision by using GMM, as long as the number of components in the model is large enough. So, GMM has a wide range of applications, such as speech recognition, image denoising, detection of chemical machining process and mechanical fault diagnosis. For a D dimensional feature vector x_t, the M th order probability density function of GMM is given as follows:

$$p(x/\lambda) = \sum_{i=1}^{M} w_i \cdot p_i(x) . \tag{7}$$

Gaussian Mixed density can be expressed by the mean value, covariance matrix, and mixed weight parameterization of the total members' density as follows: $\lambda_i = \{ p_i,\ u_i,\ \sum_i \},\ i = 1,\ 2,\ 3,\ ...,\ M$.

The covariance matrix can be reduced to a diagonal matrix if the individual components are assumed to be independent. Then the D dimensional Gaussian probability density function can be represented as follows:

$$p_i(x) = \frac{1}{(2\pi)^{D/2} \left|\sum_i\right|^{1/2}} \exp\left\{-\frac{1}{2}(x-u_i)' \sum_i^{-1} (x-u_i)\right\}. \quad (8)$$

After obtaining the training vector, the iterative expectation maximization (EM) algorithm can be employed to estimate the maximum likelihood model.

$$p(i \mid x_t, \lambda) = \frac{p_i b_i(x_t)}{\sum_{k=1}^{M} p_k b_k(x_t)}. \quad (9)$$

Iteratively calculate the weight coefficients, mean value and variance according to the following equations.

$$\overline{p_i} = \frac{1}{N} \sum_{t=1}^{N} p(i \mid x_t, \lambda), \quad (10)$$

$$\overline{u_i} = \frac{\sum_{t=1}^{N} p(i \mid x_t, \lambda) x_t}{\sum_{t=1}^{N} p(i \mid x_t, \lambda)}, \quad (11)$$

$$\overline{\sigma_i^2} = \frac{\sum_{t=1}^{N} p(i \mid x_t, \lambda) x_t^2}{\sum_{t=1}^{N} p(i \mid x_t, \lambda)}. \quad (12)$$

In the pattern recognition of GMM-UBW, verification vectors are input into the AE model and background model, in the test, and the ratio of the two models is calculated. If the ratio is higher than the prescribed threshold, the category of this AE source model is accepted. Otherwise, it is rejected. In other words, the background model provides the model for all the training instances, and sums up the model trend of all the input instances. It works as the denominator in the recognition, and has a normalizing effect on the total test voice scores [3]. Compared with GMM, GMM-UBM reduces the effect of rating difference between different voice signals, to a great extent. And thus, it has superior recognition performance. Moreover, because the AE training data is not enough, the number of GMM's mixture components cannot be set big enough. However, this number should be large enough in order to improve the recognition. The GMM-UBW trained through enough speech data can reduce the limitedness of the model's mixture component number.

GMM-UBW was originally applied to the text-independent speaker identification system. And, it also has applications, combined with support vector machine (SVM) theory, in emotional speech recognition and language recognition.

2.3 GMM-UBM STRUCTURE EMBEDDED WITH AANN

According to the error curve of AANN, a probability distribution matching the given data can be obtained. The distribution relates to the network cell and a kind of gain coefficient. The data distribution is not considered for this AANN. The error curve can only be utilized to verify the training ability of the network model. It, however, cannot provide information for signal construction in mathematical model. The GMM cannot transform the data, change its distribution. Further, the model itself has some limitedness and the matching precision cannot reach the desired requirement, due to the assumption of independence.

In view of the GMM-UBW's strong ability of data distribution and the AANN's excellent learning ability, these two kinds of pattern recognition methods are combined together. And, we proposed to recognize the AE signal by using a GMM-UBW with a AANN being embedded.

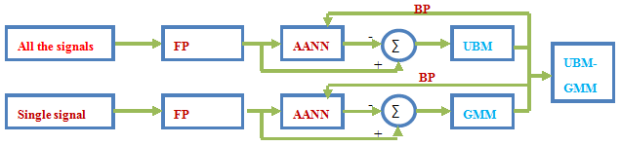

FIGURE 2 GMM-UBM embedded with AANN topping structure

As is illustrated in Figure 2, the training structure is composed of UBM and GMM. And the final output is GMM-UBW model. After extracting the characteristic parameters of the training sound signal, the feature vector is transformed through AANN. The difference between the output of the transformation and the original feature vector is input into the hybrid model. The modified output of the hybrid-model feedbacks the AANN and re-modify the AANN. The above process is repeated until the convergence conditions are satisfied. As for the UBW, the characteristic parameters of all the sound signal are input while the characteristic parameters of GMM are input one by one.

The specific training process is given as follows:

Step 1. Set the values of initial parameters and the convergence conditions of AANN and GMM.

Step 2. Input the characteristic parameters and obtain the error vector.

Step 3. Update the model parameters p_i, u_i and σ_i^2 of GMM while fixing the model parameters of AANN.

Step 4. Input the error vector into the modified GMM and obtain the likelihood probability. Transmit the error to the AANN before backwards and update its model parameter w_i.

Step 5. If the convergence conditions are satisfied, then terminate the iteration. Otherwise, turn to step 2 and continue the above process.

In the above process, the training processes for UBM and GMM are almost the same. The only difference exists in that the parameters of GMM, which is trained after UBM, are optimized based on UBM. This can save a certain amount of training time.

Construct AANN-GMM for each category (the existence of rub-impact or not). After the model training is complete, the recognition of the tested AE signal can begin. Then, input the feature vector into the AANN-GMM and obtain the likelihood probability of the categories. Finally, the recognition results are obtained.

3 Experiments and Discussions

The experimental data in this paper comes from the rotor system equipped with a rub impact bracket. The experimental equipment is illustrated in Figure 3. The rotor rub impact signal is produced by adjusting the nut bolt. The sampling frequency is 1MHz. The feature parameter method is adopted in the experiment. The feature of the AE signal is represented by seven simplified wave feature parameters. These seven parameters include the average vibration amplitude of rub impact signal, the maximum amplitude, the dynamic range of vibration amplitude and the reconstructed signal's energy of the first four contact points of the decomposed signal through wavelet package. The AE signals of no rub impact, slight rub impact and serious rub impact are provided in Figures 4, 5 and 6, respectively.

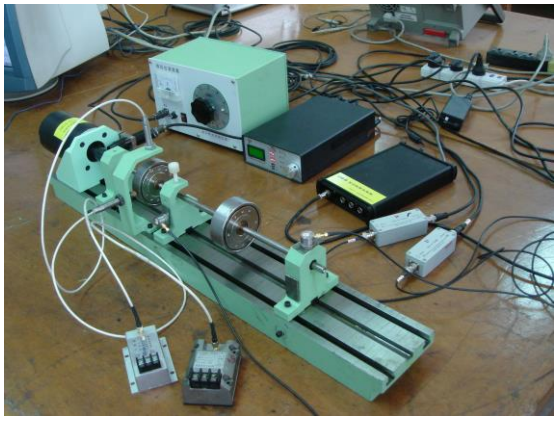

FIGURE 3 Rotor system

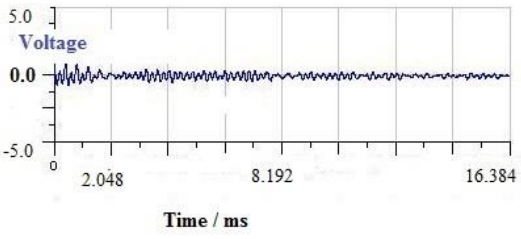

FIGURE 4 AE signal with no rub impact

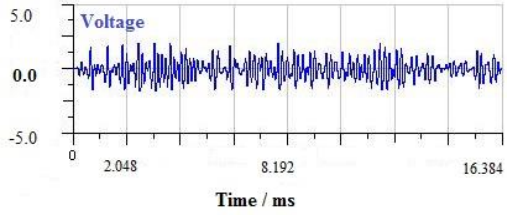

FIGURE 5 AE signal with slight rub impact

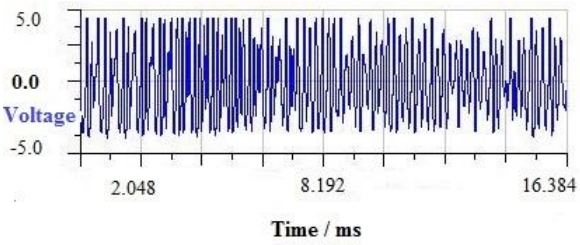

FIGURE 6 AE signal with serious rub impact

The performance of the GMM-UBW and that of the GMM-UBW embedded with AANN are analysed by using the same training data and the same test data. By adjusting the nut bolt, the three cases of AE signal, namely no rub-impact, slight rub-impact and serious rub-impact (all with respect to the rotating axis), are produced. The recognition performance of the above two models are evaluated for the above three cases of AE signal. The recognition rate comparison of the two models is provided in the following Figure 7. And, the recognition improvement of GMM-UBW with embedded AANN, with respect to GMM-UBW, is provided in Figure 8.

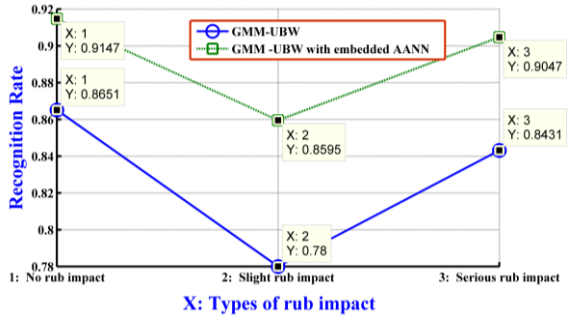

FIGURE 7 Recognition comparison between UBM-GMM and UBM-GMM embedded with AANN

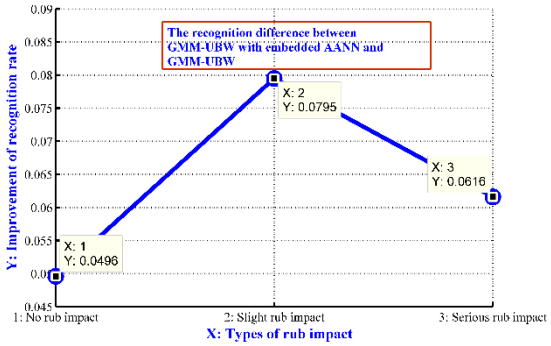

FIGURE 8 Recognition improvement of UBM-GMM embedded with AANN, with respect to UBM-GMM

The experimental results reveal that the GMM-UBW embedded with AANN outperforms the GMM-UBW for the three cases of AE signal separately. Specifically, the recognition rates are improved by 5.75%, 10.10% and 7.76% for the three cases (i.e., no rub impact, slight rub impact and serious rub impact), respectively. The results also reveal that for the case of slight rub impact, the GMM-UBW and that with embedded AANN both have the worst recognition performance, among the three cases. And, the proposed method

has the biggest improvement for this case. This indicates that the two models are not sensitive to the sound caused by the AE source. So, further work is required to extract more suitable feature vector, to improve the model structure and optimization algorithm and to better the fault detection efficiency of the AE method.

4 Conclusions

The GMM-UBW with an embedded AANN is proposed to recognize the AE signal and its recognition performance is studied in this paper. The proposed recognition method exploits the superior learning ability of the AANN to train the parameters of the whole model, by means of a two-stage training method. In the training process, the parameters of the GMM-UBM and the AANN are iteratively improved in order to obtain a superior likelihood probability. The experimental results reveal that the recognition rate of the rub-impact can be improved by using the proposed method.

Abstract

Based on certain type of two-stroke, low-speed diesel engine for marine propulsion, we, in our research project, developed a 3-D model of in-cylinder combustion processes in a diesel engine. Thus, we were able to compare simulated in-cylinder pressure against the experimental pressure under single injection with a maximum error tolerance of 0.36%, the results of which imply that the two are basically consistent. Subsequently, based on the same injection timing, a comparison was made between the performance of a diesel engine using single injection and one using dual injection. The results indicate that the additional injection can lower NOx by58.9% and soot by 30.1%. Moreover, the piston's workload is reduced by 10.1%. Through calibrating injection quality centre, adjusting injection timing of secondary injection reasonably, we gained the method improving performance of combustion and secondary injection diesel engine. By verifying, the method can promote working ability of secondary injection diesel engine effectively. After adjusting injection timing, working ability of secondary injection is as well as it of single injection, but emissions reduce sharply, thereinto, NOx reduced 12.7%, soot reduced 41.1%.

Keywords: Marine low-speed two-stroke diesel engine; injection timing; double injection; diesel performance

1 Introduction

In recent years, the government formulated the worldwide emissions regulations, Tier II regulations had been put into force in 2011, the regulations limits the NOx emission of Marine diesel engine under 14.36 g/kw*h, it fell about 20% than Tier I, and Tier III regulations will be carried out in 2016, when the NOx emissions will be reduced to less than 3.4 g/kw*h, and it drop nearly 80% than Tier I. Diesel engine manufacturers need to look for balance from the engine performance and emissions. Fuel injection technology development makes the stringent requirements possible [1]. Mixing process of gas and air, combined effect of combustion and emission, both impact the performance of diesel engine directly [2-6].

On the basis of the high pressure common rail fuel injection system of diesel engine, AnShijie [7] and others build a common rail diesel multiple injection performance test platform, and carried out the engine test and research about influence of multiple injection on diesel engine performance, the results show that using common rail technology and multiple jet drops off diesel engine exhaust temperature 50 ℃, and noise down 15 db, carbon smoke emissions improves significantly. Zhou Lei [8] and others researched the applicability of the fuel and air mixing process on large eddy simulation model in the prediction of engine early injection. The results show that the injection time moved up is advantageous to the fuel and air homogeneous mixing, mixture distribution is more uniform. WangHu [9] and others carried out the research about repeated injection and EGR coupling control experiment on the influence of the combustion and emission characteristics of diesel engine, compared with single injection, multiple injections coupling EGR control can significantly reduce carbon emissions, and fuel consumption rate debasing. Wang Benliang [10] put forward a proposal for multiple injection coordinated control strategy, aimed at pilot injecttion, main injection and post injection, and designed the control algorithm of multiple injection coordination controller, and has carried on the experimental study, the results show that the design of multiple injection coordinated control strategy can effectively realize the coordinated control on pre-injection, main injection and post injection under different conditions. Muammer Ozkan [11] and others researched the effects of heating and power efficiency in cylinder under different injection strategies, the experimental results show that the reasonable injection timing in advance can ensure the thermal efficiency and power capability and reduce NOx emissions. Mohan, B, et al. [12] discussed all kinds of injection strategy: including different curves of injection pressure, injection curve, injection timing and injection interval Angle, the influence on engine performance and emissions, the results show that pilot injection can reduce combustion noise and NOx emission, the injection interval smaller Angle can promote the soot oxidation, the appropriate injection timing can improve engine performance. So select the reasonable injection timing, and multiple injections can improve the diesel engine performance and reduce emissions.

In this paper, we take a Marine low speed two stroke diesel engine as the research object, establish the combustion model in cylinder of diesel engine, do the combustion simulation research under the condition of single jet to the diesel engine, and compared the results with experimental data. Contrast research the diesel engine performance under the condition of single injection and secondary injection, put forward the reasonable selection method of injection timing in reducing emissions under the premise of guaranteeing the power capability, it provides references for balancing diesel engine performance and emissions.

2 Establishment of the model and meshes generation

Taking a 350 mm two-stroke low-speed Marine diesel engine as the research object, for the four whole nozzle injector, spray holes are uniformly distributed. The operational parameters of the model engine are presented in Table 1. Combustion chamber space is composed by the cylinder liner, cylinder head, valve base and piston of diesel engine, cylinder grid as shown in Figure 1. Meshing is completed by special module ES- ICE of STAR - CD, the grid diagram as shown in Figure 1, geometry model and grid of top dead centre as shown in Figure 2, the top dead centre grid number is 32415.

TABLE 1 Basic parameter of a marine diesel engine

Parameter name/unit	parameter value
Cylinder power /kw	653
Diesel engine cylinder diameter /mm	350
Stroke number	2
Compression ratio	17:1
Swirl rate	1.2
Combustion chamber	Exposure to ωtype (with BUMP ring)
Intake type	pressure intercool

FIGURE 1 Diesel engine cylinder grid

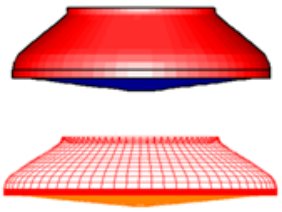

FIGURE 2 Grid of piston at top dead centre

Diesel engine cylinder gas phase flow model is based on classical hydrodynamics compressible navier-stokes equation of viscous fluid, namely according to the quality, composition, momentum and energy conservation law and the ideal gas state equation, a set of partial differential equations to describe the flow process in cylinder. The turbulence model used high Reynolds number k - Epsilon model; spray simulation adopted Huh atomized model, the Reitz - Diwakar droplets broken model and Bai bump wall model; The ignition model is compression ignition Shell model; Combustion model is laminar flow turbulence characteristic time combustion model and the EBU - LATCT model, and Zeldovich NOx generation model.

3 Initial boundary conditions

Initial conditions were given out by one dimensional simulation calculations of the machine; the initial moment pressure in cylinder is 0.485 MPa, the temperature is 363K. Boundary conditions are set according to the experience: cylinder head temperature 823K, the piston temperature 773K, and valve bottom temperature 823K. The boundary of the cylinder wall temperature is divided into three parts, the cylinder expansion direction, before one sixth is 623K, after a third of 548K, the remainder is 498K; the initial vortex ratio in cylinder is 5.5.

4 Model validations

To verify the model and algorithm, the combustion chamber combustion process was simulated under the condition of single jet; the fuel injection time is from the beginning of the 353 oCA, calculated pressure curve in cylinder is shown in Figure 3.

The Figure 3 shows that the compression pressure calculated is 13.04 MPa, explosion pressure is 16.59 MPa. And the original machine test compression pressure is 13.0 MPa; explosion pressure is 16.53 MPa, the compression stress error and the explosion pressure error were 0.31% and 0.36% respectively. The simulation result is in accordance with the test result, and it verifies the effectiveness of the algorithm.

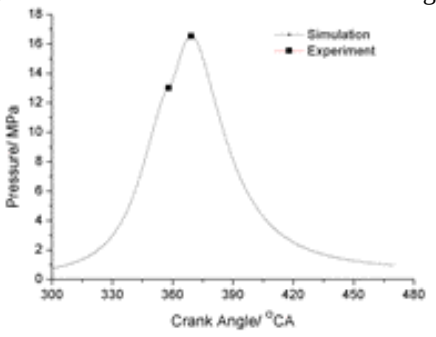

FIGURE 3 Cylinder pressure curve

5 Diesel engine performance contrastive analysis

In order to analyse the influence to diesel engine performance of different fuel injection law at the same injection current, combustion chamber combustion process was simulated under the condition of single injection and secondary injection respectively, simulation process is from exhaust valve closing time to exhaust valve open time. Injection timing of single injection and secondary injection are both 353oCA, fuel injection law is shown in Figure 4.

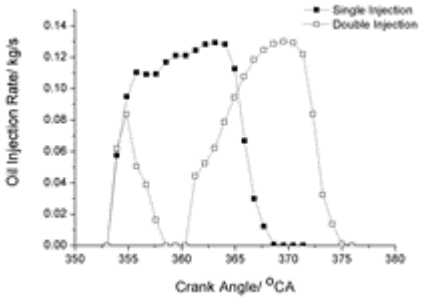

FIGURE 4 Fuel injection law

5.1 COMBUSTION SIMULATION RESULTS IN CYLINDER

Figure 5 is the distribution of oil hole in the plane (z = 27 mm) of the velocity vector diagram and fuel concentration field, temperature field and the NOx concentration field, under different fuel injection law, the piston runs to the top dead centre namely 360 oCA.

FIGURE 5 Each variable field distribution in cylinder at 360°CA

Figure 6 shows that under the condition of single jet, affectted by the eddy current in cylinder, the velocity field gradually become circular distribution, while the fuel injection ended in the 368oCA, but gas has not yet been fully burning, so local high, the centre temperature of 2571K, lead to distortion near the high velocity vector field. Under the condition of secondary injection, fuel injection has just concluded at the moment, high-speed injection fuel in cylinder, droplet spray evaporation form two strands of strong turbulence, the fuel injection rate ear along the axis is as high as 40 m/s, the gas concentration is about 15.7%, because gas is not yet fully mixed with air, combustion is not sufficient, so the centre of local high temperature is 1972K only. Due to under the condition of single jet local temperature is too high, creating a large number of NOx, the centre concentration is as high as 0.63%; With less NOx formation under the condition of secondary injection.

g) Work contrast figure

FIGURE 7 Diesel engine performance contrast figure

The Figure 7 a) and b) shows that under the condition of single injection and secondary injection ignition delay period is short, about 1oCA, fuel injection quantity is moderate, and it has a good gas mixture; Under the condition of single jet urgent combustion period for 354 oCA - 362 oCA, most high pressure rise rate is 0.45 MPa/oCA, and under the condition of secondary jet urgent combustion period is 354 oCA -358.5 oCA (pre-injection end), due to pre-injection fuel quantity is less, pressure rise rate slowly reducing, maximum pressure is 13.2 MPa only at the moment of 360oCA. Under the condition of single jet, slow burning period is 360 oCA - 369 oCA, maximum pressure is 16.5 MPa, when the secondary injection conditions, it enters the combustion period after the top dead centre, main injection stage appeared the second peak pressure, only 11.3 MPa (374oCA), lower than the first peak pressure. In a word, main injection period of the secondary injection is in the after burning period, the fuel heats in the lower expansion ratio, and the diesel engine efficiency greatly lowered.

From figure 7 c) we know, under the condition of single injection and secondary injection, heat release starting point and end point is basic same, but the secondary injection has high peak heat release rate than single injection, the secondary injection has the superior combustion performance. From figure 7 d) average temperature curve in cylinder, the secondary injection cylinder temperature curve is always lower than that of single injection, and the temperature peak appeared late, it shows that the secondary injection power capability is less than single injection.

Figure 7 e) is NOx formation history curve, we know from the figure, compared with the single injection, under the secondary injection, the formation of NOx starting moment is later, and the total generate amount is only 41.1% of the single jet, is reduced by 58.9%, this is due to under the condition of the secondary injection the average temperature in cylinder is lower, and the peak temperature appear later.

Figure 7 f) is the soot emissions contrast figure, soot under the condition of the secondary injection is only 69.9% of the single injection, reduced by 30.1%, that under the condition of secondary injection gas and oxygen mixed fully, generated less soot. Figure 7 g) shows that the secondary injection ability of doing work is 89.9% of the single injection.

To sum up, due to injection timing of the secondary injection later, main injection in the later period, led to the decrease of the diesel engine power capability, but the secondary injection has the superior combustion performance, and the NOx and soot emissions are lower than that of single injection. If you want to improve the diesel engine work ability under the condition of secondary injection, it needs reasonable adjustment of injection timing.

6 The secondary injection results after adjustment of injection timing analysis

6.1 REASONABLE SELECTION OF INJECTION TIMING

The nature of diesel engine is to change the chemical energy of fuel into the kinetic energy of the crankshaft, the Figure 7 c) heat release rate curve shows that the secondary injection has the superior performance of combustion heat release than single injection, after adjusting the injection timing, the ability of doing work of the secondary injection could reach or exceed the single injection. Due to secondary injection main combustion process is located in the after combustion period, expansion ratio is larger, work performance is poor, so it should be based on the heat release rate curve, adjusting injection timing of the secondary injection reasonably, make the heating centre of gravity (that is, the heat release rate curve integral centroid)coinciding. Because the heat release rate is a process quantity, it is difficult to control, in this paper, by adjusting the cumulative injection quality centre under the condition of secondary injection (i.e., 50% of cumulative injection quantity), with a single jet overlap, such basically guarantee the both exothermic centre of gravity coincided.

Figure 8 is cumulative injection quantity curve, cumulative injection quality centre is the dotted line in the fig-ure, the accumulative fuel injection quality centre of single jet and secondary injection is 6.9oCA and 13.6oCA respectively, to make the cumulative injection quality centre coincided, it needs the injection timing of secondary injection 6.7oCA in advance

Equations should be placed flush-left with the text margin and should be preceded and followed by one line of white, using *Microsoft Equation Editor*. Formulas fonts and sizes must match the text of your document.

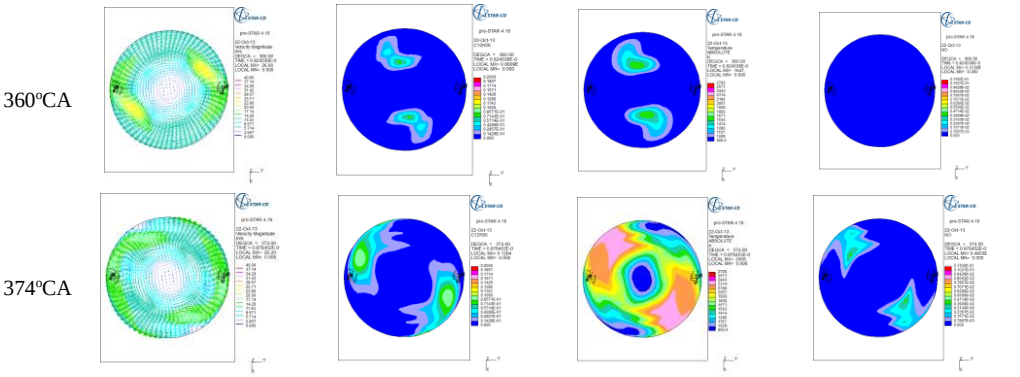
6.2 FLOW FIELD ANALYSES AFTER THE ADJUSTMENT OF INJECTION TIMING IN CYLINDER

Figure 9 for the adjustment of injection timing, under the condition of the secondary injection, 360oCA and 374oCA variables of the field.



(a) Velocity field (b) Fuel concentration field (c) Temperature field (c) NO_x concentration field

FIGURE 9 Distribution of variables in each field after injection timing adjusted

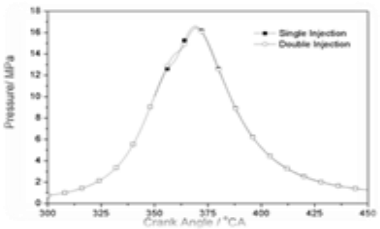
Figure 9, in the 360oCA moment, compared with the single injection, after adjusting the injection timing of secondary injection, centre speed of gas jet is 22.8 m/s, lower than that of single injection; Fuel concentration field distribution is slightly larger than single injection, the concentration of gas jet centre is about 7.9%, it shows that gas and air mixed uniformly under the condition of secondary injection. By the temperature field, the high temperature range is larger than single injection, and centre temperature is 1543K, higher than that of single injection, obviously that the secondary injection combustion performance is good, at this time there is no NOx formation.

At 374oCA, compared with single injection, the difference of velocity field between the secondary injection after adjusting and single jet is small; Range of fuel concentration field distribution is quite, and there is less difference of concentration; the distribution of temperature field is pretty, but the highest temperature is 2314K, only less than single injection, it shows that the secondary injection effectively reduces the local high temperature, temperature tends to be uniform; The NOx distribution range is small, centre concentration is only 4%, and the range is very small, that the secondary injection effectively reduced NOx formation.

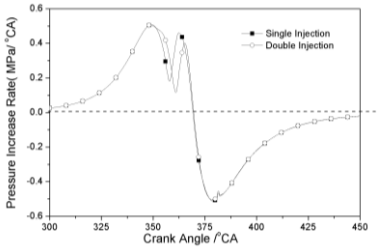
In short, after the adjustment of injection timing, oil and gas mixed more evenly, local temperature rise reduced, and it inhibits the formation of NOx.

6.3 PERFORMANCE ANALYSIS AFTER ADJUSTMENT OF INJECTION TIMING

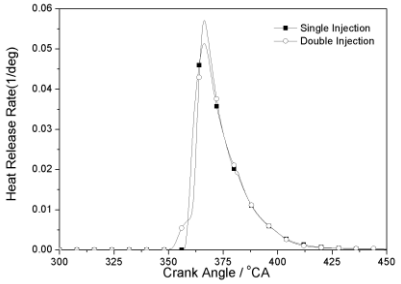
Figure 10 is after the adjustment of injection timing, the diesel engine performance comparison between the secondary injection and single injection.



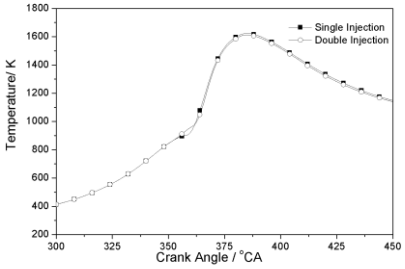
a) Average pressure curve in cylinder



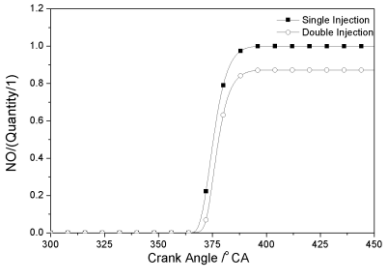
b) Pressure rise rate curve in cylinder



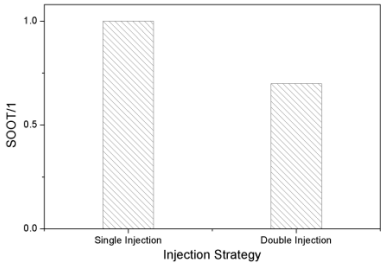
c) Heat release rate curve



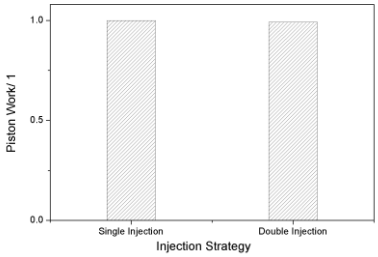
d) Average temperature curve in cylinder



e) NO_x total mass curve



f) Total quality comparison diagram of soot



g) Work contrast figure

FIGURE 10 Diesel engine performance contrast figure

The figure 10 a) and b) shows that after the adjustment of injection timing, the secondary injection ignition delay period is longer, about 8oCA, due to the fuel pre-injection quality is less, gas mixing fully, it is to lay a good foundation for the subsequent combustion; Urgent combustion period is 354oCA - 360oCA, premixed gas combust together almost at this stage, cylinder temperature rise sharply, as the main fuel injecting in cylinder, the process of fuel atomization and evaporation shorted, gas diffused and mixed combustion with oxygen, cylinder pressure rise rapidly, the high pressure rise rate is 0.4 MPa/oCA, lower than that of single injection, it shows that the secondary injection pressure change is moderate; slow-burning period is 360oCA - 365.2oCA, during this stage the peak pressure is 16.4 MPa, and was equal to that of single injection; Compared with the single injection, after combustion period of the two are basically identical.

By figure 10 c) and d), the secondary injection and single jet reach exothermic peak almost at the same time, and peak value of the secondary injection is higher than single injection, it shows that the secondary injection fuel burning more fully; the cylinder temperature curve change rule is consistent, and the secondary injection peak temperature is only 1612K, lower than that of single injection of 1623K, it shows that secondary injection combustion in cylinder is more even.

By figure10 e), NOx generation total amount of the secondary injection is 87.3% of the single jet, was reduced by 12.7%, it shows that the secondary injection high temperature area is small, NOx formation is less; By figure10 f), soot of the secondary injection is only 58.9% of single injection, down 41.1%, that shows gas of the secondary injection mixed fully in slow-burning period, therefore emissions reducing. By figure10 g), the secondary injection ability of doing work is 99.1% of single injection.

In conclusion, after adjusting the injection timing reasonably, the secondary injection has almost the same power capability as single injection, but NOx emissions reduce by 12.7%, soot emissions reduce by 41.1%. That shows by changing cumulative injection fuel quality to adjusting the injection timing of secondary injection, compared with single injection, it can ensure the ability of doing work and greatly reduce emissions.

7 Conclusions

1. Set up a combustion simulation model of marine low speed two stroke diesel engine, simulated and analysed the compression, spray, combustion, emission process of marine low speed diesel engine, and compared with the test data, the maximum error is less than 0.36%.

2. At the same injection timing, compares the diesel engine performance of the single injection and secondary injection, the results show that compared with single jet, the secondary injection caused the reduction of NOx by 58.9%, lower soot by 30.1%, but the ability to make the work fell by 10.1%.

3. The method of adjusting the cumulative injection quality centre to adjust the injection timing of secondary injection reasonably is given, it can enhance the power capability of diesel engine; And combustion simulation was done, the results show that compared with single injection, the secondary injection can ensure the ability of doing work, at the same time, reduce NOx by 12.7% and soot by 41.1%.

Abstract

In the part of hand vein image acquisition of vein recognition, we basically cannot get the images that are suitable for later process due to both the subjective factors and the objective factors. After a deep analysis on the main reasons including the different thickness of hands and mass of things on the hand, we propose the design of hand vein acquisition device based on the adaptive modulation control. The key part of the design is the proposed double-processing image quality assessment system: the first part of which involves the process of quality assessment based on the effective information of multidimensional histogram and the normalized information entropy; the second part involves adding the grey image variance and quantities of cross points with the proper weights, then two process will be made according to the final score: if the score is lower than the set threshold then image will be discarded, and on the other hand the brightness degree of the LED groups of the device will be adaptively adjusted according to the D-value of the score and the threshold so that we can get the high-quality hand vein image for later feature extraction and matching and get a higher recognition rate.

Keywords: hand vein recognition; adaptive control; two-set quality evaluation system; D-value

1 Introduction

With the development of biometric feature recognition and informative technology, the traditional identify technology cannot meet the demand of security. Vein recognition has become a new trend of biometric recognition with some great advantages [1-4]. And the currently main feature image evaluation method focuses on the fingerprint, iris and images of videos [5-7]. After a deep research and study on the existing method for image evaluation, we respectively take the statistical characteristics and structural characterristics after deburring as the feature parameters for evaluation function. The criterion of the first-set quality evaluation system we set is that: Calculating the two-dimensional histogram of hand vein images firstly, then we determine whether to store the image or not according to the spread condition of the pixel around the area of G_1=G_2; and then we calculate the information entropy of the stored image and compare the value with the pre-set threshold to get the second-stored vein image whose value is larger than the threshold (we set it 4.0 according to the recognition rate). In the second-set quality evaluation system, we firstly get the grey variance and number of cross points of the selected hand vein images, and then adopt the pre-set weight to calculate the final parameters by adding them up. The optimized weights we set are respectively 0.5826 and 0.4174 according to the recognition rate. And in the final, we get the final parameter to determine whether to leave the hand vein images for feature extraction, the normalized threshold we set in the final determination part is 0.55 according to the experiment result. And then we design the improved smart-control acquisition device based on the evaluation system, which can get the high-quality hand vein images for later feature extraction and matching and get a higher recognition rate.

2 Theory of quality evaluation system for hand vein images

In the procedure of capturing hand vein images, we usually could not get the high-quality hand vein images for later process, so it is essential for feature extraction and recognition to import quality evaluation function to realize the effective choice of the original vein images.

After a deep research and study on the existing method for image evaluation, we respectively take the statistical characteristics and structural characteristics after deburring as the feature parameters for evaluation function [8]. The explanation of the parameters is as follows:

(1) Statistical characteristics: The method censuses the spread parameters including the variance and entropy of the grey images based on the theory of transforming the original image into grey images, while the variance reflects the contrast degree and the entropy reflects the content of effecttive information.

(2) Structural characteristics: After the pre-process and the deburring process on the hand vein images, we choose the quantities of cross points of the images and the extracted ROI area as the evaluation parameters. On the one hand, we can know whether the images we obtain contain the proper amount of cross points for recognition; On the other hand,

* ***Corresponding author*** e-mail: wangguoqingcumt@163.com

we can get the idea of the amount and effectiveness of the structural information of vein images.

3 Two-set of evaluation systems on hand vein images

3.1 FIRST-SET PART OF THE EVALUATION SYSTEM

In the first part of the evaluation system, we focus on the global spread and the global effectiveness of image information that are closely related with human vision, and we choose the two-dimensional distribution histogram and information entropy to realize the first-set evaluation.

3.1.1 Choice of images based on the two-dimensional distribution histogram

As the global information and features of images, the histogram of grey vein images can show the frequency distribution of grey of pixel and we adopt this parameter as one of the evaluation system. The traditional one dimensional grey histogram is the statistical distribution of isolated pixel. And we find that if the correlation between pixels could be got and analysed, we could get a better choice on the images. So we introduce the multi-dimensional distribution histogram for analysis.

In the theory of image processing, we define the multi-dimensional distribution histogram as follows: count the frequency of grey image *f(x,y)*, and then get $Num\left(G_1,G_2,G_3,\ldots,G_k\right)$, $G_1,G_2,G_3,\ldots,G_k \in \Omega$, and the Num stands for the frequency amount that when it meets the requirement that the pixel is G_1 and the *K-1* around the pixel is $(G_1,G_2,G_3,\ldots,G_k)$, and then we get the definition of *K* dimensional distribution histogram, and then normalizing the histogram value according to the max of frequency $max(Num(G_1,G_2,G_3,\ldots,G_k))$ to get $Norm(G_1,G_2,G_3,\ldots,G_k)$, which is called *K-D* normalized histogram.

$$Norm\left(G_1,G_2,G_3,\ldots,G_k\right) = \frac{Num\left(G_1,G_2,G_3,\ldots,G_k\right)}{\max\left(Num\left(G_1,G_2,G_3,\ldots,G_k\right)\right)} . \quad (1)$$

In the definition, we normalized the *Num* and max one of the frequency values to get the *K-D-log* normalized histogram.

$$Norm_{\log}\left(G_1,G_2,G_3,\ldots,G_k\right) = \frac{\log(Num\left(G_1,G_2,G_3,\ldots,G_k\right))}{\log(\max\left(Num\left(G_1,G_2,G_3,\ldots,G_k\right)\right))} . \quad (2)$$

The max one refers to the peak value of grey frequency value, and for calculating and reckoning compare we use the algorithm of LOG to realize the transformation based on the idea of the fractal dimension of complexity measure. And according to the advantages of statistics and distribution, we can get the key parameter to realize the choice of vein images for later analysis.

On the basis of the above definition, we define the certain pixel as G_1 and the pixels in the right-side region around it as G_2, and the criterion we set is: as for the high-quality vein images, the character of its two-dimensional histogram is that the frequency value of the region $G_1 = G_2$ has a higher peak value and higher distribution density while the character of two-dimensional histogram for low-quality images is a lower peak value and scattered distribution in the region of $G_1 = G_2$.

3.1.2 Choice of images based on the information entropy

The definition of entropy is proposed by Clausius in 1865 which is used for describing the disordered state of thermodynamic system, and then it was introduced into the field of information engineering. After a long period of development and improvement, the experts in the field of image information propose the definition of information entropy to represent the average amount of statistical information of the system [9-10].

In the proposed definition, we import the definition of complexor, and it is made up of $\{x_1, x_2, x_3, ..., x_n\}$, and then we can get the following definition on the condition of supposing x_i=v and the probability $p_i=P(x_i)$:

$$H\left(v\right) = -\sum_{i=1}^{n} p_i \log_z p_i \cdot \quad (3)$$

In the above definition, H(v) stands for the probability distribution function of the defined random variables.

In the field of digital image processing, the spread of different pixel points in the images are different in images, which results in different shape features of the vein images. The amount of statistical information will be much more with the richness of grey or color of the images, which means the quality will be better. According to this the rule, we could know that the much more difference of grey level and the more the statistical information, the better the hand vein image is. Supposing that the statistical probability of grey value m is P_m, and we can get the following calculating formula:

$$H\left(v\right) = \sum_{T=0}^{z33} p_m \log_z p_m \cdot \quad (4)$$

In the above definition, H stands for the information entropy of hand vein image, and the value range of m is [0, 255]. P_m stands for the probability of grey value m, and the criterion is that the higher the value of H, the better and the higher quality of the images.

In conclusion, the criterion of the first-set quality evaluation system we set is that: Calculating the two-dimensional histogram of hand vein images firstly, then we determine whether to store the image or not according to the spread condition of the pixel around the area of $G_1 = G_2$; and then we calculate the information entropy of the stored image and compare the value with the pre-set threshold to get the second-stored vein image whose value is larger than the threshold (we set it 4.0 according to the recognition rate).

3.2 SECOND-SET PART OF THE EVALUATION SYSTEM

After the process of the first-set evaluation system, we obtain the preliminary hand vein images that can be used for subsequent analysis. Then we design algorithm to get the grey variance and numbers of cross points of the selected hand vein images, and then combine the two parameters by setting optimized weights, and then we get the final sample images for feature extraction and matching.

3.2.1 Calculation of grey variance

In this section, we define the selected images as the matrix M * N, and define *I(I,j)* as the grey value of the pixel on the line i and column j. Then we define Mean as the average value of the grey value, which can reflect the degree of brightness; On the other hand, we define Var as the grey variance of the image that reflects the contrast between the foreground and background of the images. The criterion is that: the bigger the value of the Mean and the Var, the better the vein image is.

$$Mean = \frac{1}{M \times N} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} I(i, j), \tag{5}$$

$$Var = \frac{1}{M \times N} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} \left[I(i, j - Mean) \right]^z . \tag{6}$$

3.2.2 Calculation of cross points

Although we have set the first-set part and the first one of the second-set of the evaluation system to select the high-quality vein images, there are still some selected images with low-quality bringing down the recognition rate, and after a deep analysis on the selected images, we find that there are great differences between the images after the pre-process on (especially the deburring process) the selected images, so we design the algorithm to calculate the number of the cross points. Then we find that the quality of the images differs with the number of cross points and the larger the number is the higher quality the image is.

In the pre-process of deburring, we improve it as the conditional deburring. The character, of which is that the connected points of lines and the turning points and T-shape branch points can be well kept after the deburring. But after a sudden amplification transformation we find that the conditional deburring can't realize the complete single pixel processing, which is shown as follows:

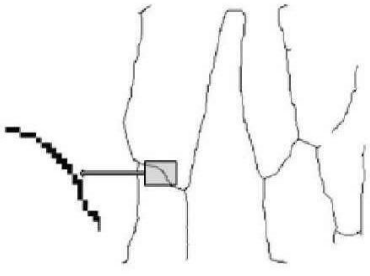

FIGURE 1 Amplification of the vein images after conditional deburring

After a deep analysis on the phenomenon mentioned above, we adopt the template process algorithm after the self-defined improved conditional deburring process on the vein images, and it can remove the single-pixel point to get the real cross points of the images. We divide the existing non-single pixel into two kinds, and as for the first kind shown in Figure 2, we need to cut off the non-single pixel according to the final matching because that these pixels are redundant.

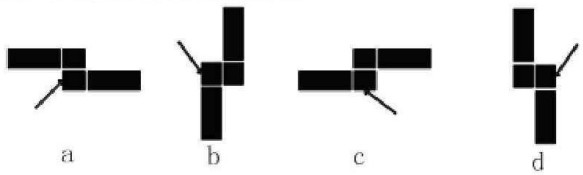

FIGURE 2 The first kind of non-single pixels

The template we adopt is shown in Figure 3, the centre of the template is the reference central point. In the chart, "1" stands for the point in the targeted images while "0" stands for that in the background images, and "x" stands for the points of the targeted images that are used for later analysis on the one hand, on the other hand, it stands for the points of the background images.

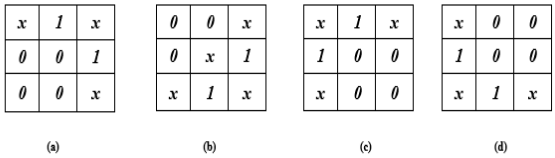

FIGURE 3 The designed template for the first kind of non-single pixels

The criterion we set here is that we firstly choose to cut off some pixels related to the template's central point's so as to decrease the width of the vein, and at the same time we cut off the points the arrow pointing to in Figure 3 (a). Then we adopt the other three pre-defined templates to realize cutting the other points off to leave the pixels that meet the requirements. Then we adopt the iterative operation with the existing operation until the first non-single pixels are cut off completely.

Then we can conclude from the analysis that the second kind of non-single pixels are as follows:

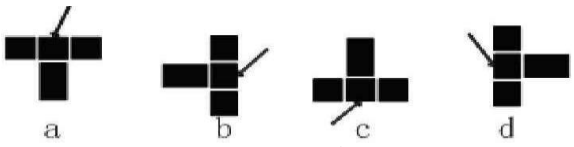

FIGURE 4 The second kind of non-single pixels

In this part, we design another template that are suitable for the second kind of non-single pixels based on the design of the first kind of templates.

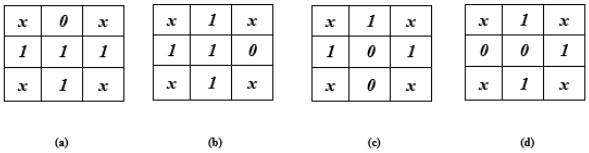

FIGURE 5 The designed template for the second kind of non-single pixels

After the process of cutting the pseudo cross points off, we can get the following vein images as shown in Figure 6 for later analysis. On the other hand, we find that the cross points of the vein image can be easily obtained after the designed templates' process, and we could design a formula to get the number of the cross points so that we can determine whether the images can be used for recognition.

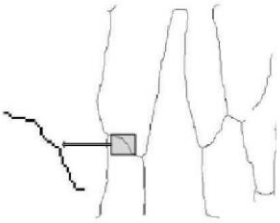

FIGURE 6 The local amplification effect image after the templates' process

In the second-set quality evaluation system, we firstly get the grey variance and number of cross points of the selected hand vein images, and then adopt the pre-set weight to calculate the final parameters by adding them up. The optimized weights we set are respectively 0.5826 and 0.4174 according to the recognition rate. And in the final, we get the final parameter to determine whether to leave the hand vein images for feature extraction, the normalized threshold we set in the final determination part is 0.55 according to the experiment result.

4 Realization of improved smart-control acquisition device based on the evaluation system

Through the process of the proposed evaluation system, we find that the final recognition rate improves a lot after leaving some low-quality vein images. So we import the thought of feedback modulation based on the evaluation system to realize the smart-control of the capturing device and increase the recognition rate in the end.

4.1 DISCUSSION ON THE CONTROL METHOD ON THE CAPTURING DEVICE

According to the imaging principle, we could know that the vein images are obtained on the condition of specified wavelength of light source, so it is required that the voltage should remain in a stable value, and we have realized keeping the homogeneity and stability of the near-infrared light source by adding the control on the power-supplying circuit and equipped the capturing device with light guide plate. And concluding from the circuit theory we can know that the strength of the light source is proportional to the electrical current, so we choose to control the light strength by the way of controlling the electrical current.

We find that the changing trend of the quality evaluation parameter will go up with the increase of the current in a certain range, but it will go down after a certain peak value, so we can realize the control on the capturing of hand vein image to obtain high-quality image by the control on the electrical current. The method we adopt is the PWM control on the circuit.

4.2 REALIZATION OF THE DEVICE

The procedure of capturing hand vein images is as follows: set the parameters of the capturing device by the self-programed software, then starting capturing and calculating the parameters of the evaluation system by the self-programed software, and then take actions mentioned above to obtain the high-quality vein images.

The concrete procedure of the control is as follows:

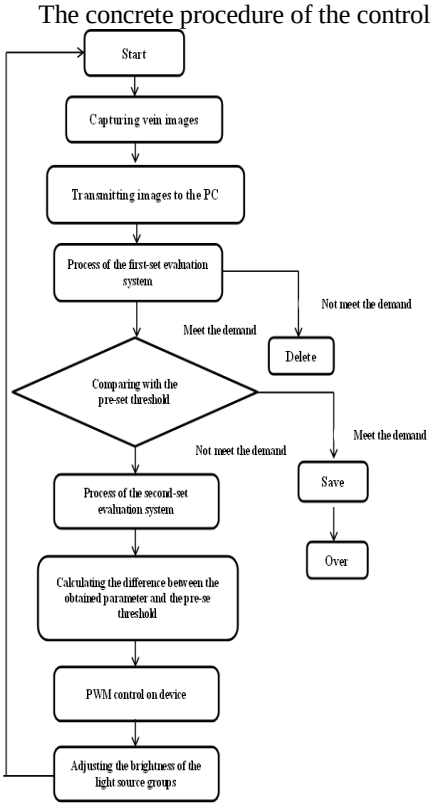

FIGURE 7 The flow chart of the smart-control system

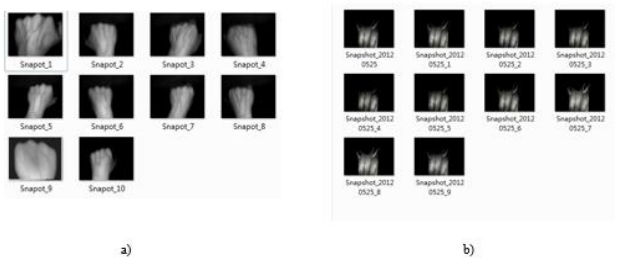
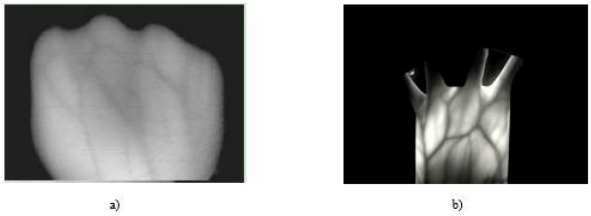
5 Experiment result and discuss

At the beginning of the study on hand vein recognition, we design a capturing device to establish the database of hand vein images for later recognition, but it cannot get a good recognition result, the beginning vein image acquisition method concentrates on transmission imaging mode uses simple control method without feedback signals to realize the control on the LED groups.



a) b)

FIGURE 8 Databases of the hand vein images of one volunteer: a) Acquisition device before optimized; b) Acquisition device after optimized



a) b)

FIGURE 9 The certain sample of the databases: a) Acquisition device before optimized; b) Acquisition device after optimized

Based on the above disadvantages of the current devices and after a deep analysis on the main reasons including the different thickness of hands and mass of things on the hand, we propose the design of hand vein acquisition device based on the adaptive modulation control. The key part of the design is the proposed double-processing image quality assessment system: the first part of which involves the process of quality assessment based on the effective information of multidimensional histogram and the normalized information entropy; the second part involves adding the grey image variance and quantities of cross points with the proper weights, then two process will be made according to the final score: if the score is lower than the set threshold then image will be discarded, and on the other hand the brightness degree of the LED groups of the device will be adaptively adjusted according to the D-value of the score and the threshold so that we can get the high-quality hand vein image for later feature extraction. The following two databases of hand vein images are respectively obtained by the two generation set of devices, and it is obviously that the smart-control device can get a better images.

Abstract

To strengthen safety supervision, satellite positioning information is needed to be uploaded as well as battery status information of pure electric buses. For the unbalanced coverage of mobile communication base station, data loss and incomplete data are prone to emergence when a large amounts of real-time data transmission through 3G/GPRS network in the poor communication environment of subregion, which is difficult to achieve large-scale farmland information collection and transmission simultaneously. Therefore, optimized Huffman coding compression algorithm for text-oriented information is promoted in this paper. The whole process test results of data exchange and decompression show that, the data compression algorithms can realize data compression effectively. The data sampling period is relatively smaller and its adjacent data is closer, the higher compression rate can be obtained by corresponding compression algorithms, and it can the basically ensure the decompression data without distortion. This will improve the efficiency of information transmission of transportation, as well as to ensure the integrity of information, which is of great significance to realization of transportation energy conservation.

Keywords: vehicle information, data compression, pure electric buses, battery status information

1 Introduction

The key operational vehicle information safety supervision has been continuously strengthened along with the national, provincial governments at all levels. The standard terminal with satellite positioning function were forcibly mounted on passenger bus, tourist charter, dangerous goods vehicles, coaches, trucks, heavy trucks, buses, taxis and so on. Some cities also require passenger bus, tourist chartered buses, taxis and other installation equipment using a video camera in order to enhance information security regulatory standards. Regardless the using of satellite positioning terminal or video camera equipment, it must bear a lot of the cost of wireless data transmission. If using new energy vehicles, such as electric buses, hybrid buses, electric taxis, etc., due to the need to upload more types of data to the regulatory status of the platform, its wireless transmission costs will rise at the same time. How to meet the requirements of the competent authorities, and saves the cost of wireless data transmission has become an important problem to be solved at present industry. The compressed data transmission is one of the important ways to solve the problem, and it can ensure the real-time and data quality of data transmission in the city communication environment, many scholars have conducted extensive research in this areas. Vehicle information is now covered by the text, pictures, video and other types of information. In order to improve data transmission quality, many researchers have proposed a variety of compression and transmission methods, for example, Hashemian [1], Sharma [2], Shi [3], Meng [4] et al proposed for the Huffman coding technology for wireless transmission of GPS, including GPS coordinate, records and other text data compression and transmission problems. Hu [5], Jou [6], Wang [7], Barr [8] et al put forward the LZW compression algorithm, which can be optimized by establishing a method to quickly find a dictionary and it can greatly reduce the time of data compression to achieve optimal compression, and improve transmission efficiency. Wavelet compression [9] method for wireless transmission of compressed gradually becomes a hot spot in recent years. In terms of traffic information, based on GML data compressions, Zhang [10] achieved a traffic emergency data and realized a framework of urban traffic emergency system architecture; Through random matrices with restricted isometric conditions of the

***Corresponding author** e-mail address: xueyj@scau.edu.cn

original high-dimensional data onto a low dimensional space, Li [11] realized the data fast and efficient compression, and via a convex optimization algorithm to complete the data decompression in traffic information processing terminal after data transmission; According to the characteristics of traffic data, Zhao [12] using its research and comparative data compression methods based on principal component analysis (PCA) and independent component analysis (ICA) method, respectively. Scholars' research results could furnish some useful suggestions in the transmission terminal data to a certain extent. However, the problem can not be ignored is, because of the unbalanced nature of the distribution of urban mobile communication base stations, urban communication environment vary greatly, the data transmission capacity is in greater differences in different parts of the city, part of the region exists communication blind area. The method proposed by scholars rarely used in acquisition and transmission terminal data on one hand, also rarely take into consideration differrences the problem in the larger urban communication environment for real-time transmission of data, that is, how to realize text, pictures, video and other information integrated transmission while coverage of communication base station is uneven with large difference between the communication environment in urban areas. In addition, the large flow of data transmission needs to consume more energy; low-power transmission [13] has important significance to prolong the length of the various devices work. Therefore, based on priority principle approach for simple algorithms, short time-consuming, minimizing overhead of data collection terminals and the backend server, the pure electric buses status information compression and transmission methods basis on optimized Huffman coding algorithms is proposed in this paper. Data collection vehicle information compression and transmission method can be achieving the optimized by encryption, compression, transmission, reception, decryption process, which is important to improve the transmission efficiency of vehicle information to ensure the integrity of information and transportation industry to achieve energy saving.

2 Optimized Huffman coding algorithms

According to national standards, Ministry of Transportation and the provincial technical standards requirements, the current standard of vehicle information including position, speed, altitude, license plates, start/flameout, lights, driving status, drivers and other types of text that collected through the data collection terminals. In addition, the new energy automotive vehicle information needed to collect additional battery status such as temperature, and overall cell voltage, current and other battery management information. The data with different format, size, and type will be uploaded via the data exchange and the wireless communication module of the vehicle terminal.

Vehicle status terminal with satellite positioning usually set 15 seconds for the data collection period when collecting for pure electric bus vehicle information. The collecting cycle for battery status information of vehicle battery management system is a relatively short period. Part of collecting cycle of vehicle battery management system is in less than five seconds, whose data generated in terms of quantity and frequency are more than the data collected by vehicle status terminal with satellite positioning.

The whole process from the point of view of data transmission, namely, data collection, transmission, reception, storage throughout the process point of view, when compared to a large number of simultaneous transmission vehicle terminal especially, the main pressure is focused on how the backend server receives a large number of short, transmission, integration of data transmitted by the terminal.

The way to solve the problem of large amounts of data transmission and access mainly includes three. First, data optimization in vehicle terminal, extract the key significance with application data, the remaining data is temporarily stored in the terminal memory device. Second, data are identified in the data receiving platform to extract of critical data, but it must guarantee the reliability of data transmission. The last, data are compressed by vehicle terminal firstly, and decompressed on the platform.

The compression-decompression method can ensure the integrity of data transmission, but also can reduce the data communication flow, which can save communication costs, but its disadvantages are also very obvious. Optimization transmission of terminal is with less disadvantages, the main disadvantage is it requires the performance processing each group of data compression, which would lead to transmission time delay. Real-time upload of vehicle information is demanding on safety supervision. Moreover, with higher hardware configuration of vehicle terminal at present, the capable of handling large amounts of data vehicle terminal hardware compression technology is promoted. Data collecting, data compressing and transmitting could be performed at the same time, which could not be simultaneously affectted.

2.1 DATA COMPRESSION ALGORITHMS

Due to the limitations of the vehicle terminal hardware conditions, the applications for data transmission compression by vehicle terminal were less in the past for a long period of time in the practical. Images, video and other data that takes up a lot of storage space are usually collected in offline mode, namely, images, video and other data in not considering the real-time requirement when used by off-line way.

Although the vehicle terminal hardware technology continues to improve, but data collection, compression and transmission operate at the same time will occupy the terminal necessarily overhead occupy the terminal. Therefore, the selection of data compression algorithms in this paper compared with traditional data compression algorithms. The main principles include that, it must reach the compression effect and the algorithm should not be too complicated in limited bandwidth resources, which would avoid the influence of compression and transmission efficiency, and not occupy too much memory. Taking up too much memory will affect data collection, as well as other applications occupy a larger memory and use a common transmission protocol.

Based on the operating environment consideration of pure electric bus, the selection of compression algorithm for

operating state of the commercial vehicle in this paper must be followed principles of less calculation, fast compression, simple algorithm and easy to implement. The algorithms must to be reached an optimum compression effect, which cannot be too complicated to avoid affecting the compression efficiency of the transmission under the limited bandwidth resources to meet the requirements of the terminal hardware and communications environment. Text data is the main data for the commercial vehicle terminal collecting (including GPS/Beidou positioning information). Optimized Huffman coding technique [1, 15] for effectively lossless compression is proposed for the GPS/Beidou position data and the other text of commercial vehicles operating state to be transmitted in this paper.

Huffman coding principle is: Set consisting of the text is represented as a set of characters with $I=\{I_1, I_2, I_3 \cdots I_n\}$, where I_x represents different characters of text. Assuming the frequency of a character I_x is F_x, the code length is L_x. To make the total length of code source text file of the shortest, you need to determine the coding mode. Making the minimum value of $\sum_{i=0}^{n} F_x L_x$, this encoding is called Huffman coding [3]. Huffman code based on Huffman tree, Huffman tree construction steps are shown as follows [3, 4].

Step 1. Set the given n weights $\{w_1, w_2, w_3, \cdots, w_n\}$ according to n binary trees, where every tree T_x has only one weight w_x is the root of 1, the left and right sub-tree are empty.

Step 2. Select the root node of the binary trees in F with the minimum weights of sub-tree as to construct a new binary tree, and the root of the new lien binary is the value of its left and right sub-tree root node the sum of the weights.

Step 3. Delete the two trees in F, while the new binary was added to F.

Step 4. Repeat Step 2 and Step 3 until F set up with only one tree, this tree is the Huffman tree.

Typically, a large number of repeated characters are existed, such as GPS data. GPS and the other repeated characters text data included by vehicle information can be regarded as redundant information to be removed. On the basis of Huffman compression coding table for rapid processing after compression by contrasting data, then stored in the storage buffer for post-processing. Among them, Huffman compression coding tables are the number of times pre-generated by the background server for text data in the statistical characters, and pre-stored in the Flash of vehicle terminal. The Realization of the process is shown in Figure 1.

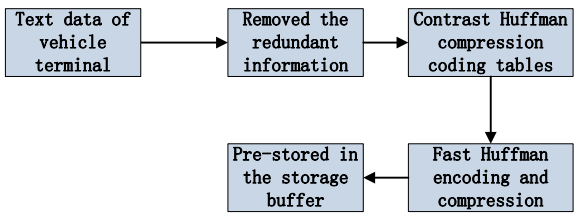

FIGURE 1 the compression flow chart of vehicle terminal text information

Huffman encoding is completely according to the characters of probability to construct coding, there is no error protection function. The algorithm needs to calculate the source character of probability statistics and obtains the probability distribution of the source symbols. This process requires a large cache using the hardware implementation of the algorithm. Generally, it believes that the decoding is complexity, and it is not conducive to the realization of hardware implementation [15, 16]. Huffman coding and arithmetic coding is a typical probability model, many scholars proposed the dictionary model for optimizing the original model, the typical optimizing algorithms such as LZW algorithm [4, 15], etc.

For compression and decompression speed, LZW algorithm is fast, and requires only one scan of the compressed data to be compressed. The compression ratio of the algorithm is very good for the continuous input stream to be compressed with high rate repetition. But the main drawback of this algorithm is the adaptability is rather poor, and the compression rate is less than Huffman algorithm. Moreover, the LZW algorithm usually needs to combine with other algorithms to reach the expected aim for some file with very low complexity. For vehicle operation status data, the data type apparently does not apply to LZW algorithm.

Huffman coding method has certain limitation, such as it need to scan flow of input symbols for two times, be stored or transmitted by Huffman tree before the storage or transmission of Huffman coding results. However, the algorithm has high compression rate, simple and practical, and all the coding has uniqueness while decoding, very suitable for vehicle information data that has high identification requirements. In order to overcome the practical problem of cache, high complexity caused by the Huffman coding, we improved the structure of Huffman tree based on the original. The main steps are as follows:

Step 1. Initialize the established binary Huffman tree, one of the root node has a weight of 0.

Step 2. To encode without the new characters of newly generated two nodes, the connection of the parent node weights add 1, and another node, which is defined as node weights of 0 nodes to define new weight of 0.

Step 3. The new characters have been encrypted through search was coded character location, in the case of the characters of the weight add 1 with coding and compared with the original weight of the same node.

Step 4. Repeat Step 2 and Step 3 until all characters are encoded.

The improved way of Huffman coding by weight set to 0, the original requires two symbols flow is simplified to a scan. The algorithm only needs to scan a probability of 1 characters, and it can only exchange the node between the binary tree needs to node numbering, which reduces the occupation of the cache, and the complexity of the algorithm is decreased. Its deficiencies are mainly embodied in the complete lost of coding error protection function, and the data requirements are relatively high.

2.2 DATA DECOMPRESSION AND PARSING

To distinguish the uploaded data from different vehicle terminal and to ensure uniqueness of uploaded data, uploaded data must be parsed and recognized. Default the parsing code for different vehicle terminal before uploading the data. Read and Match the parsing code by the reception server to achieve data uniqueness verifying. The specific processing is shown as follows.

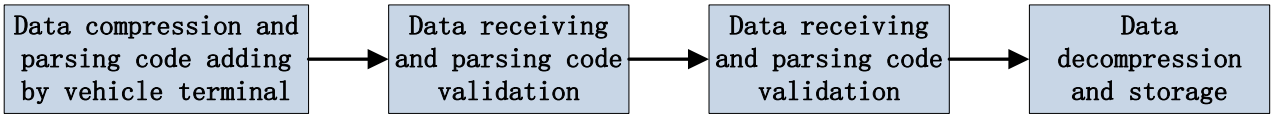

FIGURE 2 The Flow Chart of Data Parsing

Pictured above, it needs to setting parsing code corresponding to vehicle information first. Data compression and parsing code adding are processed by vehicle terminal. Backend server receives the data compression package, and matches the SIM card number, parsing code and other information corresponding to set parsing codes correspondding table. The perfectly matched data will be decompressed and written to the database.

3 Experiments and results

To meet the requirements of real-time data transmission, this paper uses 3G network as a data transmission channel for data transmission. In 3G network, the prerequisite to achieve the theoretical rate is the premise of carrier frequency for data communication, completely and exclusive to a user only. Due to the self-interference system affected by the communication environment, the use of the number of actual formation, the actual data transmission rate and theory of data transmission rate is often of large difference in the vehicle information collection environment.

3.1 DATA TRANSMISSION TEST

Data transmission test mainly completes two test including the network delay test and TCP transmission rate test in the actual environment in city village. Unicom's 3G networks were selected for communication channel for testing in city village environment. Data of vehicle status terminal with satellite positioning and vehicle battery management system were collected and uploaded, then received by server.

Round trip time (RTT) is usually used as a measure of 3G network time delay. Low delay time is of extreme importance in actual application. Lower delay is advantageous for the uplink direction to improve capacity and data throughput, and increase the coverage of high bit rate, obtain higher transmission bit rate. Typically, data transmission testing uses PING method, namely by obtainning response time of sending and receiving data packets to get connected server response time. When sending upload packets in requesting, all the serial number sequence will be added one firstly before sending, the replying information will also be marked the corresponding serial number. Then observe the Ping packet response messages to detect the link for data transmission delay calculation, such as packet loss, grouping repetition and fault sequence etc.

The following table shows the data uploaded test results in a village environment of a city. To be clear, several uploaded tests were started at 10 in the morning, ICMP packets for a total of 120 were send every time, the 3G bandwidth rate of 70-120kbps (city 3G bandwidth rate is about 700-900kbps), TCP transmission rate is close to 3G bandwidth rate.

TABLE 1 Testing results of raw data uploading

Serial Number/Test Items	Maximum Value of Ping Testing	Minimum Value of Ping Testing	Average Value of Ping Testing	Received Volume	Packet Loss Volume	Packet Loss Rate
1 (Packets:120)	7043ms	1190ms	2478ms	115	5	4.17%
2 (Packets:120)	6478ms	948ms	2136ms	117	3	2.50%
3 (Packets:120)	5735ms	1087ms	2332ms	115	6	4.17%
4 (Packets:120)	5845ms	1101ms	2447ms	113	7	5.83%
5 (Packets:120)	6089ms	1017ms	2311ms	116	4	3.33%
Mean	6238.00ms	1068.60 ms	2340.80ms	115.20	5.00	4.00%

TABLE 2 Testing results of compressed data uploading

Serial Number/Test Items	Maximum Value of Ping Testing	Minimum Value of Ping Testing	Average Value of Ping Testing	Received Volume	Packet Loss Volume	Packet Loss Rate
1 (Packets:120)	4546ms	1078ms	2213ms	233	22	8.63%
2 (Packets:120)	4997ms	1210ms	2319ms	230	25	9.80%
3 (Packets:120)	4912ms	1109ms	2190ms	238	17	6.67%
4 (Packets:120)	5221ms	1223ms	2342ms	239	16	6.27%
5 (Packets:120)	4893ms	1005ms	2201ms	234	21	8.24%
Mean	4913.80ms	1125.00ms	2253.00ms	234.80	20.20	7.92%

The result of data packets uploaded test shows that, the maximum delay time is 7043ms, the average delay time of 2340ms, which meets the basic requirements in real time data uploaded. 3G network takes the average packet loss rate 4.17% of data uploading while the network bandwidth is 70-120kbps. Relative to the GPRS data transmission mode, 3G network has been able to meet the requirement of actual application in the setting of upload strategy and selecting transport protocol, but also laid the foundation for the data compression test environment. In addition, it appears from the data uploading

test results, village area of the communication environment is relatively poor, data compression and transmission will still be of importance as well.

Due to environmental influences such as shaking hands error occurred etc., a large amount of data in the case of serious delays caused by transmission network, also had a serious packet loss in the original data uploading test. Direct transmission of original data easily lead to incomplete data, the delay is difficult to reflect the real-time data and so on in 3G networks.

Table 2 is uploading test result by APN for compressed data without identification and screening. The uploading data test method is similar to the original test data uploading method, each transmission is with 255 data packets improved by optimized Huffman coding. The difference between the two methods is to establish the corresponding APN network to upload data using 3G in the same use area.

The results of RTT test in APN network show data compression can effectively reduce the occurrence of packet loss in the area of villages of poor communication environment, while the uploading data is compressed by optimized Huffman coding before transmission.

3.2 DATA COMPRESSION AND DECOMPRESSION TEST

RTT test results showed that the time delay is less, the less the number of packet loss when transmitting a small amount of data. Transmitting a small amount of data of pure electric buses can effectively improve the efficiency of data transmission, but also to ensure the real-time data in the area of poor communication environment.

The data compression testing is shown in Table 3 for data transmission of original, after Huffman Coding, LZW algorithms and optimized Huffman Coding.

The main evaluation on the effect of data compression is mainly based on the compression rate and transmission time. Compression rate is one of the most important indexes to measure the data lossless compression algorithm. Compression rate is a direct measure of data reduction, the running time reflects the complexity of the algorithm, and the combination of the two indexes can be further estimated energy efficiency of communication. Transmission error rate is the rate between data length of accurately praised data had (compressed data containing the decompression process) not received by backend server and the data length before compressing. Packet loss rate is the ratio between the packet numbers of server has not been received and data packets had been transmitted by vehicle terminal.

It should be noted that, according to current technical standards for data collection and transmission requirements, this paper adopts 15s, 10s, 5s three data collection cycle, and the collection time is 300 minutes of pure electric buses collected operating status data as the test data source. This paper also shows the result according to the comparison of the original data, Huffman encoding, LZW algorithm, optimized Huffman coding after data transmission.

12	Optimized Huffman	5	169.14	54.03%	21.87	2.08%	0.87%

Experiment result shows that, compressed transmission effect was more notable. The transmission amount of compressed data is reduced greatly, accounting for about between the original amount of data of 1/4-1/3, and the corresponding transmission time is shortened into 1/4-1/3. In addition, it can be seen from the cycle of data collection, data sampling period is relatively smaller and its adjacent data is closer, all kinds of algorithm could get a higher compression rate. In particular, the correlation data has obtained the very good compression rate, which greatly enhances the communication efficiency of system, but also save the cost of communication.

For best results of actual test when using the optimized Huffman coding techniques, the data collection period is 15s. The test results further verify that a lower transmission error rate and transmission loss error can be obtained in the case of the transmission condition of data with less quantity and short transmission time.

The optimized Huffman coding technology has advantages of less calculation amount, high compression rate, and it is suitable for data transmission in the operation area of pure electric bus. For the LZW algorithm, the algorithm has a better compression efficiency for the correlation data in global or local, but because data field correlation of the pure electric bus operation status is small, resulting in limitation of application applied aspects of the object, and thus its compression efficiency is relatively poor in terms of optimized Huffman coding algorithm. To enhance the efficiency of real-time applications of pure electric buses operating status data, and avoid unwanted real-time transmission data occupying a lot of memory and data transmission channel, the paper also carries out data compression and transmission test after the data is filtered and identified, which are shown in Table 4.

The amount of data to be transmitted will be greatly reduced when the filtered and compressed data transmission mode is selected. Real-time data needed to transmitting can be greatly compressed in the transmission mode, which ensure data transmission for real-time application while the error rate of data transmission, data transmission packet loss rate fell to a lower level. Further, it can be seen from the data collection cycle that, the data sampling period is relatively smaller the closer adjacent data is; the data compression rate of various algorithms can be obtained. In particular, an excellent compression rate can be obtained in the case of the data with great correlation, which can greatly enhance the efficiency of communication systems, but also save a lot of communication costs.

In order to further verify the results of data compression algorithm, this paper compares the original data with the parsed decompressed data. Through the data exchanging, vehicle terminal could obtain the speed sensor data. Exchange data through data compression method based on the technology of Huffman coding for data compression, and then the original data file and compressed data files are transmitted to the backend server through 3G network. After transmission, read the received data file for decompression and inverse quantization, and compare the difference between the original data and data contrast reduction before and after data compression.

To be clear, the speed testing data was selected for a passenger bus driving data from 8:00 am to 12:00. An average of 5 seconds data collection cycle was set in the pure electric bus vehicle terminal, and it generated for a total of 2772 (theoretical value should be 2880, because of various reasons in the process of data collection, there are 108 errors, lost or not collected data samples) speed data during the period. Before the data compression, the original speed changing curve is shown in Figure 3. In Figure 3, the horizontal represents the speed of data collection time; the ordinate represents speed value, where are the same as Figure 4. After the data compression and transmission, the parsed speed changing curve is shown in Figure 4.

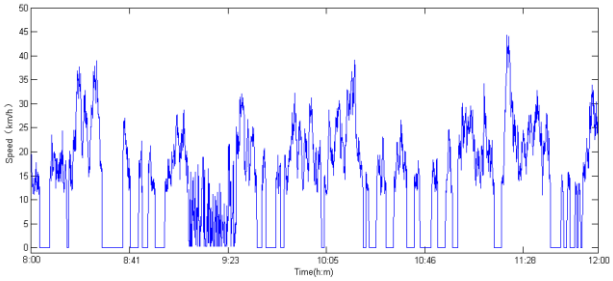

FIGURE 3 The velocity curve before data compression

Figure 4 shows the decompressed and parsed data, which have been compressed, transmitted, parsed, decompressed and warehoused to the backend server.

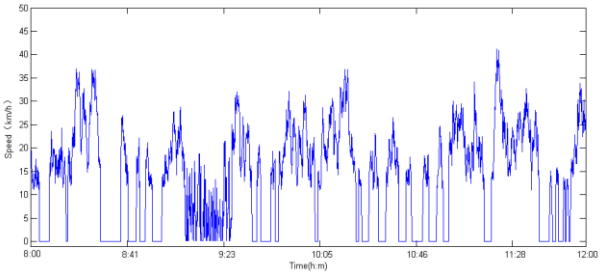

FIGURE 4 The velocity curve after data decompression

From the speed curve of the data before and after compression, the speed error value curve can be seen, the speed data consistent with original data basically before compressed through the process of compression, transmission, parsing, decompression, and data storage. Coding, compression and other data processing technology have met the basic requirements in actual application. To accurately describe the data differences between situation before and after the data compression and transmission, this paper calculated the mean variance to discriminate compression deviation after transmission of the data. After calculation, the mean square difference before and after data compression and transmission is of only 0.2789, which is within a reasonable range. The main reason for the deviation of the data exists in data loss, data failing to parse and the other reason during data transmission.

A total of 2702 data is to accurately have been parsed during 2880 speed data transmitted by vehicle terminal, the proportion of accurate transmission and parsing data is up to 96.25%, which basically meet the requirements of actual application. 108 errors, loss, and no sample data contained

the error data of 25, accounting for 0.87% of the total, loss of data 49, accounting for 1.70% of the total loss rate, no sample data of 34 due to various reasons did not collect, accounting for 1.18% of data should be collected of the total. The availability testing experiment results of compression and transmission algorithm show that, the algorithm has high efficiency and high transmission integrity.

4 Conclusions

Compression algorithm method is researched in this paper to the vehicle information including text information collection types (including position information), image and video to compress the data by using Huffman coding technology. On this basis, all kinds of vehicle information is transmitted based on NMEA-0183 various kinds of vehicle GPS monitoring transmission protocol. Through the process of vehicle information compression, transmission, decompression, parsing and storage whose data from vehicle status terminal with satellite positioning and vehicle battery management system, the compression algorithms are verified by speed data as an example. The algorithm achieved great test results in the experiments, the proportion of accurate data transmission and parse is up to 94.69%, basically meet the requirements of data uploading actual applications in different city region for the urban public transport, passenger transport, taxi and other industries. Meanwhile, the algorithm play an important role for enhancing the efficiency of wireless transmission applications and reducing the cost of data transmission as well as the time, which has the practical significance for the deployment of this base station, the selection of communication mode and the other uses. The data compression algorithms mentioned in this paper provides methods with transmission reliability and minimal distortion. It can provide reliable data transmission method for different mobile base stations coverage of the urban environment, which is important to improve vehicle transmission efficiency of information, ensure the integrity of information and the realization of transport energy conservation.

Abstract

This paper presents a method for penetration capacity calculation of wind farm based on probabilistic constraint. According to the stochastic programming theory, under a confidence interval, a mathematical model that considers the randomness of wind speed is established based on the static safety and power quality constrains. The solving method is proposed according to particle swarm optimization algorithm and stochastic simulation technique too. According to a real power system in Yunnan, the penetration capacity of wind power is calculated under different confidence interval, and the feasibility and effectiveness of this method are verified too. The related factors of affecting the penetration capacity of wind power are analysed, which provide the reference for the planning and design of wind farm.

Keywords: penetration capacity of wind power, chance constraint, stochastic simulation, confidence interval, particle swarm optimization

1 Introduction

Energy crisis and environmental pollution have become the two problems that must be faced in the development of modern society. As a renewable energy, because of low cost and less pollution, wind energy has received great attention around world. In recent years, with the rapid development of power electronic technology, the technology of wind power has made great progress. The national policy of strong support for renewable energy has made a period of rapid development of wind power construction in China. Wind power has becomes one of the most mature, large-scale development and commercialization of new energy technologies [1-14].

The random, intermittence and fluctuation of wind energy result in the wind power dispatching and have a severe impact on grid security, stability and power quality, which is the main factor restricting the installed capacity of wind power and capacity of grid connected. Therefore, to evaluate the maximum wind power capacity of system, that is, allowed capacity of wind power, is the key problem during the planning stage of wind farm.

There are no unified algorithm and formula, because of penetration capacity calculation involving many factors. The system was proposed, based on power structure, load and peak load capacity, which could evaluate the penetration capacity of wind power through power grid [4]. The wind power in Beijing Tianjin Tangshan power grid were assessed comprehensively through comprehensive analysis of the power structure, load characteristics, peak load capacity of thermal power, self capacity, pumped storage power station and tie lines planning, without considering the effect of increasing capacity of wind farm on the system static security. A mathematical model is established for wind power penetration limit in power system based on the static security constrains of power system and a new method for solving the problem is given based on interior point method [5], while there in no considering dynamic constrains related to wind power grid connected operation, which may be the key factor determining the penetration limit of wind power. According to the analysis of environmental uncertainty of wind power grid connected and dependent chance programming theory, the model was established that considered the static operation safety, the traditional power grid output limit constrains, the wind farm power down measures and wind power capacity. The wind power allowed capacity was calculated too [7].

In this paper, we propose a method to calculate the allowed capacity of wind power, based on probability constrains. At the same time, the random of wind power and equation constrains of trend are considered. According to the probability distribution of wind speed, the model is established and solved, based on the Particle Swarm Optimization (PSO) algorithm of stochastic simulation technique.

2 The wind farm and system load model

2.1 WIND FARM

The captured wind power of a fan is a function of wind speed at hub height, and the function can be expressed as

$$p = \frac{1}{2} K \rho S v^3 , \tag{1}$$

***Corresponding author** e-mail: duhuiqiu@126.com

p is the captured wind power; K is the power coefficient and the nonlinear function of the tip speed ratio and pitch angle; S is swept area of wind wheel; v is wind speed at hub height. The relationship between active power generated by the generator and wind speed can be expressed as follow

$$p=\begin{cases}0, v<v_{in}, \text{or } v>v_{out}\\ \dfrac{v^3-v_{in}{}^3}{v_n{}^3-v_{in}{}^3}p_n, v_{in}<=v<=v_n\\ p_n, v_n<v<v_{out}\end{cases}, \tag{2}$$

v_{in}, v_{out}, v_n denote cutting in speed, cutting out speed and the rated wind speed respectively; p_n is the rated power. Because of random of wind speed, the power generated by wind power has the character of random. The probability of wind speed between 0~25m/s is very high and the annual averaged distribution of wind speed in YunNan can be expressed by Weibull distribution function [10]

$$f(v)=\frac{k}{c}\left(\frac{v}{c}\right)^{k-1}\exp\left(-\left(\frac{v}{c}\right)^{k}\right). \tag{3}$$

The probability distribution of wind speed is shown in Figure 1.

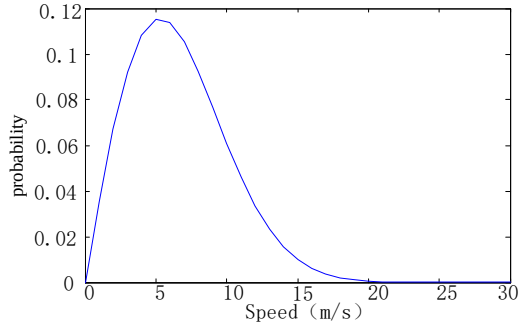

FIGURE 1 The probability distribution curve of wind speed

2.2 SYSTEM LOAD MODEL

Load changes directly affect the wind farm access capacity, experimental results show that, the system load distribution of most area can describe according to the normal distribution function in the long run.

$$\psi(p_{Li})=\frac{1}{\sigma\sqrt{2\pi}}\exp[-\frac{(p_{Li}-\mu_i)^2}{2\sigma^2}], \tag{4}$$

where p_{Li} is the system load of the i-th node; μ_i is the average load of the node; σ is variance.

3 Probabilistic constrain model of power system of wind farm

Under the condition of constrains containing random variables, if the decision making under disadvantage may not satisfy the constraints, then the decision making should make the probability of establishment for constraint condition established not less than a certain confidence level [8].

The constraint condition mainly means that power flow do not overload, the node voltage and the output of active power and wattles power of conventional generator are limited. If the loss of net is not considered, the summation of power increment of all nodes in the power grid connected wind farm is zero, in order to meet the power balance. Due to the randomness of active power output from wind power and the volatility of system load, the state variable calculated through system flow is random. The inequality constraints with random variable are expressed as the form of probability, which is established at a specified confidence level. The confidence level has a general value between 0.9 and 1. The value is smaller, the risk is bigger. The value is closer to 1.0, the result becomes more conservative. Taking the accepted largest installed capacity of wind power as goal function, the goal function can be expressed as follow:

$$f=\max(\sum_{i=1}^{n}p_{fi}). \tag{5}$$

The inequality constraints can be expressed as follow

$$\begin{aligned}&\Pr ob\{p_{x\min}\le p_{xj}\le p_{x\max}\}\ge\partial\\ &\Pr ob\{U_{\min}\le U_i\le U_{\max}\}\ge\partial\\ &\Pr ob\{Q_{g\min}\le Q_{gi}\le Q_{g\max}\}\ge\partial\\ &p_{g\min}\le p_{gi}\le p_{g\max}\end{aligned}. \tag{6}$$

The equality constraints can be expressed as follow

$$\begin{aligned}&P_{Gi}+P_{fi}-P_{\mathrm{Li}}=U_i\sum_{j\in i}U_j(G_{ij}\cos\delta_{ij}+B_{ij}\sin\delta_{ij})\\ &Q_{Gi}+Q_{fi}-Q_{\mathrm{Li}}=U_i\sum_{j\in i}U_j(G_{ij}\sin\delta_{ij}-B_{ij}\cos\delta_{ij})\end{aligned}. \tag{7}$$

P*rob* is the probability, p_{xj} is the flow of x line, p_{fi} is the wind power of grid connected at i node; p_{Li} is the system load at i node; p_{xj} is power flow at j line; ∂ is confident probability of inequality constraints.

4 Particle Swarm Optimization algorithm base on stochastic simulation

4.1 THE TECHNIQUE OF STOCHASTIC SIMULATION

The stochastic simulation, i.e., Monte Carlo simulation, provides an effective way to verify the probability constraints. The stochastic variables are sampled from known probability, which provides the basis for decision-making or tests the decision making for system. For chance constraints with stochastic variable

$$\begin{cases}\Pr ob\{p_{x\min}\le p_{xj}\le p_{x\max}\}\ge\partial\\ \Pr ob\{U_{\min}\le U_i\le U_{\max}\}\ge\partial\\ \Pr ob\{Q_{g\min}\le Q_{gi}\le Q_{g\max}\}\ge\partial\end{cases}. \tag{8}$$

The method of random simulation can be expressed as follow: n independent random individual, for example, $v_1, v_2, ...v_n$ are sampled from probability distribution $f(v)$. The n' is the number of satisfying constraints in n trials. According to the law of large numbers n'/n can be used to estimate the value of Equation (8). If $n'/n >= \partial$, the particle satisfies the probability constraints; if $n'/n < \partial$, the particle violates the probability constraints, and the value of fitness is penalized.

4.2 PARTICLE SWARM OPTIMIZATION ALGORITHM

Particle Swarm Optimization algorithm (PSO) stems from the research on group prey behavior of birds was proposed by Kennedy and Eberhart in 1995. Starting from stochastic solution, the optimal solution is searched by means of the iteration and the global optimum can be founded by following the searched optimal value. The vector $X_i = (x_{i1}, x_{i2}, ...x_{in})^T$ denotes the position of particle in space; the vector $p_i = (p_{i1}, p_{i2}, ...p_{in})^T$ denotes the optimal solution of vector of i particle in iteration; the vector $v_i = (v_{i1}, v_{i2}, ...v_{in})^T$ denotes the speed of i particle in N dimensional solution space.

In order to avoid falling into local optimum, the evolution route of particle depends not only on current position also on the previous evolution route. At the same time, the method of linear weight is employed, which ensures fast convergence speed and gets higher convergence precision. The flow- chart of program is shown in Figure 2. The evolution equation of particle is expressed as follow

$$\begin{aligned} v_i(t+1) = {} & w * v_i(t) + c_1 * r_1[Z_{best}(t) - x_i(t)] + \\ & c_2 * r_2[G_{best}(t) - x_i(t)] + \\ & c_1 * r[Z_{best}(t-1) - x_i(t-1)] + \\ & c_2 * r_2[G_{best}(t-1) - x_i(t-1)] \end{aligned}, \quad (9)$$

t is the number of iteration; c_1 and c_2 are learning factor and represent the weight of two optimal solutions respectively; r_1 and r_2 are independent random number between zero and one.

The inertia weight is

$$w = (N-n)\frac{w_{\max}(w_{\max} - w_{\min})}{N}, \quad (10)$$

n is current cycle number; N is total cycle number.

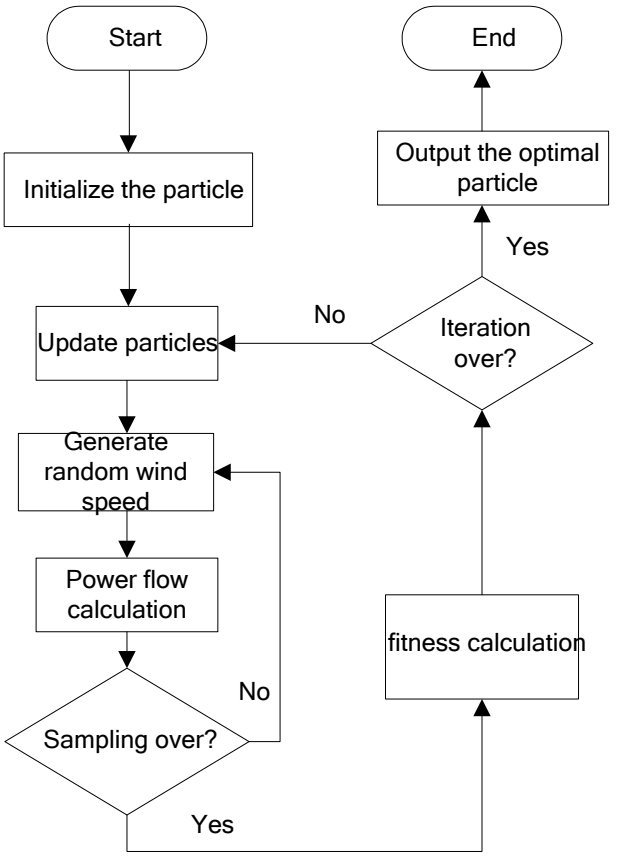

FIGURE 2 The flowchart of PSO based on stochastic simulation

5 Analysis of examples

In this paper a certain practical power grid of Yunnan is used to be analysed and calculated. The system simple topology is shown in Figure 3.

No. 1 generator is defined as the balanced unit. No. 25 and 29 base load generators do not participate in the active power regulation. The rate of wind power is 1.5 MW. The system benchmark capacity is 1000 MVA. No.13, 16, 18, 27 etc. are selected as wind farms and connected grid. The limit and upper limit of active power of conventional unit parameters for optimization are shown in Table 1.

TABLE 1 Conventional unit parameters

Unit node	Lower limit of active power (pu)	Upper limit of active power (pu)
1(Man wan)	0.56	0.94
2(Da chaoshan)	0.243	0.85
3(Zong yanghai)	0.42	0.56

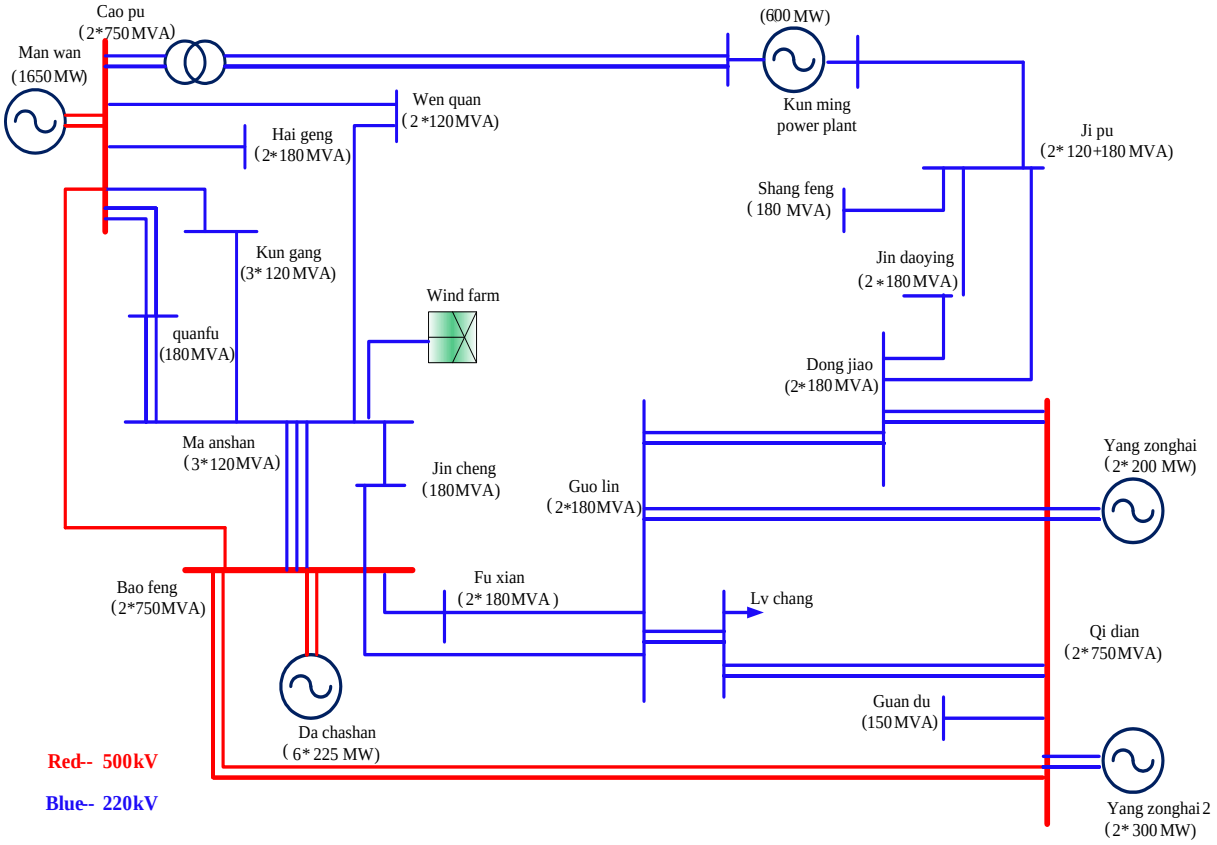

FIGURE 3 The system simple topology of a certain practical power grid of Yunnan

This paper analyses the three factors that affect the wind-power allowed capacity:

(*1*) *Different confidence level and connected grid.* Average wind speed μ =7.5m/s, the shape factor k=2, load variance=1. Wind-power allowed capacities are calculated as shown in Table 2.

TABLE 2 Penetration powers with different confidence levels and connected grids

Connected grid	**Penetration powers (p_u)**		
	α=0.99	*α=0.99*	*α=1.0*
13(Hai geng)	0.5145	0.4095	0.3795
16(Ma anshan)	0.5790	0.4620	0.4260
18(Fu xian)	0.8100	0.6540	0.6065
27(Pu ji)	0.8355	0.6585	0.6075

As seen from Table 3, wind-power allowed capacities are different when wind farms are connected into the system. Different wind-power allowed capacities can be used to determine the best access point for maximizing the acceptance of wind power. Meanwhile, wind-power allowed capacities increase relatively with the confidence probability reducing. The essence of the phenomenon is to allow some low probabilities, which violate constraint conditions, thus conservative calculation results are avoided.

(*2*) *Load levels.* To study, the total load of the system is increased by 10% compared with Table 2. Penetration powers are calculated as shown in Table 3. Due to the demand for electrical energy increasing, wind-power allowed capacities of most nodes increase with load increasing after the system load increases. Figure 4 shows the evolution curve of the optimal solution in the 16th node when α=1.0.

TABLE 3 The effect of load on wind power access capacity

Connected grid	**Wind-power allowed capacity (p_u)**		
	α=0.95	*α=0.99*	*α=1.0*
13(Hai geng)	0.6015	0.4890	0.4500
16(Ma anshan)	0.7875	0.6270	0.5790
18(Guo lin)	0.9150	0.7695	0.7065
27(Pu ji)	1.035	0.8310	0.7675

Compared with Table 2 and Table 3, wind-power allowed capacities of most nodes increase with load increasing after the system load increases. Wind-power allowed capacities of some nodes is not significantly increased because of other restrictions constraints

(*3*) *Wind speed*: The confidence probability is 0.99 in order to investigate effects of different average wind speeds. Other parameters are same as Table 2. Penetration powers are calculated as shown in Table 4 under different average wind speeds.

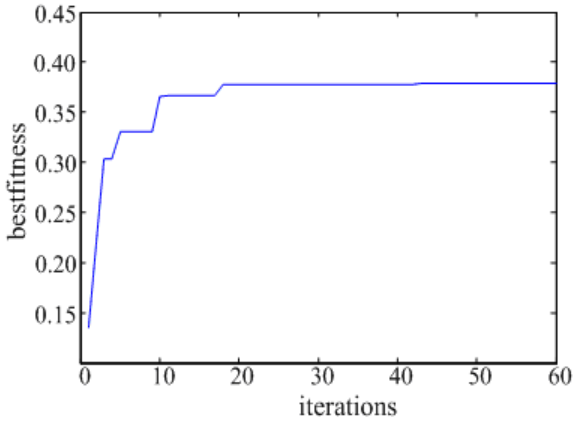

FIGURE 4 Particle-swarm optimal evolutions

TABLE 4 Effect of average wind speed of wind power access capacity

Connected grid	Wind-power allowed capacity (p_u)		
	μ=6.5m/s	μ=7.5m/s	μ=8.5m/s
13(Hai geng)	0.4680	0.4095	0.3915
16(Ma anshan)	0.5130	0.4620	0.4410
18(Guo lin)	0.7425	0.6540	0.6255
27(Pu ji)	0.7440	0.6585	0.6300

Compared with Table 2 and Table 4, the fan output increases with the increase of the average wind speed. The level of system disturbance also increases and the wind-power capacity decreases.

7 Conclusions

In this paper, an analysis method is proposed based on probability constraints. The optimization analysis model of evaluating allowed capacity is established considered wind-power randomness under uncertain environment. The program of MATLAB is developed based on stochastic simulation techniques and particle-swarm optimization algorithms. The analysis of examples demonstrates the feasibility and effectiveness of the algorithm and model. The analytical method of allowed wind-power capacity is also suitable for other renewable energy. The limitation of this method is time consuming because of the use of Monte Cano simulation techniques and only the consideration of the static system constraint. The wind power system dynamic constraint is also a key factor in the decision of the wind power access capability. How to consider these dynamic constraints into the optimization model is the focus of future research.

Abstract

To improve design quality and efficiency of turbine blade, the geometric model of blade is parameterized by using the quintic polynomial method in this paper. The geometric shape and performance of blade mainly depend on blade profile and cascade with parametric model. First of all, the blade profile lines are designed and generated in different parameters based on the theory of quintic polynomial. The effect of relative parameters on the blade profile is analysed conveniently and rapidly. Then, the geometric shape of blade is generated in the arranged blade profiles according to blade cascade position and consistency. The 3D model of blade is created by the parametric blade profile and cascade. It is shown that parametric model of blade will provide the reference and foundation for application research.

Keywords: turbine blade, quintic polynomial, parametric design, 3D model

1 Introduction

Blade is a main part in aeroengine, which affects directly work performance of engine equipment. Moreover, the geometric shape and performance of blade mainly depend on blade geometric parametric model, so it is important for design process. Since the blade profile is a complex curved surface, the design quality and efficiency have to be improved by some effective methods [1-3].

There are some researchers in parameters design of blade. Song [4] has presented the parametric design of turbine blades based on feature modelling. Bing et al. [5] have developed and achieved three-dimensional design of the mixed-flow pump impeller. The numerical simulation was employed to analyse the effects of the blade parameters. Oh et al. [6] have compared the various parameters in the effects on the cavitation performance of the mixed-flow pump impeller. Yue et al. [7] have presented the multidisciplinary design optimization for aeroengine turbine blade.

This paper is divided into four main sections; the first, entitled the main geometric parameters of blade profile and cascade. The second section: the quintic polynomial designning the blade type line. The next part: the blade type line parameter design. Finally, the 3D model from parametric design.

2 The main geometric parameters of blade profile and cascade

To analyse the blade profile process, it is a necessary to build the parametric model. Blade curve modeling is usually made up of a certain number of sections, which is along the radial in order, while the plain cascade is made up of many same shape blade profiles which is apart some distance. In order to establish the model better, it must consider the cascade in the mass, for the location in the cascade and consistency have an important effect on blade design [7-10]. In this study, the main geometric parameters of cascade are described into two parts: one is the main geometric parameters of blade and another is the blade location's parameters in the cascade, as shown the Figure1.

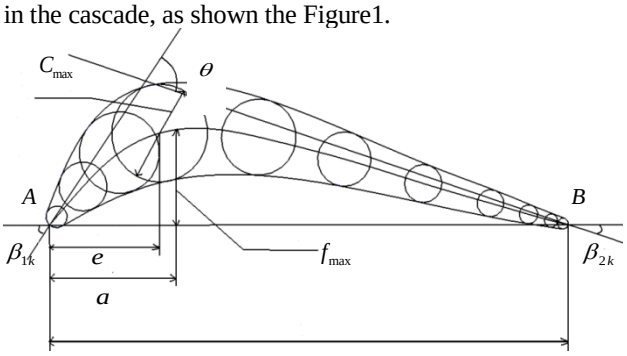

FIGURE 1 Main geometric parameters of the blade

1) Camber line: the line which crosses the centre of inscribed circle usually is called mean camber line. Chord length b: the mean camber line interacts the lending of blade at point A and the edge at point B, the line which links A to B is called chord length, usually is expressed by chord length b.

2) Maximum deflection f_{max} and the relative position: the maximum vertical distance between the mean camber line and chord length is called maximum deflection. Blade front angle β_{1k} and trail angle β_{2k} : the angle between mean camber line tangent in the front point A and chord length is called blade front angle, the angle between mean camber line tangent in the edge point B and chord length is called

trail angle. Maximum thickness $C_{\max}$: the maximum thickness represents blade.

3) Thickness, the maximum diameter of blade inscribe circle is the maximum thickness, the distance between the front point A and maximum inscribe circle centre along the chord length.

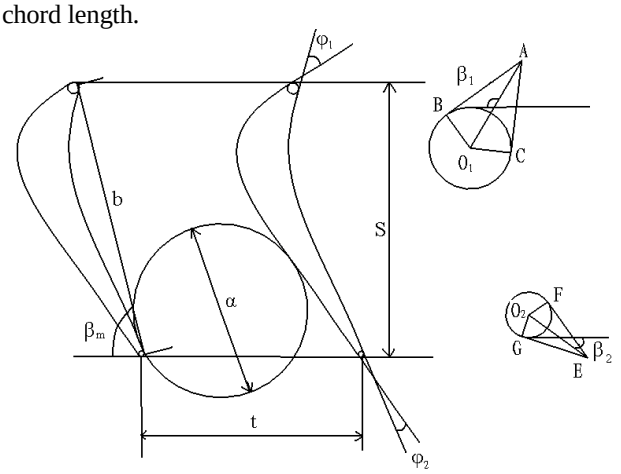

FIGURE 2 Main geometric parameters of blade cascade

4) Blade bending angle θ: the sum of the front angle and the trail angle equals bending angle, the angle between mean camber line tangent in the front point A and in the edge point B represents the bending degree, as the Figure 2 shows: $\theta = \beta_{1k} + \beta_{2k}$. Inlet angle β_1 : the angle between flow direction and frontal line in the leading edge, the frontal line is the line that connects all the blade front point A in the cascade. Exit angle β_2 : the angle between flow direction and frontal line in the trail edge. Blade type installation angle β_m : the angle between the frontal line and chord length represents the blade type's installation in the cascade. Grid pitch t: the distance that two adjacent blade type corresponding points are along the frontal line represents the blade arranges density. The blade section grid pitch shows as: $t = 2\pi R_i / N$. R_i each section radio value. Blade consistency τ : the ratio b/t is called consistency τ , as $\tau = b / t$.

The above parameters are usually used in the blade design, different parameters will design the different blade, but these parameters are not isolated, they can interfere with each other's, sometimes it is impossible that make any parameter to the optimal value, because some of these are incompatible. Such as the selection of chord length and consistency, when selecting the optimal chord length, the blade consistency may be too big or too small, and vice versa. Therefore, parameters selection must be considered synthetically and demonstrated in the test [7, 11-14].

3 The quintic polynomial designing the blade profile

3.1 QUINTIC POLYNOMIAL BLADE MODELLING THEORY

In general, turbine blade type line adopts curve combination, there are some discontinuous curvature derivative points in the curve combination, generating the peak of the velocity and pressure near the blade and degrading the turbine performance. In the analysis of airflow characteristics around the blade: turbine performance mainly depends on the blade surface boundary lawyer flow, while surface curvature radius has an effect on boundary lawyer flow. In order to make the blade surface's velocity and pressure distribute smoothly, it can use the quintic polynomial method to generate the blade type line.

The turbine principle and design parameters determine the flow parameters, formula and experience figure can determine each section geometric parameters, then select the optimal type line. Based on the type line generates the 3D blade. Different parameters generate different blade. The quintic polynomial method can be described that supposes blade type line is a quintic polynomial curve, using special point coordinate and their first derivative and second derivative fits blade section line.

Blade back and blade basin type line are $y_p = f(\mathrm{x})$ and $y_s = g(\mathrm{x})$, which are expressed as follows:

$$\begin{cases} y_p = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 \\ y_s = b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 \end{cases}, \tag{1}$$

y_p and y_s first derivative are expressed as follows:

$$\begin{cases} y_p{}' = a_1 + 2a_2 x + 3a_3 x^2 + 4a_4 x^3 + 5a_5 x^4 \\ y_s{}' = b_1 + 2b_2 x + 3b_3 x^2 + 4b_4 x^3 + 5b_5 x^4 \end{cases}, \tag{2}$$

y_p and y_s second derivative are expressed as follows:

$$\begin{cases} y_p{}'' = 2a_2 + 6a_3 x + 12a_4 x^2 + 20a_5 x^3 \\ y_s{}'' = 2b_2 + 6b_3 x + 12b_4 x^2 + 20b_5 x^3 \end{cases}. \tag{3}$$

Blade basin starting point coordinate $(x_{p1}, \mathrm{y}_{p1})$, first derivative $\mathrm{y}_{p1}{}'$, second derivative $y_{p1}{}''$. Blade basin final point coordinate $(x_{p2}, \mathrm{y}_{p2})$, first derivative $\mathrm{y}_{p2}{}'$, second derivative $\mathrm{y}_{p2}{}''$. Let blade back starting point coordinate $(x_{s1}, \mathrm{y}_{s1})$, first derivative $\mathrm{y}_{s1}{}'$, second derivative $\mathrm{y}_{s1}{}''$. Blade back final point coordinate $(x_{s2}, \mathrm{y}_{s2})$, first derivative $\mathrm{y}_{s2}{}'$, second derivative $\mathrm{y}_{s2}{}''$. Then substituted equation is expressed as follows:

$$\begin{bmatrix} 1 & x_{p1} & x_{p1}^2 & x_{p1}^3 & x_{p1}^4 & x_{p1}^5 \\ 1 & x_{p2} & x_{p2}^2 & x_{p2}^3 & x_{p2}^4 & x_{p2}^5 \\ 0 & 1 & 2x_{p1} & 3x_{p1}^2 & 4x_{p1}^3 & 5x_{p1}^4 \\ 0 & 1 & 2x_{p2} & 3x_{p2}^2 & 4x_{p2}^3 & 5x_{p2}^4 \\ 0 & 0 & 2 & 6x_{p1} & 12x_{p1}^2 & 20x_{p1}^3 \\ 0 & 0 & 2 & 6x_{p1} & 12x_{p1}^2 & 20x_{p2}^3 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ a_4 \\ a_5 \end{bmatrix} = \begin{bmatrix} y_{p1} \\ y_{p2} \\ y_{p1}^{'} \\ y_{p2}^{'} \\ y_{p1}^{''} \\ y_{p2}^{''} \end{bmatrix}, \tag{4}$$

$$\begin{bmatrix} 1 & x_{s1} & x_{s1}^2 & x_{s1}^3 & x_{s1}^4 & x_{s1}^5 \\ 1 & x_{s2} & x_{s2}^2 & x_{s2}^3 & x_{s2}^4 & x_{s2}^5 \\ 0 & 1 & 2x_{s1} & 3x_{s1}^2 & 4x_{s1}^3 & 5x_{s1}^4 \\ 0 & 1 & 2x_{s2} & 3x_{s2}^2 & 4x_{s2}^3 & 5x_{s2}^4 \\ 0 & 0 & 2 & 6x_{s1} & 12x_{s1}^2 & 20x_{s1}^3 \\ 0 & 0 & 2 & 6x_{s1} & 12x_{s1}^2 & 20x_{s2}^3 \end{bmatrix} \begin{bmatrix} b_0 \\ b_1 \\ b_2 \\ b_3 \\ b_4 \\ b_5 \end{bmatrix} = \begin{bmatrix} y_{s1} \\ y_{s2} \\ y_{s1}^{'} \\ y_{s2}^{'} \\ y_{s1}^{''} \\ y_{s2}^{''} \end{bmatrix}. \quad (5)$$

According to the solution set of Equation (4) and Equation (5), the equation of solution will be set to $y_p = f(x)$ and $y_s = g(x)$, and then it will get the blade back and blade basin polynomial expression.

3.2 THE DETERMINING METHOD OF SPECIAL POINT COORDINATE AND DERIVATIVE

When the cascade geometric parameters are known, establish coordinate as the Figure 3 shows, the blade front edge and trail edge circle centre are O_1 and O_2. The inlet edge is in coincidence with y axis and is tangent with circle O_1 at point *d*, exit edge is tangent with circle O_2 .at point *k*, chord length b is tangent with circle O_1, O_2 at point *f*, *h*, y_s and y_p represent a certain point coordinate along the y axis in the blade back and blade basin.

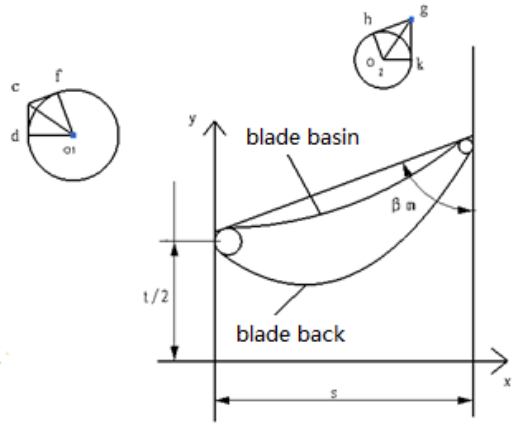

FIGURE 3 Coordinate relations schemes

1) The blade front edge and trail edge key point coordinate:

The front circle centre O_1 coordinates as:

$$\begin{cases} x_{o1} = r_1 \\ y_{01} = \dfrac{1}{2}t \end{cases}. \quad (6)$$

Tangency point *f* coordinates as:

$$\begin{cases} x_f = x_{o1} - r_1 \cos\beta_m \\ y_f = y_{o1} - r_1 \sin\beta_m \end{cases}. \quad (7)$$

The trail edge circle centre O_1 coordinates as:

$$\begin{cases} x_{o2} = s - r_2 \\ y_{o2} = y_f + (s - x_f)\cot\beta_m - r_2 \cot|\beta_m / 2| \end{cases}. \quad (8)$$

Tangency point h coordinates as:

$$\begin{cases} x_h = x_{02} - r_2 \cos\beta_m \\ y_h = y_{o2} - r_2 \sin\beta_m \end{cases}. \quad (9)$$

2) The blade back and blade basin first point coordinate and derivative

Blade back first point *C* coordinates as:

$$\begin{cases} x_{p1} = x_{01} - r_1 \cos|\beta_1 - \varphi_1 / 2| \\ y_{p1} = y_{o1} + r_1 \sin|\beta_1 - \varphi_1 / 2| \end{cases}. \quad (10)$$

Blade basin first point *B* coordinates as:

$$\begin{cases} x_{s1} = x_{01} + r_1 \cos|\beta_1 + \varphi_1 / 2| \\ y_{s1} = y_{o1} - r_1 \sin|\beta_1 + \varphi_1 / 2| \end{cases}. \quad (11)$$

Blade back first point *C* first derivative as:

$$y_{p1}^{'} = \cot|\beta_1 - \varphi_1 / 2|. \quad (12)$$

Blade basin first point *B* first derivative as:

$$y_{s1}^{'} = \cot|\beta_1 + \varphi_1 / 2|. \quad (13)$$

The blade back first point *C* and blade basin first point B second derivative value is 0.

3) The blade back and blade basin final point coordinate and first derivative and second derivative.

Blade back final point *F* coordinates as:

$$\begin{cases} x_{p2} = x_{02} - r_2 \cos|\beta_2 + \varphi_2 / 2| \\ y_{p2} = y_{o2} + r_2 \sin|\beta_2 + \varphi_2 / 2| \end{cases}. \quad (14)$$

Blade basin final point *G* coordinates as:

$$\begin{cases} x_{s2} = x_{02} + r_2 \cos|\beta_2 - \varphi_2 / 2| \\ y_{s2} = y_{o2} - r_2 \sin|\beta_2 - \varphi_2 / 2| \end{cases}. \quad (15)$$

Blade back final point *F* first derivative as:

$$y_{p2}^{'} = \cot|\beta_2 + \varphi_2 / 2|. \quad (16)$$

Blade basin final point *G* first derivative as:

$$y_{s2}^{'} = \cot|\beta_2 + \varphi_2 / 2|. \quad (17)$$

According to the above method, substituting the basic parameters of blade section to the above equals, it will get the quintic polynomial curve, and then determine the type line expression.

4 The blade type line parameter design

The program is developed by using mathematical software in the different parameters to generate the blade section type line, it can save time and clearly find that the effect of each

parameter on blade type line and relationship between the parameters and blade type line.

Using the MATLAB Graphical User Interface module, author develops the blade type parameter interface, which is based on MATLAB research. The reason using the GUI module is that computer operation user interface display in GUI graphics mode. Compared with the early computer command line interface, graphics mode interface makes user more easily acceptable in vision and is convenient to the non-professional user. It allows people to avoid remember a lot of basic commands. People can simply click the window menu to accomplish the design conveniently. Different parameters generate different design in the interface, automatic generating the blade type line. Based on the figure parameters establishes the blade section line: the interface can analyse the interaction relationship between the parameters and the blade type line.

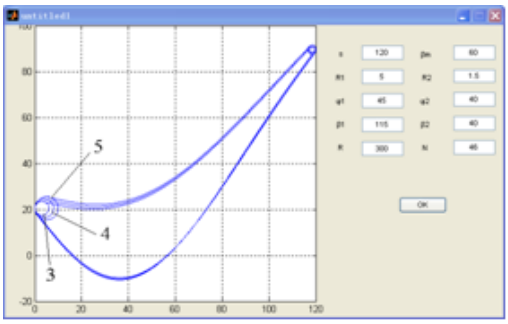

FIGURE 4 Effect of leading edge radius on type line of blade

The installation angle generates the blade type line in different parameters (50°, 60°, and 70°) in Figure 5. The installation angle is smaller, the type line is steeper, and otherwise the type line is smooth.

4.2 THE INFLUENCE OF INTAKE SIDE ANGLE OF AND AIR ANGLE ON TYPE LINE OF BLADE CROSS-SECTION

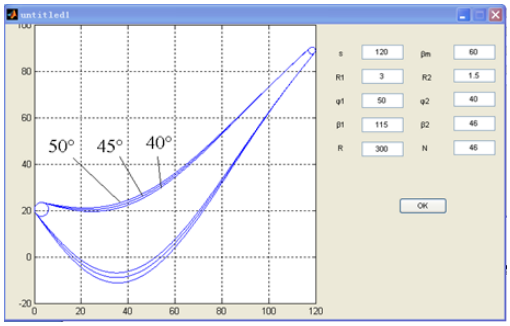

FIGURE 6 Angle of the intake side effects on type line of blade

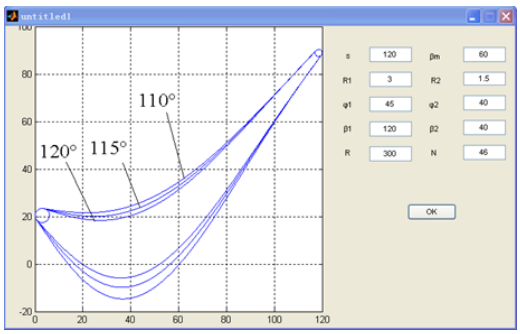

FIGURE 7 Air intake angle effects on type line of blade

4.1 THE INFLUENCE OF EDGE RADIUS AND INSTALLATION ANGLE ON THE TYPE LINE OF BLADE CROSS-SECTION

The Figure 4 shows the radius of different parameters (R1=3, 4, 5) generate the type line curve. The lending edge radius becomes larger; the blade thickness will be bigger, the blade basin and blade back curvature will also increase.

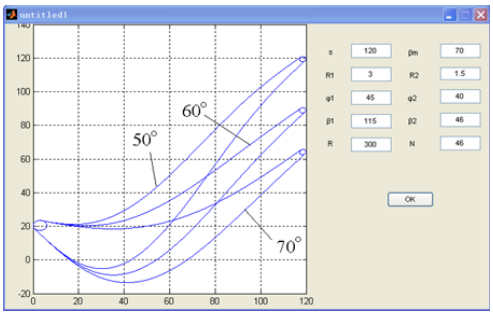

FIGURE 5 Effect of Installation angle on type line of blade

As the Figure 6 shows, with angle of the intake side increasing, blade section thickness will increase, yet the blade bending curvature decreases. In the Figure 7, when the air intake angle is 110°, the blade cross-section type line curvature is minimum, while 120° is maximum. The 3D model is created in different parameters based blade profile and cascade, as shown in Figure 8:

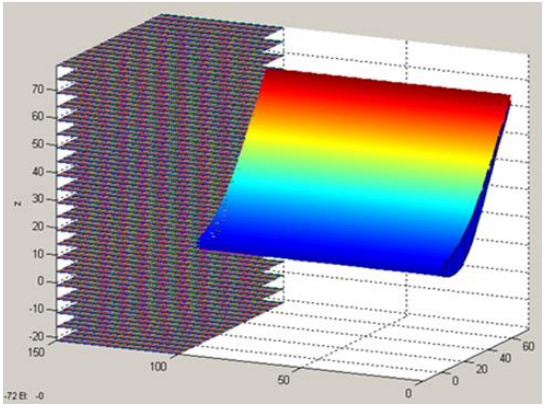

FIGURE 8 3D model of blade in different parameters

5 The 3D model and data exchange

3D model is established by using Unigraphics software based on the blade profile, which results from drawing many curves, ranging them in certain order, and then generating the blade solid model. Utilizing UG law curve function mass, it can draw the quintic polynomial, as shown in Figure 9. Finally, we draw the blade section type line by UG.

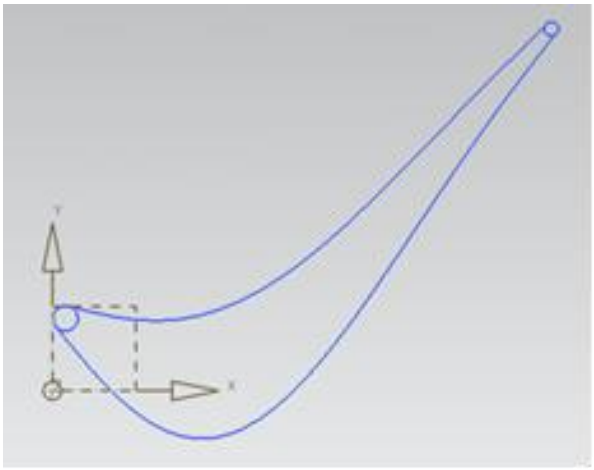

FIGURE 9 Type line of single blade cross-section

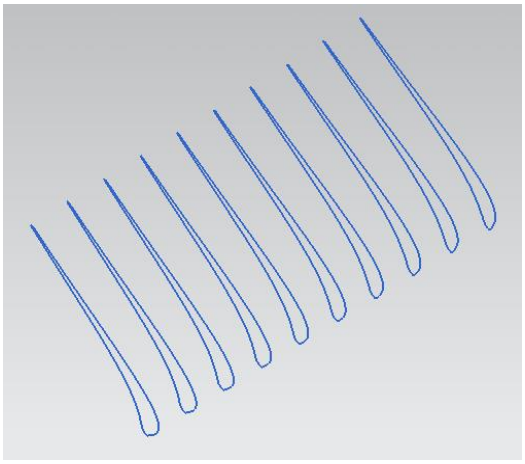

FIGURE 10 Type line of multi-blade cross-section

Many section type line curves are obtained by using the same method, as shown the Figure 10. Generated the type line curve in UG, it will be generated the blade solid model, as shown the Figure 11:

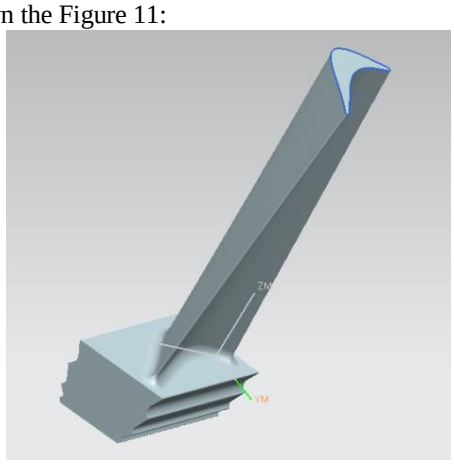

FIGURE 11 Cross-section and three-dimensional model of blade

6 Conclusions

1) In the first part of this paper, the blade design parameters and quintic polynomial method are introduced in detail. The performance of turbine depends on the boundary layer flow on blade surface; In the meanwhile the boundary layer flow is affected by curvature radius of blade surface. In order to get a smooth distribution for surface pressure and speed, quintic polynomial method is a better chose.

2) As the study presented, the blade profile generation interface, whose characters are convenient, rapid, and accurate, combined with quintic polynomial method is used to generate blade profile. As the figures got from simulations with different parameters shows, the type line has correspondent profiles for blade, from which we can understand the influence relation between different parameters clearly.

3) Finally, according to the theory of quintic polynomial method for blade profile line, the blade modeling method is studied, and based on which the blade profile line is generated by MATLAB and the 3D model by UG. Thus, quintic polynomial method can be proved to be a feasible method for generating blade model.

A speech emotion enhancement method for hearing aid

Shulan Xia*, Jilin Wang

College of Electrical Engineering, Yancheng Institute of Technology, Yancheng 224051, Jiangsu, PR China

Received 1 October 2014, www.cmnt.lv

Abstract

In this paper, emotional perception of the hearing-impaired patients for hearing aid is investigated, and a speech enhancement algorithm is proposed, which is text-independent and requires less and non-parallel training data. In addition, the conversion of prosodic and spectral parameters is also studied. The Eigenvoice Gaussian mixture model (EV-GMM) is used to transform the F0s and spectral parameters, which is built using multiple pre-stored sources emotional and target neutral speech sentences. In the training and testing stages, the duration modification is utilized to improve the performance of EV-GMM training and converted output quality and an adaptive median filter is proposed to smooth the trajectory of the converted speech. Perceptual and objective experiments are presented, simulation results corroborate the effectiveness of the proposed algorithms.

Keywords: hearing aid, emotional speech enhancement, EV-GMM, duration modification

1 Introduction

Emotional communication is very vital for social activities. However, hearing-impaired patients lack this communication for their defective hearings. Although in recent years, the hearing aid research in China is deeper and deeper [1-4], but the little study focused on emotional problems for hearing-impaired patients has yet still been done. The emotion enhancement for hearing aid is an efficient technique to compensate this problem, which refers to transforming the emotional character of the source emotion to enhance the emotional feelings of the hearing-impaired patients.

One strategy for emotion enhancement is based on voice conversion methods. For example, the GMM-based voice transformation algorithm is directly applied to carry out the emotion transformation in [5], it is found the prosody features mainly dominate the emotion state and the transformation of spectral parameters is not sufficient for conveying the required target emotion. In [6], the relevance of the speech components including F0, residual signal and spectral envelope is investigated.

Another alternative method is based on unit selection. In [7], the GMM classification and regression tree (CART) model has been adopted to transform the prosody from neutral speech to target one. In [8], the F0 contours are generated using hidden Markov model (HMM) and the syllable contours are selected from the database using the cost function. In [9], the emotion transformation based on prosodic unit selection is explored and discussed. It is obvious when the corpus is large, these approaches seem to work better than prosodic and spectral voice conversion methods, however, the emotion database is too large, and hard to design and label, etc.

Based on these works, the emotional speech enhancement system, which is completely text-independent and need less non-parallel training data, is proposed. The feature modifications of pitch, duration and spectral envelope are investigated, and an efficient EV-GMM framework is proposed to improve the performance of emotion enhancement. Meanwhile, the duration modification is incorporated in the training and testing phase to improve the enhancement performance, and the efficient adaptive median filter is also adopted to smooth the enhanced speech and reduce the discontinuity problem.

The paper is organized as follows. Section 2 gives a brief introduction of the emotion corpus. Section 3 describes the proposed prosody and spectrum enhancement methods. Then different experimental results are discussed in section 4. Finally, the conclusions are made in section 5.

2 DATASET

A mandarin emotional speech corpus including five types of emotional states (happiness, sadness, anger, fear and surprise) and one neutral state was established for the experiments. Two broadcast professionals including one male named LIN and one female named HUA were hired for the recording. 100 sentences with no apparent emotional tendency were provided for the material. Each sentence in the six simulating speaking styles was uttered resulting total 600 sentences for each speaker. The speech sentences were recorded in a quiet lab environment with 11.025KHz sampling rates and 16 bit precision, each of them has around 3~4ms valid speech.

The corpus for each speaker is divided into two parts in this paper: source set and target set. The first includes four types of pre-stored emotional speaking styles and one testing emotional one, and the latter contains the neutral speech.

3 Prosody and spectrum transformation

It is well known the prosody transformation plays an important role in emotion transformation, so it can be regarded

***Corresponding author** e-mail: xslnj@126.com

as a particular voice transformation focusing on prosodic level. In this section, the transformations of prosodic features including F0 and duration are investigated, and a spectral transformation is also performed to enforce the performance.

3.1 F0 TRANSFORMATION

3.1.1 Baseline F0 transformation

One typical F0 transformation is based on GMM which is previously applied to spectrum transformation [10, 11]. Denoting the F0s of source emotional and target neutral speech by f_x and f_y respectively, f_x and f_y are modelled by a joint GMM, the probability is as follows

$$p(f_x, f_y \mid \lambda) = \sum_{i=1}^{M} \alpha_i N(f_x, f_y, \mu_i, \Sigma_i) . \quad (1)$$

And the converted function can be written as

$$F(f_x) = E(f_y \mid f_x) = \sum_{i=1}^{M} p_i(f_x)[\mu_i^y + \frac{\Sigma_i^{yx}}{\Sigma_i^{xx}}(f_x - \mu_i^x)], \quad (2)$$

$$p_i(f_x) = \frac{\alpha_i N(f_x, \mu_i^x, \Sigma_i^{xx})}{\sum_{k=1}^{M} \alpha_k N(f_x, \mu_k^x, \Sigma_k^{xx})} , \quad (3)$$

where $\boldsymbol{\mu_i} = \begin{bmatrix} \mu_i^x \\ \mu_i^y \end{bmatrix}$ and $\boldsymbol{\Sigma_i} = \begin{bmatrix} \Sigma_i^{xx} & \Sigma_i^{xy} \\ \Sigma_i^{yx} & \Sigma_i^{yy} \end{bmatrix}$ are the mean and covariance matrices of the *i*-th component, and the size of GMM components is *M*. In this method, the parallel utterances of source and target are needed for the model training.

3.1.2 Proposed F0 transformation

The proposed F0 transformation is based on EV-GMM algorithms, which is motivated by the voice transformation based on speaker adaptation [12] and many-to-one voice transformation [13], the EV-GMM has similar form as prior GMM, except for the mean value of source speaking style, which takes the form as

$$\mu_i^x = b_i(0) + B_i \omega , \quad (4)$$

where $b_i(0)$ is the bias value for the *i*-th component, $B_i=[b_i(1),b_i(2),\ldots,b_i(J)]$ is a matrix consisting with *J* basis vectors, and $\omega = [\omega_i(0), \omega_i(2), ..., \omega_i(J)]^T$ is a *J*-dimensional weight vector.

The EV-GMM allows the adaptation of arbitrary input new emotional speech by adjusting the values of the weight vector ω, which is estimated by the maximum likelihood eigendecomposition (MLED) [14] method as follows,

$$\hat{\omega} = \int p(f_x^u, f_y \mid \lambda^{ev}) df_y , \quad (5)$$

where λ^{ev} means the EV-GMM model, and f_x^u is a new source emotional F0 sequence for training. Using the GMM trained with pre-stored source emotional and target neutral speech pairs as the initial model and expectation maximization (EM) algorithm, an adapted EV-GMM for the new source emotional speech can be achieved. The transformation of F0s is directly performed using the adapted F0 EV-GMM model.

3.2 DURATION MODIFICATION

As is well known, different emotions have different speaking rates, which are determined by the number of frames. The simple duration modification based on an average linear ratio is adopted and it takes the form as

$$\hat{D}_n = D_e \frac{\bar{D}_n}{\bar{D}_e} , \quad (6)$$

where D_e and $\hat{D}_n$ are the durations of source emotional and converted speech, $\bar{D}_e$ and $\bar{D}_n$ are the average durations of source emotional and target neutral speech respectively.

Duration as an important emotional feature should be taken into account to separate different emotions. Unfortunately, it is overlooked by traditional voice transformation which mainly bases on spectral and F0 modifications. A new strategy is developed to address this issue in emotional transformation framework, the durations of source emotionnal utterances are modified to map those of target neutral ones in the training process of EV-GMM, the durations of source emotional speech can be seen as a pre-processing module, and It is depicted in Figure 1.

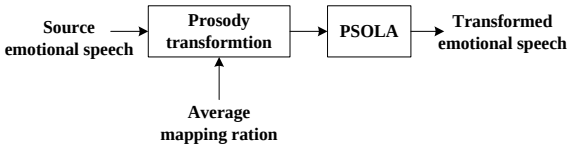

FIGURE 1 A flowchart of duration modification

3.3 SPECTRUM TRANSFORMATION

The spectral transformation works as styles of F0s and the transformation is also straightforward performed using the spectral adapted EV-GMM, which is based on the GMM transformation method as proposed by Kain [6].

3.4 POST-PROCESSING BY RAMF

The emotion transformation is performed on a frame-by-frame basis. One main shortcoming is the discontinuities in the converted speech. A ranked-order based adaptive median filter (RAMF) [15] technique previously applied to image processing has been presented here to remove the unrepresentative points and smooth the converted speech. Assuming *W* is a rectangle filtering window, S_{cur} are the values of current points, $S_{\min}$, $S_{\max}$, S_{med}, are the minimum, maximum and median values of points in the filtering windows. The modified RMAF can be seen a two-level structure: level *A* and level *B*.

Level A: $\begin{aligned} A_1 &= S_{med} - S_{\min} \\ A_2 &= S_{med} - S_{\max} \end{aligned}$. (7)

If $A_1 > 0$ and $A_2 < 0$, then turn to level B, otherwise, increase the size of W to repeat level A until the size of $W > S_{\max}$, then S_{cur} is used as the output.

Level B: $\begin{aligned} B_1 &= S_{cur} - S_{\min} \\ B_2 &= S_{cur} - S_{\max} \end{aligned}$. (8)

If $B_1 > 0$ and $B_2 < 0$, then S_{cur} is used as the output, or S_{med} is adopted as an output.

4 Evaluation experiments

Several objective and subjective experiments were designed to evaluate the performance of the proposed emotion transformation algorithm. On one hand, an objective experiment is conducted to measure the distance of F0 contours between source emotional and target neutral speech. On the other hand, the subjective tests including ABX, mean opinion score (MOS) were conducted by listening test with ten experienced listeners. Five kinds of transformation methods were compared. They are the traditional GMM based transformation method using parallel data, proposed EV-GMM transformation method considering pitch only (PO), pitch and duration (PD), pitch, spectrum and duration (PSD), and pitch, spectrum and duration adding RAMF (PSDR).

In order to train the EV-GMM model, four types of emotions including happiness, sadness, anger and fear were used as pre-stored source speech, and a neutral one was used as target speech, all of them was phonetically balanced utterances and aligned by dynamic time warping (DTW) technique. The first 50 (sentence: 1-50) parallel utterances for each emotional and neutral pairs totally 250 were used for training EV-GMM. The testing emotional transformation is conducted between surprise and neutral, and a traditional GMM based transformation method using surprised and neutral parallel training dataset were used for comparison. Sentences 91-100 of surprise and neutral were used for evaluation, and sentences 51-90 were for the training of tradetional GMM method.

It is noted that F0s were in log-scaled domain, and the 16 order line spectral frequencies (LSFs) were extracted. The sizes of EV-GMMs for F0 and spectrum were optimized as 256 and 512, respectively. the numbers of GMMs for F0 and spectrum were set as 16 and 64, respectively.

4.1 OBJECTIVE EVALUATION

The objective evaluation experiment was performed to assess the performance of prosody transformation, the error measurement in this section is a mean error normalized by the initial F0 distance between source and target speech, which can be written as

$$\xi = \frac{\frac{1}{N}\sum_{i=1}^{N} | y_i - F(x_i) |}{\frac{1}{N}\sum_{i=1}^{N} | y_i - x_i |}, \quad (9)$$

where x_i and y_i are the F0 values for source and target speech respectively, N is the number of frames, and $F(\ )$ refers to the F0 converted function.

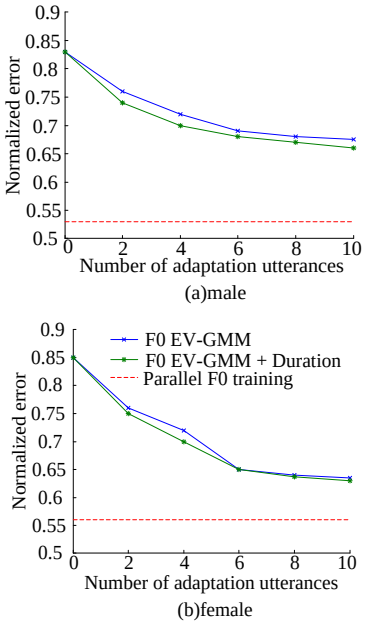

FIGURE 2 Normalized error

Figure 2 depicts the performance of presented prosody transformation method with different number of adaptation data. It can be found that the mean error decreases with more adaptation data, since it correspondences a more accurate F0 modeling. Incorporating the duration modification can greatly enhance the performance of F0 transformation. Moreover, it can be seen when the training data is above four for male and six for female, the errors remain approximately consonant, which means the number of sentences is enough to model the F0 distributions.

4.2 SUBJECTIVE EVALUATIONS

In order to evaluate the similarity between converted and target neutral speech, an ABX test was designed to judge whether X is close to A or B, where X means the converted emotional speech, A and B either the source surprised or target neutral speech.

Table 1 shows the percentages of the converted speech that were closer to the target using the above mentioned methods. It is obvious proposed EV-GMM (with the PCR of 79%) based can achieve satisfactory results compared to traditional GMM using parallel training data (with the PCR of 85%), and the prosody including pitch and duration mainly contribute to the emotion transformation, the spectrum transformation and RAMF module can enhance the transformation performance.

TABLE 1 Percentage of correct responses using ABX test

Methods	Percentage of correct response (%)	
	Male	*Female*
Parallel training	85.1	86.3
PO	69.1	65.3
PD	75.5	72.4
PSD	77.2	76.2
PSDR	79.4	77.5

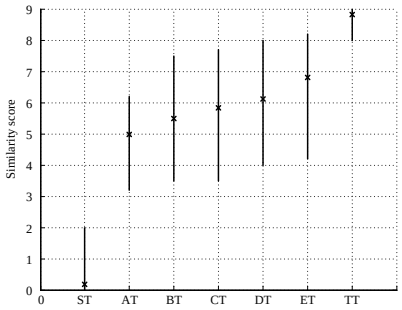

FIGURE 3 Similarity test

A MOS test is also conducted to assess the quality of the converted emotional speech, each converted speech based on GMM and proposed EV-GMM was shown to the listeners, who were asked to rate the quality using 10-point scores with 0 for "totally different" and 9 for "identical". The pairs of speech include source speech (S), target speech (T), converted speech using PO (A), converted speech using PD (B), converted speech using PSD (C), converted speech using PSDR (D) and converted speech using parallel training data (E) respectively. Different sentences were used to make the pairs, so listener can judge the similarity between different speech pairs.

Figure 3 summarized the result of MOS, the mean score in each case was marked "X", and the vertical solid lines indict the variances of scores. The "ET" using parallel training data outperforms other pairs, and "AT" which adopts F0 only for EV-GMM transformation performs worst, the mean score of "DT" is nearer to that of "ET", which indicts the proposed method can achieve an acceptable performance compared with ideal transformation methods using parallel data.

5 Conclusions

A novel emotional speech enhancement method for hearing aid is proposed in the paper, which is based on EV-GMM and relaxes the constraints of parallel training data. The idea of the algorithm is to transforming the emotional character of the source emotion to enhance the emotional feelings of the hearing-impaired patients. Objective test shows the mean error is small and comparable to that using the baseline GMM based transformation using the parallel corpus. The subjective performances also demonstrate the efficiency of presented method that is indicated by listening tests.

Further work will be focused on subjective evaluations for hearing-impaired persons.

Abstract

Given to the current problems existing in the operation of railway freight stations and the entire railway freight transport network, in order to integrate the railway freight stations and optimize the traditional railway freight transport mode, we first propose a strategy on the optimization and integration for railway freight stations, then design a hybrid neural network model to recognize the operating performance of each railway freight station by classifying them into four ranks based on the proposed strategy. The characteristic of the proposed model is its combination of the respective advantages of unsupervised learning algorithm based neural network and supervised learning algorithm based neural network. Finally, an empirical study from Hohhot Railway Administration is given to verify the feasibility of the proposed model. The simulation results of the empirical study indicate that (1) the accurate recognition of training samples has significant influence on the classification result; (2) the proposed model can recognize the operating performance of the railway freight stations under relatively high accuracy.

Keywords: Railway Freight Station, Optimization and Integration, Hybrid Neural Network Model, SOM Neural Network, Probabilistic Neural Network

1 Introduction

Railway freight stations are the nodes where goods get into or out of the railway network, rail wagons get classified and freight trains get sorted [1]. They play an important role in the railway freight transport organization. And there are enormous railway freight stations dispersed on the wide railway network in China, which provides the freight market with great convenience in a long period. However, with the development of social economy, optimization and adjusttment of industrial structure, and perfection of logistics industry in recent years, the traditional transport organization based on the dispersed layout of railway freight stations cannot adapt the tendency of the freight transport intensive development. Therefore, problems existing in the operation of railway freight stations tend to be obvious, such as insufficient shipment, inefficient operation, and delay of goods transport, waste of transport resources and so no. Railway freight transport hence falls behind compared with other transport modes, for example, highway freight transport. In 2006, China Ministry of Railways of China proposed "Two Integration, One Construction" revolution to overcome these problems. Since then, studies on optimization and integration for railway freight stations have been placed great emphasis on.

Optimization and integration for railway freight stations can be considered as a typical classification problem based on the operating performance of each railway freight station. According to their operating performance, railway freight stations can be classified into different ranks. Railway freight stations in different ranks will play different roles in the railway freight transport network in order to make up a flatter railway network system. Railway freight transport organization can be then further optimized based on this flatter railway network.

As for the optimization and integration methods, besides qualitative methods, some quantitative methods have been applied in the optimization and integration for railway freight transport resources, including Analytical Hierarchy Process (AHP) analysis [2, 3], fuzzy comprehensive evaluation method [4-6] and Pareto (also named ABC) analysis [7]. However, these methods rely on individual experiences of evaluators to some extent and have less comprehensive consideration of various influencing factors. The limitations of these methods in the calculation are apparent, especially when the scale of data and samples is tremendous. Therefore, study on optimization and integration for railway freight stations still has a large research potential.

Recent studies on the classification problem in other research fields have attached great importance to artificial intelligence, due to its well capacity of processing large size of data, high calculation efficiency and accuracy. As one of the most mature and widely used artificial intelligence methods, artificial neural networks have been proved well feasible in many relevant studies. Some studies are presented as follows.

Azami et al. [8] focused on the BP neural network for the recognition of the quality of GPS satellites. In this study, taking geometric dilution of precision as the evaluation index, the GPS satellites was classified into six classes by six modified BP neural networks, and the resilient BP neural network proved the highest accuracy and the least calculation time in the simulation. Park and Cho [9] studied on

the welding quality evaluation and applied LVQ neural network and BP neural network to classify electrode force patterns into five standard patterns. The experiment result in this study indicated the success rate for the testing samples of BP neural network was higher than LVQ neural network, while its calculation time is longer than LVQ neural network. Tan and Du [10] designed a feature extraction model and combined it with RBF neural network to perform the remote sensing image classification. The classification accuracy of the proposed model was verified by comparing with BP neural network and minimum distance classification method. Tambouratzis et al. [11] adopted hierarchical feature map to optimize the basic SOM neural network. In this study, texts classification problem based on their register and author style was used to verify the feasibility of the modified SOM neural network model. Ryoo et al. [12] described a fuzzy neural network and temperature response curve fitting based method to classify the unknown materials. In this experiment for three materials, the superiority of the modified method was verified that the agreement between measured curve and approximated curve was suitable. Using gene expression data, Sun et al. [13] applied discrete wavelet transform-based feature extraction and probabilistic neural network jointly to classify tissues into six classes. In the empirical study, the proposed DWT-based method possessed higher accuracy than the no DWT methods. Wang et al. [14] presented a novel tumor classification approach by combining probabilistic neural network with a neighborhood rough set model. In this study, tumor was classified into five classes by different gene datasets. 4-fold accuracy of colon dataset, leukemia dataset, and SRBCT dataset was up to 96.77%, 100% and 100%, respectively. Debska and Guzowska-Świder [15] proposed an artificial neural network based classification model to recognize the quality of beer. In this study, thirteen elements were selected as the characteristic of the quality of beer. RBF neural network model and MPL neural network model were applied to undertake the classification. The simulation result indicated that artificial neural network techniques allowed then discrimination between qualities of beer samples with up to 100% of correct classifications. Huang and Pan [16] used a probabilistic neural network to carry out the classification of operating performance of the enterprises. In this study, the input data of the neural network were selected by data mining technique. After inputting fifteen variables from five aspects, probabilistic neural network could give higher classification accuracy compared with BP neural network.

On the basis of the previous studies above, in Section 2, we propose a strategy on optimization and integration for railway freight stations in Section 2. In Section 3, we analyse the characteristic of supervised learning algorithm based neural network and unsupervised learning algorithm based neural network. In Section 4, by combining the respective advantages of the two kinds of neural networks, we definite a hybrid neural network model for the recognition of operating performance of the railway freight stations and present its modelling process. In Section 5, an empirical study from Hohhot Railway Administration is used to verify the feasibility of the proposed model and explain the importance of the accurate recognition of training samples. Finally, the conclusions of this study are drawn in Section 6.

2 Strategy on optimization and integration for railway freight stations

2.1 OPERATING PERFORMANCE OF RAILWAY FREIGHT STATIONS

Due to the difference of the environment where a railway freight station locates and the transport resources it owns, railway freight stations will perform different operating performances in the railway freight transport organization.

In this study, we use four ranks to distinguish the operating performance of the railway freight stations by referring some relevant studies on enterprise management [16, 17]. Operating performance rank designed in this study is as shown in Table 1.

TABLE 1 Operating Performance Rank of Railway Freight Stations

Rank	Operating Performance	Representation
I	Excellent	(1,0,0,0)
II	Good	(0, 1, 0, 0)
III	Medium	(0, 0, 1, 0)
IV	Poor	(0, 0, 0, 1)

In order to describe the characteristic of a railway freight station and further apply it to recognize which rank the operating performance of this railway freight station belongs to, we mainly take four aspects into consideration, including social environment factors, freight operation factors, transport location condition factors and freight transport facility factors, and establish an evaluation index system, which is as shown in Figure 1. If the i^{th} (i=1, 2, …, 16) index is represented by x_i, the characteristic of a railway freight station can be described by an index vector $X = (x_1, ..., x_i, ..., x_{16})$.

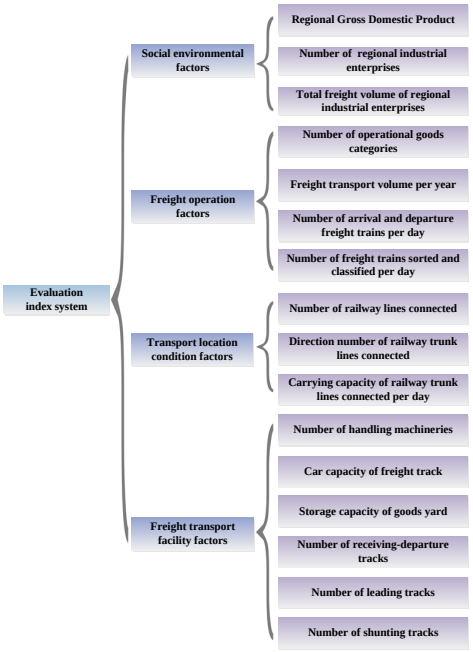

FIGURE 1 Evaluation Index System of the Operating Performance of Railway Freight Stations

2.2 OPTIMIZATION FOR THE RAILWAY FREIGHT TRANSPORT ORGANIZATION BASED ON THE OPERATING PERFORMANCE OF RAILWAY FREIGHT STATIONS.

Based on the ranks in Table 1, railway freight stations are classified into 4 ranks. Due to the poor operating performance of the railway freight stations in Rank IV, they should be closed and the transport resources occupied by them should be recycled by railway freight stations in Rank I, II and III. As for railway freight stations from Rank I to III, the roles they play in the railway network are given as follows.

Railway freight stations in Rank I are the 1st layer nodes in the railway network. They are the sites where through freight trains from different directions get sorted or classified. They locate in the crossing of railway trunk lines and possess adequate facilities corresponding with the sorting and classification of the freight trains. Railway freight stations in Rank II are the 2nd layer nodes in the railway network. They organize the highway-railway intermodal transport and undertake loading and unloading, storage, sorting, flitting and distribution of goods. Therefore, railway freight stations in Rank II should have well railway brunch line transport conditions and possess adequate facilities including handling machines, freight tracks and goods yard, as well as better freight operation environment. Railway freight stations in Rank III are 3rd layer nodes. They are the most widespread nodes in the railway freight network. These stations are the end of the internal freight transport chain. Their main operations include providing pickup and home-delivery services and conducting the freight marketing business. The railway freight network can be divided into several freight organization zones composed of "one 1st layer railway freight station, a few 2nd layer railway freight stations and several 3rd layer railway freight stations" as shown in Figure 2.

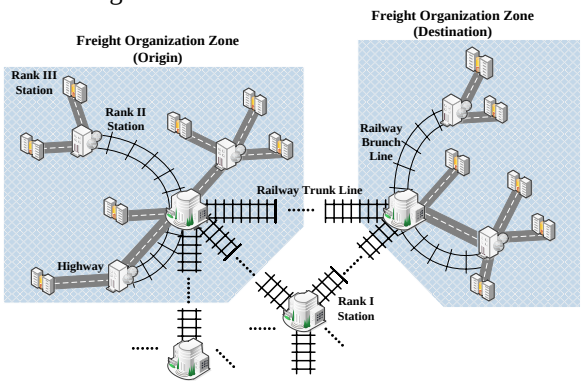

FIGURE 2 Optimized Operation Mode of Railway Freight Transport Network

According to the analysis above, the operation mode of railway freight transport network can be optimized as shown in Figure 3. Figure 3 indicates the basic transport organization mode in the railway freight transport network. In the transport organization, railway transport plays a dominated role and is the main force of the transport organization. Highway transport is the supplement and its participation can enhance the flexibility of the transport organization and extend the freight transport service chain as well. Different composite modes can be selected based on the goods volume and the centralization degree of the goods flow destinations.

In the optimized operation mode, the dispersed railway freight transport resources can be integrated, the advantage of highway and railway in short and long distance transport can be taken, and the operation of railway freight transport can be simplified.

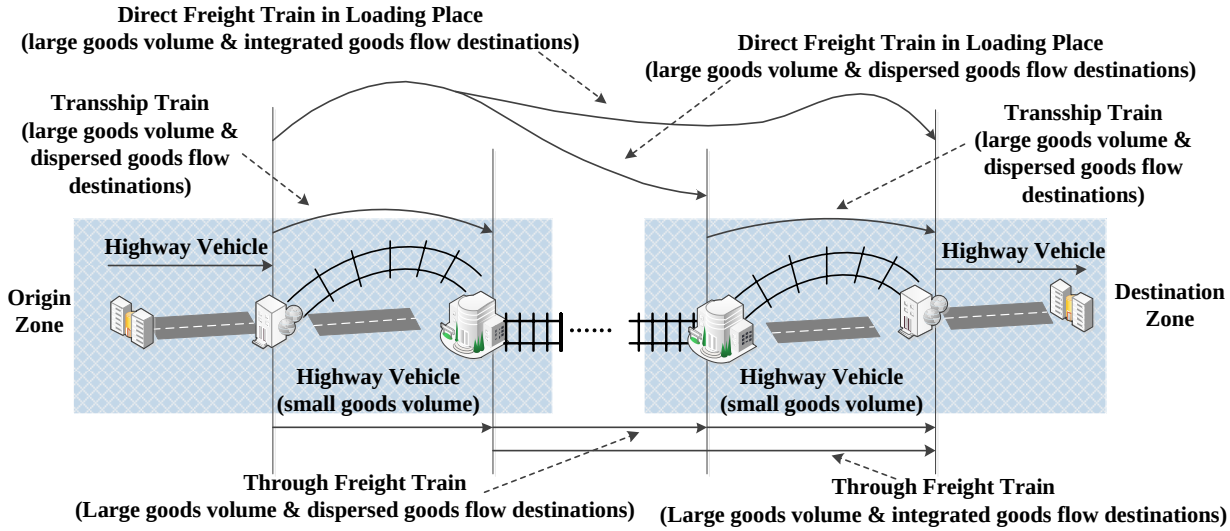

FIGURE 3 Transport Mode in the Optimized Railway Freight Transport Network

3 Supervised and unsupervised learning algorithm based neural networks

According to the learning algorithm, artificial neural networks can be mainly classified into 2 categories, including supervised learning algorithm based neural networks and unsupervised learning algorithm based ones. Their respective characteristic is stated as follows.

3.1 SUPERVISED LEARNING ALGORITHM BASED NEURAL NETWORKS

The common characteristic of the supervised learning based neural networks is the requirement of their learning process for the training samples whose outputs should be determined in advance. Once the training samples and their outputs are given, the classification result will be a certainty. Therefore, the classification accuracy depends on the recognition of the training samples. In the previous study, the training samples were usually selected by individual experiences, which may result in the conflicts or mistakes due to different experiences and will reduce the classification accuracy, especially when the classification ranks are various and the data size of the experimental sample set is tremensdous.

Supervised learning based neural networks include BP neural network, linear neural network, RBF neural network and its deformation modes (generalized regression neural network and probabilistic neural network) and so on.

Compared with other neural networks, probabilistic neural network has many advantages in the classification, such as simplified operation, faster convergent rate, higher stability and better fault tolerance [18, 19].

3.2 AN UNSUPERVISED LEARNING ALGORITHM BASED NEURAL NETWORK

SOM (Self-Organizing Map) neural network adopts an unsupervised and competitive learning algorithm to map the multi-dimensional data onto a 2-dimensional map [20, 21], which can classify the samples into several clusters without determining the training samples and their expected output in advance and can avoid subjective affect from individual experiences consequently. However, the output value of the neural network depends on its parameter setting, including the learning rate and the number of competitive neurons and maximum iteration times, which results in the uncertainty of the classification result.

4 Modelling of the hybrid neural network model for the recognition of the operating performance of railway freight stations

4.1 DEFINITION OF THE HYBRID NEURAL NETWORK MODEL

Generally, the selection of training samples and recognition of their outputs are determined by the researchers, for example, studies presented in [8-16]. Due to the different experience of different researchers, the selection and recognition of the training samples may be various, which leads to conflicts and even mistakes existing in the classification result. Sometimes, the wrong recognition of some training samples leads to the relatively low classification accuracy. It easily happens especially when there is tremendous information to be processed.

Therefore, based on the analysis in Section 3, we design a hybrid neural network model to recognize the operating performance of the railway freight stations. The hybrid neural network consists of two parts: SOM neural network for the preliminary recognition and probabilistic neural network for the accurate recognition. The respective advantages of the supervised learning algorithm based neural network and the unsupervised learning algorithm based neural network can be combined in this model.

According to the preliminary recognition result by SOM neural network, we can select accurate recognized samples as training and testing samples, and use them to train and test the probabilistic neural network. Finally, a well-constructed probabilistic neural network can be gained to recognize the validation samples. The block diagram of the hybrid neural network is as shown in Figure 4.

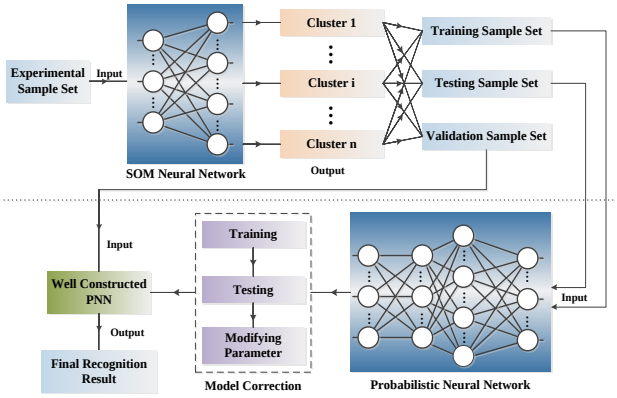

FIGURE 4 Block Diagram of the Hybrid Neural Network Model

4.2 MODELLING PROCESS OF SOM NEURAL NETWORK

SOM neural network is a 2-layer artificial neural network composed of an input layer and a competitive layer. The learning process of SOM neural network consists of three sub processes: competition process, cooperation process and adaption process [21]. Its modelling process is presented as follows.

Step 1. Initialize the SOM neural network.

In this step, the number of competitive neurons (n) and the number of maximum iteration times (T) are determined. Weights connecting the input neurons to the competitive neurons are set in range [0, 1] randomly. In the t^{th} training process, w_{ij}^t is the weight connecting the i^{th} input neuron to the j^{th} competitive neuron, so the weight vector of the j^{th} competitive neuron is $W_j^t = (w_{1j}^t, ..., w_{ij}^t, ..., w_{mj}^t)$, where m is the number of input neurons and equals the number of the evaluation indexes. In this study, m=16.

Step 2. Input the index vector X of a railway freight station by the input neurons.

Step 3. Calculate the Euclidean distance between X and W_j^t by Eq.1.

$$dist_j^t = \left\| X - W_j^t \right\| = \sqrt{\sum_{i=1}^{m} (x_i - w_{ij}^t)} \quad j = 1,2,..,n \tag{1}$$

The Euclidean distance reflects the degree that a competitive neuron matches the index vector of a railway freight station. It will be configured as a parameter in the next step.

Step 4. Gain the winning competitive neuron and its neighbour neuron set.

In this step, if the Euclidean distance between the index vector and the weight vector of the j^{th} competitive neuron satisfies Eq.2, the j^{th} competition neuron is defined as the winning neuron and can be represents by j^*. Its neighbour neuron set $N_{j^*}^t$ can be then determined.

$$dist_j^t = \min\{dist_k^t\}_{k=1}^n, \tag{2}$$

Step 5. Modify weights by Eq.3.

$$w_{ik}^{t+1} = \begin{cases} w_{ik}^t + \alpha_t \cdot (x_i - w_{ik}^t) & k \in \{j^*, N_{j^*}\} \\ w_{ik}^t & else \end{cases} \quad k = 1,2,...,n \quad i = 1,2,...,m \tag{3}$$

where α_t represents the learning rate of the neural network and $\alpha_t \in [0,1]$. Its value decreases with the iteration process.

Step 6. Judge the termination condition is attained or not.

If $t<T$, set $t=t+1$, and then repeat Step 2 to Step 6, otherwise stop the algorithm and give the output value of the input index vector X.

Step 7. Calculate the output value of the competitive layer.

In this step, the output value of the k^{th} competitive neuron and the entire competition layer can be calculated by Eq.4 and Eq.5, respectively.

$$y_k^t = \begin{cases} 1 & k \in \{j^*, N_{j^*}\} \\ 0 & else \end{cases}, \quad k = 1,2,...,n \tag{4}$$

$$y_t = \sum_{k=1}^{n} y_k^t . \tag{5}$$

When inputting the index vectors of different railway freight stations into the neural network, if the output values of the competition layer are equal, these railway freight stations belong to the same rank, otherwise they belong to different ranks.

4.3 MODELLING PROCESS OF PROBABILISTIC NEURAL NETWORK

Probabilistic neural network is a 4-layer feed-forward neural network composed of an input layer, a pattern layer, a summation layer and an output layer. It is a type of classifier based on Bayesian decision and Parzen estimation [22]. Its modelling process of is presented as follows.

Step 1. Input the index vector X of a railway freight station by the input neurons whose number equals the number of evaluation indexes.

Step 2. Calculate the output value of the pattern neurons.

In this step, the ith pattern neuron corresponds with the i^{th} training sample X_i. Using radial basis function as its transfer function, the output value of the ith pattern neuron can be calculated by Eq.6.

$$y_{P_i}(X) = \exp(-\left\| X - X_i \right\|^2 / 2\delta^2), \quad i = 1,2,...,n \tag{6}$$

where n represents the number of training samples.

Step 3. Calculate the output value of summation neurons.

Weights connecting the i^{th} pattern neuron to the j^{th} summation neuron are set as Eq.7.

$$w_{ij} = \begin{cases} 1 & training\ sample\ i \in Rank\ j \\ 0 & else \end{cases}, \quad j = 1,2,...,k \quad i = 1,2,...,n \tag{7}$$

where k represents the number of operating performance ranks.

Using $y_{P_i}(X)$ $(i = 1,2,...,n)$ as its input, the summation neuron will do weighted summation and output the value by Eq.8.

$$y_{S_j}(X) = \sum_{i=1}^{n} [w_{ij} \cdot y_{P_i}(X)], \quad j = 1,2,...,k \tag{8}$$

Step 4. Gain the classification results by output neurons.

The probability of railway freight station Z ∈ Rank j can be calculated by Eq.9.

$$P(R_j \mid Z) = \frac{P(Z \mid R_j) \cdot P(R_j)}{P(Z)}, \tag{9}$$

where $P(Z \mid R_j)$ represents the conditional probability of X, P(Z) is a constant, which has no effect on the classification results. $P(R_j)$ represents the prior probability of Rank j, and can be calculated from training sample set by Eq.10.

$$P(R_j) = \frac{n_j}{n}, \tag{10}$$

where n_j represents the number of training samples that belong to Rank j.

Parzen estimation is applied to estimate the unknown $P(Z \mid R_j)$ by the training sample set according to Eq.11.

$$P(Z \mid R_j) = \frac{\sum_{i=1}^{n} \exp(-\left\|X - X_i^j\right\|^2 / 2\delta^2)}{\sqrt{(2\pi)^2 \cdot \delta^d \cdot n_j}} = \frac{y_{S_j}(X)}{\sqrt{(2\pi)^2 \cdot \delta^d \cdot n_j}}, \quad (11)$$

where d represents the number of evaluation indexes, δ represents the smoothing parameter, and X_i^j represents the ith training sample that belongs to Rank j.

When all prior probabilities of the railway freight station belonging to each rank are all equal, there is $P(Z \mid R_j) \propto y_{S_j}(X)$. Therefore, according to "winner takes all" algorithm [23], the output value of the output neurons can be determined by Eq.12.

$$y_j(X) = \begin{cases} 1 & y_{S_j}(X) > y_{S_q}(X) \\ 0 & else \end{cases}, \quad j, q = 1, 2, ..., m \quad j \neq q \quad (12)$$

Besides, the output values of the probabilistic neural network satisfy Eq.13.

$$\sum_{j=1}^{k} y_j(X) = 1. \quad (13)$$

5 Empirical study: evidence from hohhot railway administration

5.1 DATA COLLECTION AND PRE-PROCESSING

There are 108 railway freight stations managed by Hohhot Railway Administration. Part of their initial data of the evaluation index system are as shown in Table 2.

Before simulation, the initial data should be normalized into range [0, 1] by Min-Max technique (Eq.14) in order to improve the both classification accuracy and calculation efficiency of the hybrid neural network model [24].

$$x_i' = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}} \qquad i = 1, 2, ..., 16, \quad (14)$$

where $x_{\max} = \max\{x_1, ..., x_i, ..., x_{16}\}$ and $x_{\min} = \min\{x_1, ..., x_i, ..., x_{16}\}$. x_i and x_i' represent the data before and after normalization, respectively.

5.2 MODEL SIMULATION

In this study, we use Matlab R2012b to perform the model simulation by a Lenovo laptop with Intel Core i5 3235M 2.60GHz CPU and 4GB RAM. In the SOM neural network simulation, the topology of the SOM neural network is set as shown in Figure 5 and the maximum iteration times is set to 500.

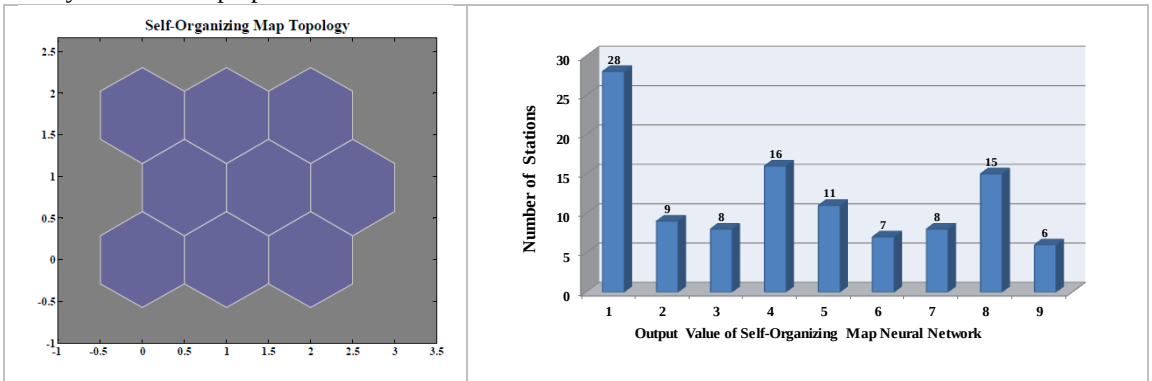

FIGURE 5 Topology of SOM Neural Network

FIGURE 6 Preliminary Recognition Result of the SOM Neural Network

When completing the SOM neural network simulation, the preliminary recognition result is as shown in Figure 6.

Based on the preliminary recognition result, the training samples and testing samples we select are as shown in Table 3. Their expected output corresponds with the binary representation in Table 1.

TABLE 3 Selection of Training Samples and Testing Samples

Rank	Training Samples	Testing Samples
I	Baotouxi, Hohhot, Baotoubei, Linhe	(1) Wuhaixi, (2) Erlian
II	Gongjiban, Baotou, Baotoudong, Fengzhen, Salaqi, Wanshuiquan	(3) Baita, (4) Jiningnan, (5) Saihantala, (6) Wuhaibei
III	Hantaichuan, Hantaichuanbei, Xiangshawan, Erdaoshahe, Gongwusu	(7) Jilantai, (8) Kabuqi, (9) Laoshidan, (10) Lasengmiao, (11) Lasengzhongmiao
IV	Kundulunzhao, Bikeqi, Gongmiaozi, Chasuqi, Toudaoqiao	(12) Tuguiwula, (13) Mingan, (14) Ejina, (15) Xinghe, (16) Daluhao

After several testing, the smoothing parameter we set finally is 1.5. The testing result is as shown in Figure 7. As we can see from Fig. 7, the ratio of correct and wrong number of testing samples is 15:1, which indicates the correct recognition rate is relatively high.

5.3 COMPARISON AND ANALYSIS

In order to verify the importance of the selection of training samples on the recognition result, assume BaotouIVi is mistaken for Rank II, Baotoudong is mistaken for Rank I, Hantaichuan is mistaken for Rank IV, and Toudaoqiao is mistaken for Rank III, then the testing result is as shown in Fig. 8.

The ratio of correct and wrong number of testing samples is 9:7. The comparison between Figure 7 and Figure 8 indicates that the wrong selection of a few training samples can result in the severe reduction of the correct recognition rate of the testing samples, which will further lead to the mistaken in the recognition of the operating performance of the entire railway freight station samples.

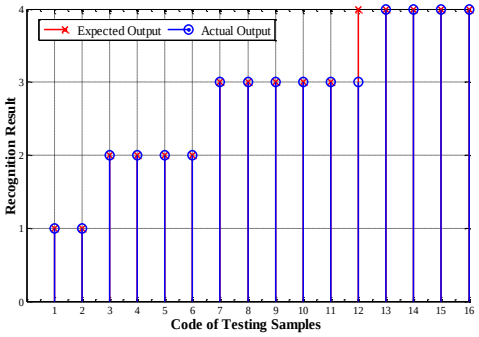

FIGURE 7 Testing Result of the Probabilistic Neural Network

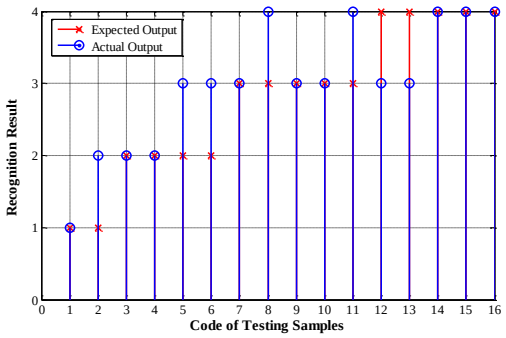

FIGURE 8 Testing Result with Some Wrong Training Samples

In order to verify the performance of the proposed model, we also utilize a 3-layer BP neural network to recognize the operating performance of the testing samples.

The parameters of BP neural network are set as follows. The number of hidden neurons is 40, the number of maximum iteration is 500, and the goal of training accuracy is 10^{-8}. The training performance of BP neural network and its testing result are as shown in Figure 9 and Figure 10, respectively. The ratio of correct and wrong number of testing samples is 13:3, which is lower than the probabilistic neural network.

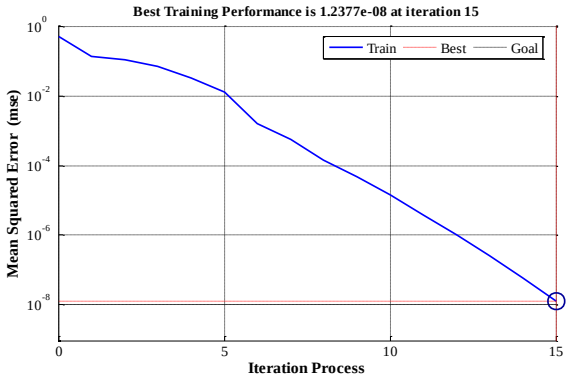

FIGURE 9 Training Performance of BP Neural Network with Given Parameters

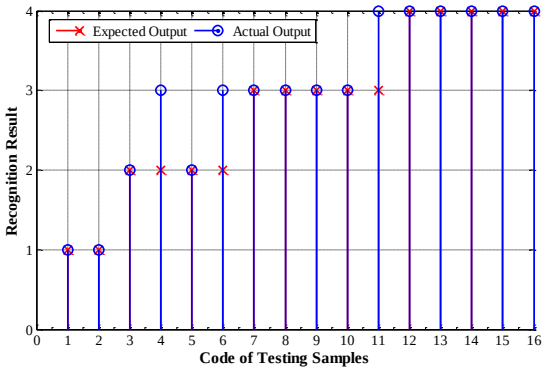

FIGURE 10 Testing Result of BP Neural Network

5.4 FINAL RECOGNITION RESULT

The final simulation result of the hybrid neural network is as shown in Table 4. There are 7 railway freight stations in Rank I, 21 railway freight stations in Rank II, 53 railway freight stations in Rank III, and 27 railway freight stations in Rank IV.

TABLE 4 Operating Performance of the Railway Freight Stations

Rank	Railway Freight Stations	Total Number
I	Baotouxi, Hohhot, Baotoubei, Linhe, Wuhaixi, Erlian, Jining	7
II	Gongjiban, Baotoudong, Baotou, Fengzhen, Salaqi, Wanshuiquan, Baita, Jiningnan, Saihantala, Wuhaibei, Dalahai, Baiyunebo, Ceke, Wuhai, Bayangaole, Jiningnan, Zhenglanqi, Duolun, Zhelimu, Xilinhaote, Zhenglanqi	21
III	Hantaichuan, Hantaichuanbei, Xiangshawan, Erdaoshahe, Gongwusu, Jilantai, Kabuqi, Laoshidan, Lasengmiao, Lasengzhongmiao, Dongxing, Wulateqianqi, Dongshenxi, Guchengwan, Xinxiancheng, Taigemu, Miaoliang, Chagannuoer, Wurigentala, Benjing, Hayehutong, Taosihao, Gujiabao, Minzu, Suji, Zhurihe, Qisumu, Jiangui, Wulashan, Baotounan, Dongshengxi, Eerduosi, Xinjie, Hohhotnan, Suhongtu, Hangjinhouqi, Tukemumiao, Baiyinkulun, Huade, Jinjiadian, Jingpeng, Kailu, Lindong, Linxi, Sanggendalai, Mengtagenlai, Sharinai, Pingandi, Yuzhoudi, Zhelimu, Zhengxiangbaiqi, Baiyunebonan, Xilinhaotexi	53

6 Conclusions

In this study, we propose a strategy on optimization and integration for railway freight stations and design a hybrid neural network model to recognize the operating performance of the railway freight stations. Following conclusions can be drawn from the simulation results.

(1) The model can recognize the operating performance of each railway freight station under relatively high accuracy by classifying them into four ranks according to the proposed strategy.

(2) The accurate selection of the training samples has a significant influence on the recognition of the operating performance of the railway freight stations, which can be seen from Figure 7 and Figure 8. The unsupervised learning algorithm base neural network - SOM neural network can help us select the training samples and testing samples accurately, if necessary.

(3) Compared with the widely used BP neural network, probabilistic neural network performs higher recognition accuracy of the operating performance of railway freight stations.

However, in this study, there are still some imperfections presented as follows. Therefore, further research is required.

(1) The transport mode in the optimized railway freight transport network (See in Figure 3) limits to the qualitative analysis. How to organize the freight transport in the optimized railway freight transport network needs to be further analysed quantitatively.

(2) The optimization and integration method for the railway freight stations we propose in this study is currently in the design stage. Its feasibility needs to be further verified in the practical transport production.

Abstract

In order to accurately, continuously detect solution *pH* on line, regarding C8051F020 as the control centre, the output voltage of glass electrode is amplified through high input impedance circuit utilizing potentiometric method to obtain related voltage signal of *pH* value. Standard solution and temperature sensor ADT7301 are utilized for system calibration and moving average filter of the detected *pH* values, thereby achieving real-time online detection of *pH* value. Detection results are accurate and reliable; low power consumption and miniaturation also facilitate rapid collection and analysis of data under different environments.

Keywords: pH detection, C8051F020, glass electrode

1 Introduction

The *pH* value is a basic parameter for the acid concentrations of the solution, and an important standard determining the quality of a variety of water system such as industrial water, environmental water and domestic water. Common methods of detecting *pH* parameters are chemical analysis, paper strip analysis and potential analysis. Chemical analysis and paper strip analysis cannot achieve online real-time monitoring, so in this research, potentiometric method is utilized to design a portable sensor for rapidly detecting the *pH* value of water samples, which is suitable for operating personnel to duly analyse and estimate water quality on the spot. The sensor detects *pH* value by composite glass electrode, amplifies weak voltage signal through signal processing circuit and converts the signal into standard voltage signal. Temperature compensation is needed in *pH* detection, ADT7301 digital temperature sensor is utilized for temperature detection in this research, which can effectively improve the accuracy of detection.

2 Principle of *pH* detection

Detection of *pH* is to measure the concentration of hydrogen ions, and the definition of *pH* is the negative logarithm of hydrogen ion concentration, namely, $pH = -\log[H^+]$. The *pH* value 0 indicates strong acidic solution, while *pH* 14 indicates strong alkaline solution. At room temperature, the solution with $pH = 7$ is neutral solution. In this research, pH is measured through potentiometric method. Glass electrode and silver-chloride electrode are regarded as the indicating electrode and reference electrode, respectively, and the two electrodes are encapsulated together to form a composite glass electrode. After the sensor is inserted into the test solution, composite glass electrode and test solution can form a primary battery, and the positive pole and negative pole of primary cells are two output lead wires of composite glass electrode. In measuring the *pH* of the solution, the electrodynamic force between glass electrode and reference electrode will change with the change of hydrogen ion concentration in sample solution. If the electric potential difference between two electrodes is zero, then *pH* value of test solution is 7, and the potential of *pH* composite electrode is 0V. According to Nernst equation, the relationship between output electrodynamic force of primary battery, absolute temperature of test solution and pH value of test solution is as below [1].

$$E = E_0 + KT(pH_x - pH_s), \tag{1}$$

wherein, E is the output electrodynamic force of primary battery; constant E_0 is the potential difference determined by electrode material, internal reference solution, internal reference electrode and liquid junction potential; constant K is the Nernst factor; T is the absolute temperature of sample solution; pH_x is the pH value of the test solution; constant pH_s is the pH value of buffer solution in the composite glass electrode.

Through Equation (1), the output electromotive force of original battery is generated by pH value and temperature of test solution together, so after simultaneously measuring output electrodynamic force and solution temperature of primary battery, pH value of the test solution can be calculated according to Equation (1).

3 System hardware design

The overall system structure is shown in Figure 1. C8051F020 microcontroller is the control core of the system.

***Corresponding author** e-mail: yusongjlmail@126.com

Through signal processing circuit with high input impedance, weak electrical signals of *pH* detection electrode are sent into the built-in A/D module of microcontroller, conducting temperature compensation through thirteen-bit digital temperature sensor ADT7301. External advanced ferroelectric memory chip FM31256 is regarded as non-volatile memory to automatically save data when the system is powered down. Human-machine interface is composed of matrix keyboard and LCD dot matrix, which can communicate with the host computer through RS232 bus.

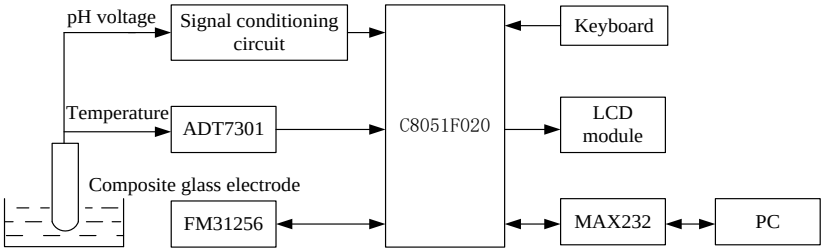

FIGURE 1 Block diagram of *pH* detection system

3.1 STRUCTURE AND PERFORMANCE CHARACTERISTICS OF C8051F020

C8051F020 is a mixed-signal system microcontroller produced by Cygnal Company [2], the instruction set of which is fully compatible with MCS-51. Compared with previous 51-series microcontrollers, C8051F020 has a lot of new features, but its reliability and speed should been improved. Generally, the change in the *pH* value of solution is a slow transition process, which does not need A/D converter with high sampling rate. C8051F020 microcontroller has twelve-bit successive approximation A/D converter and sampling holder, connecting with the outside world through an eight-port analog multiplexer. The A/D converter has a nonlinear accuracy of 0.25LSB and a sampling rate up to 100kbit/s at the highest resolution. Therefore, there is no need to configure an appropriative A/D converter if C8051F020 microcontroller has been chosen as system MCU. Meanwhile, C8051F020 microcontroller has built-in in-system programming Flash (64K bytes), RAM (4352 bytes) and E^2PROM (512 bytes), so we do not need to design additional extenders and data memories, and the on-chip E^2PROM is directly utilize to store system parameters. C8051F020 has six operating modes and automatically enters the sleep state when the system is not working, thus effectively lowering the power consumption of the system.

3.2 DETECTION MODULE OF *PH*

In detection module, *pH* composite electrode and amplification circuit constitute the detection unit. If the *pH* value of test solution is distributed in the range of 0-14, *pH* composite electrode will output bipolar analog signals. However, due to the high internal resistance of *pH* composite electrode $\left(10^8\Omega \sim 10^{10}\Omega\right)$, the output signals are relatively weak, usually hundreds of millivolts. Therefore, output signal needs amplification and translation to meet the input range of A/D analog-digital conversion circuit; composite *pH* electrode has high resistance, so the key of detection circuit is to achieve high input impedance and consider impedance matching, which requires input impedance of detection circuit to maintain in the range of $10^{12}\Omega \sim 10^{13}\Omega$, thus effectively reducing detection errors. Detection circuit of *pH* value is shown in Figure 2.

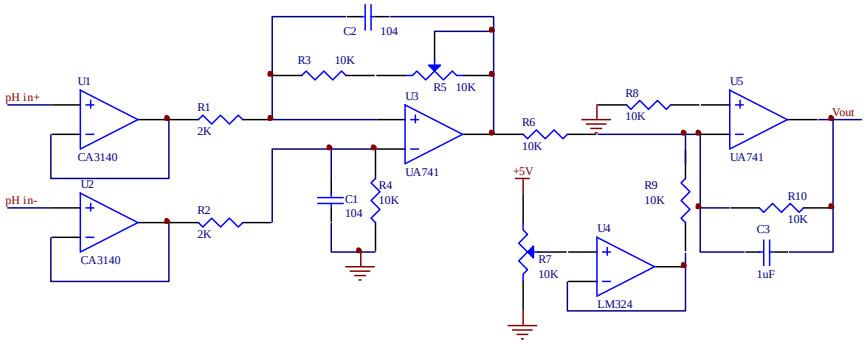

FIGURE 2 *pH* detection circuit

In order to reduce detection noise and improve system stability, an operational amplifier CA3140 is utilized in this research, which is a BIMOS operational amplifier developed by the Radio Corporation of America. On the integrated chip, piezoelectric PMOS transistor technology, the advantages of high-voltage bipolar transistor, MOS/FET input and the technology of bipolar output are utilized by combining the excellent performance of COS/MOS op amp for the first time. COS/MOS op amp is characterized by high input impedance, low bias current, low noise and high gain, and mainly utilized to complete impedance matching, reduce detection noise and improve system stability. In order

to improve input impedance of the whole transmitter, transforming part of input impedance is made up of CA3140 with input impedance up to $10^{14}\Omega$. Each CA3140 is connected to a voltage follower, constituting the first stage circuit to improve input impedance. Besides, due to the symmetrical structure, CMRR can be effectively improved if two devices have the same parameters, and the common-mode signal and offset error signals can also offset.

Generic op amp UA741 is chosen as the second-stage differential amplifier, and amplification can be deduced by Equation (2).

$$Vout = (\frac{R_1 + R_3 + R_5}{R_2 + R_4})V_+ - \frac{R_3 + R_5}{R_1}V_-, \quad (2)$$

where $Vout$ is output of U_3 in Figure 2; V_+ and V_- are the output voltages of two voltage followers. Amplification can be set by changing the resistance value of variable resistor. Through the addition operation between the amplified signal and output of LM324 follower circuit, the output signal of second-stage differential amplifier is added to a fixed voltage, thus realizing level conversion and finally achieving the output of 0.5V-4.8V signal through the reverse amplifier circuit composed of UA741.

3.3 TEMPERATURE DETECTION

In this design, 13-bit digital temperature sensor ADT7301 is utilized to detect temperature. The sensor, with no other external circuitry, does not need to convert analog signal to digital signal, and it can directly output digital quantity. ADT7301 makes the system structure more simple and reliable. ADT7301 and microcontroller C8051F020 utilize SPI communication mode; the serial interface consists of four wires-C/S, SCLK, DIN and DOUT. Temperature detection circuit is shown in Figure 3.

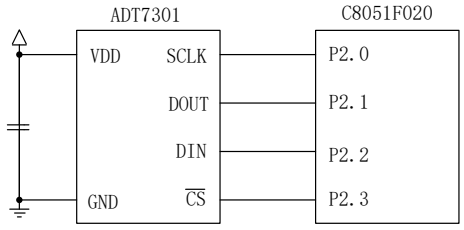

FIGURE 3 The temperature detection circuit

A bandgap temperature sensor for temperature detection and a thirteen-bit A/D converter [3] are integrated in ADT7301 chip, which has a low supply current, high temperature conversion precision, low power and flexible, convenient serial interface. Crystal oscillator is also integrated in AD7301, so clocks can be directly connected to serial port at work, with no need of A/D conversion. The chip has two modes-normal operating mode and power-saving mode. In normal operating mode, the internal clock oscillator will drive automatic conversion timing, so that the chip electrifies the analog circuitry once per second for a temperature conversion, which generally takes 800us. After the conversion, chip analog circuit will automatically power off, and then automatically power on after one second. Therefore, the latest temperature conversion value can always be obtained in temperature value register. Temperature value register is a fourteen-bit read-only register utilized to store temperature conversion result of ADC, and the result is composed of thirteen-bit binary complement code and one-bit sign bit, the top digit. This sensor has a detection accuracy of ± 0.5℃, temperature resolution of 0.03125℃ and detection range of -40℃~+150℃.

By setting control register ADT7301, the chip can be set to power-saving mode. In power-saving mode, the on-chip oscillator is turned off without temperature conversion in ADT7301 until the normal operating mode. By writing zero to the control register, the chip will restore to normal operating mode. Power-saving mode of C8051F02 microcontroller can effectively reduce the power consumption of the system.

4 Electrode calibration and temperature correction

4.1 ELECTRODE CALIBRATION

Before use, *pH* sensor should be set to zero. The specific way is to insert *pH* composite electrode into the solution with temperature of 25℃ and *pH* value of 7, and adjust the zeroing end of *pH* detection circuit until output voltage signal of amplifying circuit is 0V. Then the glass electrode needs calibration. Due to reasons including the manufacturing process of glass electrode, the actual values of parameter E_0 and K in Equation (1) are different from their theoretical values, changing with the aging of electrodes. Therefore, in order to accurately detect *pH* value of the solution, standard buffer solution with the known *pH* value should be utilized for the correction of above-mentioned parameters. The calibration method is to select standard buffer solution $pH = 4.01$ and $pH = 9.18$ [4]. Specific means are as follows: the *pH* values of two standard buffer solutions are supposed as pH_1 and pH_2, respectively, and the output electrodynamic forces are E_1 and E_2; two solutions are calibrated under the same temperature, thereby obtaining relationship between output electrodynamic force E and pH value through Equation (1), shown in Equation (3).

$$\begin{aligned} E_1 &= E_0 + KT(pH_1 - pH_s) \\ E_2 &= E_0 + KT(pH_2 - pH_s) \end{aligned}, \quad (3)$$

$$K = \frac{E_2 - E_1}{T(pH_2 - pH_1)}. \quad (4)$$

For the test solution,

$$E_x = E_0 + KT(pH_x - pH_s). \quad (5)$$

Therefore, the *pH* value of test solution can be obtained.

$$pH_x = pH_1 + \frac{E_x - E_1}{KT}. \quad (6)$$

The *pH* value of two standard buffer solutions pH_1, pH_2, the corresponding electrodynamic force E_1, E_2 and the calculated parameter K are stored in E^2PROM. And *pH* of the test solution can be obtained through Equation (6). During the process of *pH* detection, the temperature of standard solution and test solution should be kept close and constant to prevent sudden changes in temperature.

4.2 TEMPERATURE CORRECTION

Based on Equation (1) and Equation (6), *pH* electrode output voltage changes with the change in the temperature of test solution, while *pH* value of the solution has no correlation with the temperature. Therefore, the temperature should be accurately detected to ensure the accuracy of instruments. In this research, a software method is utilized to correct thirteen-bit output of ADT7301. Theoretically, the digital quantity of ADT7301 has a corresponding relationship with temperature, shown in Equation (7).

$$T = N \cdot \frac{190}{2^{13}} + (-40). \quad (7)$$

At temperature *t*, the actual digital quantity of ADC will change from the ideal value N to N' due to errors. If N' is substituted into Equation (7) for calculation without correction, there will be errors in the detection results. In this research, the actual digital quantity N' of ADT7301 is corrected into ideal value N. Then N is substituted into Equation (7), thus eliminating detection errors. Equation (8) is the correction equation.

$$N = \frac{N_{150} - N_{-40}}{N'_{150} - N'_{-40}}(N' - N'_{-40}) + N_{-40}, \quad (8)$$

wherein, N_{150} and N_{-40} are the ideal digital quantity of ADT7301 at 150℃ and -40℃, the values of which are 2^{13}-1 and 0, respectively; N'_{150} and N'_{-40} are the actual digital quantity of ADT7301 at 150℃ and -40℃, the values of which are measured and stored in E^2PROM. In actual detection, the digital quantity needs correction through Equation (8) before being substituted into the Equation (7), thus calculating the final temperature value [5].

5 System workflow and software filtering

According to requirements and characteristics of portable *pH* detection, system software can complete self-diagnostic of hardware and system initialization, handle keyboard commands and interface tasks, and conduct data acquisition and processing, temperature compensation and alarm. Figure 4 is the flow chart of main program. To reduce errors in detection data and ensure the stability and reproducibility of detection, using the method [6], the combination of moving arithmetic average filter and anti-pulse interference average value is utilized in the detection subroutine.

Assuming that $u(n)$ is the *pH* detection result at the n-th time, and L is the length of the moving average filter window, the filter output $x(n)$ at the n th time can be calculated through Equation (9).

$$x(n) = \frac{1}{L-2}\left\{\sum_{i=1}^{L} u(n+i) - \max_{1\le i\le L} u(n+i) - \min_{1\le i\le L} u(n+i)\right\}, \quad (9)$$

wherein, $\max_{1\le i\le L} u(n+i)$ is the maximum value; $\min_{1\le i\le L} u(n+i)$ is the minimum value.

According to Equation (9), we need to sample L times in detecting a *pH* value, obtain L *pH* values with little differences and form the basic sequence, $u(n+1), u(n+2), \ldots, u(n+L)$. Then the first value of the sequence is removed after every sampling; the remaining values sequentially move forward by one bit; the sampled new value will be inserted at the last bit of the sequence, thereby obtaining a new sequence. After deleting the maximum and minimum value of new sequence, the average of remaining $L-2$ values is calculated as $x(n)$, the final result of detection. The value of L is determined by A/D conversion rate and the required stability time of detection. Based on actual tests and references [6], the value is $L = 9$ in this research.

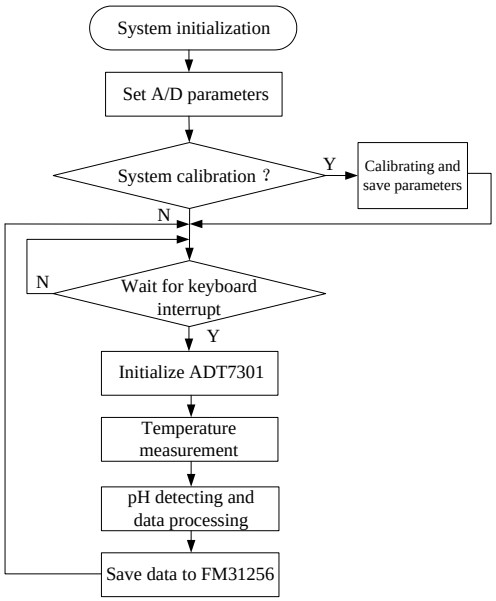

FIGURE 4 Flowchart of *pH* detection sensor

6 Experiment results and analysis

The standard buffer solution with the *pH* of 4.01 (Hach Company) was selected in this research. The experiment was carried out at about 25℃. The standard solution was put in a container with ice water or hot water to change the temperature of buffer standard and verify the accuracy of temperature compensation. In order to verify the reproducibility

of sensor probe and the entire system, each standard solution was measured six times; the probe was put in the solution for 5 minutes each time; *pH* values were determined after the readings of *pH* sensor is stable. Table 1 is a part of the experimental results. According to Table 1, the difference between the detected six *pH* values is less than 0.008, showing good reproducibility of the sensor; the difference between detected value at different temperatures and theoretical value is less than 0.006, indicating that temperature has little influence on the detection results.

TABLE *pH* value of experimental data detection sensors

Standard solution		Times						Theoretical value
pH	*Temperature /℃*	*1*	*2*	*3*	*4*	*5*	*6*	
4.01	5	4.002	4.006	3.999	4.002	3.998	4.003	4.00
	25	4.014	4.011	4.009	4.013	4.015	4.014	4.01
	35	4.035	4.033	4.029	4.031	4.032	4.034	4.03

7 Conclusions

A method for online *pH* detection is proposed in this research with complete design of hardware and software programs. Impedance matching method is utilized to eliminate the influence of high resistance in glass electrode, and electrodes are calibrated through standard buffer solution, thus eliminating zero drift and electrode deviations. Besides, the output of temperature sensor is calibrated by software to effectively improve the accuracy of temperature detection. The accuracy and repeatability of sensors are effectively improved by establishing *pH* value sequence and utilizing moving average filter to process the *pH* values, realizing long-term, on-line and high-precision detection at the range of -40℃~+150℃ in the *pH* detection system.

Digital controller for electric vehicle synchronous motor rotor

Weihua Chen*

State Key Laboratory of Alternate Electrical Power System with Renewable Energy Sources

North China Electric Power University, Beijing 102206, China

Received 1 March 2014, www.cmnt.lv

Abstract

At present, the number of electric vehicle is increasing, and, in case of big vehicle speed change, the vehicle motor cannot be used efficiently. In order to resolve this problem, it is necessary to improve the topological structure and control strategy, and design a new converter. In this paper, we apply a two-channel synchronous Buck converter. The main circuit is to achieve the maximum power output by the stage regulation, while the improved converter topology realizes the overall system function. The experimental results show that the new converter has superior performance in big vehicle speed change, and has the high quality energy output. This research has an important practical significance to improve the utilization of renewable energy.

Keywords: power system, electric vehicle, digital controller, inverter, converter

1 Introduction

With new kind of vehicle developing, electric vehicle is getting more and more attention of researchers [1]. Now the utilization of drive motor for electric vehicle is usually in the way of the asynchronous motor mode. Asynchronous motor is with low price, but the poor performance. So its application is limited [2-4]. While synchronous motor has a lot of advantages, such as good mechanical characteristic and adjustable air gap. It may operate efficiently in the big speed range with greatly improved power efficiency and reduced operation and maintenance costs. Synchronous motor has become an important development direction in drive motor for electric vehicle, characterized by being more economical, convenient, and practical.

The research on the utilization of synchronous motor for ele-ctric vehicle mainly concentrates on synchronous motor physical structure, while paying little attention to how to control synchronous motor. The resulting consequence is the fact that synchronous motor does not operate perfectly for electric vehicle. Traffic jam is very serious in many large cities all over the world, vehicles have to start and strop frequently, so the traditional synchronous motor control cannot gain synchronous motor effective performance. This research aims to improve the performance of electric vehicle under big speed range by designing a new excitation converter control strategy for synchronous motor [5-7].

Some research has been done on the topology structure and control strategy of the excitation converter. The excitation converter used the two-channel synchronous Buck circuit topology. On the control strategy, phased control strategy and adaptive PI control method based online parameter adjustment were used. DSP chip TMS320F2812 was used as the control core to realize the switch controlling, data processing, communication and other functions. Through the improvement of excitation converter topology and control strategy, we can improve the performance of ecitation converter and the performance of synchronous motor under big speed range, and promote the development and utilization of electric vehicle.

2 Excitation converter topology

The excitation converter adopts the two-channel synchronous Buck parallel connection, as shown in Figure 1. The purpose of the two-channel synchronous Buck parallel connection is to increase the output current ripple frequency and reduce its amplitude. It can improve the dynamic response speed by reducing the output filter inductor. Under the same power output condition, the two-channel synchronous Buck parallel connection preferment [8-13].

Double closed loop is composed of voltage loop and current loop independently, as shown in Figure 1. It can realize the constant pressure output or constant current output. Firstly, Voltage loop sample the output voltage of *Vo*, and then compare it with the set voltage value *Vr*. The difference between the two voltages is put into the adaptive PI regulator, shown in the dashed box. Current loop is with the same voltage loop. Adaptive PI regulator can adjust proportion coefficient KP and integral coefficient KI. This can be used to realize cycle current or voltage control and overcurrent protection. Voltage loop work during quick response stage in the converter, while current loop work during the steady constant current stage in the converter.

***Corresponding author** e-mail: cwhwc@163.com

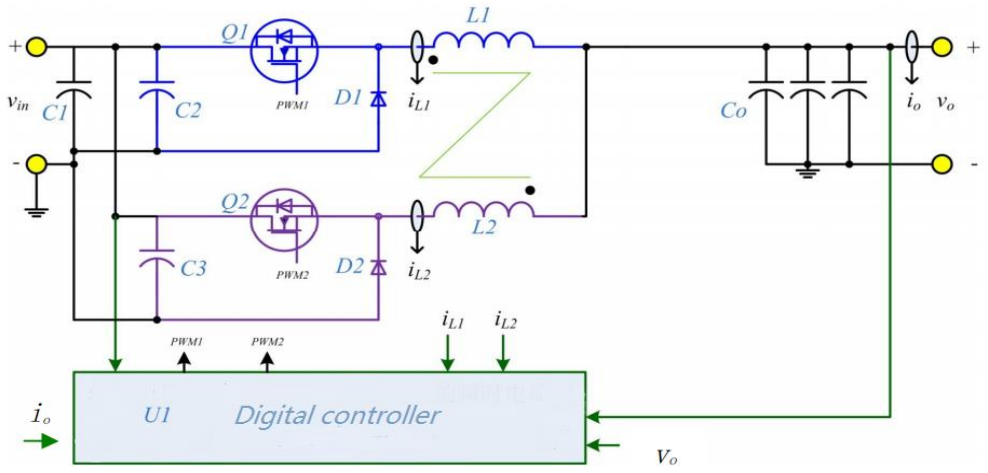

FIGURE 1 Two channel synchronous Buck converter main circuit topology diagram

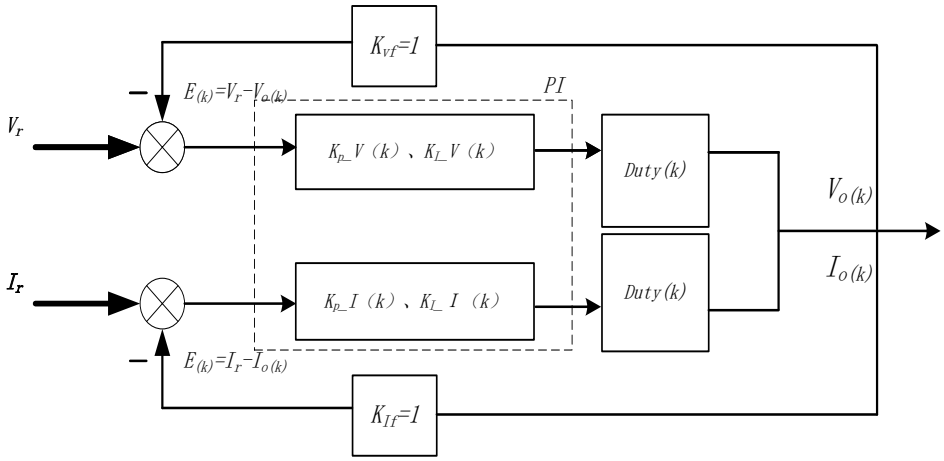

FIGURE 2 Double closed loop control structure diagram

Here introduced several parameters: *Vr* is the symbol of converter expected output voltage value (equal to the desired output current of *Ir* with the equivalent resistance of Re product, Re identification, see section third). *Vin* is the converter input voltage *Vo* converter; the actual output voltage. *D* is the power tube gate driving signal duty ratio of PWM wave; *ΔV* is expected output voltage and the actual output voltage difference, namely Delta *V*=*Vr*-*Vo*.

In electric vehicle, torque speed requirements change quickly. The rotor excitation current need to response quickly, namely the excitation converter can make rapid response to the different output needs. At the same time the overshoot and steady state error of the output are smaller. But the PI controller with fixed parameters is difficult to meet the requirements. This paper presents a simple, efficient adaptive PI controller to solve the problem [14, 15].

The mathematical equations for the adaptive PI controller are

$$\begin{aligned}\Delta u(k) &= u(k)\text{-}u(k\text{-}1)\\ &= K_p(e(k)\text{-}e(k\text{-}1)) + K_I e(k)\end{aligned}, \tag{1}$$

where the two parameter K_P, K_I tuning is adaptive PI control key points.

In order to make the converter voltage output can quickly track the desired voltage value, and the start-up phase voltage overshoot in a proper range, let the coefficient K_p is expected to duty ratio divided by the voltage difference

$$K_p = \frac{d}{\Delta V} \tag{2}$$

and let

$$d = \frac{V_r}{V_{in}}. \tag{3}$$

So coefficient K_p is

$$K_p = \frac{k_1 \times (k_2 \times V_r - V_{start})}{V_{in} \times (k_2 \times V_r - V_o)}, \tag{4}$$

where k_1 is the correction coefficient, k_2 is the actual voltage output and the expected voltage output ratio from fast response stage switching to a steady flow stage. By many tests, k_2 is from 0.85 to 0.9. Because the voltage close loop control

begin at the end of soft starting, so we need to subtract voltage V_{start} at the soft start end time.

In addition, let

$$K_I = \frac{K_P}{k_3}, \tag{5}$$

where k_3 is the coefficient of integral coefficient.

3 Converter control strategy

3.1 CONVERTER CONTROL STRATEGY

The work state of converter is divided into soft start stage, fast response stage and steady flow stage. So, the converter control strategy is divided also.

1) Soft start stage. The converter begins by soft start. The voltage output rises from zero to 8 percent of desired voltage value. In this stage, the duty ratio of PWM increases gradually, while the converter voltage output and current output and increases slowly. The purpose of the soft start is to preheat the power devices and circuits. Improving output steadily to prevent overshoot accident. On the other hand, it can identify load parameter. If we do not set the soft start of the converter in the start-up stage, the power switching devices work at the condition with the duty cycle of 100%. So there will be a lot of surge current into the output capacitor. Sometimes, the output voltage overshoot are large. And the surge current may also damage switch tube and other devices. Using the strategy of soft start can eliminate the surge current and avoid the overshoot of output voltage.

2) Fast response stage. In the fast response stage, in order to make the converter voltage output and current output can reach near the given value rapidly; voltage loop with adaptive PI controller is used to reduce the values of voltage output and the current output rise time effectively.

3) Steady flow stage. When the value of voltage output reaches ninety percent of the expected voltage output value, it is the time to be steady flow stage. At this stage, a current loop with adaptive PI controller is used.

3.2 PARAMETER IDENTIFICATION

In the soft startup stage, the control system gets the converter values of voltage output and current output through sensors. The excitation coil resistance is calculated on-line sometimes to obtain the equivalent resistance value with the method of least squares. The biggest advantage of online parameter identification is that effects factors such as temperature, rotation and others on the excitation coil resistance would be contained in the identification parameters naturally once the parameters identification finished. And it is easy to implement and calculation. But each the identifycation parameter may be different. The purpose of parameter identification is to provide the basis parameters for adaptive PI control.

4 Communication and protocol

The integrated control system of electric vehicle covers the parameters of motor stator, rotor, battery's working condition, vehicle speed, and the operation of the driver. The CAN bus technology is used to connect the device for obtaining the above parameters. It is the key to realize the electric vehicle set control. As a multi machine serial communication protocol, the CAN protocol is mainly used for network communication with multi node. The data frames for the CAN protocol is shown in Figure 3. As a practical application, designers need to develop communication protocol at the top level satisfied with their own project. Designers need to fill the data field in the data frame and to set the standard communication rate.

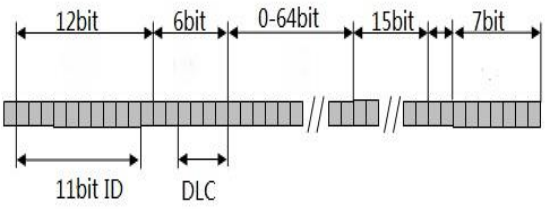

FIGURE 3 Schematic diagram of CAN standard frame format

Considering the communication between excitation converter system and other electric vehicles modules, the standard data frame is used in the paper. The data length is 8 bytes. A kind of simple and effective communication protocol top layer is made. Five communication frames are designed. They are frame 1, frame 2, frame 3, converter output frame, converter device temperature frame respectively. Frame 1, frame 2, and frame 3 are sent from the stator side controller to converter. Converter output frame and converter device temperature frame are sent from converter to the stator side controller. As shown in Table 1-5.

TABLE 1 CAN communication protocol - control frame 1

Name	Begin-end	Unit	Reset value	Smallest value	Biggest value

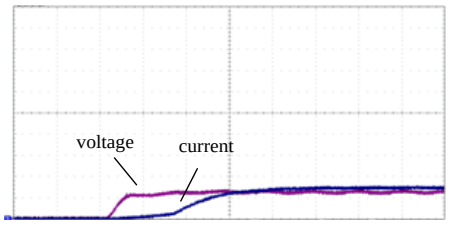
Switching_Component_Temperature	17-32	℃	0	-50	250
Inductor_Temperature	33-48	℃	0	-50	250

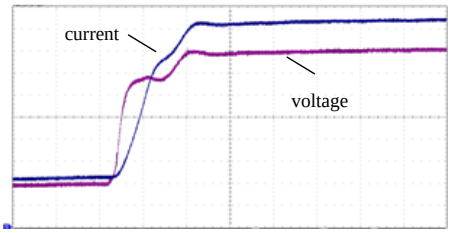
In this design physical implementation of CAN communication relies on the CAN module meets the CAN2.0B protocol standard built-in TMS320F2812 chip. The CAN module communication rate is up to 1Mbps. And it is of low power mode and CAN bus wake-up function. Considering the practical engineering, the configuration of CAN bit rate is 500bps. In the experiment, the PC with USB2CAN function is used for the simulation of stator side controller and converter doing CAN communication and control. It is obviously that the CAN communication is of good reliability.

5 Case studying

A prototype is built to make the related tests. And the test results are recorded. Figure 4 and Figure 5 is the converter start-up test wave form and dynamic response wave form respectively. Figure 6 is the steady state ripple wave form converter. In the experiment, resistors and inductors are used to simulate converter load. The rated load is a resistor of 35Ω and a series inductance 650mH.

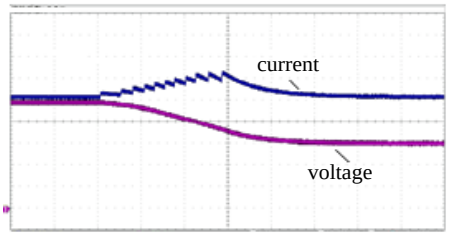


a) Soft start stage

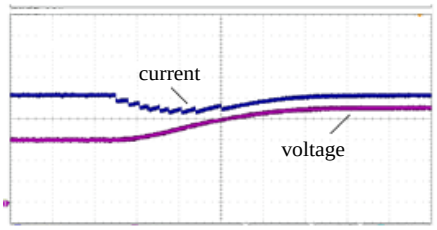


b) Regulating stage

FIGURE 4 Test waveforms at rated load starting



a) Load decreasing



b) Load increasing

FIGURE 5 Test waveforms at rated load starting

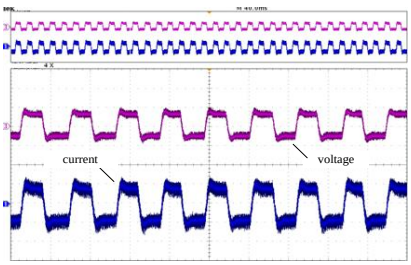


FIGURE 6 Voltage and current output ripple peak value

As we can see from Figure 4, the output values increase rapidly during the converter start-up stage. The response time is less than 100ms. The voltage overshoot is less than 15V. The current overshoot is less than 1A. It can be seen from Figure 5 that converter dynamic responses rapidly when load changes. The response time is less than 200ms. It can be seen from Figure 6 that the converter steady state voltage ripple is less than 1V and that the steady state current ripple is less than 50mA.

In addition, the converter power and efficiency is test, as the results shown in Table 6. In the two long tests, converter has a stable output. The values of output power are more than 800 watts. The values of efficiency are more than 95%. The above values satisfy the requirements of power and efficiency.

5 Conclusions

This paper describes the main design ideas of the synchronous motor rotor excitation converter for electric vehicles. The two channels synchronous Buck interleaves. The topology of converter is optimized. The control stage and adaptive PI converter are used. It can quickly achieve the desired output value during the different output demand. Making CAN communication protocol is not only to meet the communication needs of converter and stator side controller, but also provides reference and space for electric vehicles to build the more complex internal communication network in the future. The prototype is with good output and regulation performance. It meets the basic requirements of application in vehicle rotor excitation converter.

Abstract

Piston ring is one of the important parts in diesel engine, and its excessive wear reduces the sealing performance of the combustion chamber, the method on monitoring wear of piston rings with the magneto-resistive sensor is researched from the simulation viewpoint, the research shows that the amplitudes reduce with the increase of the piston ring wear. The theoretical basis for monitoring piston ring wear with a MR sensor is provided.

Keywords: piston ring wear, magneto-resistive sensor, diesel engine

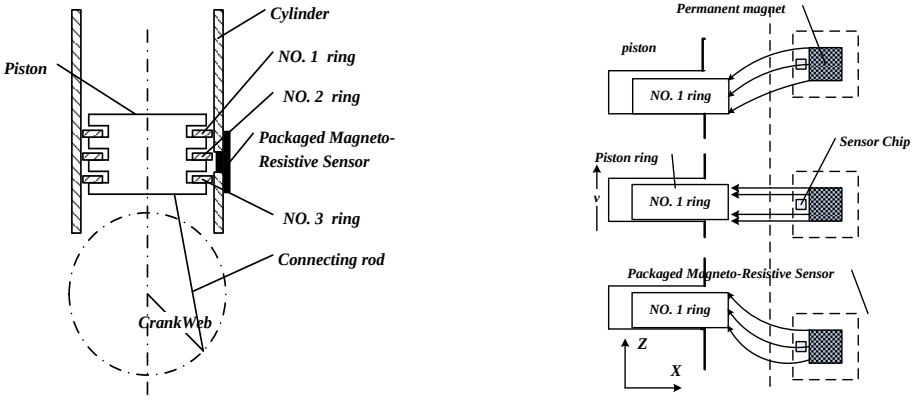
1 Introduction

Piston ring is one of the important parts in diesel engine, and its excessive wear reduces the sealing performance of the combustion chamber, which reduces the performance and the reliability of the diesel engine. In order to obtain the real-time operation status of the piston ring, the on-line monitoring methods should be researched. The wear of the piston ring can be measured by a magnetic sensor, and some monitoring system can achieve the monitoring function at present [1, 2].

Literature [3] studied the online monitoring method for the general piston rings based on the magneto-resistive sensor. On the research foundation of the literature [3], the effect of piston ring motion was researched in the paper, and it provides the theoretical basis for the practical application in the diesel engine.

2 Detection principle of magneto-resistive sensor

When a diesel engine works, the piston and the piston ring reciprocate within the cylinder and a magneto-resistive (MR) sensor is installed on cylinder liner to measure magnetic field intensity, as shown in Figure 1a. Figure 1b shows the distributions of the magnetic flux density when the piston ring passes the MR sensor. The change of the magnetic field intensity in Z direction can be found according to dealing with monitoring data. If the piston rings wear, the amplitudes of the magnetic field intensity on monitoring point would change respectively. And then the output amplitudes of the MR sensor change also, so that the wear of the piston rings can be detected.



1a 1b

FIGURE 1 Sketch map of magnetic lines of force

***Corresponding author** e-mail: qingchen.sun@lr.org

According to detection principle, the piston ring wear can be monitored with the amplitude change of magnetic field intensity, which may be bound up with its radial motion, including speed and acceleration, and has nothing to do with the axial movement, so the simulation must be finished to find out the relation between the radial motion and the wear of the piston ring.

3 Dynamics simulation on piston ring

3.1 DYNAMIC ANALYSIS ON PISTON RING

It needs to computer the balance equation of piston ring to find its radial motion. Figure 2 shows the force analysis of piston ring [4, 5].

The force of ring in axial direction includes:

$F_{a,con}$, the force between the ring groove and ring, including the oil film pressure $F_{a,oil,con}$ and the contact pressure between the ring groove and ring $F_{a,gro,con}$.

$F_g = mg$, the gravity of ring.

$F_{a,gas}$ the axial cylinder pressure.

$F_{a,fric}$ the friction force between the cylinder wall and piston ring.

The axial equation is given as:

$$m\frac{d^2y}{dt^2} = F_{a,con} + F_{a,gas} + F_{a,fric} + mg \ . \tag{1}$$

The force in radial direction includes:

$F_{r,con}$, the force between the cylinder wall and ring, including the oil film pressure $F_{r,oil,con}$ and the contact pressure between the cylinder wall and ring $F_{r,cyl,con}$

$F_{tension} = k_r(h' + h_0)$ the tension of piston ring, where k_r is the radial elastic coefficient of the piston ring.

$F_{r,gas}$ the radial cylinder pressure.

$F_{r,fric}$ the friction force between the ring and groove,

$F_{rl,gas}$ the gas force acting on the ring surface near cylinder wall due to the less lubricating oil.

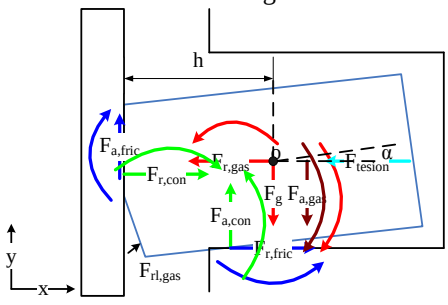


FIGURE 2 Force diagram of piston ring

The radial Equation is given as:

$$m\frac{d^2h}{dt^2} = F_{r,con} + k_r(h' + h_0) + F_{r,gas} + F_{r,fric} + F_{rl,gas} \tag{2}$$
$$= F_{r,oil,con} + F_{r,cyl,con} + k_r(h' + h_0) + F_{r,gas} + F_{r,fric} + F_{rl,gas}$$

The Torque equation is given as:

$$I\frac{d^2\alpha}{dt^2} = M_{a,con} + M_{a,gas} + M_{a,fric} + M_{r,con} + M_{r,fric} + M_t \ , \tag{3}$$

where $M_t = k_t\alpha$, $k_t = \dfrac{Eb^3 \ln\left(\dfrac{D}{d}\right)}{3(D+d)}$.

I is the moment of inertia, α the angle of inclination, E the modulus of elasticity, b the axial height, D the outer diameter, d the inner diameter.

The axial motion equations of the piston and piston ring can be described as:

$$y = y_p + y_{rp} \ , \tag{4}$$

$$\frac{dy}{dt} = \frac{dy_p}{dt} + \frac{dy_{rp}}{dt} \ , \tag{5}$$

$$\frac{d^2y}{dt^2} = \frac{d^2y_p}{dt^2} + \frac{d^2y_{rp}}{dt^2} \ , \tag{6}$$

where y is the axial displacement of piston ring centre of gravity, y_p the axial displacement of piston, y_{rp} the axial displacement between piston ring and piston.

According to the relationship between y_p and crank angle, piston ring motion trajectory can be found.

3.2 THE RADIAL MOTION SIMULATION ON PISTON RING

The wear limit of the piston ring is 4 mm for the marine diesel RTA52U, so the wear rage of the piston ring was set from 0 mm to 4 mm with a 1 mm step, thus the piston ring motions were simulated in various wear conditions according to the previous equations.

The radial velocity and displacement of piston rings were found during a working cycle of diesel engine. Figure 3 shows the radial velocity and displacement curves of the piston rings without wear.

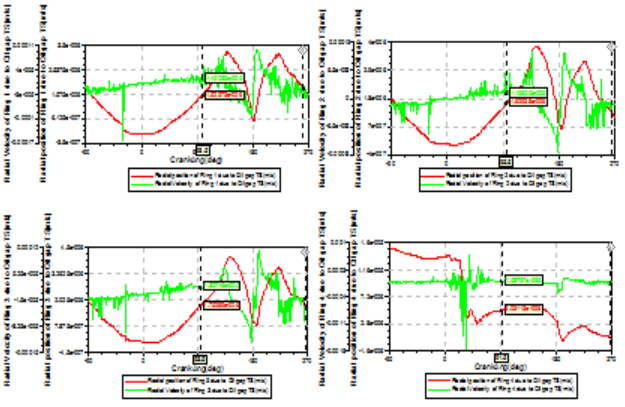

FIGURE 3 The radial velocity and displacement of piston rings

According to simulation results, it can be found that the change tendencies of the radial velocity and acceleration are almost the same for the piston rings except NO.4 ring (oil ring), and the minimal radial displacement occurs at the maximum combustion pressure.

When the piston rings passed the monitoring point in various wear conditions, the radial motions of piston rings were found, as shown in Table 1.

TABLE 1 Motion parameters for ring passing sensors (100 r/min)

Piston ring	Wear value 0mm		Wear value 1.0mm	
	Radial speed(m/s)	*Radial displacement (m/s2)*	*Radial speed(m/s)*	*Radial displacement (m/s2)*

4 Simulation on magnetic field intensity

A finite element model consisting of a piston, piston rings, a cylinder liner, and a magneto-resistive sensor was established on the basis of actual size, the magnetic field intensity of the monitoring point could be simulated. The piston ring motions of finite element model were set according to the previous results. Thus, the magnetic field intensity was simulated under different wear conditions, as shown in Figure 4. The relation between the amplitudes of the magnetic field intensity and the piston ring wear is shown in Figure 5. It shows that there is corresponding relationship between the amplitudes and the ring wear, and the amplitudes decrease with the increase of the ring wear.

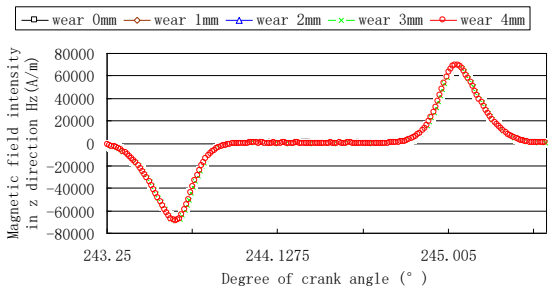

FIGURE 4 Calculation waveform

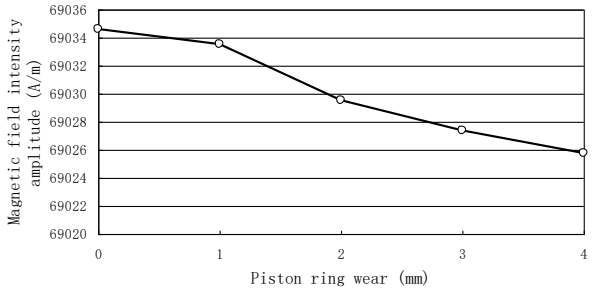

FIGURE 5 The relation between amplitudes and ring wear

5 Conclusions

The magnetic field intensity on the monitoring point is simulated for RTA52U marine diesel engine during a working cycle, the method on monitoring wear of piston rings with the magneto-resistive sensor is researched from the simulation point of view, it can be found the ring radial movements do not affect the amplitudes of the magnetic field intensity, and there is corresponding relationship between the amplitudes and the ring wear. Furthermore, the amplitudes reduce with the increase of the piston ring wear. It provides the theoretical basis for monitoring piston ring wear with a MR sensor.

Abstract

The sorting control system is the critical procedure in the final product line of cold rolling mill. Taking the tinning steel sheet sorting control system of shearing production line of WISCO's cold rolling plant as an example, the process of steel sorting control system is introduced. The running principle and control concept of steel sheet position tracking and sorting are particularly presented. The practical application proves that the system can position the tinning steel sheet which is moving in high speed, which is of high controllability and reliability.

Keywords: sorting control, position tracking, magnet system, self-adapt regulating, dropping posture control

1 Introduction

The primary task of cold rolling plant shearing production line [1] is to automatically detect the sheet defects, and shear the sheet to specified length, then automatically separate the finished products from the inferiors, finally pack manually and deliver. The steel sheet sorting system [2] is the key step in the whole production process. The Figure 1 and Table 1 are the process flow of sheet sorting system ().

***Corresponding author** e-mail: Liaoxuechao2008@sina.com.cn

2 Process flow and control principles of the system

2.1 SYSTEM PROCESS FLOW

The system process flow [3] is: steel coil is uncoiled by decoiler, then going through the thickness gauge {B}, straightener, pinch roll and pinhole detector {F}, and be feeded into flying shear. The steel coil is cut to specified length steel sheets by flying shear, and then transmitted to belt transportting system to automatically select [4]. The steel sheets are separated into quality products or the inferiors, and then stacked to specific stacking table, transmitted to packaging roll, finally packing and transport manually [5].

When a new steel coil is uncoiled and sheared [6], the previous sheets are identified as inferior sheet, the operator press the inferiors falling button and drop the previous sheets into inferior stacking table [7].

The thickness gauge {B} detects the sheets' thickness on-line [8]. If the sheet thickness exceeds the positive and negative deviation range, the certain segment sheets are identified as inferior products. The pinhole detector {F} includes left and right pinhole detecting units [9]. If any detecting unit inspects the pinhole defect, the certain sheet is identified as inferior products. On the examining table [I], the quality control inspectors inspect each sheet. If the sheet has surface defect, the certain sheet is identified as inferior products. All the defect sheets will be stacked into inferiors stacking table.

The flying shear cut the steel coil into specified length sheets [10], the sheets are conveyed into main transmitting belt {T0} by the 4#, 5# Entry belt {T4, T5}. Several permanent magnet steel bodies are installed in the middle part of main transmitting belt so as to attract the sheets just beneath the main transmitting belt. There are three magnetic field control systems {W1, W2 and W3} in the main belt above the stacking table belt [11]. When the system working in certain time frame, the system's magnetic field can counteract the permanent magnet steel bodies' magnetic field. Then the sheets under the permanent magnet steel bodies will drop onto the stacking table belt, and transmit to corresponding stacking tables.

The sheet box can be automatic adjusted to appropriate length and width, so as to contain the sheets. When the sheet quantity of quality stacking table reach the specified quantity, the sheets can be automatic packaged and transported.

2.2 SYSTEM PROCESS FLOW

The key points of the sorting control system are:

1) The system should accurately track the position of sheets, which is transmitting at a high speed (300 m/min), so as to find the inferior sheets detected by the pinhole detector and thickness gauge and make it drop into the inferior stacking table.

2) The system should be adaptive to the speed of three belts {T0, T4, T5} according to the sheet's length. The sheets' distance can be extended to a proper value, so as to be easy for the phototube to track the sheets.

3) Because the system's running speed is very high, the magnetic control system should control the sheets' dropping location and dropping location accurately according to the sheets' length and running speed, so as to avoid the pile-up accident.

3 Self-adaption sorting control model

3.1 DEFECT SHEETS POSITION TRACKING

The key point of the whole sorting control system is sheets' position tracking, especially the inferiors sheets' position tracking.

The three stacking table and flying shear {P0, P1, P2 and P3} are equipped with four phototubes, through which the sheets number can be counted and tracked.

Supposing:

- N_0: flying shear phototubes' counting number;
- N_1, N_2, N_3: P1, P2, P3 phototubes' counting number;
- L_1: the distance between thickness gauge {B} and pinhole detector {F};
- L_2: the distance between pinhole detector {F} and flying shear{H};
- L_0: the length of sheet.

We define a array R to save the defect sheet counting number.

If at the T_1 time, system detected a thickness defect sheet [12], and then thickness defect sheet counting number at the current time can be calculated according to formula (1) and storage to array R:

$$X_1 = \text{RND\_}(\frac{L_1 + L_2}{L_0}) + N_0 + 1. \tag{1}$$

If at the T_2 time, system detected a pinhole defect sheet [13], and then pinhole defect sheet counting number at the current time can be calculated according to Equation (2) and storage to array R:

$$X_2 = \text{RND\_}(\frac{L_3}{L_0}) + N_0 + 1, \tag{2}$$

where the symbol RND. represents rounded down operation.

The distance L_3 is actual sheet length between pinhole detector and the head of the next sheet.

Namely: $L_3 = L_2 + L_4 - L_5$, where L_4 is the distance between flying shear and the head of the next sheet.

The system real-time collects the counting pulse signal of pinch roll {D} speed encoder {K1}. Supposing that the counting pulse value of K1 per rotation is n_1, pinch roll's diameter is Q_1. Then corresponding distance s1 of each K1 pulse can be calculate as:

$$s_1 = \frac{Q_1 \times \pi}{n_1}, \tag{3}$$

Figure 2 is the schematic plot of calculating distance L_3. Supposing, at the time of P0 rising edge, counting value of K1 is M_1. At the time of F rising edge, counting value of K1

is M_2. The distance L_4 can be calculated as: $L_4 = (M_2 - M_1) \times s_1$.

The distance L_5 is distance correction factor, $L_5 = V_l \times 0.1666$, where V_l is pinch roll's line speed.

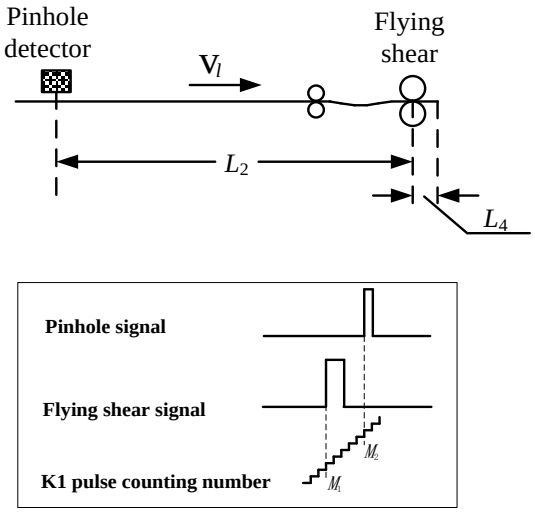

FIGURE 2 Schematic plot of calculating distance L3

Assuming the pinhole locating between the two sheets, the system make the following processing, supposing distance:

$$\Delta L = L_3 - RND\_[L_3 / L_0], \tag{4}$$

if $\Delta L < 0.1$, then the current sheet and previous sheet are all defected sheets, the counting number X_2 and X_2-1 will be stored into the array R;

if $\Delta L > 0.9$, then the current sheet and next sheet are all the defect sheets, the counting number X_2 and X_2+1 will storage into the array R;

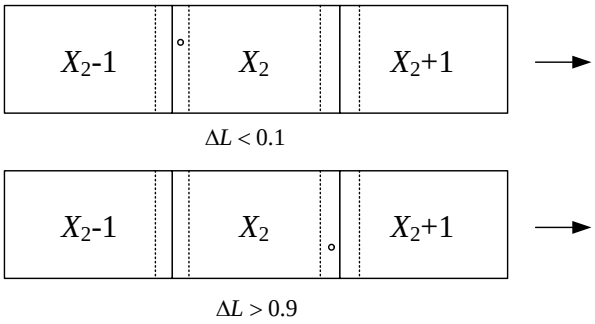

FIGURE 3 The situation of the pinhole locating between two sheet

Every time array R receiving a new element, system will sort the array R to maintain the defected sheet counting number value from small to large.

When P1 detects the counting number $N1$ to be equal to the detect sheet counting value in array R, mean: $N_1 = R[i]$, then system will drop this defect sheet into inferior stacking table.

3.2 TRANSMITTING BELT SPEED CONTROL

The system should adaptive control the speed of three belts [T0, T4 and T5] according to the sheet's length [14].

The distance between tow sheets should be extended to a proper value, so as to be easy to phototube tracking the sheets [14]. Consequently, the sorting control system can run in high speed. Thus, the speed of S roll and six belts should be real-time controlled.

Supposing:

-V_0: the max speed of main belt T0; V3
-V_1: the max speed of S roll; V0
-V_4: the max speed of belt T4; V1
-V_5: the max speed of belt T5; V2
-V_s: the max speed of stacking belt T1, T2, T3.

The speed of V_1 can be ascertained according to the sheet length. Then the other speed can be calculated as follows:

$$V_0 = V_1(1 + k_0), \tag{5}$$

$$V_4 = V_1(1 + k_4), \tag{6}$$

$$V_5 = V_1(1 + k_5), \tag{7}$$

where k_0, k_4, k_5 is the speed scale factor, which can be calculated through algorithm of Figure 2. p_0, p_4, p_5 is the setting initial value of k_0, k_4, k_5, which is the experience value according to main belt length and running speed. In this sorting system, p_0=0.25, p_4=0.1, p_5=0.2.

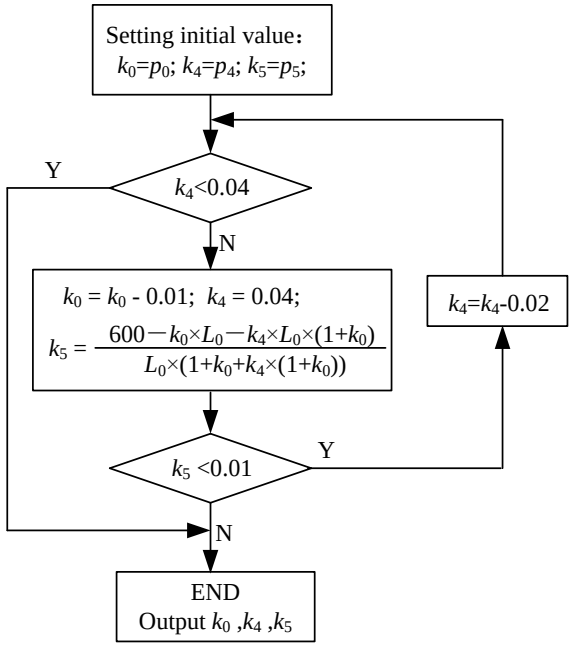

FIGURE 4 speed scale factor calculating algorithm flow

Through the above algorithm, the belt speed is getting higher and higher (the specific relationship is $V_0 > V_2 > V_0 > V_1$). So the sheets after cutting by flying shear can be extended to a certain distance (approximately 600mm), so as to be easily tracked by phototubes.

When the sheets drop into the stacking table belt, the belt conveys it to the stacking box in a lower speed V_s, V_s=V_0/3.5.

3.3 SHEETS DROPPING CONTROL

Because of the sheets running at the very high speed (the max speed can reach 300m/min) in the line, every dropping position and posture of the sheet must be accurately controlled, to avoid the sheets scratching with each other and piling up in the stacking box [14].

Take the 1# stacking table as an example, the principle of how to control the dropping location and posture is described as follows:

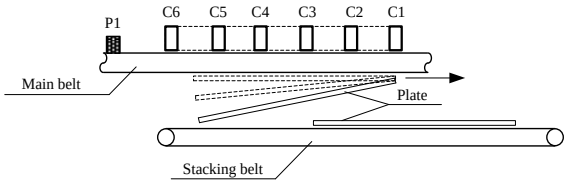

FIGURE 5 dropping control schematic diagram of 1# stacking table magnetic system

Supposing the distance between P1 and electromagnet C6 is S, the sheet length is L_0, the line speed of T0 is V_0.

The system real-time collects the pulse counting signal of the main belt encoder. Supposing that the counting pulse value of K2 per rotation is n_2, main belt roll's diameter is Q_2. Then corresponding distance *S2* of each K2 pulse can be calculated as:

$$S_2 = \frac{Q_2 \times \pi}{n_2}. \tag{8}$$

When phototube P1 detects the sheet, the system starts counting. Supposing its' counting number is *m*. When *m* satisfies the Equation (8), system will consider that the sheet reaches the dropping location, 1# Stacking table magnet system working, and the sheet drops to the 1# stacking belt.

$$m \times S_2 \geq L_0 + S_2 - V_0 \times t, \tag{9}$$

where *t* is a experience delay time.

At first, C6 losses of field, and then C5, C4, C3, C2, C1 successively loss of field delayed by a certain T period. So the sheet will drop smoothly and steadily to the stacking table belt (the sheet tail dropping firstly, the sheet nose dropping later.)

When *m* satisfies the Equation (9), system will consider that the sheet already dropped to the stacking belt, 1# Stacking table magnet system will stop working.

$$m \times S_2 \geq L_0 + S_2 + S_1, \tag{10}$$

where S_1 is the experience delay distance.

Because the main belt speed is 3.5 times higher than the stacking belt, the current dropping sheet tail will fold to the stacking belt, and it's head will fold to previous dropping sheet's head, so as to avoid the sheets scratching with each other in high speed. The sheets fold with each other and transmit to the stacking box through stacking belt.

4 Some methods of improving sorting accuracy

In order to improve the sorting control accuracy, the following hardware and software methods can be adopted:

1) Because of the time interval between pinhole signal and phototube signal is very short and the signals are easy to be interfered, the system firstly adopts limiting shake filtering method to process these signals, then call corresponding interrupt service program to respond to these signal, so as to improve the sorting system response speed of defected sheets.

2) During the running process, system will real-time regulate the relevant parameters (mainly including delay time parameter *t* and delay distance S_1) according to the running speed and sheets separation distance.

3) In order to ensure all the defected sheets will drop into the inferior stacking table and improve the system accuracy, system adopt the following methods to dispose defect signals:

- Pinhole defect signal: when pinhole defect appears between two sheets, these two sheets will be dropped into the 1# inferior stacking table.

- Thickness gauge signal: Supposing the thickness defect signal appear at T_1 time and disappear at T_2 time, the sheets passing thickness gauge during these time (T_1 to T_2) will all drop into the 1# inferior stacking table, as well as the next three sheets.

5 Conclusions

Sorting control system is an important part of cold rolling shear production line, the system section speed and accuracy is especially worth to be further in-depth studied. The essay, based on the sorting control principle, detailed analyses the realizing method of self-adaption control model in details, mainly including sheets high speed running, sheets real-time accurately tracking, sheets dropping posture accurately control and sheets defect detecting etc. The sorting control model can be applied to the similar industrial production lines.

Abstract

Permanent magnet motors are very important components in commercially available equipments and industrial applications due to high reliability and robust performance, and it is important to take an appropriate and effective approach to diagnose fault for them. The implementation of probabilistic neural network (PNN) with the statistical features for permanent magnet motor is developed in this paper, and the statistical features are determined according to the stator current characteristics of motor to effectively reduce dimensionality of sample space. The experimental results demonstrate that, compared with RBF network, the proposed method is more effective in identifying various types of faults.

Keywords: Permanent Magnet Motor, Probabilistic Neural Network, Statistical Feature

1 Introduction

Nowadays motors are the most extensively applied to all types of industries owing to their high reliability, simple construction and robust design [1]. Especially for permanent magnet motors, they have been used in many modern industrial fields owing to their high efficiency, low weight place and high torque [2]. But they are always exposed to a variety of complex environments and conditions which are accompanied with the natural aging process of any machine, moreover, they are very sensitive to the strict constraints because of the environment of embarked systems, thus causing the motor various failures. In this way, Fault detection of electrical machines has received extensive attentions in recent years. There are many methods to detect mechanical and electrical problems in motors, which include vibration, stator current, magnetic flux density, etc. Direct observation and measurement method is used in detecting traditional motor fault diagnosis, but it is unable to meet the requirements of modern motor manufacturers [3]; Parameter estimation method needs to establish a precise dynamic model of the motor and identify the motor electromagnetic parameters through the model, thus resulting in unclear fault characteristics [4, 5].

Recently BP neural network is developed for fault diagnosis of motors and many electric power systems [6-8]. However, BP neural network has the shortcomings of slow convergence speed and a tendency to the local optimum which have a serious impact on its generalization ability to fault diagnosis [9, 10].

PNN, as a subgroup of Radial Basis Neural Networks, is good suitable for dealing with classification problems, it is based on Parzen's method of density estimation and Bayes' decision strategy. The most important advantage of PNN is the simple structure, training manner and only one free parameter. In PNN, the smoothing factor has to be adjusted by the user and it can be adjusted at run time without the requirement of network retraining. So a significant contribution in this work is that the composition of statistical features is used to train PNN as a novel classifier for the fault diagnosis of permanent magnet motor, and to evaluate performance of the classifier the BP network is compared in term of the classification accuracy and train time.

2 Probabilistic neural network

The PNN was first proposed by Specht [11], it can be considered as a normalized radial basis function network in which there is a hidden unit centred at every training case, the probability density is the scaled sum of the kernel function for all training samples and the Gaussian function is used frequently. For PNN, his most important advantage is that it has a simple structure and only one free pamaerter named as the smoothing factor; one can adjust it without having to consider network retraining at run time. The probability density function is expressed as follows:

$$\hat{f}_j(\vec{x}) = \frac{1}{(2\pi)^{p/2}\sigma^p m_j}\sum_{i=1}^{m_j} exp\left(-\frac{(\vec{x}-\vec{x}_{ij})^T\cdot(\vec{x}-\vec{x}_{ij})}{2\sigma^2}\right), \quad (1)$$

* ***Corresponding author*** e-mail: zwg770123@163.com

where, $\hat{f}_j(\vec{x})$ is the probability of vector $\vec{x}$ occurring in set m_j, $\hat{f}_j$ is the estimated density for the *j*-th class, $\vec{x}$ is test case, $\vec{x}_{ij}$ is *i*-th training sample of the *j*-th class, *p* is dimensionality of $\vec{x}_{ij}$, σ: is the smoothing factor, m_j is number of training cases in the *j*-th class.

PNN is a four-layered feed-forward network topology that implements Bayes' decision criterion, the simple architecture is depicted in Figure 1.

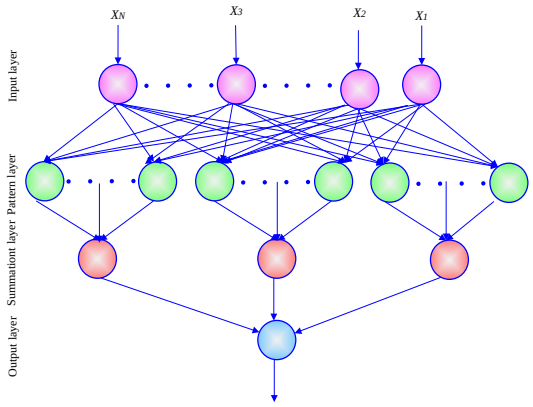

FIGURE 1 Architecture of the PNN

The PNN consists of input layer, pattern layer, summation layer and output layer [12]. The input layer simply distributes the input to the neurons in the pattern layer and does not perform any computation. For the pattern layer, it contains one pattern neuron for each training case, with an exponential activation function, a pattern neuron computes the squared Euclidean distance between a new input vector and the ith training vector of the jth class, the output of the neuron is calculated by the following multiscalar Gaussian function:

$$\hat{f}_j(\vec{x}) = \frac{1}{(2\pi)^{p/2}\sigma^p}\sum_{i=1}^{m_j} exp\left(-\frac{(\vec{x}-\vec{x}_{ij})^T\cdot(\vec{x}-\vec{x}_{ij})}{2\sigma^2}\right). \quad (2)$$

For each class, the summation layer contains a summation neuron, the summation neuron for the first sums the output of the pattern neurons that contain the training cases of the first class, the number of the neurons of the pattern layer is identical to the number of the training samples. The summation neuron for the second class sums the output of the pattern neurons that contain the training cases of the second class, and so on, the activation for each class in the summation neuron is identical to the estimated density function value of this class, the summation layer neurons calculate the maximum likelihood of the pattern vector by using equation (1). Finally, the output neurons of the output layer can obtain the result of the summation neurons. The neurons of the output layers are threshold discriminators that implement Bayes' decision criterion and the output neuron can generate the respective estimated probabilities for the test case, the neuron in the decision layer determines the class belongingness by:

$$l = \arg\min_{1\le k\le c}\{\rho_k\}, \quad (3)$$

where *c* is the number of classes of the training set and *l* is the estimated class.

3 Experimental results

For the permanent magnet motor, the current frequency is very high and the amplitude varies considerably with frequency, and the obtained sample is high-dimensional, it makes many classifiers become very complex and time-consuming in training process. To overcome the above difficulties, one must guarantee that a classifier should have a better classification accuracy with fewer feature dimensionalities.

TABLE 1 Statistical features definition

Feature number	Statistical features	Formula or description
Feature 1	Maximum value	Maximum amplitude value in a given current signal
Feature 2	Minimum value	Minimum amplitude value in a given current signal
Feature 3	Absolute mean value	$\sum_{i=1}^{N}\lvert x_i\rvert / N$
Feature 4	Standard deviation	$\sqrt{\sum_{i=1}^{N}(x_i-\bar{x})^2/(N-1)}$
Feature 5	Median value	Middle amplitude value separating the greater and lesser halves in a given current signal
Feature 6	Range	Difference in maximum and minimum amplitude values in a given current signal

So in order to reduce the dimensionality of the extracted samples and obtain a low-dimensional feature vectors, we need to select an appropriate sample space and implement feature extraction. Feature extraction is regarded as a process of computation of some measures for the signal, a sample set of statistical features namely Maximum, Minimum, Absolute mean value, Standard deviation, Median value and Range, are selected for the study in Table 1. These statistical features are extracted from the current signals correspondding to various faults; Table 2 describes 6 kinds of faults; Figure 2 shows 6 kinds of different current fault signals, and Table 3 shows the statistical features correspondding to Figure 2; Figure 3 shows the scatter diagrams between any two features, it is clear that the relationship characteristics between any faults are expressed, and there not exist any two features which can distinguish all the faults. A total of 240 data sets are used in the training, each of fault consists of 40 training samples, and the trained network is tested with data sets consisting of 40 test samples, in which each of fault contain 10 test samples.

TABLE 2 Fault definition

Fault numbers	Fault description
Fault 1	The rusty spot in the bearing inner and outer rings and ball
Fault 2	Something wrong with the bearing retainer
Fault 3	A greater pitting in the bearing inner ring
Fault 4	Something wrong with the two bearing concentricity
Fault 5	A phase winding short circuit
Fault 6	No fault

The PNN and statistical features are used in fault classification of the permanent magnet motor, the network architecture and the training process are also taken into account, in addition, the performance of network generally depends on the sizes of the training set and test sets. In the developed classifiers for classification, the smoothing factor plays a viral role in the PNN, and an appropriate smoothing factor is often data dependent, meanwhile, the proper choice for the smoothing factor also improves the accuracy of the PNN. If the smoothing factor is too small, individual training patterns will be regarded only in isolation, and we only can obtain a nearest neighbor classifier, but if the smoothing factor is too high, details of the density can be blent together [13]. In general, there is no uniform approach for solving determine the smoothing factor, but we can determine it by minimizing the error, we use different smoothing factors to evaluate the performance of the PNN.

20 different values that range from 0.1 to 2 are adopted in order to better evaluate the performance to train a more accurate model. The estimation results of the PNN for the training samples using the above given values are depicted in Figure 4. It can be seen that the smoothing factor largely has effects on the training accuracy for PNN, and that the value $\sigma = 0.9$ generates the smallest training error.

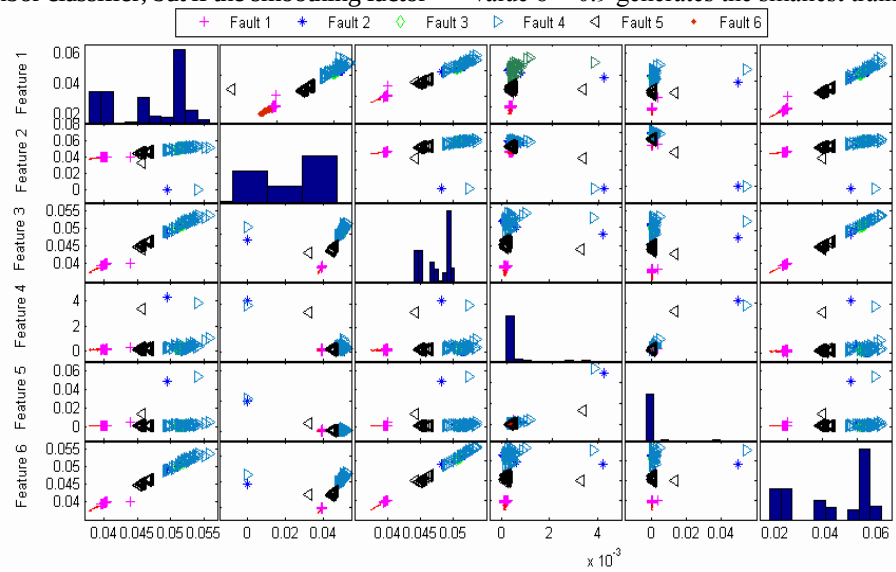

FIGURE 3 Scatter diagram between any two features

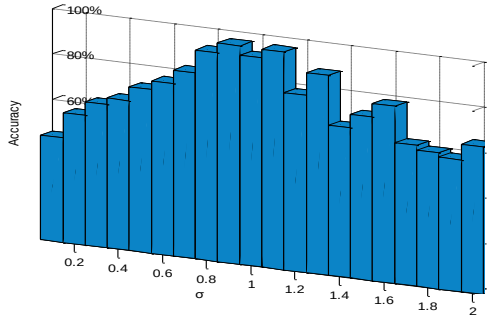

FIGURE 4 Effects of smoothing factor on training error

To compare the performance of the proposed method, the authors also processes RBF neural network for the experiment. The RBF network has three layers, including an input layer, a hidden layer with a nonlinear RBF function for activation and a output layer, the input of the network linearly combines radial basis function with some neuron parameters. For the experiment, the neuron number of the input layer of the RBF network is 6, the neuron number of the hidden layer is self-determining by autonomously increasing other neuron into it, the neuron number of the output layer of the RBF network is 6, and its training parameters are set as follows: the target error is set as 0.001 and the epoch is set as 800, the training process of RBF network is depicted in Figure 5. Then the two trained classifiers are used in testing using 60 testing samples, the comparison results of the between the two classifiers are shown in Table 4, it can be seen that from Table 4, compared with RBF network, the PNN classifier is more timesaving in training and has a higher test accuracy, thus manifesting more robustness, when the representative training samples is enough, a Bayesian optimal classifier must be obtained.

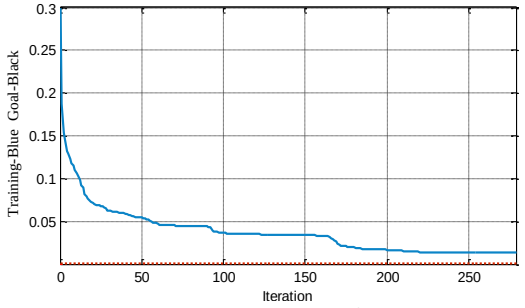

FIGURE 5 Training process of RBF

TABLE 4 Comparison between BP neural network and DDAG-SVM

Method	Training accuracy	Testing accuracy	Training time
PNN	97.62%	95.62%	0.60s
RBF	96.46%	92.08%	17.82s

4 Conclusion

In this study, PNN is used as a robust classifier for diagnosing various faults using the statistical features extracted from the stator current signals of the permanent magnet motor, the extracted statistical features effectively reduce dimensionality of sample space, the comparative experiment shows its the superiority of the performance, and the proposed method in the present work gives a possible application to the monitoring system in industry, which can largely reduce the accidents and ensure the safety of human life.

Abstract

Evaluation for laboratory learning is based on different factors, while each factor is varied by individuals. Hence it is difficult to express the quantitative nonlinear functional relationship among the evaluation indexes. With limited sample, Support Vector Machine (SVM) could be generalized by compromising between model's complexity and learning ability. That is its advantage on the evaluation of small sample, nonlinear and multi-indexes. It is a good try to apply Support Vector Machine (SVM) to laboratory learning evaluation. With Support Vector Machine (SVM), the relationship between the learning quality and evaluation indexes could be revealed. Experiments show that Support Vector Machine (SVM) model is with high prediction accuracy, faster speed and simple algorithm. It is suitable and more reasonable for laboratory learning evaluation.

Keywords: Support Vector Machine (SVM), evaluation model, laboratory learning quality

1 Introduction

Being different from that of classroom teaching, the valuation of laboratory teaching consists of various factors. An objective, comprehensive, impartial and accurate evaluation is significant to the improving of teaching quality, motivating of learning, and even the optimizing of discipline construction. Evaluation on college laboratory learning combines theory with practice. It works under evaluation index system, while the system is guided by educational theories. Educational theories are the summary of educational practice, which reveal the law of education [1]. On the other side, laboratory learning evaluation is based on different factors, while each factor is varied by individuals. Students have to abide the rules and regulations at the laboratory as well as to be innovative and motivate to experiments. It is also a basic quality for the students to keep the laboratory tidy and safe when they are learning. That shows the laboratory learning is interacted with multi-factors, which should be taken into account at the evaluation [2, 3].

Being lack of approximation capability to nonlinear relationship, the use of multiple linear regression and partial least square method is restricted. As a new technology with the features of nonlinear mapping, learning classifying and real-time optimizing, artificial neural nets (ANN) opened a new way on pattern recognition, nonlinear classification and artificial intelligence. It also has been applied a certain into educational evaluation. However, the features of large calculation, continually local extremum, and low generalization impact the application of ANN [4]. SVM is a new machine learning method based on statistical learning theory. Its topological structure depends on support vector. Differs from that of ANN depended on designer's experience, it solve Ann's problem of high dimension, local minimum and small sample. It covers the advantages of neural network and gray-scale model. After revealing the relationship between the laboratory learning quality and influence factors by learning the existed sample, an accurate and objective evaluation on a specific laboratory learning could be realized by SVM.

Laboratory learning evaluation is essentially a classification by some decision-making mechanism and parameters. To the limited sample, SVM could be generalized by compromising between model's complexity and learning ability. That is its advantage on classification. SVM also overcomes the shortcomings of multi-layer feedforward neural network. It specially aims at the limited samples, not only for an optimal solution of infinite samples, but for the one of the current existed samples. It becomes a quadric form algorithm of optimization finally, which theoretically could achieve a global optimal solution. By the nonlinear transformation, SVM transfers the issue to a high dimensional feature space, and realizes the original nonlinear classification by constructing a linear classification function in the space. That ensures the category is with the ability of generalization, solves the curse of dimensionality and reduces the impact to the speed. To the classification, multi-layer feedforward neural network could realize the nonlinear classification, but the classifier would not be the best. SVM based on statistical theory ensures the optimality of classification theoretically, while the generalization ability of algorithm is further ensured [5]. On the other side, the laboratory learning evaluation is a typical multi-class problem. It is feasible to apply SVM to construct a multi-class model for the evaluation.

2 SVM

SVM (Support Vector Machine) is a pattern recognition proposed by Vapnik et al in 1995. It is good at solving the problem of small sample, nonlinear and high dimensional machine learning. Its basic idea is: to form an optimal hyper-plane at sample space or feature space to get a max distance between the hyper-plane and the sample sets, so that to gain the maximum generalization ability [6].

2.1 FUNDAMENTAL THEORY OF SVM

SVM is the youngest and most important part of statistical learning theory. It becomes a conventional tool on machine learning as it matures theoretically and practically. So far, it is on the highest performance on application to the text and image classifications of pattern recognition [7].

SVM realizes the following thought: it maps the input vector X to a high dimensional feature space by a nonlinear mapping selected in advance. An optimal classification hyper-plane is formed in the feature space. In order to get an optimal classification hyper-plane in the feature space Z, the display format of Z is not taken into consider, only the calculation of inner product of vectors of SVM and the feature space is needed.

According to functional theories, when kernel function $K(x_i,x_j)$ satisfies Mercer condition, an inner product in a transformation space is corresponded. The basic thought of nonlinear SV is mapping the input vector x_i to a high dimensional Hilbert space (feature space) by a nonlinear mapping selected in advance. An optimal classification hyper-plane is formed in the feature space. The inner product between any two points in the space could be reflected by the kernel function, which is corresponded to the input vectors in the original space.

Different inner product kernel functions of SVM form different classifiers. Here are the major 3 kernel functions.

Firstly, polynomial kernel function. See Equation (1).

$$K(x, x_i) = [(x, x_i) + 1]^p . \tag{1}$$

Secondly, radial basis function (RBF), namely Gaussian kernel function. See Equation (2).

$$K(x, x_i) = \exp\left(-\frac{\|x - x_i\|^2}{2\delta^2} \right). \tag{2}$$

The significant distinction between RBF classifier and traditional classifier is: the centre of each primary function corresponds to an SV, and its output weight is automatically determined by algorithm. RBF is the most effective kernel function so far.

Thirdly, sigmoid function. See Equation (3).

$$K(x, x_i) = \tanh\left[k(x \bullet x_i) - \delta \right]^q . \tag{3}$$

In this case, SVM acts as a multilayer perception with an implicit strata. The hidden node is automatically determined by algorithm. Moreover, in the algorithm, there is no local minimum, which perplexes neural network [8].

2.2 SVM SORTING ALGORITHM

At present, 3 methods have been proposed to solve SVM multiclass classification problem. They are: One-Against-Others, One-Against-One and Decision Directed Acyclic Graph (DDAG) [9].

2.2.1 One-Against-Others

It was proposed by Vapnik in 1998. The basic thought is: to construct several two-class classifiers and combined them together to accomplish the multi-class classification. Each classifier separates one class from the others, and infers the affiliation of an input *x*. It constructs k SVM two-class sub-classifiers for class k. The i^{th} SVM adopts training samples in the i^{th} class as the positive training samples, while adopting the others as negative ones. The unclassified samples are classified to the class with maximum classification function. Disadvantages: Firstly, every SVM classifier takes all the samples as training samples. When the quantity is large, the training time is long. Secondly, the two-class problems are asymmetric, which means the number of two-class samples are imbalanced.

2.2.2 One-Against-One

It was proposed by Knerr. It constructs all the possible k(k-l)/2 two-class classifiers in the training samples of class k. Each two-class classifier separates class *i* and class j by a simple classification rule. There is many two-class problems in it, so more classifiers are needed than that of One-Against-Others. However, the scale of each problem is much less than that of One-Against-Others. So the training speed is faster. But if k is too large, sub-classifiers will be more and the training speed would slow down.

2.2.3 Decision Directed Acyclic Graph

It was proposed by Platt etc. It is the same with One-Against-One at the training phase. But at the decision phase, DAG started from root node is used. Every internal node is a two-class classifier, and the leaf node is the final class. DDAG is faster at decision than that of One-Against-Others and One-Against-One. However, the result of classification is uncertain. Different classifier as the root node may lead to different classification result.

3 Laboratory learning evaluation model based on SVM

The evaluation includes the aspects of knowledge application, thinking innovation, experiment operation and safety, and experimental attitude. Knowledge application means students' ability of learning, principle theory grasping and practical application. Thinking innovation means innovation consciousness, independently thinking, cooperation,

and exploring to solve problems. Experiment operation and safety means safety awareness, and sanity habit. Experimental attitude means initiative, responsibility, being truthful and practical, and spirit of teamwork [10].

3.1 EVALUATION INDEX SYSTEM OF LABORATORY LEARNING

The students in the laboratory class of Basis of Database at Chongqing Three Gorges University were taken as the sample. Each sample has 7 indexes. Evaluation on knowledge application is based on the experiments and lab reports of database *x1*, form *x2* and programming *x3*. *x4*, the evaluation on thinking innovation is based on comprehensive assessment on the experiment and lab report. *x5*, the one on experiment operation and safety is based on the average value of ordinary checks. *x6*, the one on experimental attitude is based on the comprehensive assessment to the experimental discussion and optional experiments. What's more, a network learning system has been founded to record students' network learning. The average value *x7* based on each online testing is taken as the other index.

According to the above index system, 100 samples in a grade were taken as the dataset of training and testing. The evaluation result was classified into 5 ranks: excellent (identified as 1), good (identified as 2), middle (identified as 3), pass (identified as 4) and failed (identified as 5). Each sample was composed by 7 inputs and 1 target output. To group the data into two, each group randomly consisted of data from all the 5 ranks. The first group with 60 samples was training dataset. The second one with 40 samples was testing dataset. The visualization figure of training data is showed as Figure 1. Its abscissa axis is student's number, the vertical axis is the classification result. Please see Figure 1.

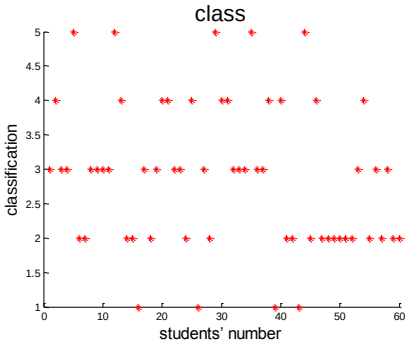

FIGURE 1 Classification of training samples

3.2 NORMALIZATION OF INPUT SAMPLES

It is important to normalize data before adopting SVM, which could eliminate the influence of dimension. Firstly, according to the features of the index data, the big index would weaken the influence of small index to the model if it is not normalized. Secondly, SVM needs to calculate inner product kernel function of sample point. Without normalization, the overlarge value will cause trouble on calculation. In order to reduce the complexity of calculation and shorten the time of training, every data was normalized to [0, 1].

There are many methods of normalization. The frequently-used are MinMax and Exponential Function. MinMax is a linear transformation, by which the original sense of the data could be preferably remained with fewer information loss after normalization. Hence MinMax was adopted to normalize the input samples to [0,1], which is showed as the following. See Equation (4).

$$x_t^{'} = \begin{cases} \dfrac{x_i - \min}{\max - \min}, & if \quad \min < x_i < \max \\ 0, & if \quad x_i < \min \\ 1, & if \quad x_i \geq \max \end{cases} . \tag{4}$$

The original data of evaluation on laboratory learning is showed as Table 1. Please see Table 1.

3.3 DESIGN OF MULTI-CLASSIFIED SVM EVALUATION MODEL

The SVM-based laboratory learning evaluation is the classification of learning quality by the pattern classification of SVM.

The evaluation data is formed by the data of 5 ranks, so it is multi-classified. Because the classification patterns are not so many, so One-Against-One was selected. k(k-l)/2 SVM classifiers were constructed to the data of class K. Each classifier only classified two class. This model is simple and has well ability on classification. The well performed RBF kernal was adopted as SVM kernel function.

Two parameters have to be determined in SVM training process: penalty parameter C for mistaken classification, and RBF kernel control parameter. In order to reduce human influence, meanwhile the real-time requirement is not strict in the evaluation system, cross-validation was adopted to search for optimal parameter. It helped the system to be with some adaptivity. The working process of the system is showed on Figure 2. Please see Figure 2.

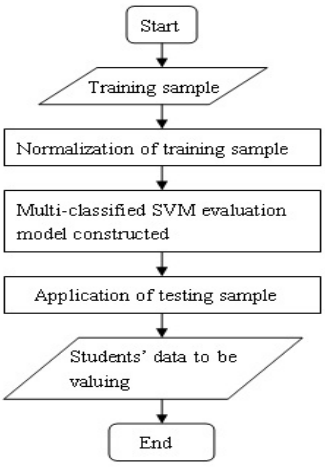

FIGURE 2 Process of evaluation system

4 Experimental result and analysis

The experimental result is showed on Figure 3. In the laboratory learning evaluation of the 40 students, only 6 are not fit the real one. The other 34 are in accordance to the reality. The accordance rate is 85%. It proves that the trained multi-classified SVM evaluation model could simulate teacher's evaluation thought. It could analysis the evaluation data rapidly and reduce the randomness of human evaluation from different teachers, which helps to rank the students more objectively and precisely. Please see Figure 3.

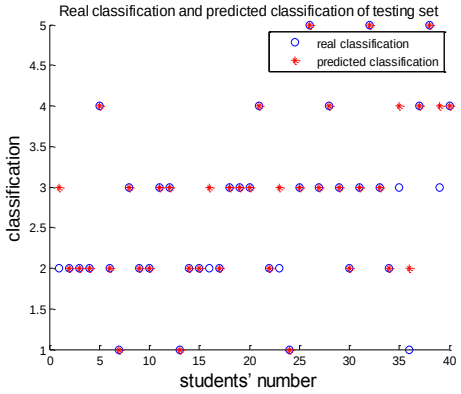

FIGURE 3 Real classification and predicted classification of testing set

5 Conclusions

Because it is difficult to show the quantitative nonlinear functional relationship among the evaluation indexes, the final evaluation rating is usually subjective and one-side. The founding of laboratory learning evaluation system makes the evaluation more logically and reasonably. SVM learning model, with the ability of approximating any nonlinear relationship between input and output, could seek out the relationship between learning quality and the evaluation indexes by learning the given sample. Experiment shows that SVM model is with high prediction accuracy, faster speed and simple algorithm. It is suitable to the laboratory learning evaluation. It is theoretically and practically significant to the development of laboratory teaching.

Abstract

The infeasible solutions are often generated in population as evolutionary computation solving the combinatorial optimization problems. The number of infeasible solutions impacts the performance of the evolutionary computation searching the optimal solution, in the worst case the algorithm ceases to run. In genetic algorithms, encoding of infeasible solutions is referred to as lethal chromosomes. In this study, we discover a property of lethal chromosomes that: although lethal chromosomes carry out the infeasible solutions in genetic algorithms, their statistical property implies an underlying similarity with the exact solution of the optimization problems. Hereby we propose an operation using statistical property of lethal chromosomes to handle with the lethal chromosomes themselves. Simulation experiments on a large number of test cases demonstrated that it can improves obviously the performance of genetic algorithms to use the statistical property of lethal chromosomes.

Keywords: Genetic Algorithm, Infeasible Solution, Lethal Chromosome, Evolutionary Computation.

1 Introduction

With representing the solution of problem as a chromosome, genetic algorithm (GA) refers the chromosomes that violate the constraint conditions to as lethal chromosomes (LCs). In the population of GA, due to crossover and mutation operations, LCs are often generated with high rates. The greater number of LCs in the population, the worse search performance of the GA.

Early, Iima Hitoshi (1995) investigated the effects of LCs on the performance of the GA, but did not propose a method for handling these problems [1]. Mengchun Xie (1996) proposed an algorithm model to revive the LCs by random crossover and mutation operations [2]. In recent years, researches focusing on the problems associated with infeasible solutions have made some progress. Lyndon While et al. (2009-2013) have been made some achievements on problems associated with infeasible solutions in evolutionary computation [3-7].

In this paper, we propose genetic algorithm on multidimensional knapsack problem (MDKP) that handles the LCs with a reviving operation (RGA). Specifically, we (2009) previously proposed another genetic algorithm using lethal chromosomes on multi-knapsacks problems [8]. But regrettably, we mistakenly referred the multi-knapsacks problems to as multidimensional knapsack problem in [8]. This paper is really to solve the multidimensional knapsack problem, and the reviving operation is totally different.

2 A genetic algorithm using LCs on MDKP

As an NP-hard problem, MDKP is to find a subset of objects that maximizes the total profit while satisfying some resource constraints, which can be formulated as:

$$Maximize \quad \sum_{j=1}^{n} v_j x_j \,, \tag{1}$$

$$s.t. \quad \sum_{j=1}^{n} w_{ij} x_j \le c_i \quad \forall i \in I \,, \tag{2}$$
$$x_j \in \{0,1\} \quad \forall j \in J,$$

where n is the number of objects, m is the number of resources, v_j is the value associated with object j, w_{ij} is the consumption of resource i for object j, c_i is the available quantity of resource i (capacity of knapsacks for the i^{th} resource), and x_j is the decision variable with object j and is set to 1 if j^{th} object is selected (and is otherwise set to 0). $I = \{1, 2, \ldots, m\}$, $J = \{1, 2, \ldots, n\}$.

To solve the MDKP, many researchers consider the GA or other evolutional algorithm. P.C. Chu (1998) presented a GA for MDKP with a repair operator [9]. Günther R. Raidl (1999) proposed a weight-coding in GA for MDKP [10]. Günther R. Raidl (1998) presented an improved hybrid GA for MDKP [11]. Jens Gottlieb (2000) solved the MDKP with a permutation-based GA [12].

2.1 ALGORITHM STRUCTURE

Our RGA has two types of chromosome pools, namely, the *living island* and *lethal island*. The former contains chromosomes, referred to as non-lethal (feasible) chromosomes, which satisfy all constraints. The latter consists of the LCs. In the living island, chromosomes are evolved by genetic operations, and in the lethal island, LCs are revived by reviving operations. This structure is described as following way.

```
1  while initializing population do
2  |  Generate initial population, and then move the
   |  non-lethal chromosomes into the living island, the
   |  lethal chromosomes into the lethal island;
3  end
4  while evolving process do
5  |  for living island do
6  |  |  All of the chromosomes in the living island
   |  |  evolve into the next generation by genetic
   |  |  operations, and the new lethal chromosomes
   |  |  move to lethal island. In this process, the
   |  |  vaccine must be trained;
7  |  end
8  |  for lethal island do
9  |  |  Each chromosome in the lethal island is handled
   |  |  by reviving operations and is then moved to the
   |  |  living island;
10 |  end
11 end
12 Repeat the evolving process until meeting the
   termination conditions of the GA;
```

ALGORITHM 1 Algorithm structure of RGA

We use roulette as selection operation, two-point crossover and mutation rates of 0.05 in genetic operations. Next, we mainly focus on reviving operation, which is performed in *lethal island*.

2.2 REVIVING OPERATION

Idea of the reviving operation is introduced from immune system of biology and medicine. As FIGURE 1, the previous infection led the system to generate the immune memory; the system handles the re-infection with previous memory for avoiding from being infected again.

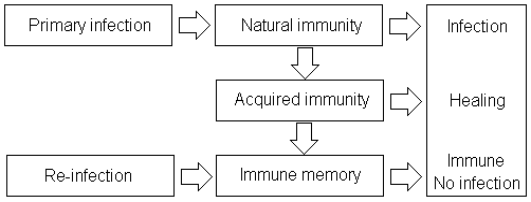

FIGURE 1 Immune system

In this context, we record the statistical information of previous LCs as immune memory, and then handle the succeeding LCs by previous memory. The operation to handle the LCs is called reviving operation in this paper.

As an immune memory, a multi-valued string schema $s_1s_2...s_n$ is constructed and has the initial value that $s_j = 0$, $\forall j \in J$. The $s_1s_2...s_n$ will be used as *immune memory* by reviving operation, so we call it *vaccine*. During the RGA evolving, while every LC referred as $x_1x_2...x_n$ generated, to perform the ALGORITHM 2 flushing the vaccine $s_1s_2...s_n$.

```
   Input: a lethal chromosome x_1 x_2 ... x_n
   Output: flushed vaccine s_1 s_2 ... s_n
1  for (j = 1 to n) do
2  |  if (x_j = 1) then
3  |  |  s_j ← s_j + 1;
4  |  end
5  end
```

ALGORITHM 2 Training the vaccine with lethal chromosomes

By this way the $s_1s_2...s_n$ is a changing string, which is refurbished by every lethal chromosome while evolution of population as long as LCs appearing. As LCs generated are handled by reviving operation in every generation, while the vaccine is refurbished by LCs while the vaccine is used by reviving operation in RGA.

In order to achieve an efficient implementation of the reviving operation, a pre-processing routine is applied to vaccine $s_1s_2...s_n$ that sorts and renumbers genes of LC according to the *increasing* order of s_j's. Assuming $x_1x_2...x_n$ with pre-processing routine is the LC to be revived, proposed reviving operation is described by pseudo-code as following.

```
   Input: a lethal chromosome
   Output: a revived chromosome
1  Let W_i = Σ_{j=1}^{n} w_ij x_j, ∀i ∈ I;
2  for (j = 1 to n) do
3  |  if (x_j = 1) and (W_i > c_i, ∀i ∈ I) then
4  |  |  x_j ← 0;
5  |  |  W_i ← W_i − w_ij, ∀i ∈ I;
6  |  end
7  end
8  for (j = n to 1) do
9  |  if (x_j = 0) and (W_i + w_ij ≤ c_i, ∀i ∈ I) then
10 |  |  x_j ← 1;
11 |  |  W_i ← W_i + w_ij, ∀i ∈ I;
12 |  end
13 end
```

ALGORITHM 3 Reviving operation

3 Computational experiments

A set of standard test data of the MDKP was referred and used by P.C. Chu [9], Günther R. Raidl [10, 11], and Jens Gottlieb [12]. These test data contain 10 instances for each combination of $m \in \{5, 10, 30\}$, $n \in \{100, 250, 500\}$, and $\alpha \in \{0.25, 0.50, 0.75\}$, where $\alpha = c_i / \Sigma_{j=1}^{n} w_{ij}$ being the tightness ratio of instance. Since the exact solution values for most of these problems are unknown, the quality of a solution is measured by the percentage gap of the objective value *fitns* with respecting to the optimal value of the LP-relaxed problem f^{LP}_{max}: $\%\text{-}gap = 100 \times (f^{LP}_{max} - fitns) / f^{LP}_{max}$. The proposed RGA is tested on these 270 MDKP instances and the mean results are shown in TABLE 1.

TABLE 1 Computational results of other algorithms and RGA

Problems	**Average *%-gap***					
All of 270 instances	GA with H1	GA with H2	Swap	Insert	Improved GA	RGA (proposed)
Average	0.589	0.646	0.641	0.629	1.13 - 0.53	0.5472

We also list the available results of other references in TABLE 1 to compare with. The first columns indicate test is on the 270 instances. The next columns in turn report the other results of average *%-gap*. That are *GA with H1* and *GA with H2* proposed by Günther R. Raidl [10], *Swap* and *Insert* are from Jens Gottlieb [12], and the *Improved GA* reported by also Günther R. Raidl [11] for *%-gap* obtained from initial population to $(10^6)^{th}$ generations. The last column reports the results of RGA with the computer condition that CPU is Celeron 1.0 and the algorithms were coded in Visual C++.net (2003).

To analyse the test results, above all we discuss the condition of experiment. The *GA with H1* and the *GA with H2* was tested with population size of 100 and 10^5 solutions had been evaluated. *Swap* and *Insert* had evaluated 10^6 non-duplicate solutions and then get results. *Improved GA* recorded the best solution from initial population to $(10^6)^{th}$ generations. Comparing with them, RGA obtain the results with population size of 50 and running terminates at $(10^4)^{th}$ generation.

Averagely for all instances, RGA obtained the *%-gap* as 0.5472, which is smaller than the results from the algorithm *GA with H1*, *GA with H2*, *swap* and *Insert*, but except the *Improved GA*. *Improved GA* of Günther R. Raidl [11] obtained the best average *%-gap* as 0.534 at $(10^6)^{th}$ generation, it is very great. Because such an experiments to 10^6 generations will cost too CPU seconds to finish for us, we test the RGA only for 10^4 generations and obtained the finial average *%-gap* as 0.5472 with population size 50. Relatively, the population size Günther R. Raidl adopted in *Improved GA* is 100. To compare with *Improved GA* at same generations, we calculated the average *%-gap* obtained also at $(10^4)^{th}$ generation for *Improved GA* according to data in Refs. [11], the result is 0.6211 which greater than 0.5472 despite of large population size 100.

4 Discussion on feature of LCs

To analyse the feature of LCs, we firstly give a definition of *similarity ratio* between two chromosomes. To any two chromosomes X_1 ($x_1^1 x_2^1 \ldots x_n^1$) and X_2 ($x_1^2 x_2^2 \ldots x_n^2$), the *similarity ratio* of them is defined by:

$$similarity\ ratio(X_1, X_2) = 100\frac{1}{n}\sum_{j=1}^{n}(x_j^1 \odot x_j^2), \qquad (3)$$

where, if $x_j^1 = x_j^2$, then $x_j^1 \odot x_j^2 = 1$; otherwise $x_j^1 \odot x_j^2 = 0$. Actually, the *similarity ratio* is used to measure how many the two chromosomes have same value genes.

In order to study feature the vaccine contained, it is hypothesis that at a certain generation $s_1 s_2 \ldots s_n$ is processed to a binary-value string $s'_1 s'_2 \ldots s'_n$ by the way that: for $\forall j \in J$, if ($s_j > t$) then $s'_j \leftarrow 1$, otherwise $s'_j \leftarrow 0$, where t is the threshold be used to classify the s_j's into one or zero, the t is determined as an appropriate value so that it takes the max *similarity ratio* for $s'_1 s'_2 \ldots s'_n$ and *exact chromosome* (*exact solution*) of the problem. Here it is assume that the exact chromosome is known beforehand. We consider the value of *similarity ratio* of $s'_1 s'_2 \ldots s'_n$ and exact chromosome as *feature of vaccine*.

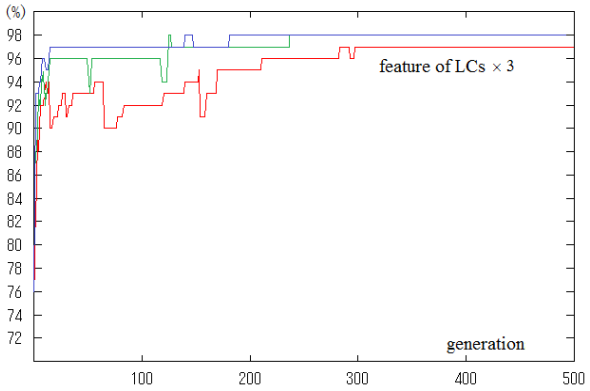

FIGURE 2 Feature of LCs ["feature of LCs" (×3).]

To three MDKP instances picked from OR-library [9] that $m = 5$, $n = 100$, we firstly solve their exact chromosomes with branch and bound method (BBM) to measure the *feature* of vaccine. Their curves of *feature of vaccine* in RGA are shown as FIGURE 2.

We could learn from FIGURE 2 that (i) the *features of vaccine* are increase in the overall; (ii) the *features of vaccine* rise to a high degree at later generation that some to 97 % and some to 98 %. That also means most of genes of exact chromosome could be indicated the value via to classifying the corresponding *bit* of vaccine with a threshold *t*.

5 Conclusions and future research

The paper discovered an important feature of lethal chromosomes, and proposed RGA to use this feature of lethal chromosomes based on reviving operation. Appling RGA to MDKP, a large number of testing results indicate that using lethal chromosomes based on reviving operation could obviously improve search performance of GA. At same time there are also some works should to be done to improve the performances of RGA deeply.

In addition to the method of reviving operations should be researched further in the future, researches should focus on not only lethal chromosomes, but also to excavate the more evolutional resource in infeasible solution regions. On the other hand, if the proposed reviving operations are improved to decrease the time complexity and allow rapider operation, the GA will be applicable to a wider range of field.

Abstract

Aiming at the mechanism model are influenced by multiple random factors, this paper establishes canopy temperature models based on BP network and RBF network respectively. The models take the temperature, humidity, illumination, soil temperature and ditch depth in the closed greenhouse as input neurons and takes canopy temperature as the output neuron. The results show that both models can well predict ditch-cultivated crop canopy temperature. The mean error between the simulation value and measured value of BP network model is 0.8408℃, and root-mean-square error of 0.5789℃. Actual output and expected output of RBF network model differ little, mean error of 0.2236℃ and root-mean-square error of 0.3496℃. In contrast, RBF network model can more accurately predict crop canopy temperature of ditch-cultivated than BP network model.

Keywords: Ditch-cultivated, Canopy Temperature Model, Artificial Neural Network

1 Introduction

Crop canopy is important space for crops' photosynthesis and transpiration. The change in canopy temperature is influenced by growing environment of crops. It is significant basis to measure water status of crops and provides necessary data support for irrigation control and greenhouse management [1, 2]. So, study on the relationship between crop canopy temperature and each environmental factor and establishment of canopy temperature model are of great significance.

Currently, both Chinese and foreign experts establish multiple simulation models for plant canopy temperature focus on field [3, 4], multi-span greenhouse and Venlo greenhouse [2, 5-8] and study effects of plant canopy temperature under different environments on water status and plant growth conditions. Modeling approach for existing plant canopy temperature is mechanism method, i.e. energy balance method with environmental data as variables and multiple regression equation method. Microenvironment of ditch-cultivated in closed greenhouse is more complex than common greenhouse, and also influenced by multiple random factors. Besides, it is difficult to confirm soil parameters. Thus, modeling with mechanism method greatly influences prediction accuracy of ditch-cultivated crop canopy temperature. ANN has the self-learning ability to simulate human thinking and can realize self-adjustment according to environmental changes. In addition, it owns nonlinear adaptation information processing capability and very strong fault-tolerant capability and can overcome errors caused by parameter selection in mechanism method. ANN expresses dynamic modeling of complex environment through limited parameters and is thus applied widely in information processing, intelligent control and production. In addition, it opens up a new research approach for establishing crop canopy temperature model.

This paper takes potted Chinese cabbage under ditch-cultivated mode in closed greenhouse and adopts BP network and RBF network to establish crop canopy temperature models, respectively. Temperature, humidity, illumination, soil temperature and ditch depth in the closed greenhouse serve as the input of the network and crop canopy temperature in the ditch serve as the output of the network. Then, the relationship between crop canopy temperature under ditch cultivation environment and environmental factors is analysed to provide theoretical support for further optimizing structural design and optimum greenhouse control of ditch cultivation method and analysing plant irrigation and water status.

2 Introduction of artificial neural network

ANN was first put forward by Warren S McCulloch and Water H Pitts in 1943 and owns such advantages as parallel processing, distributed storage, self-learning and associative

* ***Corresponding author*** e-mail:Gdwang211@yahoo.com.cn

memory. It develops on the basis of multiple disciplines including biology, cognitive science, modern neurosciences and computer science and reflects fundamental characterristics of functions of human brain. It is widely applied and developed in artificial intellectual control and optimization, pattern recognition and graphic processing, prediction and intelligent information management, communication and complex system modeling.

2.1 NEURON MODEL

ANN is formed through widely interlinking large quantities of neurons and used to simulate the structure and functions of brain nervous system. Neuron as a basic unit of neural network abstracts and simulates biological neurons. Figure 1 shows a simplified neuron model. It is a nonlinear component with multi-input and single output.

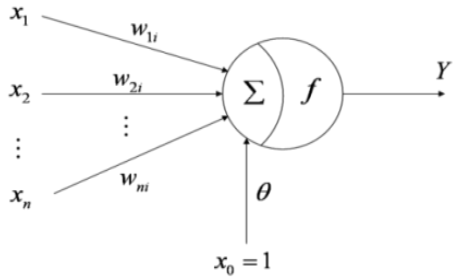

FIGURE 1 The model structure of single neuron

Its input-output relationship can be described as:

$$I_i = \sum_{j=1}^{n} w_{ji} x_j - \theta_i , \tag{1}$$

$$Y = f(I_i) , \tag{2}$$

where, w_{ji} is connection weight from cells j to cells i (for excited state, w_{ji} takes positive value; for inhibitory state, w_{ji} takes negative value); x_j refers to input signal from other cells $(j = 1, 2, \cdots\cdots, n)$; θ_i is the threshold value of neuron unit; n means the number of input signals; Y refers to neuron output; $f(.)$ is a transfer function. The transfer function can be a linear function, but it is usually the nonlinear function like the step function or *S* curve.

ANN explores human image thinking. It simplifies knowledge expression. After network structure is confirmed, ANN can carry out self-learning and self-correction of deviation according to sample data and imply "summarizing rules" gained through self-learning in weight matrix.

2.2 BP NEURAL NETWORK

Back-Propagation model is an error back propagation learning algorithm used for multilayer feed-forward neural network and was proposed by Rumelhart, Hinton and Williams in 1986. BP network contains input layer and output layer as well as one-layer or multi-layer hidden layers. Its structure is shown in Figure 2:

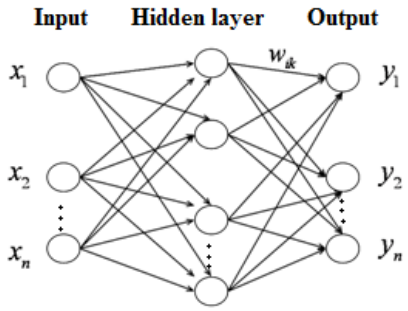

FIGURE 2 The structure of BP networks

When information is inputted in the network, the information is first transmitted to the hidden layer through the input layer, and then transmitted to the next hidden layer after the conversion by the transfer function until information is transmitted to the output layer to output. The information will go through the conversion by the transfer function whenever it passed one layer. The transfer function of BP network should be differentiable anywhere. Usually, *S* function is adopted. For example:

$$f(x) = \frac{1}{(1+e^{-x})} . \tag{3}$$

BP learning algorithm is a learning algorithm with the tutor. It adjusts network connection weight through the deviation between actual output and expected output of the network so that the network can gain expected output for any input. BP learning algorithm trains the network with a group of training samples. Each sample contains input and expected output. During the training, firstly, input information in the training samples is transmitted into the network; the network conducts calculation from the first hidden layer and transfers the calculation result to the next layer until the result is transmitted to the output layer. Every layer of neuron only influences the state of the next layer of neuron. If expected output is not gained in the output layer, calculate the error between the output value of the network and the expected output of the sample; then the network returns the error signal along the original connection passage layer by layer and adjusts connection weight of the nodes in each layer so as to gradually reduce the error until the error meets requirements.

BP network is composed of forward transfer of information and back propagation of the error. Forward transfer is used to calculate network and solve the output for an input. Back propagation is used to transmit the error layer by layer and modify the connection weight so that the network can calculate correctly. Once the network is used to solve practical problems after the training, only forward propagation is needed, without the need of back propagation.

2.3 RBF NEURAL NETWORK

Radial Basis Function is composed of input layer, hidden layer and output layer. Its structure is shown in Figure 3. The nodes in the input layer transmit input signal to the hidden

layer. The nodes in the hidden layer are composed of radial functions like Gaussian function. The basis function in the nodes in the hidden layer influence input signal partially and have local approximation capability. When the input signal approaches the central scope of the basis function, nodes in the hidden layer will generate large output. The nodes in the output layer usually adopt linear function.

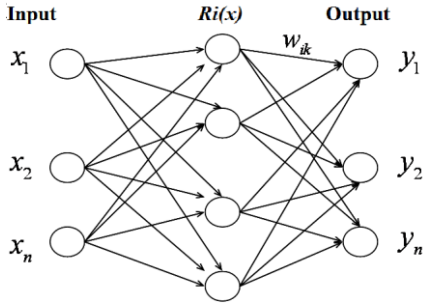

FIGURE 3 The structure of RBF networks

Common basis function in RBF neural network is Gaussian function:

$$R_i(x) = \exp[-\frac{\|x - c_i\|^2}{2\delta_i^2}] \quad i = 1, 2, ..., m, \tag{4}$$

where, c_i is the centre of the i^{th} basis function; δ_i refers to the variable of the i^{th} perception which decides the width of the basis function embracing the central point; $\|x - c_i\|$ is the norm of vector quantity $x - c_i$ and expresses the distance between x and c_i.

RBF neural network mainly adopts stochastic algorithm and self-organizing learning algorithm to select network centre. The two learning algorithms cannot be used for online learning in dynamic input mode. The foundation of valid algorithm is that all possible sample data must be gained in advance. Thus, they are only applicable to offline learning in static mode. Beside, the number of neurons in the hidden layer of RBF network based on above two learning algorithms should be confirmed artificially. Since it is necessary to consider the number of neurons in the hidden layer and a suitable norm, the difficult in solving problems increases.

Zhu Mingxing and Zhang Delong come up with RBF network model based on nearest neighbor-clustering learning algorithm. Nearest neighbor clustering learning algorithm is an online self-adaptation clustering learning algorithm. It is unnecessary to confirm the number of neurons in the hidden layer in advance. RBF network through clustering is optimal. Besides, the algorithm can be used for online learning [9].

According to nearest neighbour clustering learning algorithm, the output of RBF network should be:

$$f(x^k) = \frac{\sum_{i=1}^{M} w_i \exp(-\frac{|x^k - c_i|^2}{r^2})}{\sum_{i=1}^{M} \exp(-\frac{|x^k - c_i|^2}{r^2})}. \tag{5}$$

The radius r decides complexity of dynamic self-adaptation RBF network. If r is smaller, the number of clusters gained is more; the calculation amount is larger; the precision is higher. If r is larger, the number of clusters gained is less; the calculation amount is smaller; the precision is lower. Since r is a one-dimensional parameter, an appropriate r can be usually found through experiments and error information. It is much more convenient than confirming the number of hidden units and a suitable norm. Since each pair of input-output data may generate a new cluster, such dynamic self-adaptation RBF network actually carries out adaptive adjustment of the parameter and structure simultaneously.

3 Brief introduction to basic information

The experiment is conducted in a closed greenhouse in water-saving irrigation experiment station (east longitude 108°04'; northern latitude 34°17'; elevation 506m) of key laboratory of agricultural water-soil engineering in arid region of Northwest A&F University in Yangling, Shaanxi. The closed greenhouse is 3m wide and 12m long. The height of the ridge is 2.5m. It is covered by white polyethylene film. The tested cultivar is Chinese cabbage, which is cultivated with substrate. Substrate moisture in the pot is adequate during seeding. In the growing process, supplement water 2 times of water consumption caused by transpiration at the interval of 2 days.

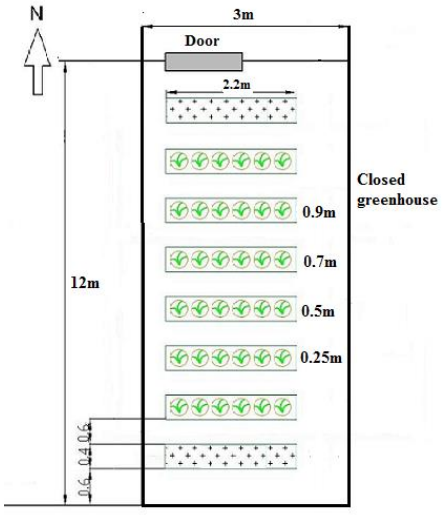

FIGURE 4 Layout of experience

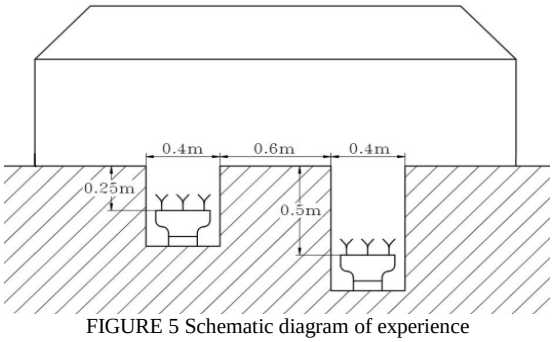

FIGURE 5 Schematic diagram of experience

Multiple rows of ditches with different depth are excavated along the east-west direction in the closed greenhouse. The length and width of each ditch are 2.2m and 0.4m respectively, at the interval of 0.6m, as shown in Figure 4 and Figure 5. Substance surface of the pot is placed in the ditches with the depth of 0.25m, 0.5m, 0.7m and 0.9m respectively. Repeat 5 times for each ditch. To prevent effects of ditch wall desquamation and soil moisture on air humidity, the plastic film is covered on the ditch wall and the bottom of the ditch.

Temperature and humidity in the greenhouse are collected with temperature and humidity collector. The probe is hung at 0.5m in the greenhouse. TES1339 professional illuminometer is used to measure the illumination. Intelligent agriculture controller is adapted to measure soil temperature. The sensor is buried underground at 0.25m in the ditch. The data are stored at the interval of 10min. The data measured at 7:00~20:00 on July 8-13, 2013 are selected as model training and verification data. The main measurement items and test instruments are shown in Table 1.

TABLE 1 List of experimental apparatus

Measurement items	Measuring instrument	Technical parameter
Temperature	Temperature and humidity collector	Measuring range: -30~70℃; Measuring accuracy: 0.01℃
Humidity	Temperature and humidity collector	Measuring range: 0~99.9; Measuring accuracy: 0.1
Illumination	TES 1339 Professional illuminometer	Measuring range: 0.1lux~200000lux; Measuring accuracy: 0.1lux
Soil Temperature	Temperature collector	Measuring range: -40~80℃; Measuring accuracy: 0.2℃
Depth Ditch	Meter	Measuring range: 0~2m; Measuring accuracy: 0.001m

4 Crop canopy temperature model based on ANN

According to the analysis of canopy temperature transmission mechanism, the temperature, humidity, soil temperature and illumination in the greenhouse as well as ditch depth and their change rate have certain mapping relation with crop canopy temperature in the greenhouse. The change of any parameter can impose direct influences on crop canopy temperature in the greenhouse. So, this model predicts crop canopy temperature through monitoring changes in the temperature, humidity, illumination, and soil temperature and ditch depth on July 8-13, 2013. Since the experiment mainly considers effects of high-temperature environment in the closed temperature on ditch-cultivated crop canopy temperature, the data at 7:00～20:00 on each measuring day are selected. 200 groups of data are gained after abnormal data and repeated data are eliminated. The data are divided into 2 sample sets. 170 groups of data as training sample set of the network are used to train the network established. 30 groups of data as inspection sample set of the network are used to inspect accuracy of model prediction after the training.

4.1 CROP CANOPY TEMPERATURE MODEL BASED ON BP

Crop canopy temperature model based on BP network is shown in Figure 6.

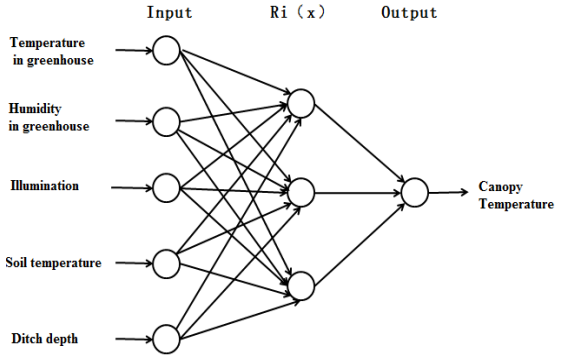

FIGURE 6 BP model of canopy temperature

The number of neurons in the input layer is 5, including the temperature, humidity, illumination, and soil temperature and ditch depth in the greenhouse. The number of neurons in the output layer is 1, indicate as crop canopy temperature. In BP network model, the hidden layer adopts *S* activation function. The output layer adopts linear activation function. It is known from empirical formula and actual training that the number of neurons in the hidden layer is 27.

$$(S_i+1)S_h+(S_h+1)S_o=n_pS_o\,, \tag{6}$$

S_i means the number of neurons in the input layer; S_h is the number of neurons in the hidden layer; S_o is the number of neurons in the output layer; n_p is the number of training samples.

Since the dimension of network input and output is different and the quantity differs greatly, normalization processing of sample data must be conducted before network training to prevent small numerical value information from being submerged by large numerical value information, i.e. normalize input signal to [0, 1]. The normalization equation is:

$$X^*=\frac{X-X_{\min}}{X_{\max}-X_{\min}}\,, \tag{7}$$

X^* refers to normalized data (the value is between 0 and 1); X is the actual value of network input data; $X_{\max}$ and $X_{\min}$ are the maximum value and the minimum value of input data.

To verify effectiveness and reliability of BP neural network model on canopy temperature prediction, MATLAB software is used to train and simulate BP neural network model. Since the length of the paper is limited, simulation results of only 12 groups of experimental data are provided, as shown in Table 2.

In accordance with the simulation results, actual output and expected output of BP network model differ little, with mean error of 0.8408℃ and root-mean-square error of 0.5789℃. It thus can be seen that BP network has relatively accurate prediction result for ditch-cultivated crop canopy temperature.

TABLE 2 Simulation results of BP networks model

NO.	Input					Output	Measured

11	44.17	64	12.61	10.9	0.9	33.226	32.19
12	48.94	57.11	36.58	10.9	0.9	34.523	34.21

4.2 CROP CANOPY TEMPERATURE MODEL BASED ON RBF

Negative gradient descent is adopted to adjust BP network weight. Such method has certain limitations. It has the shortcomings as follows: slow convergence rate; long training time; easy to be caught in local minimum. Radial basis function network is superior to BP network in terms of approximation capability, classification ability and learning rate. Thus, this paper adopts radial basis function network to establish crop network temperature model in order to improve prediction precision of canopy temperature.

In a bid to verify effectiveness and reliability of RBF neural network model on canopy temperature prediction, MATLAB software is used to train and simulate RBF neural network model. The same 200 groups of measured data serve as sample data of the neural network. The input of the neural network includes the temperature, humidity, illumination, soil temperature and ditch depth in the greenhouse. Expected output of the network is crop canopy temperature. The neural network model is as shown in Figure 7.

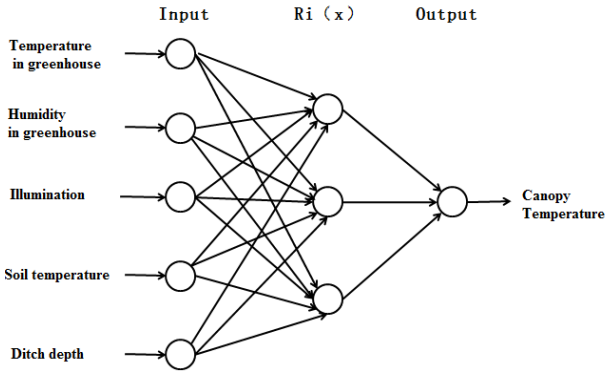

FIGURE 7 RBF model of canopy temperature

To prevent small numerical value information from being submerged by large numerical value information, normalization processing of sample data must be conducted before network training to normalize input signal to [0, 1]. 170 groups of experimental data are taken as the training samples of the network after normalization. During the training, the width of the basis function is 0.15. After the training, the number of neurons in the hidden layer is 92. 30 groups of data serve as inspection sample set of the network. It is known through network training that the model has fast convergence rate and short training time. Table 3 shows RBF network simulation results of 12 groups of experimental data.

TABLE 3 Simulation results of RBF networks model

NO.	Input					Output	Measured
	Temperature / ℃	*Humidity/%*	*Illumination/klx*	*Soil temperature / ℃*	*Ditch depth/m*	*Canopy Temperature/ ℃*	*Canopy Temperature/ ℃*
1	36.84	41.56	16.27	14.1	0.25	35.106	35.1
2	44.17	32	42.02	14.2	0.25	42.645	42.48
3	48.94	31.78	47.06	14.21	0.25	45.082	45.23
4	36.84	36.44	11.01	13.55	0.5	33.05	32.96
5	44.17	29.78	41.09	13.6	0.5	41.518	41.6
6	48.94	29.11	44.46	13.67	0.5	45.026	45.31
7	44.17	27.78	19.88	12.2	0.7	36.32	34.94
8	48.94	28	41.76	12.22	0.7	38.489	38.61
9	46.35	27.56	32.26	12.25	0.7	36.992	36.88
10	36.84	66.67	5.628	10.9	0.9	29.457	29.44
11	44.17	64	12.61	10.9	0.9	32.464	32.19
12	48.94	57.11	36.58	10.9	0.9	34.206	34.21

Based on the simulation results, RBF network model has fast computing speed. Besides, the simulation value and measured value differ little, mean error of 0.2236℃ and root-mean-square error of 0.3496℃. It thus can be seen that

RBF network has more accurate prediction result of ditch-cultivated crop canopy temperature than BP network.

5 Conclusions

Aiming at the mechanism model are influenced by multiple random factors and it is difficult to confirm soil parameters, this paper takes Chinese cabbage as the object of study and establishes canopy temperature simulation models based on BP network and RBF network respectively. The models take the temperature, humidity, illumination, soil temperature and ditch depth in the greenhouse as input neurons and takes canopy temperature as the output neuron. Moreover, experimental verification of the models is carried out through the measured data. The results show that both models can well predict ditch-cultivated crop canopy temperature. The mean error between the simulation value and measured value of BP network model is 0.8408℃, and root-mean-square error of 0.5789℃. Actual output and expected output of RBF network model differ little, mean error of 0.2236℃ and root-mean-square error of 0.3496℃. In contrast, RBF network model can more accurately predict crop canopy temperature than BP network model.

Analysis on vibration of small-scale hydroelectric generating unit

Liying Wang*, Lisha You

School of Water Conservancy and Hydropower, Hebei University of Engineering, Handan 056021, China

Received 1 June 2014, www.cmnt.lv

Abstract

An analytical model for the vibrations of operating conditions of small-scale hydroelectric generating unit is developed based on frequency domain and time domain. Firstly the vibration of unit 2 in Xida hydropower station is tested by using intelligent data logger, where the DASP10 software is used to collect the data and analyse them; and then the data are analysed by the time domain analysis, shaft centreline orbit analysis and auto-spectrum analysis respectively. Finally some instructive conclusions on the exceedance of shaft degrees and the overweight phenomena are drawn, which may assist an overhaul to raise the operating efficiency and the power output.

Keywords: Hydroelectric Generating Unit, Vibration, Time Domain Analysis, Shaft Centreline Orbit, Auto-spectrum Analysis

1 Introduction

In recent years, a large number of small hydropower stations have sprung up in many urban and rural areas, it has become an indispensable part of residential living electricity and industrial electricity in China, but the small-scale hydroelectric generating units have a poor performance in the quality and efficiency at present due to low investment, the limitation of technical level and there is often lack of the monitoring and analysis of unit vibration, which causes many units damage [1]. At present, the analysis and research methods, which are used in turbine vibration have the following kinds: fluid numerical calculation, model test, real machine test, and system modelling identification study [2-5]. In this paper, according to the reality and other factors, the real machine test method is used to monitor and analyse the vibration of unit 2 in Xida hydropower station, meanwhile the obtained data are analysed by the time domain analysis, shaft centreline orbit analysis and auto-spectrum analysis respectively, some instructive and important conclusions on the exceedance of shaft degrees and the overweight phenomena are drawn.

Xida hydropower station located in She county of Handan was founded in the late 1980s, and it belongs to the typical small hydropower, its rated power is 500kw, its rated speed is 375r/min. In the daily operation process, the engineering technicians find that there exists an abnormal vibration and a higher oil temperature in the bearing of units after excitation.

2 Experimental test systems

2.1 MONITORING POINT ARRANGEMENT

Unit 2 in Xida hydropower station is the test object, the X, Y directions of large shaft flange and water guide bearing all decorate eddy current transducers, and the X, Y, Z directions of upper bracket, lower guide bearing, water guide bearing and the head cover respectively arrange acceleration sensors. Figure 1 is the test site arrangement.

FIGURE 1 Test site arrangement

2.2 WORKING CONDITIONS SET

The test is divided into 12 working conditions which are as follows: the boot, plus exciting ,synchronization, load increasing to 250kw, load increasing to 500kw, load increasing to 600kw, keeping 600kw, load reducing to 500kw, load reducing to 250kw, splitting, reducing excitation, shutdown.

3 The basic analysis method

3.1 TIME DOMAIN ANALYSIS METHOD

Time domain analysis method is most commonly used in vibration signal analysis, the waveform is generated by the original waveform signal, which has a strong intuitive, and can accurately show the change trend of the signal amplitudes with the time [6, 7].

* ***Corresponding author*** e-mail: 2000wangly@163.com

In vibration measurement, there are three basic parameters: displacement, velocity and acceleration, the formulas are given below respectively:

$$x = A\sin(\omega t + \phi), \tag{1}$$

$$\dot{x} = A\omega\cos(\omega t + \phi), \tag{2}$$

$$\ddot{x} = -A\omega^2 \sin(\omega t + \phi). \tag{3}$$

3.2 SHAFT CENTRELINE ORBIT ANALYSIS

Shaft centreline orbit is refers to the axis of rotation in the rotating machinery and the axis is relative to the trajectory of the bearing. In the actual operation process, the abnormal vibration of hydroelectric generating unit will respond on the locus of journal bearing. The Shaft centreline orbit diagram shows the operation situation, which is a simple visual image method, and one can see the change situation from the diagram, and is easier to determine the vibration sources, which influence the stability of unit [8, 9].

3.3 AUTO SPECTRUM ANALYSIS

Auto-spectrum analysis transforms signals from time domain to frequency domain, and each periodic harmonic component corresponding to the spectrum of the signals is obtained. With the change of factor generated by the frequency of the vibration signals, the vibration will be changed., the frequency domain analysis is carried out on the collected signal to better grasp the dynamic law of vibration. The meaning of auto-spectrum analysis is a more complex signal of waveform in a specific period, which is, transformed various harmonic amplitudes the frequency and phase information and they are divided into multiple independent harmonic components [10, 11].

The signals are transformed by fast Fourier, which is defined as follows:

$$x(\omega) = \int_{-\infty}^{\infty} x(t)e^{-j\omega t}dt, \tag{4}$$

where: $\omega=2\pi f$, $f(t)$ is time domain data sequence and $x(\omega)$ is the frequency spectrum function of the sequence. Its inverse transformation form is:

$$x(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} x(\omega)e^{j\omega t}dt, \tag{5}$$

$x(\omega)$ is a complex function:

$$x(\omega) = |x(\omega)|e^{j(\omega)}, \tag{6}$$

$|x(\omega)|$ is the amplitude function of $x(\omega)$. In practice, the amplitude-frequency drawing cannot be coming out, the frequency density of $x(\omega)$ usually can be used to make an approximate description:

$$x(\omega) = 2\pi x(f). \tag{7}$$

In this test, the spectrum analysis is used to judge the vibration of hydro-generator units. In analysis, FFT is used to make a frequency domain analysis for the vibration signals.

4 The analysis results

4.1 TIME DOMAIN ANALYSIS RESULTS OF SHAFT SWING

Under the working condition of the above 12, the data are analysed respectively for time domain analysis; the results are shown in Figure 2.

It can be seen that, from Figure 2, when the conditions are in a state of stable work, shaft swing is beyond status, the maximum superscalar is 0.465mm and 0.447mm in X and Y directions, (the allowed values is 0.250mm); under most of the working conditions, the shaft swing at water guide bearing in X and Y direction is in the acceptable range, only in the part of the time period, it is in excessive state, X direction is 0.353mm and 0.263mm, Y direction is 0.575mm and 0.362mm, (the allowed values is 0.250mm). When the working conditions are changing, the shaft swing is also in excessive state, the maximum superscalar is 1.808 mm and 0.974mm in X and Y directions under the reduction excitation condition, (the allowed values is 0.250mm); the shaft swing at water guide bearing in X direction is in excessive state, the biggest superscalar is 0.766mm under the reduction excitation condition, (the allowed values is 0.250mm), the shaft swing in Y direction is in the acceptable range only under the processes of synchronization, load increasing and keep 600kw. Under other conditions, the swing is overweight; the largest superscalar also occurs under reduction excitation condition, the value is 1.206mm, (the allowed values is 0.250mm). Based on the above analysis, we can draw a conclusion that the shaft swing is the biggest in the reduction excitation condition.

FIGURE 2 The time domain of shaft swing at flange and water guide bearing under various conditions

4.2 SHAFT CETRELINE ORBIT ANALYSIS RESULTS OF SHAFT CSCILLATION

The x-y graph analysis is proceeded at flange and water guide bearing under all conditions, due to space problem, we take the working condition of load increasing to 600kw as an example; the axis trajectory deviation is shown in Figure 3 and Figure 4, From the graph, we can see that when conditions change or the load is adjusted, the axis trajectory is unstable and produces deviation, the offset direction is roughly same, and the offset amplitudes are different.

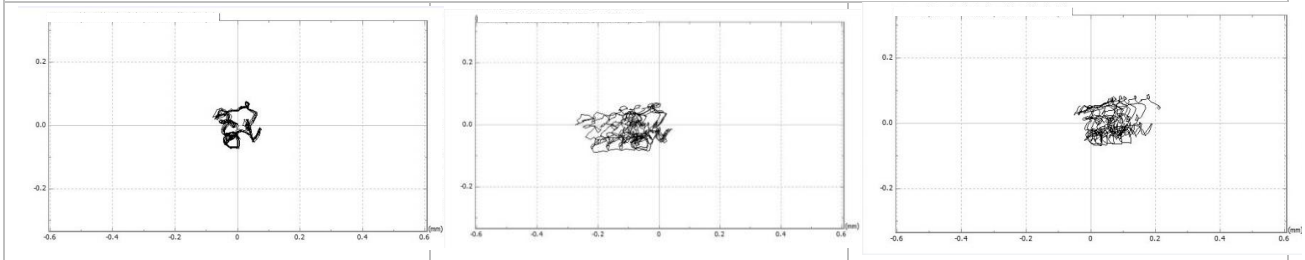
FIGURE 3 The axis trajectory for shaft flange



(a) Under stable operation condition | (b) Under load increasing to 600kw condition | (c) Under load increasing to 600kw condition

FIGURE 4 The axis trajectory for water guide bearing

4.2 AUTO SPECTRUM ANALYSIS RESULTS OF SHAFT OSCILLATION

The auto-spectrum analysis is used in shaft oscillation; the analytical results under each condition are shown in Table 1. From the Table 1, we can find that the vibration frequencies mainly concentrate in 1HZ, 2HZ, 6HZ, 19HZ, 25HZ, and 50HZ, the turbines rotation frequency is 6.25HZ, the vibration frequency 6HZ is close to rotation frequency 6.25HZ, the frequencies 25HZ and 50HZ respectively are 4 times and 8 times of rotation frequencies, mainly from the different number of guide vanes and runner blades, the frequencies 1HZ and 2HZ are from 0.15 to 0.3 times of rotating frequencies.

TABLE 1 Auto-spectrum analysis (HZ)

Direction	X of flange	Y of flange	X of water guide bearing	Y of water guide bearing
the boot	7,1	7,1	7,1,25,20	7,1
plus exciting	6,1	6,1	6,1,25,19	6,19
synchronization	6,1	6,1	6,1,25,19	6,19
load increasing to 250kw	6	6,1	6,1,25,19	6
load increasing to 500kw	6,1	6,1	6,1,25,19	6
load increasing to 600kw	6,1	6,1	6,1,25,19	6
keeping 600 kw	6	6	6,25,19	6
load reducing to 500kw	6,1	6,1	6,1,25,19	1,6
load reducing to 250kw	6,1	6,1	1,6,19	1,6,19
splitting	1,6	6,1	1,6,19	1,6,19
reducing excitation	6,1	6,1	1,6,25	1,6
shutdown	4,1	4,1	1,4,25	1,4

4.3 THE REASON OF SHAFT SWING

Based on the above analysis, we can discover that the shaft swing is biggest change in the reduction excitation condition, it is because that the generator unbalanced magnetic pull and the bearing clearance are not uniform, moreover, the hydraulic turbine thrust bearing is positioned in the upper guide bearing and the swing of flange is always greater than that of water guide bearing, the shaft swing exists in the inflection point. In runtime, the shaft swing degrees of the main frequency is close to 6.25HZ, the rotation frequency of the turbine indicates that the axis of turbine is not straight or has some mechanical l problems such as bad entering and so on.

When the working condition changes, the shaft centreline orbit has a large range of migration, which is concerned on the electromagnetic factor and hydroelectric factor. The flange shaft orbit is elliptical and the water guide bearing shaft orbit is distorted and has more spikes, the reason is that the runner blades are impacted by water, and the different number of guide vanes and runner blades lead to the hydraulic factors such as frequency difference of water conservancy.

5 Conclusions

In all working conditions, the shaft degrees are beyond the scope of the standard state, when the conditions change, the shaft centreline orbit will appear larger range of deviation. The cause of this abnormal situation is more complex, on

the one hand, the main shaft axis is not straight has an undesirable phenomena, on the other hand, the hydro-generator exists unbalanced magnetic pull and uneven bearing clearance and so on.

In addition, there exists overweight phenomena in upper bracket, lower guide bearing, water guide bearing and head cover; when the load is 500kw, the vibration is the most serious. From the vibration frequency analysis, it also can be reflected that the causes of turbine vibration is more complex, not only the mechanical and electromagnetic aspects, but hydraulic factors are all should be considered.

Acknowledgments

Supports from Xida hydropower station are highly appreciated. The helpful comments from colleagues and classmates are also gratefully acknowledged.

Abstract

Coal mine safety is a very important link in the current coal mine production. Currently, there are a lot of kinds of methods for the evaluation of coal mine safety environment in order to solve the evaluation of the coal mine safety status. However, the complexity and diversity of coal mine environment cause that there is no method can evaluate coal mine safety status. So a new method is proposed, which called two-stage fusion structure according to China's natural environment of the underground coal mine, is used to evaluate the condition of coal mine safety. Firstly, it gets various parameters for affecting the safety of underground using the first level evaluation method; secondly, the second level fusion method is used to realize the coal mine security situation assessment. The experimental results show that this method has better performance more than other methods in evaluating coal mine safety.

Keywords: the first level fusion algorithm, fusion decision, mine safety, better performance

1 Introduction

In recent years, Coal mine disaster accidents frequently happen, which makes people's life lose. It is very important to evaluate the security situation in time, correctly determine the mine safety status to avoid or reduce the coal safety accident [1].

Currently, there are some coal mine safety evaluation methods: expert system, data envelopment analysis method, neural network and support vector machine [2]. Expert evaluation system is mainly based on expert experience and knowledge of coal mine safety, the evaluation results has much to do with expert level, so the evaluation results is difficult to reflect subjectively the degree of coal mine safety; data envelopment analysis is not yet mature, it is difficult to reflect the mapping relation between evaluation index and evaluation results, and at the same time it has certain limitations, the evaluation accuracy is lower. Neural network is a kind of "black box" evaluation method, which needs a lot of sample data for coal mine safety evaluation, but the evaluation results is poor if using the pure quantitative method to evaluate coal mine safety, the same as artificial intelligence [3].

Production of coal mine is a special industry which contains personnel management, machinery operation, mining technology, geological conditions and natural environment, and all the factors have differences [4, 5]. In the coal mine safety evaluation process, firstly, needs to establish a scientific and perfect coal mine safety evaluation, then calculates the index weight, and finally gets the safety level.

Therefore, in order to improve the coal mine safe evaluation accuracy and reliable, the article proposes two-level fusion structure, which is based on improved real-time adaptive weighted fusion algorithm and fuzzy information fusion theory. The method adopts the improved real-time adaptive weighted algorithm to achieve a spatial real-time data fusion which was distributed in different geographical location firstly, and then used Gaussian functions and fuzzy transform information fusion theory to get coal mine safety evaluation. The experimental results show that the method is feasible and effective for multi-sensor mine safety evaluation system.

2 The two-level fusion algorithm structure

Gas, carbon monoxide, oxygen, temperature, wind speed in the air are the fatal factors which affect the safety status under the shaft. This paper puts forward a sensor group which contains gas, carbon monoxide, oxygen, temperature, and wind speed sensors to monitor different positions of a mining area and then using the improved real-time adaptive weighted fusion algorithm to deal with monitoring parameter values to realize the first level data fusion in the spatial domain, and at last adopting the fuzzy information fusion theory to achieve the secondary decision of system. The model of the method is shown in Figure 1.

***Corresponding author** e-mail: zss@hpu.edu.cn

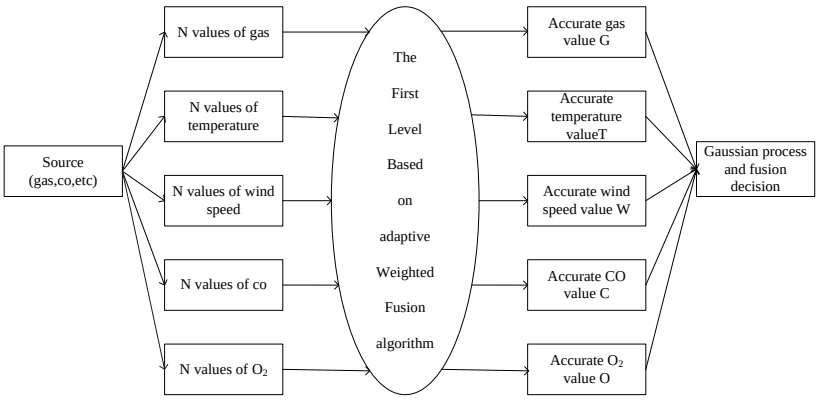

FIGURE 1 The model of two-level fusion structure

3 The first level fuzzy algorithm

The parameters in a mining area are monitored, such as gas, co, and wind speed and so on, and the sensors are distributed in a large scale. To understand the status of the mine safety comprehensively and accurately, multi-sensor groups must be used to complete the task about monitoring data. The parameter, which is monitored by sensor group is more accurate than single sensor. To processing underlying data of system, this paper proposes the real-time adaptive weighted fusion algorithm, which does not need prior knowledge and the programming is easily to realize to get the first level fusion in spatial domain.

3.1 THE FIRST LEVEL FUZZY ALGORITHM

Adaptive weighted fusion algorithm is a common method to fuse the underlying data for multi-sensor. The use of this method is not restricted even in the case of weak or inadequate information [6]. Taking the data from gas sensor as an example, the description of algorithm is as follows:

1) In the coal mine safety evaluation system which contains multi-sensor group, the weight of gas sensor is set as $W_{i1}(\mathrm{i}=1,2,\cdots,n.)$, variance is $\sigma_{i1}^2(\mathrm{i}=1,2,\cdots,n.)$ and W_{i1} is needed to be fulfilled: $\sum_{i=1}^{n} W_{i1}=1$.

2) The gas estimation true value was X, a gas sensor measured value was X_i for a moment, the optimal fusion value $\hat{X}(\mathrm{x})$, which meets the optimal condition that the mean square error was minimum, and the last $\hat{X}(\mathrm{x})$ needs to meet Equation (1):

$$\hat{X}(\mathrm{x})=\sum_{i=1}^{n} W_{i1}X_i \tag{1}$$

The total mean square error of $\hat{X}(\mathrm{x})$ [7]:

$$\sigma^2=E[X-\hat{X}(\mathrm{x})]^2=E[\sum_{i=1}^{n} W_{i1}^2(X-X_i)^2]+ 2\sum_{i=1,j=1,i\neq j}^{n} W_{i1}W_{j1}(X-X_i)(X-X_j)] \tag{2}$$

Because X_1, X_2,…, X_n were independent each other $E[(X-X_i)(X-X_j)]=0\ (i\neq j,i,j=1,2,\ldots\mathrm{n})$:

$$\sigma^2=E[\sum_{i=1}^{n} W_{i1}^2(X-X_i)^2]=\sum_{i=1}^{n} W_{i1}^2\sigma_{i1}^2. \tag{3}$$

According to the multivariate function extreme value theory, we can calculate the corresponding weighted factor when the total mean square error is minimized [8]:

$$W_{i1}^*=1/\sigma_{i1}^2\sum_{i=1}^{n}\frac{1}{\sigma_{j1}^2},\quad i=1,2,\ldots\mathrm{n}. \tag{4}$$

The minimum mean square error is [9]:

$$\sigma_{\min}^2=1/\sum_{i=1}^{n}\frac{1}{\sigma_{i1}^2}. \tag{5}$$

The above estimation is based on the real-time values of the gas sensors in some time, and if the estimation is constant, we can estimate according to average historical data [10]. Estimation and the total mean square error at this time are as follows respectively:

$$\overline{X}=\sum_{i=1}^{n} W_{i1}\overline{X_i}(\mathrm{K}). \tag{6}$$

$\overline{X}$: The gas optimal fusion for the first level fusion.
K: The frequency for historical data measurement.

$$\overline{\sigma^2}=\frac{1}{K}W_{i1}^2\sigma_{i1}^2=\frac{\sigma_{\min}^2}{K} \tag{7}$$

$\overline{\sigma^2}$: The optimum fusion of the minimum variance.

3.2 THE RESULT OF FIRST LEVEL FUSION

The mine gas concentration which comes from a coal mine safety production monitoring and control system is denoted by X_i (%) and its variance is σ_{i1}^2 and weights W_{i1}. The properties of each sensor, as X_i, is displayed in Table 1.

TABLE 1 The properties of the gas sensor σ_{i1}^2

G_i	G_1	G_2	G_3	G_4	G_5	G_6
X_i	0.54	0.55	0.45	0.22	0.57	0.44
σ_{i1}^2	0.53	0.48	0.54	0.53	0.39	0.44
W_{i1}	0.151	0.166	0.147	0.152	0.203	0.181

By Equation (6), we could calculate the optimal fusion value of gas concentration 0.4678.

The system could obtain the optimal fusion about temperature, wind speed, etc. by using the above method.

The improved adaptive weighted fusion method is implemented in the first level of data fusion to get relatively accurate parameter information. As the parameters are independent and it is difficult to assess the condition about mine. So the system is required to use fuzzy information fusion theory to realize the secondary fusion processing.

4 The second level fuzzy algorithm

A precise method to describe the association between parameters is very difficult because underlying parameters from the first level fusion are independent. So the application of fuzzy information fusion theory is helpful to make the coal mine security situation evaluation more accurate.

4.1 THE THEORY OF SECOND LEVEL FUSION

Making the absolute subordinate relations of general set become flexibly and the elements to membership of collection can take any value in [0,1] are the basic idea of fuzzy set. The idea is suitable for describing and processing uncertainty sensor data [10, 11]. The theory, which is based on Gaussian membership function and fuzzy transformation can make decisions in the secondary fusion processing of evaluation system.

(U,V,R) is the fuzzy comprehensive evaluation model [13], U is comment set, and V is factors set. n kinds of coal mine safety status and the status collection: $\{U_1,U_2\cdots U_n\}$; the first level fusion feature parameters constitute a collection $\{V_1,V_2,\cdots V_m\}$. R_{ij} is the possibility of status set from characteristic parameter. It is the degree of membership to U_i and V_j, at last it constitutes a fuzzy relation matrix R. The factors weight vector: $A=(A_1,A_2,\cdots A_m)$ is derived from the different influence degree of characteristic parameters for judging result.

The fuzzy transformation is as follows: $B=A\circ R=(B_1,B_2,\ldots,B_n)$,

$$B=(A_1,A_2,\ldots,A_m)\circ\begin{pmatrix} R_{11} & R_{12} & \cdots & R_{1n} \\ R_{21} & R_{22} & \cdots & R_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ R_{m1} & R_{m2} & \cdots & R_{mn} \end{pmatrix}, \quad (8)$$

B : The possibility of coal mine safety status,
A : The factor weight vector,
R : The fuzzy matrix,
B_j : The degree of membership of fuzzy subsets about the comprehensive evaluation of down-hole safety status.

4.2 THE RESULT OF SECOND LEVEL FUSION

The gas concentration, temperature, wind speed, co concentration and oxygen concentration are the main factors, which affect the coal mine safety; the first level fusion structure achieves data fusion from different sample point to the same parameters in spatial domain. For secondary decision-making fusion, firstly, the first level fusion parameters are given different weights according to the experimental data and then get weight vector $A^*(A_1^*,A_2^*,A_3^*,A_4^*,A_5^*)$, it is the first step to realize fuzzy information fusion algorithm. Next, it is time to make sure the degree of membership of each coal mine status from the environment parameters.

For continuous analogy parameter variable, Cauchy fuzzy sets and Gaussian pattern matching algorithm are two different mathematical methods to seek membership [12]. Because constructing the process of Cauchy fuzzy sets is more complex and Gaussian membership function is chosen, the basic idea is as follows: $\{N_1,N_2,\ldots,N_n\}$ makes up of n kinds of status in status database, where $N_i(i=1,2\cdots,n)$ represents different status and each status corresponding to a standard joint feature vector containing k characteristic parameters: $\overline{N_i}=\{N_{i1},N_{i2},\cdots,N_{iK}\}$, $N_{ij}(j=1,2,\cdots,K)$ represents the j^{th} standard characteristic parameter of the i^{th} kind state. All kinds of parameter respectively can become a vector containing K characteristic parameters after the first level fusion in a period of time; $\overline{X_i}=(X_{i1},X_{i2},\cdots,X_{iK})$, where $X_{ij}(j=1,2,\cdots,K)$ represents the j^{th} characteristic parameter of the i^{th} kind state.

For the i^{th} kind condition:

Cauchy fuzzy sets and Gaussian pattern matching algorithm are two different mathematical methods to seek membership [12]. Because constructing the process of Cauchy fuzzy sets is more complex and Gaussian membership function is chosen, the basic idea is as follows: $\{N_1,N_2,\ldots,N_n\}$ makes up of n kinds of status in status database, where N_i $(i=1,2\cdots,n)$ represents different status and each status corresponding to a standard joint feature vector containing k parameters: $\overline{N_i}=\{N_{i1},N_{i2},\cdots,N_{iK}\}$, $N_{ij}(j=1,2,\cdots,K)$ represents the j^{th} standard characteristic parameter of the i^{th} kind state. All kinds of parameter respectively can become a vector containing K characteristic parameters after the first level fusion in a period of time; $\overline{X_i}=(X_{i1},X_{i2},\cdots,X_{iK})$, where $X_{ij}(j=1,2,\cdots,K)$ represents the j^{th} characteristic parameter of the i^{th} kind state.

For the i^{th} kind condition:

1) Membership functions of the parameters:

$$\mu_{N_{ij}}(X_{ij}) = \exp\left(-\frac{(X_{ij}-N_{ij})^2}{2\sigma_{ij}^2}\right). \quad (9)$$

X_{ij} : The j^{th} characteristic parameter of the i^{th} kind state.

N_{ij} : It means the j^{th} standard characteristic parameter of the i^{th} kind state.

σ_{ij}^2 : It means the j^{th} standard deviation of the i^{th} kind state.

2) Vector membership function:

$$\mu_{\overline{N_j}}(\overline{X_i}) = \sum_{t=1}^{K} \alpha_t \times \mu_{N_{ij}}(X_{ij}). \quad (10)$$

$$\sum_{t=1}^{K} \alpha_t = 1,\ \alpha_t > 0,\ t = 1,2,\cdots,K. \quad (11)$$

α_t : It represents the weight coefficient of the t^{th} characteristic parameter.

3) The result of fuzzy transform:

$$B = A^* \circ \mu_{\overline{N_j}}(\overline{X_i}) = (A_1^*, A_2^*, A_3^*, A_4^*, A_5^*) \circ \begin{pmatrix} \mu_{\overline{N_1}}(\overline{X_1}) & \mu_{\overline{N_1}}(\overline{X_2}) & \mu_{\overline{N_i}}(\overline{X_3}) \\ \mu_{\overline{N_2}}(\overline{X_1}) & \mu_{\overline{N_2}}(\overline{X_2}) & \mu_{\overline{N_2}}(\overline{X_3}) \\ \mu_{\overline{N_3}}(\overline{X_1}) & \mu_{\overline{N_3}}(\overline{X_1}) & \mu_{\overline{N_3}}(\overline{X_3}) \\ \mu_{\overline{N_4}}(\overline{X_1}) & \mu_{\overline{N_4}}(\overline{X_2}) & \mu_{\overline{N_4}}(\overline{X_3}) \\ \mu_{\overline{N_5}}(\overline{X_1}) & \mu_{\overline{N_5}}(\overline{X_1}) & \mu_{\overline{N_5}}(\overline{X_3}) \end{pmatrix}. \quad (12)$$

5 Results and analysis

The elements in B represent respectively three kinds of status: safety, generally safety and dangerous. The influence degree of each sensor group in system was different, this paper set the gas (G), temperature (T), wind speed (V) and carbon monoxide (C) and oxygen (O) as the weight vector $A = (0.21, 0.13, 0.37, 0.17, 0.12)$ through parameters test and data analysis for many times in one coal mining.

TABLE 2 Fuzzy matrix

Evaluation factors	Safety state	General safety	Dangerous state
G	0.520	0.480	0
T	0.240	0.740	0.020
V	0.123	0.637	0.240
C	0.162	0.420	0.418
O	0.105	0.213	0.682

For a certain moment, the system transmitted the five parameters from the first level fusion to the centre of decision fusion, then the fusion centre could get the fuzzy matrix according to Gaussian membership function and at last the system compounded and normalized processing the weight vector of characteristic parameters and fuzzy matrix to realize safety status evaluation coal mine.

We could get the fuzzy matrix from Equation (9), (10) and (11), fuzzy matrix in Table 2:

We could get the result from Equation (12): $(B_1, B_2, B_3) =$

$$(0.21, 0.13, 0.37, 0.17, 0.12) \circ \begin{pmatrix} 0.520 & 0.480 & 0 \\ 0.240 & 0.740 & 0.020 \\ 0.123 & 0.637 & 0.240 \\ 0.162 & 0.420 & 0.418 \\ 0.105 & 0.213 & 0.682 \end{pmatrix}.$$

$$= (0.274, 0.440, 0.256)$$

The fusion degree of membership of B_2 is the largest; we could determine "general safety" as coal mine status at the moment according to maximum membership judgment rules.

Every sensor group degree of membership value is presented in Table 3. We got down-hole safety determination according to decision rules and at same time obtained comprehensive judgments on the basis of fuzzy subset.

TABLE 3 The contrast between single sensor recognition and fusion recognition

Mine state	Factors	Safety	General safety	Dangerous	Results
Safety	G	1.000	0	0	Safety
	T	0.820	0.180	0	Safety
	V	0.505	0.327	0.168	Safety
	C	0.328	0.473	0.199	General safety
	O	0.256	0.323	0.421	Dangerous
	Fusion	0.422	0.373	0.168	Safety
General safety	G	0.520	0.480	0	Not sure
	T	0.240	0.740	0.020	General safety
	W	0.123	0.637	0.240	General safety
	C	0.162	0.420	0.418	Not sure
	O	0.105	0.213	0.682	Dangerous
	Fusion	0.274	0.440	0.256	General safety
Dangerous	G	0	0.050	0.950	Dangerous
	T	0	0.180	0.820	Dangerous
	W	0.327	0.311	0.362	Dangerous
	C	0.103	0.324	0.573	Dangerous
	O	0.231	0.572	0.197	General safety
	Fusion	0.265	0.345	0.390	Dangerous

Through experimental contrast, it can be seen that one kind sensor for the evaluation of mine safety status is uncertain, but the application of fuzzy fusion increases credibility of state evaluation, enhances and improves the performance of the safety evaluation system.

6 Conclusions

The two-level fusion structure is proposed in this paper, which based on data fusion technology in spatial domain and information fusion algorithm. With the two-stage fusion structure implemented in coal mine safety evaluation system, the contrast experiment shows that the improved adaptive weighted fusion algorithm disposes the data on the space is more reliable, and at same time, fuzzy fusion algorithm in the secondary structure can improve the credibility of the whole evaluation system. Therefore, the practical application of structure in coal mine safety evaluation is feasible. Besides, the time complexity algorithm needs to be part of our future.

Seismic signals wavelet packet de-noising method based on improved threshold function and adaptive threshold

Liu Shuchong*, Chen Xun

Institute of Disaster Prevention, Sanhe 065201

Received 1 March 2014, www.cmnt.lv

Abstract

Wavelet analysis is one of the effective method to improve the signal to noise ratio and resolution of seismic data, a wavelet packet seismic signal denoising method based on a new threshold function and adaptive threshold was put forward according to the distortion problem of traditional threshold function denoising method, which make up the defects of traditional thresholding method. Wavelet packet decomposition techniques was used for seismic wave signal denoising processing, and the synthetic seismic signals and actual seismic data was done wavelet packet decomposition processing through MATLAB, better removing high frequency random noise to retain the useful signals. Experimental results showed that the method can effectively remove noise and improve seismic resolution, with better denoising effect.

Keywords: seismic signal, adaptive threshold, denoising, resolution

1 Introduction

In seismic exploration, the signals-noise-ratio of seismic data will directly affect the reliability of seismic data, the accuracy of parameter extraction and the resolution enhancement effect etc. Therefore, denoising research plays a very important role in seismic data processing. In the high-resolution seismic exploration, seismic records have very wide frequency band, in the frequency range of significant wave may contain surface wave, random noise interference noise, which makes effective separation of signal to noise more important. Currently in seismic data processing the de-noising method are more, but each de-noising method has its own applicable conditions. Wavelet transform technique as a new approach has been widely applied to the signal denoising because of its time-frequency analysis and multi-resolution and other characteristics will have a good research value and application prospect when applied to the seismic signal noise elimination treatment. Wavelet packet transform [3-4] is the promotion of the wavelet transform, is a more detailed analysis and reconstruction methods. It divides the band by multiple-levels, further divide the high frequency portion which wavelet analysis cannot be subdivided and can adaptively select the appropriate frequency band so as to match the signal spectrum according to the characteristics of the analysed signals, thereby improving time-frequency resolution.

A wavelet packet seismic signal denoising method based on improving threshold function and adaptive threshold was presented for a more sophisticated decomposition to the low-frequency and high-frequency of seismic signals, wavelet packet coefficients derived were processed by the improved refinement threshold function and self-adaptive thresholding, which could effectively remove the noises, reduce the useful signals removal. Synthetic seismogram denoising and real seismic signal de-noising was achieved by simulation. Studies show that the improved threshold function and adaptive threshold wavelet packet seismic signal denoising method is very effective in denoising, have got better denoising effect.

2 Wavelet packet transform

2.1 WAVELET PACKET DEFINITION

In the multi-resolution analysis, $L^2(R) = \bigoplus_{j\in Z} W_j$ show multi-resolution analysis is that the Hilbert space $L^2(R)$ is decomposed to subspaces $W_j (j \in Z)$ orthogonal according to a different scale factor j. In which, W_j is the closures for the wavelet function $\varphi(t)$ (wavelet subspace). The wavelet subspace W_j was done frequency subdivision as binary fractions, in order to achieve the purpose of improving the frequency resolution. The scale subspace V_j and wavelet subspace W_j characterize uniformly with a new subspace U_j^n, and order

$$\begin{cases} U_j^0 = V_j \\ U_j^1 = W_j \end{cases}, (j \in Z) . \tag{1}$$

The Hilbert space orthogonal decomposition $V_{j+1} = V_j \oplus W_j$ could unify using U_j^n decomposition:

**Corresponding author* e-mail: luckyorng1009@gmail.com

$$U_{j+1}^0 = U_j^0 \oplus U_j^1, j \in Z . \quad (2)$$

Define subspace U_j^n is the closure space of function $u_n(t)$, U_j^{2n} is the closure space of $u_{2n}(t)$ and order $u_n(t)$ satisfies the following two-scale equation:

$$\begin{cases} u_{2n}(t) = \sqrt{2}\sum_{k\in Z} h(k)u_n(2t-k) \\ u_{2n+1}(t) = \sqrt{2}\sum_{k\in Z} g(k)u_n(2t-k) \end{cases}, \quad (3)$$

where $g(k) = (-1)^k h(1-k)$, that is two coefficients have orthogonal relationships. When $n = 0$, the above equation becomes

$$\begin{cases} u_0(t) = \sum_{k\in Z} h_k u_0(2t-k) \\ u_1(t) = \sum_{k\in Z} g_k u_0(2t-k) \end{cases}, \quad (4)$$

$u_0(t)$ and $u_1(t)$ are respectively scale function $\phi(t)$ and wavelet function $\varphi(t)$, Equation (4) is the equivalent representation of Equation (2). This equivalent representation were extended to $n \in Z_+$ (non-negative integer), that is equivalent representation of Equation (3)

$$U_{j+1}^n = U_j^{2n} \oplus U_j^{2n+1} \qquad j \in Z, n \in Z_+ . \quad (5)$$

This allow the wavelet subspace further subdivided as binary:

$$\begin{aligned} &W_j = U_j^1 = U_{j-1}^2 \oplus U_{j-1}^3 \\ &U_{j-1}^2 = U_{j-2}^4 \oplus U_{j-2}^5, U_{j-2}^5 = U_{j-2}^6 \oplus U_{j-2}^7 \\ &... \\ &W_j = U_{j-k}^{2^k} \oplus U_{j-k}^{2^k+1} \oplus ... \oplus U_{j-k}^{2^k+m} \oplus ... \oplus U_{j-k}^{2^{k+1}-1} \end{aligned}, \quad (6)$$

in which orthonormal basis $\left\{2^{(j-k)/2}\varphi_{2^k+m}(2^{j-k}t-l); l \in z\right\}$ are called wavelet packet corresponding to $k = 1,2,...j; j = 1,2...$ and subspaces $U_{j-k}^{2^k+m}$.

Assume $g_j^n(t) \in U_j^n$, then $g_j^n(t)$ can be expressed as $g_j^n(t) = \sum_l d_l^{j,n} u_n(2^j t - l)$. Wavelet packet decomposition are that $\left\{d_l^{j,2n}\right\}$ and $\left\{d_l^{j,2n+1}\right\}$ are obtained by $\left\{d_l^{j+1,n}\right\}$, that is

$$\begin{aligned} d_l^{j,2n} &= \sum_k a_{k-2l} d_k^{j+1,n} \\ d_l^{j,2n+1} &= \sum_k b_{k-2l} d_k^{j+1,n} \end{aligned}. \quad (7)$$

Wavelet packet reconstruction are that $\left\{d_l^{j+1,n}\right\}$ are obtain by $\left\{d_l^{j,2n}\right\}$ and $\left\{d_l^{j,2n+1}\right\}$, that is

$$d_l^{j+1,n} = \sum_k [h_{l-2k} d_k^{j,2n} + g_{l-2k} d_k^{j,2n+1}] . \quad (8)$$

2.2 DENOISING

In seismic exploration, the general wave interference include: surface waves, high frequency random noise, side wave, multiples, etc, in which the high-frequency surface wave and random interference waves have more serious impact on the effective wave, therefore it need to reduce noise processing to extract the useful signals. For non-stationary seismic signals, the wavelet packet decomposition technique is an effective noise reduction method.

In the wavelet analysis, the signal is decomposed into low frequency portion and high frequency detail rough. However, only the low-frequency portion is used for the second layer decompose while the high-frequency part without treatment, when the scale increases frequency resolution of wavelet analysis became lower and the resolution in high frequency became poor.

Wavelet packet analysis is further promotion of the wavelet analysis, which provides a more complex and flexible analysis tools. Wavelet packet analysis subdivide the low-frequency part and high-frequency portion of last layer while the high frequency part of the signal can be described more detailed, with a more precise local analysis capabilities. Typically, wavelet packet noise reduction steps [5, 6].

The first was wavelet packet decomposition of the signal: Choose a wavelet and determine a wavelet decomposition level *N*, then do *N*-layer wavelet packet decomposition on the seismic waves signal *S*. Described with a three-tier decomposition, the wavelet packet decomposition tree were shown in Figure 1. In Figure 1 *A* represented a low frequency, *D* represented high frequency, the end serial number represented wavelet packet decomposition layers, namely the scale number. The original signal *S* is equivalent to:

$$\begin{aligned} S = {} & AAA3 + DAA3 + ADA3 + DDA3 + \\ & AAD3 + DAD3 + ADD3 + DDD3 \end{aligned}. \quad (9)$$

The second was to calculate the optimal tree: compute the best tree for a given entropy criteria. Commonly used entropy criteria were Shannon threshold norm log energy sure and user and so on.

The third was thresholding quantization of wavelet packet decomposition coefficiences. Select a threshold and do coefficients thresholding quantization for each wavelet packet decomposition coefficients. Wavelet transform coefficient values are compared with a threshold, it is believed that the values smaller than the threshold value were generated by the noise and set to zero, the values greater than the threshold values were corresponding to the signal mutation point and retained in order to achieve the purpose of denoising. In the process of denoising there were usually three treatments: force denoising the default threshold denoising given soft (or hard) threshold denoising.

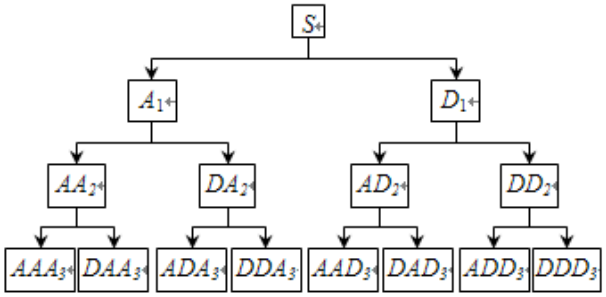

FIGURE 1 Wavelet packet decomposition technique

Soft (or hard) threshold denoising [7, 8] are most commonly used, but there is distortion.

The fourth was signal reconstruction: Do wavelet packet reconstruction on signals according to the L layer wavelet packet decomposition low-frequency coefficients of the original signal and high frequency coefficients after threshold quantization processing.

3 Selection of wavelet and threshold functions

3.1 DETERMINATION OF THE BEST WAVELET PACKET BASIS (CALCULATION OF OPTIMAL TREE)

A signal with length of $L = 2^N$ could have 2^N kinds of different signal decomposition method, while the number of full two forks trees with depth of N are 2^N. This number is too large to enumerate every situation, and the minimum entropy criterion can be obtained by an optimal signal decomposition method.

There are several types of traditional standards based on entropy: Shannon entropy, threshold entropy, norm entropy, logenergy entropy, sure entropy and user entropy and so on. Shannon entropy is defined as follows:

$$El(s_i) = -s_i^2 \log(s_i^2) \quad 0 \log 0 = 0 . \tag{10}$$

The signals were decomposed layer by layer, the entropy of each decomposition node was calculated, entropy values of a node and its child nodes were compared, the base obtaining minimum entropy is the optimal wavelet packet basis.

3.2 SELECTION OF THRESHOLD FUNCTION

Wavelet thresholding denoising was threshold processing of high frequency coefficient according to the characteristics of noise manifests high-frequency signals, if the coefficients less than the threshold it was considered by the noise and set zero, if the coefficients greater than the threshold value it correspond to the useful signals and should be retained, thereby to achieve the purpose of de-noising.

The choice of traditional threshold is the hard threshold processing and soft threshold processing. Soft threshold processing is comparing the absolute value of signals and the threshold, when the absolute value of data is less than or equal to the threshold, set it to zero, when greater than the threshold, it becomes the difference between the point with a threshold value. The hard threshold is comparing the absolute value of signals and the threshold, if less than or equal to the threshold the point was set zero, greater than the threshold value it remains unchanged.

Hard thresholding:

$$\hat{W}_{j,k} = \begin{cases} W_{j,k}, |W_{j,k}| \geq \lambda \\ 0, |W_{j,k}| < \lambda \end{cases} \tag{11}$$

Soft thresholding:

$$\hat{W}_{j,k} = \begin{cases} \text{sgn}(W_{j,k})(|W_{j,k}| - \lambda), |W_{j,k}| \geq \lambda \\ 0, |W_{j,k}| < \lambda \end{cases} . \tag{12}$$

In hard threshold, $\hat{W}_{j,k}$ were discontinuous on the points of $W_{j,k} = \lambda$, which brings oscillationto the reconstructed signal; Despite the $\hat{W}_{j,k}$ calculated in soft thresholding have overall good continuity, $\hat{W}_{j,k}$ and wavelet coefficients of noise signal have constant deviation, reconstructed signal appears to be too smooth that precision declined. Because of some flaws of hard and soft threshold function itself, there is a certain deviation in reconstructed signal, it need to improve the threshold function, to reduce the deviation of the wavelet coefficients, to make it continuous in wavelet space, with higher order derivatives. So an improved threshold function to combine hard and soft thresholding was proposed [9, 10]:

$$\hat{W}_{j,k} = \begin{cases} W_{j,k} - 0.5\dfrac{\lambda^n \cdot k}{(W_{j,k})^{n-1}} + (k-1)\lambda, W_{j,k} > \lambda \\ 0.5\dfrac{|W_{j,k}|^m \cdot k}{(\lambda)^{m-1}} sign(W_{j,k}), |W_{j,k}| \leq \lambda \\ W_{j,k} + 0.5\dfrac{\lambda^n \cdot k}{(W_{j,k})^{n-1}} - (k-1)\lambda, W_{j,k} < -\lambda \end{cases} . \tag{13}$$

In Equation (13), *m*, *n*, *k* are the adjustment factor for improving threshold function, which enhance the flexibility of the threshold function. Parameters *m* and *n* determined the form of threshold function, the parameters *k* values between zero and one, if *k* = *0*, the threshold function is equivalent to the soft threshold function, if *k* = 1, then the threshold function is equivalent to the hard threshold function. Therefore, the adjustable parameter *k* can overcome the discontinuity of hard threshold functions and the constant deviation of soft threshold function when dealing with wavelet coefficients, but also retains the original advantages of the soft and hard threshold. Improved threshold function have infinite order continuous derivative, which provides the foundation for selecting wavelet adaptive threshold.

4 Selection of adaptive threshold

Traditional threshold function will produce the phenomenon of over-kill, perform poor in practical applications. Since the noise has a negative singularity, its magnitude and dense

degree decreases with the increase of scale, but the signal is the opposite. With the increase of the scale, amplitude and dense modulus degree of maxima controlled by the noise quickly reduced and amplitude and dense modulus degree of maxima of the signal will be significantly increased. It can be seen that using the same scale thresholds on the same level are clearly inappropriate, because at a lower scale it will removes useful information and at the largest scale it will leave parts of the noise.

Adaptive threshold is a adaptive threshold selection algorithm using the wavelet transform coefficients of minimum risk mount as threshold. By the Baswarr theorem, the square of wavelet coefficients have energy dimension, therefore the square of decomposed wavelet coefficients are sorted, the risks are calculated according to the given threshold values, which will gets its likelihood estimation. The non-likelihood minimization is done and the selected threshold values are obtained, which is a soft threshold estimator. The specific algorithm is:

1) The square of the wavelet transform coefficient $w_{j,k}$ of each layer are arranged in ascending order, to get a vector $w=[w_1, w_2, ..., w_n]$, $w_1 \le w_2 \le ... \le w_n$, wherein n is the number of wavelet coefficients.

2) Calculate the risk vector $R=[r_1, r_2, ..., r_n]$, then $r_i = \left| n-2i+(n-i)w_i + \sum_{k=1}^{i} w_k \right| / n$, where r_i is the introduced risk vector elements.

The minimum r_i yielded by the above equation multiple iterations are denoted by r_0, and the corresponding w_i are denoted by w_0.

3) Calculate the threshold value

$$\lambda = \sigma (w_0)^{\frac{1}{2}}. \tag{14}$$

5 Simulation

In order to compare the different threshold noise reduction methods, the original signals and the noisy signals are selected as the standard signal $f(n)$ and $s(n)$, the length of signals are L, the signal-noise-ratio (SNR) is defined as the Equation:

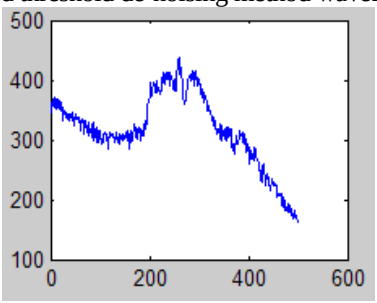
$$SNR = 10 * \log \left[\frac{\sum_{i=1}^{L} f^2(i)}{\sum_{i=1}^{L} (s(i)-f(i))^2} \right] (db). \tag{15}$$

Root mean square error (RMSE) between the original signal and the estimated signals is defined as:

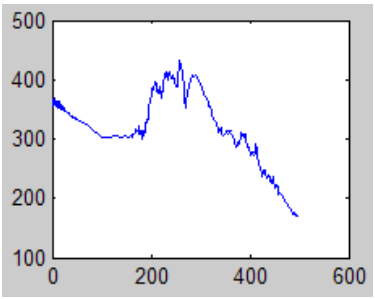
$$RMSE = \sqrt{\frac{1}{L} \sum_{i=1}^{L} (s(i)-f(i))^2}. \tag{16}$$

5.1 DENOISING OF SIMULATION SIGNAL

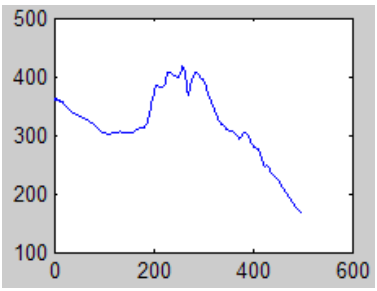
In order to verify the effect of improved threshold denoising method, leleccum signals in matlab are selected in simulation experiments, "sym5" wavelet basis are selected in wavelet packet decomposition, the maximum decomposition scale is three. Figure 2a are the original analog signals, Figure 2b are conventional wavelet thresholding waveforms, Figure 2c are the improved threshold de-noising method waveform.



a) The original signals



b) Signals of conventional wavelet thresholding denoising



c) signals of improved thresholding denoising

FIGURE 2 simulation signal denoising

As can be seen from Figure 2, the two denoising methods improve the signal to noise ratio. Most of the noise have been suppressed, but the use of the improved threshold denoising method get small distortion and better smoothness, high-frequency useful information of signals are relatively well preserved, the SNR is higher than the conventional wavelet threshold de-noising and has a good effect.

4.2 SYNTHETIC SEISMOGRAM DENOISING

Seismic data simulation was done by using MATLAB, common shot gather profiles are synthesized with a low-frequency ricker wavelet and a high-frequency ticker wavelet superimposed, specific parameters: a depth of one hundred meters, upper reflective layer velocity of two thousand me-

ters every second, lower speed of three thousand meters every second, the minimum offset of two meters, the number of channels of sixty, a record length of one hundred and twenty millisecond. Figure 3 is the synthetic common shot gathers, Figure 4 is common shot gathers with 5db random noise, Figure 5 is the common shot gathers after the common wavelet packet denoising. Figure 6 is the common shot gathers after the improved threshold wavelet packet denoising.

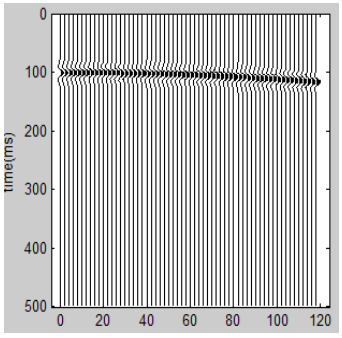


FIGURE 3 Synthetic common shot gathers

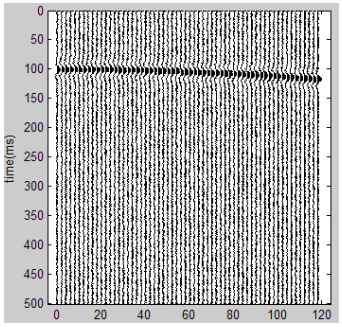

FIGURE 4 Common shot gathers with noise

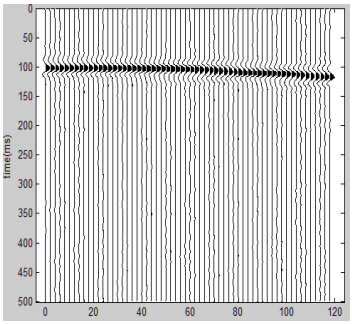

FIGURE 5 The common shot gathers after the common wavelet packet denoising

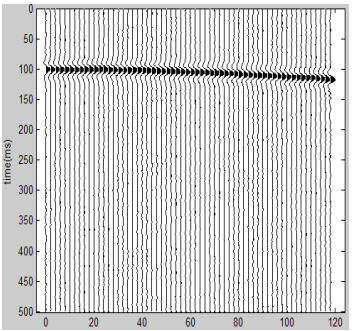

FIGURE 6 The common shot gathers after the improved threshold wavelet packet denoising

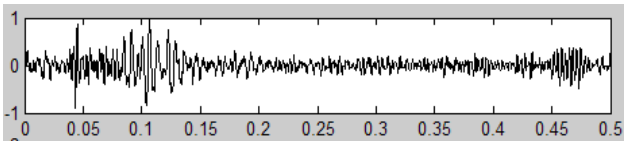
It can be seen from Figure 5 and Figure 6, when the valid signal contains high frequency components, the denoising visual effects of improved method is better than conventional wavelet thresholding denoising. The SNR of conventional wavelet thresholding and the new threshold wavelet packet denoising were 25.3018 db and 32.1148 db, SNR have also increased, SNR of improved threshold wavelet packet denoising are higher.

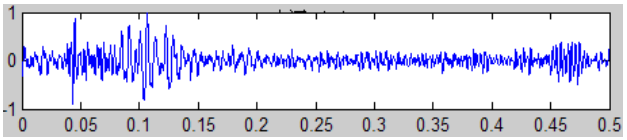
5 Seismic data denoising

The interference noise is inevitable in real seismic data acquisition and the collected data must be denoised. In the test Germany SUMMIT distributed seismograph were used for observation seismic data of a monitoring point, channels were twenty-six, channel spacing were one kilometers, offset distances (two short distances) were ten kilometers, gun dot distances were two kilometers, the detector arrays and source arrays were with one line, recording time was six seconds. Actual seismic data are generally stored in the format of segy, it need to convert, and to remove the channel header and volume header in real data processing. sym4 wavelet were selected for three times decomposition to the acquired seismic wave.

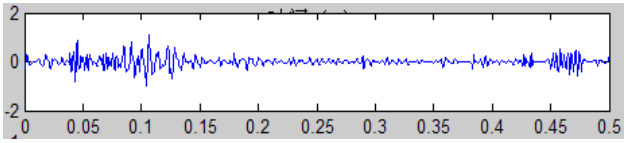
Figure 7a are part data of the original signal in one channel, Figure 7b are signals after conventional wavelet thresholding denoising, and Figure 7c are signals of improved threshold function denoising.



a) The original signals



b) The signals after conventional wavelet thresholding denoising



c) The signals of improved threshold function denoising

FIGURE 7 The common shot gathers after the improved threshold wavelet packet denoising

As can be seen from Figure 7 that most noises of seismic signals by hard threshold function denoising are filtered, which also weaken the details of the original signals, resulting in distortion, which is the results of the coefficients less than the threshold value are set to zero caused by hard threshold value function. The amplitude of soft threshold function denoising and the original seismic signals are of maximum distortion. Instead, the smoothness of seismic signals with the new threshold function denoising are best, the useful signals

components are well reserved reducing the distortion. It can be seen visually seismic signals denoised by improved threshold function are closest to the original signals.

6 Conclusions

An denoising method based on improved wavelet threshold function and adaptive threshold wavelet packet seismic signals was presented. In wavelet packet decomposition process, the improved threshold function and a hierarchical adaptive threshold were selected to apply to the synthetic seismogram and real seismic records. It can be seen from the SNR improvement and simulation results, that this method can effectively remove noises from the sampled signals, keep the useful signal and improve signal to noise ratio of seismic data.

Abstract

The way to improve the accuracy and reliability of automatic unscrambling and identification technology on X-ray fluorescence spectrometer spectrum is studied in this essay. Accordingly, two different automatic identification methods based on Fast Fourier Transform and Wavelet Transform are presented. By the tool LabVIEW, such two methods are applied to the qualitative analysis on X-ray fluorescence spectrums, and the features of such two methods are compared. Based on the experiments and analysis on amount of samples, it can be concluded that the automatic identification method based on the Wavelet transform theory is better than the other method for the former has a better local resolution. Therefore, the characteristic values of the singular points are more clearly recognized by the method based on the Wavelet transform. Through the study in this essay, theories on automatic identification are enriched, which set a foundation for further studied in future.

Keywords: X-ray fluorescence spectrometer, spectrum identification, LabVIEW, fast Fourier transform, wavelet transform

1 Introduction

X-ray fluorescence spectroscopy technology as a widely used ray-detection technology, began in the early 1950s. Since the spectrum is less interfered, accurate, precise, fast, can detect multiple elements, has a wide range of measurement, and performs non-destructive testing, it is applied to various fields, which becomes an indispensable and means in the laboratory and no alternatives. And now it becomes an indispensable method for analysis of substance composition. X-ray fluorescence spectroscopy detection technology has overwhelming advantages such as fast analysis speed, wide range of elements, which can be tested, simple pretreatment, free of pollution, low cost and non-destructive testing, etc. Nowadays, there are more and more types of X fluorescence spectrometers. Those X fluorescence spectrometers can be divided into two types according to the method of acquiring and distinguishing the characteristics of the X-ray fluorescence spectroscopy: wavelength dispersive X-ray fluorescence spectrometers (WDXRF) and energy dispersive X-ray fluorescence spectrometers (EDXRF) [1].

An X-ray fluorescence spectrometer is generally made up of three parts in structure: a light source for exciting the sample (X-ray tube), a detection system (for dispersion, detection, and controlling the spectrometer), and a data processing system [2]. Incident X-rays are generated from the X-ray tube for exciting the sample. Accordingly, secondary X-rays can be emitted from the to-be-tested elements of the sample by the excitation, in which different secondary X-rays emitted from excitation of different elements each owns specific energy characteristics and wavelength characteristics. The energy of such secondary X-rays are collected and measured by the detection system, and through a data processing software in the detection system, the collected fluorescence information of such secondary X-rays are calculated into types and contents information of the to-be-tested elements of the sample. Spectrum characteristics of a certain element is not only related to the energy and intensity of the excitation source, but also related to the level of such element in the sample. According to the spectrum characterristics of such element, the content information thereof can be obtained by converting.

There are mainly three types of analysing methods of the X-ray fluorescence spectroscopy detection technology: qualitative analysing method, semi-quantitative analysing method and quantitative analysing method [3]. The qualitative analysing method is discussed in this essay, which indicates the aforementioned solution and identification methods on the spectrum. The Moseley's law tells that the wavelength of the secondary X-ray emitted from the to-be-tested element is one to one related to the atomic number. In qualitative analysis, characteristic peaks and common interference lines of the scanned spectrum figure should be identified, thereby to determine the types of elements contained in the sample, and thus to determine the types of materials of the sample.

Currently, the automatic recognition algorithm of the X-ray fluorescence spectrometer is being studied by various spectrometer manufacturers. According to the algorithm, by determining the peak of the scanned spectrum, calculating the net intensity of the background and peak, as well as pairing with the characteristic spectrum line database, the types of the to-be-tested elements and the types of the spectrum lines are determined. However, the actual working situation is complex and changing. For example, when the

**Corresponding author* e-mail: dr.xjning@gmail.com

content of an element is too little or there exists interference between of spectral lines of different elements, the artificial identification by experiences of the operator is essential. First, the characteristic X-ray lines of the target X-ray tube and the associated lines of the peak are identified. Afterwards, the remaining spectrum lines are marked according to energy. When unknown spectrum lines are analysed, other factors such as the origin and nature of the sample should also be taken into consideration, so as to get comprehensive judgments.

In order to improve the accuracy and reliability of the automatic recognition and reconciliation of spectrums, this essay presents a method for feature extraction and recognition based on fast Fourier transform, and a method for spectrum solution based on wavelet. And such two methods are proved and compared by specific experiments with LabVIEW.

2 RELATED WORK AND BACKGROUND

Spectrum recognition models either domestic or international are essentially divided into two types: a spectrum matching method based on spectrum reconstruction and standard spectrum similarity measurement, and an intelligent recognition method based on sample knowledge. The spectrum matching method is to compare the reconstructed spectrum with the reference spectrum, and to measure the similarity or correlation between them by a certain measurement function, so as to identify the sample. The similarity measurement function can be a distance function (Euclidean distance, Mahalanobis distance), similarity coefficient, correlation coefficient, spectral information divergence or spectrum vector angle, etc.; and the reference spectrum can generally be a standard spectrum in the spectrum database.

According to the data used during the matching process, the spectrum matching method can be divided into two types: direct matching and indirect matching. The direct matching method uses the reconstructed spectrum to match the reference spectrum data directly; whereas the indirect matching method encodes or transforms the spectrum data first, and uses the encoded and transformed data to match, such as encoded spectrum matching, amplitude and phase of the Fourier frequency of the spectrum, wavelet or fractal dimension matching, other than using the raw spectrum data to match directly.

When the X-ray fluorescence spectrum analysis method is carried out, due to the interaction of X-rays substances, such as coherent scattering, incoherent scattering, Compton scattering and other reasons, the Almighty certain peaks of the characteristic X-ray may superimpose on the background. In the qualitative and quantitative analysis, it is very necessary to subtract the background accurately in order to obtain the peaks of the spectrum and the net intensity of peak areas. It is a very critical and difficult technology to subtract the background effectively and accurately. Therefore, various digital filtering and deconvolution algorithms are powerful tools for the spectrum solution.

In recent years, more and more advanced intelligent methods have been used in such field. The intelligent identification method is on the basis of physical spectrum knowledge. According to this method, appropriate diagnostic spectrum features or spectrum parameters with identification ability are selected first, then identification rules are established, and samples are identified accordingly. Characteristics or parameters of the spectrum can be the similarity measure for the whole spectrum, such as the matching degree or matching rate compared to the standard spectrum, or the parameters of specific bands, or both. The identification rules can be generally expressed in 3 ways: uniqueness identification (existence identification), i.e., when some certain conditions are met, it can be considered that some certain element exists; negative identification, i.e., when one or more features occur, it can be considered that some element must not exists; likelyhood identification, i.e., the likelihood whether the material to be identified is determined according to the conditions.

The intelligent identification method combines the full spectrum matching method and the feature spectrum band identification method, which takes the advantages of the two methods, and establishes an identification rule referring to the expert system. As such, the reliability and automation of the identification are greatly improved. For example, someone introduces the genetic algorithm to the solution of X-ray fluorescence spectrum and achieves good results. The genetic algorithm is a kind of probabilistic algorithm based on simulation on the laws of life, which searches for a solution suitable for the environment. Some studies present a method that takes the fractal dimension as the spectrum identification feature. In this method, the fractal dimension of the spectrum signals is obtained by phase-space reconstruction. Different spectrums can be identified through comparing the fractal dimension of the spectrum signals. Someone also proposes another spectrum identification scheme based on multi-spectral features and integrated neural network, and implements system design. However, most of the aforementioned methods and corresponding implementation software are on the basis of human involvement or assistance. This paper attempts to present an automatic spectrum identification method based on traditional signal processing methods and advanced algorithms. Under the current condition, overly complex algorithms do not required for the automatically recognizes by machines, while characteristic values are needed used for the machine's independent judgment.

The basic ideas of both the Fourier transform automatic identification method and the wavelet transform automatic identification method require a standard library, which is used to compare the calculated characteristic values of the samples with the characteristic values in the library obtained by the same method. Therefore, it is very significant to create such a feature library. The general spectrums of an alloy, which includes Stainless steel, cobalt alloy, nickel base alloy, Titanium alloy and middle-low alloy steel are chosen as the spectrum library, wherein each library contains multiple spectrums. The spectrum library is characterized by a processing method based on the fast Fourier transform and characterized by a processing method based on wavelet trans-

form respectively, which will be mentioned below. The feature libraries corresponding to the two methods thus obtainned. The alloy of Stainless steel, cobalt alloy, nickel base alloy, Titanium alloy and middle-low alloy steel are selected as the testing samples. The spectrums of the samples are general random spectrums completely different from the feature libraries.

A suitable experimental environment and proper tools are in need on the basis of aforementioned works, We had chosen the NI LabVIEW environment. LabVIEW (Laboratory Virtual Instrument Engineering Workbench) is a kind of graphical programming language, which uses icons to create applications instead of text lines. In traditional text-based programmming languages, programs are executed in sequences of statements and directives. Whereas, in LabVIEW a dataflow programming mode is used, that VI (abbreviation of virtual instrument, refers to program modules in LabVIEW) and execution sequences of functions are determined by the data flow between nodes of block diagrams. With the LabVIEW programming language, flow charts or diagrams are used instead of program codes. LabVIEW is an end-user oriented tool, which adapts terms, icons and concepts familiar with technical staffs, scientists, and engineers as much as possible. LabVIEW can enhance the ability of building your own science and engineering systems, and can provide a convenient way to implement instrumental programming and data acquisition systems. The working efficiency of the instrument system can be greatly improved with LabVIEW in its principle researching, designing, testing and implementation.

3 The spectrum unscrambling and identification method based on fast Fourier transform

The Fourier transform would be firstly taken into consideration if Mentions signal analysis in transform domain. Through the discrete Fourier transform (DFT), a finite-length sequence *x(n)* can be transformed into a discrete finite-length sequence *x(k)* in its frequency domain [4].

$$x(k)=\sum_{n=0}^{N-1}x(n)W_N^{nk},\ k=0,1,2,\ldots,N-1. \tag{1}$$

Whose inverse discrete Fourier transform (IDFT) is

$$x(n)=\frac{1}{N}\sum_{k=0}^{N-1}x(k)W_N^{nk},\ n=0,1,2,\ldots N-1, \tag{2}$$

wherein $W_N=e^{-j2\pi/N}$, and *x(n)* and *x(k)* may be a real number or a complex number. It can be concluded that to calculate a sample sequence, *N* times of multiplication operation and *N*-1 times of addition operation of complex numbers should be done. Therefore, it is difficult to perform real-time processsing with DFT because of its huge amount of computations.

Since it is very important to do discrete Fourier transform in signal analysis, it is very necessary to find fast algorithms for discrete Fourier transform and corresponding inverse transform. Fast Fourier Transform (FFT), namely fast discrete Fourier transform (FFT) is a kind of fast DFT algorithm that invented by J.W.Cooley and J.W.Tukey in 1965, wherein the periodicity and symmetry of the factor of the W_N is utilized. The Discrete Fourier Transform is equivalent to multiplying a sequence *x* (as a column vector of *n* elements) by a $n\times n$ matrix F_n, which needs n^2 multiplications. Whereas the fast Fourier transform is to change the matrix F_n into a special form, which can reduce the times of multiplications into approximate $5n\log_2 n$ times. If n=1000, then by the fast Fourier Transform, the times of multiplications can be reduced from millions to about 50, 000.

In the later decades, it is further developed with the FFT algorithm, wherein the most commonly used FFT algorithms now are radix-2 algorithm and split-radix algorithm. It is known that the FFT algorithm has been introduced in detail in many other documents, so this essay will not describe it in detail.

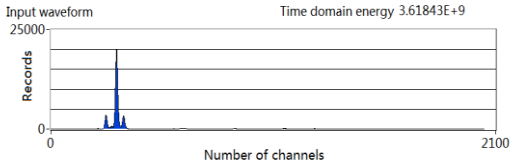

FIGURE 1 A spectrum captured by X-ray fluorescence spectrometer

Referring to Figure 1, a spectrum is shown. In physical, it is the channel value that corresponds to the horizontal axis, rather than a time-sequence. However, in a broad view, it can still be taken as a complete process. The aforementioned fast Fourier transform can be performed using the signal analysis tool in LABVIEW, as shown in Figure 2.

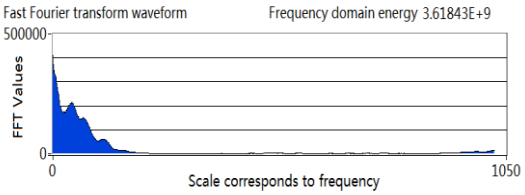

FIGURE 2 The result of fast Fourier transform

It is shown in the Figure 1 and Figure 2 that the energy in time domain calculated from the original pattern before the transformation must be equal to the energy in frequency domain calculated after the transformation, which is in line with Parseval's Theorem. It should be noted that the points in the abscissa only needs half of the original after the Fourier transform, even a quarter or less effective portion thereof with experiences. Accordingly, the amount of computation can be greatly reduced. Unfortunately, it is clear that the characteristic frequencies of almost all the general spectrum samples after the FFT in different spectrum patterns cannot be clearly distinguished by the Fourier transform. In order to make the FFT method continue, a method which combines the energy values and the boundary detection is used, considering the Parseval's Theorem. In this essay, the energy value is selected as the characteristic value, and then transformed by FFT transform, and last detected by its boundary for spectrum pattern recognition.

As shown in Figure 3, the energy value of the to-be-identified spectrum pattern is compared with that of the sample spectrum pattern in Library. The situation should be

very clear if the two energy values are not in the same magnitude. Otherwise, a threshold of range should be defined if the two energy values are close to each other. Additionally, comparison between the boundary values can be performed under the premise that the energy values are as the characteristic values. The pink line and blue line in the Figure 3 represent the top boundary value and bottom boundary value respectively. The identified spectrum pattern is transformed by FFT transform and compared with the boundary values. Points out of the boundaries are marked in red. In this figure, points that do not match occupy 0 percent of the total number of points, in some instances, this value may become large. Therefore, such percentage can also be taken as the threshold value of range for automatic identification.

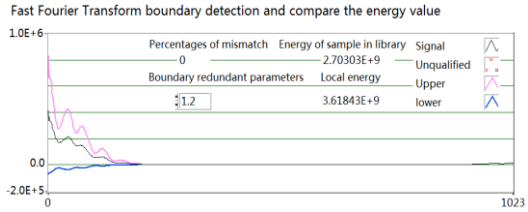

FIGURE 3 The spectrum unscrambling based on Fast Fourier transform

As can be concluded from the identification result, the material as shown in the Figure 3 is probably stainless steel.

4 The spectrum unscrambling and identification method based on wavelet transform

The basic principal of wavelet transformation is: after being dilated and translated, the original signal is decomposed into a series of sub-band signals with good local features in time domain and frequency domain, thus achieving local time and frequency analysis [5]. Wavelet transform is strongly correlated to the data, which make the energy of the signal exist only in some large wavelet coefficients in the wavelet domain, whereas the energy of the noise distributes throughout the whole wavelet domain. Thus, through the wavelet decomposition, the amplitude of the wavelet coefficients of the signal should be greater than that of the noise. It is considered that whose amplitude of the wavelet coefficients is relatively larger should be generally the signal, while whose amplitude of the wavelet coefficients is relatively smaller should probably be the noise. Therefore, wavelet transform shows better performance of detection in non-stationary signals with low SNR. When the scale of a signal to be detected changes, there will be a wavelet with an appropriate scale to match it. On the contrary, by the short time Fourier transform, the profiles of the signal can only be detected when the basic function matches the signal scaling function, while it is difficult to get a satisfactory result in other cases.

The purpose of Wavelet transform and the purpose of Fourier transform are the same: the signal is expressed as a linear combination of basic functions. The difference between the two transformations is: the basic function of the Fourier transform is the harmonic function $e^{-j2\pi/N}$, whereas the basic function of the wavelet transform is the Mother Wavelet Function $\Psi(t)$ with compact support generation. In the wavelet transform, a wavelet sequence is obtained through dilating and translating to the mother function $\Psi(t)$:

$$\psi_{a,b}(x)=\frac{1}{\sqrt{a}}\psi(\frac{x-b}{a}),\quad a,b\in R;a\neq 0 \tag{3}$$

where a is the dilating factor, b is the translating factor.

As to a given function $f(t)\in L^2(R)$, its continuous wavelet transform is:

$$W_f(a,b)=<f,\psi_{a,b}(x)>=\int_{-\infty}^{\infty}f(x)\psi_{a,b}(x)dx =\frac{1}{\sqrt{a}}\int_{-\infty}^{\infty}f(x)\psi(\frac{x-b}{a})dx \tag{4}$$

The selection of the basic wavelet function is very important, which often depends on the application [6]. The wavelet function generally has two basic characteristics geometrically: it must be an oscillating function and it must be a function with rapid convergence. The above two criteria should be followed When selecting a wavelet function or constructing a wavelet function. Different dilating factors and translating factors will bring about great changes in geometrical shapes of the wavelet function.

Since the translating factor corresponds to the time t, and the dilating factor corresponds to the frequency *f*, the time-frequency plane (*t, f*) becomes a time-scale plane (*b, a*). The principal of weak signal detection based on Wavelet transform is to put the signal with the noise on a time-scale two-dimensional plane, and then process the signal in time-division and frequency-division modes based on distinct characteristics of the signal and the noise. When the scale parameter a increases, the basic function $\psi_{a,b}(x)$ turns to a broadening wavelet, which corresponds to a low frequency function, whose frequency resolution is improved, but time resolution is reduced. Otherwise, when the scale parameter a decreases, the basic function $\psi_{a,b}(x)$ turns to a compressed wavelet, whose time resolution is improved, but frequency resolution is reduced. When the signal to be analysed has a sudden change, it is better to choose a smaller "a" to improve the resolution in the time domain. Therefore, the wavelet transform is more suitable for studying signals which are non-stationary and contains short-term transient components [7]. There is a special signal processing package for wavelet calculation in LabVIEW. It is very convenient to do experimental verifications on the idea of wavelet-based identification.

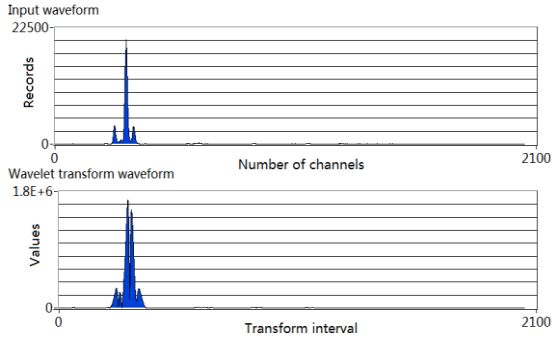

FIGURE 4 The waveform of wavelet transform

As shown in Figure 4, in the upper part, the input signal is a spectrum recorded by the X-ray fluorescence spectrometer. The abscissa of the spectrum physically represents the channel number of the spectrometer, while the ordinate of the spectrum represents values recorded by the instrument in every channel. In the lower part of the figure, there shows a waveform transformed from the input signal by broadly wavelet transform.

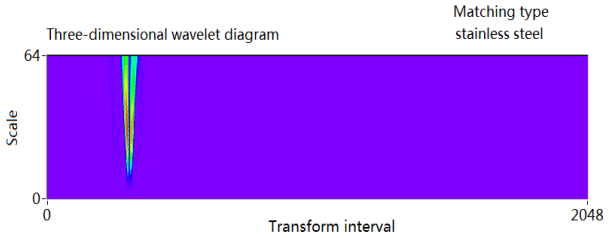

FIGURE 5 Singular points detection in a three dimensinal wavelet digram

As can be seen in Figure 5, it should be noted that the parameter SCALS here controls the scaling ratio of Wavelet transform. And the peaks with different amplitudes of the spectrum in the figure can be considered as singular points of the signal, which can be used as characteristic values of the spectrum. Thus, it can be taken as a detection process of singular points that the solution and identification s process of the spectrum [8]. For a long time, the Fourier transform is a main tool for study the singularity of functions. In detail, by studying the attenuation in the Fourier transform domain of the function of to infer whether there is singularity on the function and how serious the singularity is. However, referring to Fourier transform, its ability to distinguish details is often unsatisfactory. In contrast, wavelet transform is more spatially localized. Accordingly, it is more effective to use wavelet transform to analyse the location of singularity and the singular degree.

A multi-scale peak detection can be carried out toward the data that processed through continuous wavelet transform from the original spectrum, and the detected peaks as shown in Figure 5. Positions of singularity can be considered as characteristic values for identifying the spectrum. The magnitude of the ordinate and the resolution of the abscissa of the wavelet transform data can be used as scaling parameters of the multi-scale peak detection. Peaks less affected can be excluded by adjusting the amplitude threshold, and a proper characteristic value can be accurately found from the overlapped peaks by adjusting the resolution parameter. The characteristic value is corresponding to the position of transform interval, and it can also be corresponding to the channel number of the original input spectrum. Accurate spectrum identification can be performed by comparing that characteristic value with the characteristic library of different materials recorded in the sample library.

Figure 5 gives the automatic identification result, the material shown in the in figure is probably stainless steel.

5 Experiments and results

Two automatic recognition algorithms were designed for testing sample data in LABVIEW environment, which were based on fast Fourier transform and wavelet transform. Sample data contain general spectroscopy spectrum of Stainless steel, cobalt alloy, nickel base alloy, Titanium alloy and middle-low alloy steel five alloys. Before the experiment, we were prepared alloy feature library for each algorithm.

5.1 TESTING FOR THE AUTOMATIC IDENTIFICATION METHOD BASED ON FAST FOURIER TRANSFORM

The FFT method similar to a spectrum matching filtering method (Matched Filtering) is a kind of method to identify a specified target from a background whose spectral information is unknown. The basic idea thereof is to take the material spectrum in a standard spectrum database as a vector in the Q mean space, and to build a filtering vector detector according to the matching degree between the spectrum of the image and the reference spectrum vector, then to filter the input image, so that the spectral response of the target is maximized while the spectral response of other end of the element is suppressed. As such, the contrast between the target and the background is maximized and an optimal matching is achieved, and then an appropriate threshold should be selected, and the target information can be extracted.

Originally, the matching filtering is developed for calculating the relative abundance of the material content of less. Therefore, when the content of the target substance is not few, it should be careful and cautious to apply the method and to interpret the results of the method. The Mixture Tuned Matched Filtering (MTMF) [9] is a composite method, which combines the linear mixed decomposition method and the matched filtering method. It combines the advantages of matched filtering method that do not need other background end elements and the constraint condition that the content of each end element of the image element in the linear mixed decomposition method should be positive and the sum of the content should be 1, thereby the detection limit of the elements is reduced, and the trace elements in the samples that other methods could not detect would be detected.

In Table 1, results by artificial matching identification of 51 samples are excerpted, which are compared with the results by FFT automatic identification algorithm. As can be seen, most of the results are consistent, except that the results in No. 24 and No. 25 by automatic identification identified the stainless steel as the nickel base alloy. After careful analysis, it can be known that by the automatic identification algorithm based on FFT, for both the No. 24 and No. 25 samples, it is difficult to clearly distinguish whether they belong to stainless steel or nickel base alloy, either by energy identification condition or by boundary matching condition. As to the energy identification condition and the boundary matching condition, the libraries of the stainless steel and the nickel base alloy themselves are also very similar. This kind of situation is improved in the automatic identification algorithm based on wavelet.

TABLE 1 FFT Automatic identification test results

In Table 2, results that comparing and matching a sample with the samples in the library database of FFT algorithm are excerpted, in which the calculation process of such automatic identification algorithm can be reflected. First, it can be seen that for the energy identification condition, the sample is relatively easier to pass cobalt alloy, stainless steel and Titanium alloy. Then the boundary matching condition should be considered, and also the statistical analysis law, through which it can be determined that the sample belongs to Titanium alloy.

To summarize, confirmed by experiments of hundreds of samples, the accuracy rate of identification can reach 90%

by the FFT transform automatic spectrum pattern identification method based on the energy threshold of range and boundary threshold of range. However, there are still some spectrum patterns that could not be clearly distinguished by their characteristics after FFT transform, even the energy value of such spectrum patterns can be easily confused with the sample libraries of different materials. So such spectrum patterns could not effectively be identified through the Fourier transform method. In order to solve such problem and further improve the accuracy of spectrum patterns identification, a wavelet method is introduced here.

5.2 TESTING FOR THE AUTOMATIC IDENTIFICATION METHOD BASED ON WAVELET TRANSFORM

The spectrum is with high spectral resolution, multi-bands, massive data, strong correlation between the bands, high data redundancy, so it is necessary to reduce the dimensions of the data and to weaken the noises before selecting the end elements and identifying the materials. The functions for the wavelet transform are:

1) To separate the information from the noise. After the transformation, the transformation components are arranged in a descending order according to their corresponding characteristic value, whose noise components decreases, while corresponding component information of greater characteristic value is more. Corresponding component information of smaller characteristic value gradually becomes less, while the noise level increases. Corresponding components whose characteristic values are very small and tend to be constant are almost all noises. Therefore, separation the information from the noise can be achieved, and the noise of each component image can be removed on target, or components whose noises are dominant can be abandoned, so as to remove noises.

2) To reduce the dimensions. After the transformation, the correlation between the original spectral bands can be eliminated, so that the information can be concentrated in a small number of components, thus redundancy of data can be reduced. Through observing the characteristic values and corresponding images, the intrinsic dimension of the data can be determined. Selection of end elements and identification of samples can be carried out in transformed low-dimensional space, so as to shorten the duration of data processing and improve the efficiency of processing.

3) To separate features. The spectrum information of samples is isolated in the transformed feature space after wavelet transformation, wherein the spectrum converges on the class feature vector set, and some weak information is enhanced in noise removing transformation. Accordingly, the separability of the data from the sample is increased, and the reliability of the identification is improved.

In Table 3, results by artificial matching identification of 51 samples are excerpted too, which are compared with the results by wavelet automatic identification algorithm. It can be seen that only one sample No.31 cannot be identified by the automatic identification algorithm. As a matter of fact, all the experimental results are not shown in the Table 3 due to the length limitation of the table. There is only this one, which could not be identified in all the hundreds of experiments we have done. Simultaneously, the characteristic values of the samples that calculated through the automatic identification algorithm based on wavelet are shown in Table 3. It can be seen that the numbers of characteristic values that calculated from different samples are different. Value1 and Value2 of each sample (if any) are better consistent. In fact, it can be identified what material the sample belong to basically from the first and second characteristic value. For some samples with more characteristic values, it is better to continue to match with the library database, of course, the premise is that there is similar characteristic value record in the library database, and to prove that the characteristic value is not illegal. For the sample No.31, it can be seen that its characteristic value does not match with stainless steel well. Therefore, it could not get a result by the automatic identification algorithm. The reason may be there some errors occur during the data acquisition process. Interestingly, it can be identified by the automatic identification algorithm based on FFT, which is actually worth further studying.

To summarize, verified by experiments on amount of samples, the identification accuracy of the automatic spectrum identification method based on Wavelet transform can reach 99%. Quite differences were found between the identified spectrum and its corresponding material in the sample library for the unique error, there possibly was something wrong during the data collection process using the spectrometer. It can be concluded that the automatic spectrum identification method based on wavelet transform owns some advantages, but there is still space for further improvement with such method.

6 Conclusions

Methods of automatic unscrambling and identification on spectrums captured by X-ray fluorescence spectrometers are discussed in this essay. It is difficult to accurately distinguish the peaks in the spectrum in the time domain only with experiences, because the peaks in the spectrum are always overlapped and are easily confused. It should be noted that such time domain is a broad concept which is corresponding to the channel number of the abscissa of the spectrum. Therefore, in order to achieve fast and accurate automatic spectrum identification, a method for unscrambling and identifying characteristics based on fast Fourier Transform and a method based on wavelet transform are proposed herein.

It can be concluded from the results of experiments by the aforementioned two methods that: by the method based on fast Fourier transform, the spectrum is transformed from the time domain into the frequency domain (broadly) to find characteristics of the spectrum in the frequency domain, but actually in some spectrums it is difficult to distinguish peaks of different time points (channel numbers) in the frequency domain because the peaks are also overlapped. In contrast, by the method based on wavelet, it can be clearly and accurately to find the characteristic values of the spectrum and thus effectively to identify various elements and materials, wherein the characteristic of "being amplified in part" of non-stationary and short-term transient component accompanied signals is fully utilized.

Accordingly, a theoretical idea for automatic spectrum identification and solution for X-ray fluorescence spectrometers is provided based on the discussion on the aforementioned two methods, and a basis for further development of faster and more accurate qualitative analysis method is built.

Abstract

This work discussed the technique for fine detection of mine collapse column by anti-explosive ground penetrating radar (GPR) and its feasibility. In stage of theoretical research, numerical forward modelling was used to study the response characteristics of collapse column on radar profile. In actual exploration, the spatial distribution pattern of collapse column was accurately stored by installing complex environment observing system in the pit. In processing and explanation, the disturbance types of mine were comprehensively analysed, and various measures were taken in the suppression of interference signals to obtain better exploration effects. The study showed that fine detection of collapse column can be realized by anti-explosive ground penetrating radar under the complex conditions in the pit.

Keywords: Anti-explosive ground penetrating radar (GPR), collapse column, fine detection

1 Introduction

Mine collapse column is one of the key problems for mine production [1]. Collapse column is generally formed by sinking of overlying rock. Such sinking results from the cavity, which is caused by the underground water corrosion of soluble rock underlain in coal measure strata. If the collapse column without solid filling is connected with runoff belt in aquifer of mining area with rich underground water, water burst and even inundation may possibly occur when work surface is directly exposed or gets close [2].

The detection of collapse column in the pit is mainly by drilling and geophysical prospecting. Drilling is perceptual but limited by the layout condition of drill hole, so it cannot completely reflect the distribution of collapse column [3]. With advantages of area detection, geophysical prospecting is widely applied to obtain obvious geological effects. The main methods include seismic detection, direct current electric method, transient electromagnetic, and pit penetration. However, it is difficult to arrange effective observing system in the complex and narrow space of mine when using seismic detection, direct current electric method, etc. Therefore, the exploration completeness and accuracy of collapse column will be affected [4, 5]. Moreover, geophysical prospecting is also limited by the gas environment in the pit. Equipment not reaching anti-explosive safety grade cannot be used in the pit.

Anti-explosive GPR can safely work in the pit. With small volume, light weight, and collection method of point detection or continuous detection, it can flexibly arrange the survey lines according to specific environment. Moreover, the screen-type design can effectively shield interference in the pit [6]. Meanwhile, featured with high resolution and efficiency of common GPR, it can finely detect the spatial distribution of collapse column [7]. This work mainly introduced technology methods and application effects about the detection of mine collapse column by anti-explosive GPR.

2 Theory of GPR

The concept of GPR was proposed by Germany Letmbatch and Lowy in 1910 at the earliest. It can detect the target by emitting high-frequency impulse electromagnetic (in frequency scope of 106~109Hz) to the medium [8]. Mediums with different relative dielectric constants have different reflections of electromagnetic wave, and its factor r can be expressed as follows:

$$r = \frac{\sqrt{\varepsilon_1} - \sqrt{\varepsilon_2}}{\sqrt{\varepsilon_1} + \sqrt{\varepsilon_2}}, \tag{1}$$

where ε_1 and ε_2 represent relative dielectric constants of medium 1 and medium 2, respectively. The distribution scope of the constant is 1 (air) < ε <81 (water). The larger the difference between relative dielectric constants, the stronger the reflection energy of electromagnetic wave will be.

Figure 1 show the principle that the GPR emits high-frequency electromagnetic pulse to the medium. The travel time of impulse wave can be expressed as follows:

$$t = \frac{4z^2 + x^2}{v}, \tag{2}$$

where, t is the two way travel time of electromagnetic wave, z is reflector depth, v is the wave speed in underground medium, and x is the distance between transmitting antenna and receiving antenna (distance between receiver and transmitter).

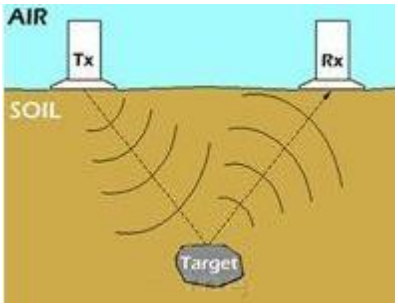

FIGURE 1 Schematic diagram for the principle of ground penetrating radar (GPR) detection

This study used ZRT intrinsically safe GPR developed by China University of Mining and Technology (Beijing). It can be safely used in the gas environment of pit. With central frequency of 180MHz, this radar antenna adopted screened antenna "integrating with receiving and transmission". Compared to the exploration depth *z*, the distance between receiver and transmitter can be deemed as $x \approx 0$ for the close distance between receiving antenna and transmission antenna. Therefore, the two-way travel time of impulse can be expressed as follows:

$$t = \frac{2z}{v}, \tag{3}$$

where wave speed *v* is related to the relative dielectric constant of medium. The larger the relative dielectric constant of medium, the slower the radar wave will transmit in the medium. The relational expression between both is as follows:

$$v = \frac{c}{\sqrt{\varepsilon}}. \tag{4}$$

When the speed of electromagnetic wave in medium *v* is known, the depth of reflection target *z* can be obtained by Equation (3) according to the measured accurate time *t*.

When transmitting in the medium, the properties of electromagnetic wave, including amplitude, phase, and waveform will change with the electromagnetic property and geometrical morphology of medium. Therefore, the structure and nature of medium can be deduced according to the received data about travel time, amplitude, and waveform of radar wave. Radar detection reflects the measured medium with profile, which is the record for the form of reflection wave. The positive and negative energy are represented with black and black, or the gray and color scale, respectively. Compared with other geophysical prospecting, GRP can more intuitively reflect the detection results, and can make preliminary reference and judgment at site.

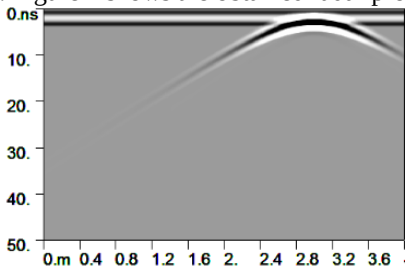
3 Geophysical characteristics of collapse column

Collapse column of coal measures is generally caused by the continuous upward collapse in large-span solution cavity of soluble rock series underlies in coal measures. There is a large difference between electrical property of coal measures and that of the rock mass in collapse column in coal measure strata. Therefore, the radar reflection wave with strong energy can be formed in the boundary of collapse column. In general, the development of collapse can be divided into 4 stages: early development stage, strong development stage, decline stage, and dead stage [9]. For the collapse column in different development stages, the filling degree of inner cement, water transmissibility and abundance, the damage status of surrounding rock distribution, and the associate structure are all completely different. Therefore, their geophysical characteristics are different in electric property.

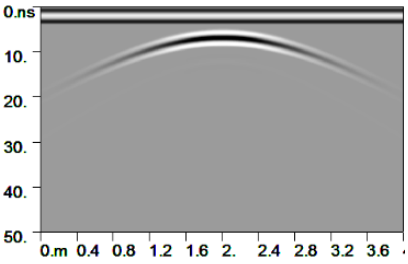
In general, collapse column is elliptic cylinder or oblate cylinder in space, and irregular cylinder in profile [9]. The dielectric constant of collapse column is obviously different with that of surrounding rock stratum and coal bed. Moreover, with water or air in marginal area, the difference of dielectric constant and conductivity may surge to enhance the reflection energy of radar signal. Although the reflection energy is strong, the distribution of wave group is in disorder because of the complex binding form between collapse column and its margin and surrounding rock [10].

In order to study the radar respond characteristics of collapse column, finite difference time domain was adopted to simulate the radar wave generation and the transmission in coal and rock medium.

Firstly, a collapse column with elliptic cross section was designed, and its long axis was 3.2 meters and short axis 1.8 meters in horizontal. Then, the collapse column was detected by simulating GPR penetrating the lateral wall of lane with survey lines parallel to long and short axis were laid in horizontal. Figure 2 shows the obtained radar profile.



a) Simulated effects of radar profile when survey line parallel to the short axis of collapse column in horizontal



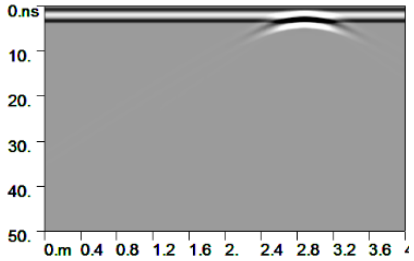
b) Simulated effects of radar profile when survey line parallel to the long axis of collapse column in horizontal

FIGURE 2 Simulated radar profile of collapse column in horizontal section

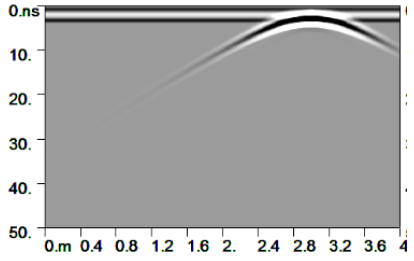
In simulated profile, the response of detected collapse column parallel to long axis should be obviously wider than that to short axis. Therefore, the distribution for the long and short axis of collapse column can be differentiated according to this characteristic.

In addition, the contrast simulation was conducted for the change of collapse column conductivity and dielectric constant caused by different moisture contents. Water may increase the conductivity and dielectric constant of collapse column [11]. Figure 3 shows two respond profiles of collapse column with different conductivities and dielectric constants. In this figure, Figure 3a shows the non-aqueous condition that the conductivity is 10-7S/m and dielectric constant is 7. Figure 3b shows the aqueous condition that the collapse conductivity is 10-2S/m and dielectric constant is 14. According to the radar profile, the response energy of aqueous collapse column is obviously higher than that of non-aqueous collapse column [12].

Furthermore, the contrastively simulations detection of collapse column has been used according to the change of conductivity and permittivity of collapse column for different moisture content as well. The conductivity and permittivity of collapse column will increase because of the water in medium, so in the radar response profile of collapse column of two group different conductivity and permittivity in the Figure 3, Figure 3a shows the conductivity of collapse column is 10-7S/m, and the permittivity is under no water circumstance value 7. Figure 3b shows there contain water in the medium, the conductivity of collapse column is 10-2S/m, the permittivity of it is 14. The response energy of collapse column of containing water is significantly higher than collapse column of no water according to the radar profile [13].



a) Profile of non-aqueous collapse column



b) Profile of aqueous collapse column

FIGURE 3 Comparison chart for simulated profiles of collapse column with different aqueous conditions

According to the forward modelling radar profile, characteristics of collapse column were judged in aspects of layout position, form, water containing, etc.

4 Actual detection

There is a collapse column with 73m long axis and 45m short axis between main rail haulage roadway and air return roadway in the primary mineable coal bed in Shanxi Province. As shown in Figure 4, the exploration of air return roadway keeps away from this collapse column by bypassing up to the mountain. Coal faces 8102 and 8103 are located in the north to collapse column.

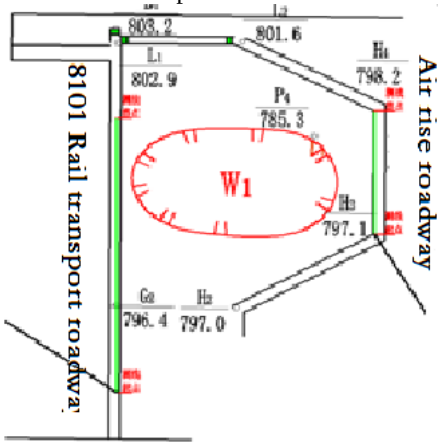


FIGURE 4 Schematic diagram for survey lines of 8101 rail haulage roadway

4.1 DATA COLLECTION

This mine is a newly-established shaft without detailed geological data, so two main radar survey lines were laid for the lateral walls of two roadways neighboring to collapse column after knowing the surrounding rock in transportation roadway and air return way. As shown in Figure 5, two survey lines of lateral walls along crossheading of rail are 110m long, while those along air return roadway are 50m long. As shown in Figure 6, two short survey lines were set in lateral wall and head on work faces 8103 and 8102, which were 18m and 19m long.

This study used ZRT intrinsically safe GPR developed by China University of Mining and Technology (Beijing). Its central frequency is 180MHz. In order to reach 30m detection depth, the time window for collection was set as 700ns, and the sampling point number as 1024. Detection was conducted by continuous collection for 4 times.

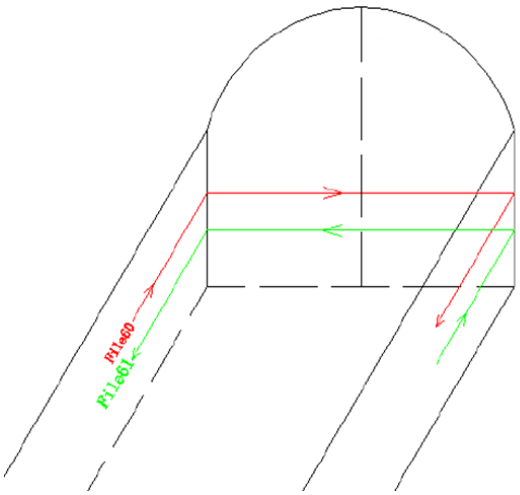

FIGURE 5 Schematic diagram of radar survey line layout

4.2 DATA PROCESSING

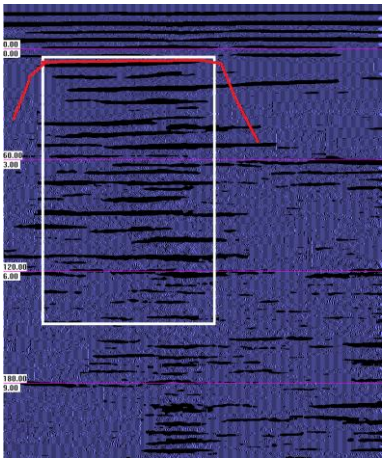
Self-developed GR processing and explaining software was adopted in the processing of collected data. In regular processing, gain adjustment, one-dimensional filtering, FK filtering, and wavelet transform were used. In addition, signal-to-noise ratio can truly reflect the change of detected medium and ensure data quality [14].

4.3 EXPLANATION OF REGULAR DATA

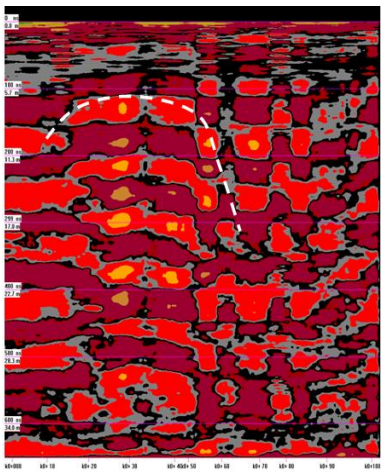
GPR detects anomalous body with the variance of electromagnetic property. GPR analyses the variance between collapse column boundary and surrounding mediums and the reflection of collapse column on radar profile according to the geological data. Then, the distribution scope of collapse column can be determined. The time profile of radar is mainly identified according to the changes of reflection energy on different time axis because there is a large difference of electric property between collapse column boundary and surrounding rock mass. Non-aqueous collapse column may generate disordered reflection waves which are superposed after multiple reflections under the obvious reflecting layer. If the collapse column is aqueous and water-transporting, however, the radar wave energy may be adsorbed and reduced under the reflecting layer of strong margin, while the reflection energy layer may be enhanced. In addition, the depth of abnormal position can be judged by reading the reflection time of abnormality distributing on radar profile according to the relevance between transmission speed of electronic wave in medium and relative dielectric constant of medium [15].

1) Figure 7 shows the detection results of radar in the rail haulage roadway. In the profile detected in rail haulage roadway, there is an obvious lithological variance belt during 100ns-250ns. According to geological data, it can be regarded as the boundary affected by collapse column. The surrounding rocks of haulage roadway are mainly mud rock of Taiyuan Fm in carboniferous system, and their relative dielectric constant is in scope of 8-15. Therefore, the boundary affected by collapse column can be estimated according to the formula of radar wave speed and the equation of time interval during radar wave transmission. This boundary is about 5-12m away from the lateral wall of rail haulage roadway, and its form distribution in plane conforms to the circular arc of collapse column boundary. Moreover, the reflection clutters are still disordered in the lower part of time axis on profile, and the energy does not generate strong absorption and reduction. Therefore, it can be determined that this collapse column is not water-transporting.

2) Figure 7 shows the radar detection results of air return roadway up to the mountain. The air return roadway up to the mountain is located in the east to collapse column. In the radar time profile, strong reflection energy layer can be seen during 120ns-260ns. Therefore, it can be determined that this roadway is in the boundary affected by collapse column. The roadway is about 7-15 meters away from the lateral wall, and has the boundary shape of collapse column. However, the energy on and below reflecting layer obviously enhances than the profile detected in rail haulage roadway before. According to the analysis on radar response characteristics in forward simulation, the moisture content in the collapse column near the air return roadway is higher than that near the rail haulage roadway.



a) Profile of waveform variable area

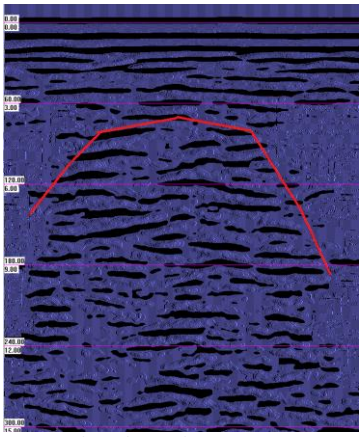


b) Colorful profile

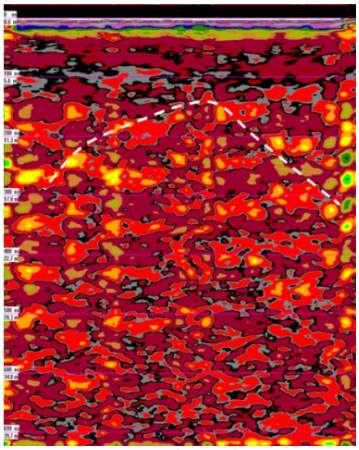
FIGURE 6 Radar detection profile of collapse column in rail haulage roadway

According to the comprehensive analysis on the radar profile of two survey lines, this collapse column has moisture change in partial region, but does not been connected. Therefore, it can be determined that the collapse column is not water-transporting in horizontal.

3) Radar detection results in other regions are as follows. There is anchor network, steel-frame shed, and support plank in the most detection position of lateral wall and frontal plane on 8103 work face. Therefore, the coupling with surrounding rock is bad, and the interference signal is strong during radar detection, which affects the detection results to some extent. After a series of signal processing, the signal-to-noise ratio increases. However, there is no obvious reflecting layer on radar profile when detecting the frontal plane, while an obvious energy reflecting variance belt is found when detecting the lateral wall (See Figure 8). It can be judged as the reflection caused by collapse column. However, the survey line at this section is short, so the judgment of position distribution may have large error.

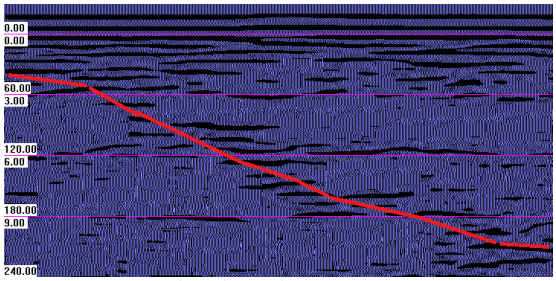


a) Profile of waveform variable area

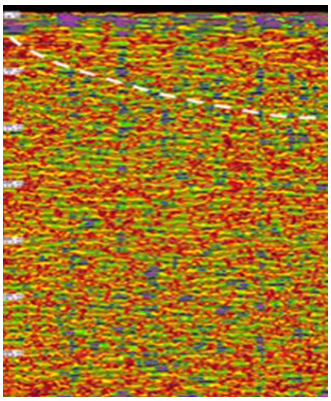


b) Colorful profile

FIGURE 7 Radar detection profile of collapse column in air return roadway up to the mountain



a) Profile of waveform variable area



b) Colorful profile

FIGURE 8 Schematic diagram of reflecting energy variance belt in lateral wall on work face

According to all above results, the basic form of collapse column distribution is determined by radar detection on the horizontal plane surrounded by the lateral wall, rail haulage roadway, and air return roadway up to the mountain on 8103 work face. In order to verify the detection accuracy of GRP in the pit, the explanation achievements are compared with original geological data of tunnel prospecting and drilling. It can be found that the collapse column conforms to the distribution in horizontal. In Figure 9, the area circled with green imaginary line is the distribution scope of collapse column in horizontal determined according to radar profile. And the area circled with red active line is the distribution scope of collapse column provided in the geological data of this mine. These two areas have high superposition if the survey lines are laid long enough to ensure the detection accuracy.

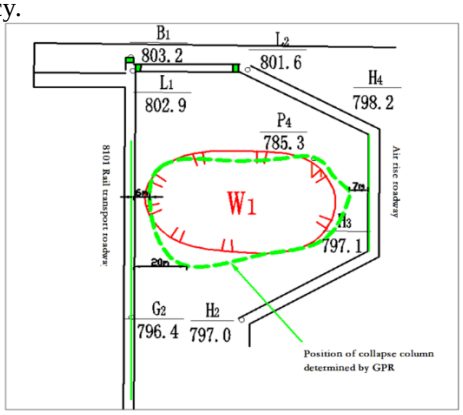


FIGURE 9 Comparison diagram between collapse column positions in radar detection and geological data

5 Conclusions

Theoretical analysis and actual engineering study are conducted on the detection of collapse column in the pit with anti-explosive GPR. Scientific and rational layout of survey lines and utilization of limited space in complex mine environment are significant to obtain radar data with high signal-to-noise ratio.

With rational and sufficient layout of survey lines, the anti-explosive GPR can reflect the spatial distribution of collapse column and moisture and water-transporting of collapse column. Moreover, effective layout of survey lines can be used to accurately determine the distribution scope of collapse column in horizontal.

Practices show that anti-explosive GPR has advantages of high resolution, flexibility, lossless, anti-interference, etc. when detecting the collapse column in the pit. Therefore, it is incomparably advantageous to other geophysical methods. Except collapse column detection, anti-explosive GPR in the pit can also be applied to safety detection of other disaster sources in the mine pit.

Abstract

The continuous casting roller bearing was one of the important parts of continuous caster [1], its working temperature was relativity high, the working load was also very large and the working condition was complex. Since the external heat of casting roller bearings was much higher than internal, the continuous casting roller bearing was different from the general high-speed rolling bearing with heavy load. If the external heat that the bearing suffered could not dissipate in time, the extreme high working temperature might accelerate the failure of the bearing and severely reduce the productivity of the caster. To optimize the thermal structure of the continuous casting roller bearing, the thermal coupling analysis of the bearing should be conducted. Firstly, the stress field of the working continuous casting roller bearing should be analysed by ANSYS and the three-dimensional geometric CAD model and the CAE model of it should be established. Then find out the location where the bearing suffered the largest force by stress analysis, in the case of bearing block with cooling water, load the working temperatures to the bearing, after analysing, the result showed that the external temperature was the main contributor of internal stress, and the rolling element was the part inside of the bearing which suffered the largest stress. To optimize the structure of the continuous casting roller bearing, the rolling element was turned into axial hollow structure, which could reduce the extreme stress of the rolling element bearing. By analysing all the maximum thermal stress of rolling element in different feasible hollowness, and finally the most suitable hollowness could be found out. The analysis results above showed that the optimization of the rolling element structure of the bearing could effectively reduce the internal stress and improve reliability of bearings in high working temperature. The conclusion of this study was significant in bearing optimizing or designing.

Keywords: thermal stress, coupling, structural optimization, continuous casting roller

1 Introduction

Casting roller bearing [2] was a kind of rolling bearing, the motion of internal rolling bearing was quite complex, since the bearings could be easily damaged in high temperatures, and the temperature analysis and stress analysis of continuous steel billet and continuous caster itself were quite complex, it was too hard to give a theoretically description or analysis of the bearing. There had been many experts and scholars from China or foreign countries who contributed themselves in finding the cause of failure of the bearing on the basis of researching its temperature. But they almost tend to study the complex internal heat which generated by heavy load and high-speed operation, but there was still few studies under the situation of external heat generation higher then internal. The analysis of rolling bearing temperature field is mainly based heat transfer theory [3]. Analyse and calculate the distribution of bearing temperature field during the heat transfer process by using a combination of theory and simulation methods, the parts which had risk to failure and the steady temperature field without lubricating oil could be predicted during the steady process of bearing. The analysis of the rolling bearing temperature field was mainly based on heat transfer theory; researchers could only study it by actual measuring through the site and testing in the laboratory, which largely relies on the experience accumulated by long-term of work, and these methods still had practical significance on today's studies. However, with the development of iron and steel smelting technology and computer science, traditional experimental methods had shown a lot of drawbacks, which unable to give an accurate result in practical; therefore they could not meet the current needs of the development of steel industry. At present, many research institutions and production enterprises, both here and abroad, applied the finite element techniques to metallurgical equipment design and optimization studies, analysed and calculated the distribution of bearing temperature field during the heat transfer process by using a combination of theory and simulation methods, predict the parts which had risk to failure and the steady temperature field without lubricating oil during the steady process of bearing. They had made a lot of phase achievement. Therefore, conducting mathematical simulation by using the finite element analysis software had become an important means of future research work.

2 The construction of finite element model of the continuous casting Roller

2.1 THREE-DIMENSIONAL MODEL OF THE CONTINUOUS CASTING ROLLER

The relationship feature of casting rolling bearing model was very complex which was not easy to use the self-modelling, so the mesh division should be use finished in professional software. The methods that most researchers used are: Firstly, use certain CAD drawing software (such as SOLIDWORKS, PROE, UG, etc.)to transform two-dimensional engineering drawing into the overall structure three-dimensional drawings, and then export to the file (such as iges, step, etc.) that CAE pre-processing software could recognize, finally introduce the model into CAE pre-processing software and make necessary topologies corrections and mesh division [4], the whole CAE model structure could be eventually finished. Since exporting in STEP format might always lost key feature of the model, in this paper, IGS format was used to export the model after finished it with three-dimensional graphics software, for better topology correction and mesh division in CAE pre-processing software. According to the bearing models and drawings provided by a steel mill, use the popular 3D CAD software to build a three-dimensional CAD assembly model of the whole casting rolling bearing (as shown in Figures 1 and 2).

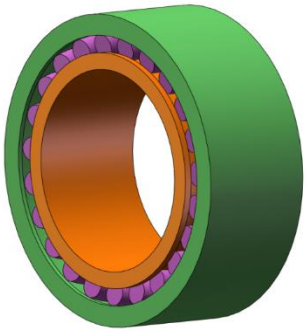

FIGURE 1 Three-dimensional CAD model of the continuous casting roller

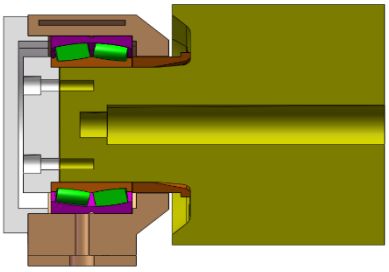

FIGURE 2 Three-dimensional CAD assembly model of the continuous casting roller (section view)

All parts were sat by the way of parametric feature modelling. Firstly, draw sketches of every part, and then generate solid parts according to the shape of each part by stretching, rotating, excision, etc. In sketching and feature modelling, the dimension of three-dimensional geometric model of the part should be set strictly in accordance with the engineering drawings and technical requirements. Every position of parts in the assembly should be located follow the coaxial, overlapping surfaces, parallel with the distance and other different assembly principals. In the assembly process, all the connections in the assembly should be joined in full accordance with requirements of the drawings and specifications of the mechanical coupling.

2.2 BUILD THE FINITE ELEMENT MODEL OF THE CONTINUOUS CASTING ROLLER

In this paper, the mesh model was built by using CAE pre-processing simulation software, in strict accordance with the dimensions and structural characteristics of the three-dimensional CAD geometry model.

This paper mainly considered the impact of load on the bearing, so the commonly used SOLID45 unit should be chosen in the stress analysis. According to the characteristics of the bearing structure, solid elements were used in the meshing process. The model should be reasonable divided to ensure the accuracy of simulation results with the number of grid as less as possible. The model should be divided into mesh after carefully considering, with a large amount of grids, although the computing result could be more accurate, it might also take higher computer resources and a lot more time to finish this simulation. In meshing for bearing stress analysis, the number of grids could be reduced reasonably. As for the density of grid, using the uniform grid, could not only ensure the reasonable amount of meshes, but also avoid the unexpected error caused by the mutations of grids.

Figure 3 was a three-dimensional mesh model of the casting roller, which was used for thermal analysis of the bearing; Figure 4 is a partial mesh structure of bearing caster roller. In order to better simulate the actual working conditions, the assembly mesh model of casting roller bearing was shown in Figure 5. Meshing assembly model was the most difficult task, because of the water cooling pipe inside of it [5], the internal meshing should be divided as well, the tetrahedral and pentahedral mesh were also been used where the shape was extremely irregular. Mesh quality of this site is not as high as hexahedral mesh but the number of tetrahedral mesh or pentahedral mesh grid were little, the impact of the entire model was negligible.

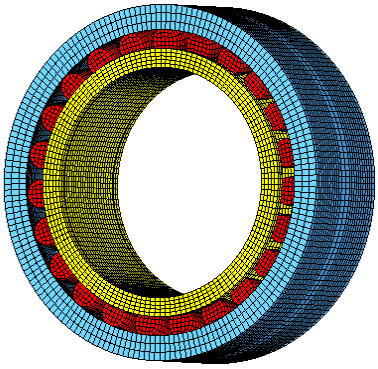

FIGURE 3 The three-dimensional mesh model of the continuous casting roller bearing

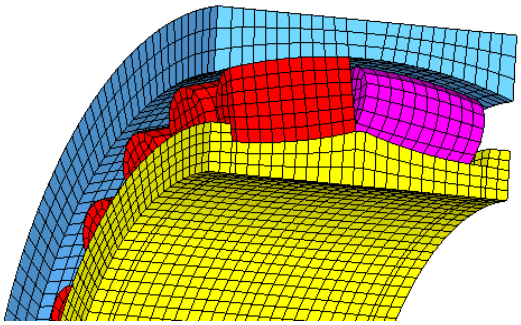

FIGURE 4 The part of three-dimensional mesh model of the continuous casting roller bearing

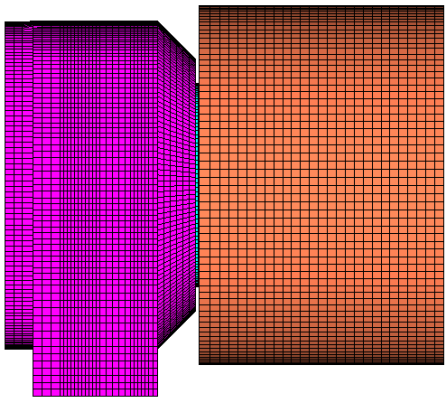

FIGURE 5 The three-dimensional mesh model of the continuous casting roller bearing assembly

3 The continuous casting roller bearing stress field analysis

3.1 MECHANICAL ANALYSIS OF THE CONTINUOUS CASTING ROLLER

3.1.1 The mechanical analysis of the continuous casting roller

In calculating the force [6], the bulging force of steel billet should be considered, the bulging force caused by static pressure of molten steel should be calculated by the mechanical model which based on a certain pair of static pressure between molten and continuous casting roller. As for the force on the nip rolls, it should be calculated follow the theory of material mechanics, such as the equal cross-section beam with both ends fixed and a uniform distributed load (static pressure of molten steel). The calculation of the force on *i*-th roller:

$$F_i = \rho g h_i l_i \left(w - 2k\sqrt{\frac{L}{V_c}} \right), \tag{1}$$

where ρ is the density of liquid steel, the units are kg·m^{-3}. h_i is the relative height of *i*-th pair of rollers to the steel surface, the units are m. l_i is the spacing between *i*-th pairs of roller, the units are mm. w is the width of the billet, the units are mm. L is the arc length of the billet from the mold level, the units are mm. V_c is casting speed, the units are m·min^{-1}. K is the integrated coagulation factor, the units are mm·min$^{-1/2}$.

In the sector segments, when a light dynamic pressure is given to the billet, these segments would get a reacting force caused by the deformation of billet. Therefore, the force could be calculated by flat rolling theory, when the soft-reduction process was conducted on the rollers. As shown in the Equations (2) and (3):

$$P = \sigma 2\delta\sqrt{2R\Delta h - \Delta h^2}\ , \tag{2}$$

$$\Delta h = Ql\ , \tag{3}$$

where σ is the average pressure on unit rolling, the units are t·mm^{-2}. δ is the thickness of casting billet, the units are mm. R is the radius of the pressured rollers on continuous casting roller, the units are mm. Δh is the reduction of casting roller, the units are mm. Q is the reduction rate of casting roller, the units are mm·m^{-1}. l was roller distance, the units are m.

If the production model of steel billet was Q235, the width of billet was 1550mm and the casting speed was 1.2 m/min^{-1}. After calculating, the pressure of No.20 free roller in sector segments (lower roller) was 273KN. All the stress analysis in this paper was based on the 20th free roller (lower roller) casting roller.

3.1.2 The mechanical analysis of the continuous casting roller bearing

Took stress analysis of the No. 20 free roller bearing in sector segment continuous casting roller. Where there were two rollers with total two pairs of bearings, the mechanical analysis of the continuous casting roller was shown in Figure 6.

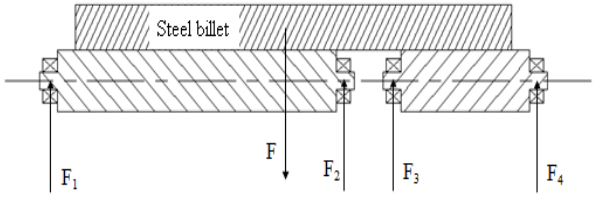

FIGURE 6 The schematic diagram of force on the continuous casting roller

F is the force between roller and casting billets. **F$_1$**, **F$_2$**, **F$_3$**, **F$_4$** are the reaction force given by the bearing.

As shown in the graph, the equation could be drawn according to the mechanical balance [7]: $F-F_1-F_2-F_3-F_4=0$.

By further calculations the following result could be drawn, $F_1=0.27F$, $F_2=0.31F$, $F_3=0.23F$, $F=0.19F$.

Then it could be drawn the maximum stress of second bearing, $F_2=0.31\times273KN=84.63KN$.

The load carrying capacity of the bearing according to the data provided by the manufacturer was shown as follow, $F_{load}=Cr\times e=394KN\times0.32=126.08KN$.

By comparison, it could be known that the supporting bearings in ideal conditions would not be overloaded.

3.2 THE BOUNDARY CONDITIONS OF THE CONTINUOUS CASTING ROLLER THERMAL STRESS ANALYSIS

The coefficient of thermal expansion between different structures that interacted or different parts of the same structure were mismatched. When temperature rose or lowed degree of expansion and contraction was inconsistent with each other, which led to the generation of thermal stress.

3.2.1 The boundary conditions of the continuous casting roller thermal stress analysis

The constraints of continuous casting roller bearing only existed in one place, it was the constraint at the bottom seat of the bearing. That was at the bottom bearing node constraint on its outer surface in radial and tangential and axial displacement of three directions.

3.2.2 The working load of the continuous casting roller thermal stress analysis

Bearing load under steady state was the force from continuous casting roller of bearing. Owing to the model involved only a part of the continuous casting roller, when the applied load needed to bending load, temperature load on the model, using APDL [8] language to read the temperature field calculation results file, the finite element software would automatically obtain the temperature value of each node.

When there was only stress simulation for stress field, the boundary conditions were the same, but it did not need to add the temperature load.

3.3 THE THERMAL STRESS ANALYSIS OF THE BEARING IN THE BEARING SEAT WITH COOLING WATER

The simulation results of maximum stress and thermal stress in each part of the continuous caster roller bearing were recorded, as shown in Table 1.The Table 1 showed that under the temperature load, the continuous casting roller bearing stress almost increased twice and the influence of the temperature on the load bearing was very obvious, and the stress was only 20.4 MPa less than the allowable stress, working under such a high stress the casting roller bearing was easy to failure and it showed that the failure of continuous casting roller was significantly related to the temperature. At the same time, it could be seen that although the temperature of the inner ring was highest, it was still smaller than rolling elements and the maximum stress and the rolling element was the part, which suffered the largest stress in the continuous casting roller bearing.

TABLE 1 The result of each part of the continuous casting roller bearing maximum stress compared with the thermal stress

	Maximum stress (MPa)	**The maximum thermal stress (MPa)**	**The allowable stress of bearing material (MPa)**
Continuous casting roller bearings roller	249.3	411.3	431.7
Outer ring	120.2	245.1	
Inter ring	176.0	321.8	
Rolling element	249.3	411.3	

4 The optimization analysis of the continuous casting roller bearing

Take the inner ring as a benchmark, the temperature of rolling elements was different in different positions of the bearing and the stress was changeable. Because of rotating of the bearing, it could be understood that the temperature changed with the rotating of rolling elements and the thermal stress was also continuously variable. And this change will lead to the fatigue damage of bearing rolling elements. The structure of the bearing rolling body should be changed to reduce the stress, so as to improve the life of the bearing.

The middle part of rolling bearing was changed into a hollow to improve the stress distribution. And the rolling body was changed into a hollow [9], the heat transfer in the heat convection and heat radiation under the same condition was relatively small. Because of the hollow, the rolling body could produce self-deformation due to offset the stress produced by thermal and quality, so, the stress of the overall rolling body decreased. And it prolong the working life of bearing.

Hollowness was used to represent the size of roller hollow. Hollowness refers to the ratio of the radius of hollow roller and actual radius of the hollow, it was an important parameter of hollow roller bearing and it must be moderate. The hollowness was too small to reflect the superiority of hollow roller or too large to reduce the bearing ability. It was not appropriate. According to the convention, the thermal stress was analysed of rolling bodies with hollow degree of 20%, 30%, 40%, 50%, 60%, 70%. The result of simulation analysis was shown in Figures 7-12.

From Figures 7-12,it could be seen that with the increase of rolling body hollow ratio, the stress of the rolling body was constantly decreasing, which once again showed that the finite element analysis was consistent with the actual situation. However, the hollow ratio of rolling body could not increase indefinitely, to ensure the bearing strength and service conditions, there should be an upper limit.

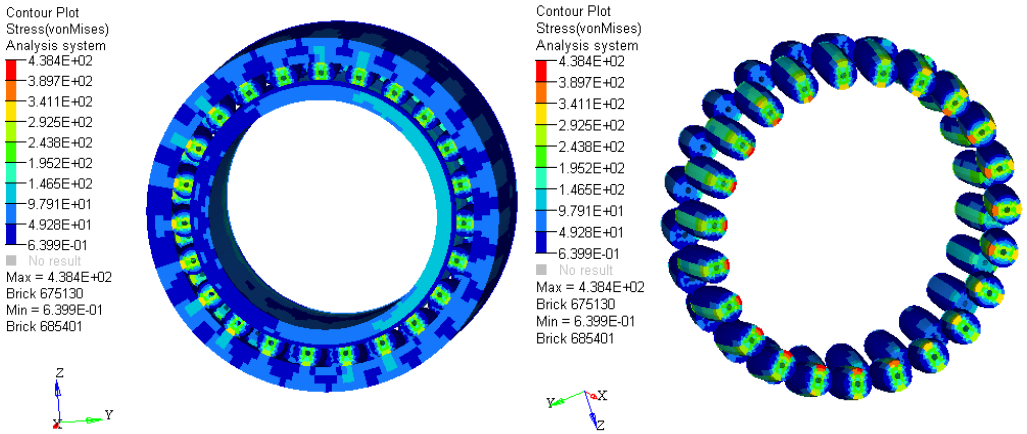

FIGURE 7 The thermal stress field of bearing when the roller hollowness was 20%

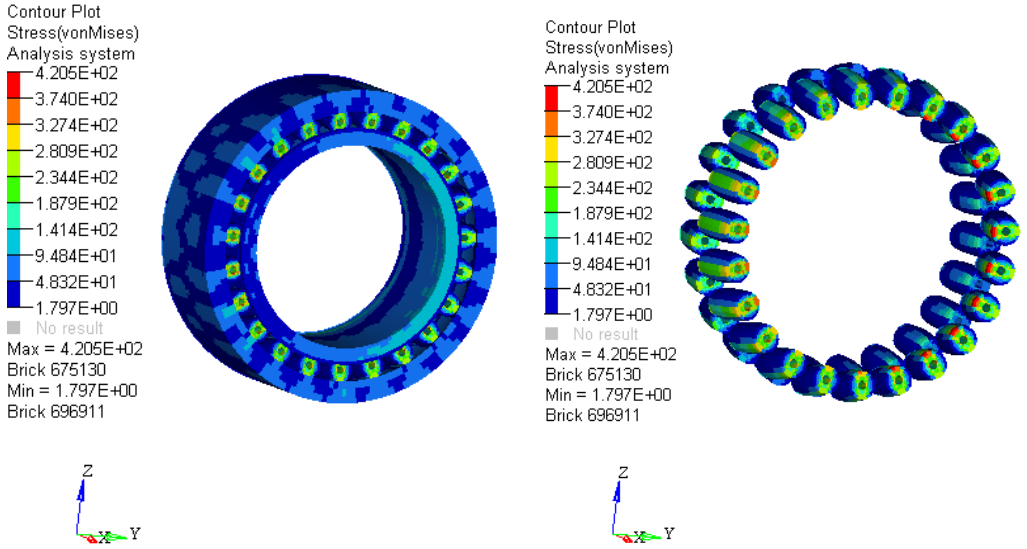

FIGURE 8 The thermal stress field of bearing when the roller hollowness was 30%

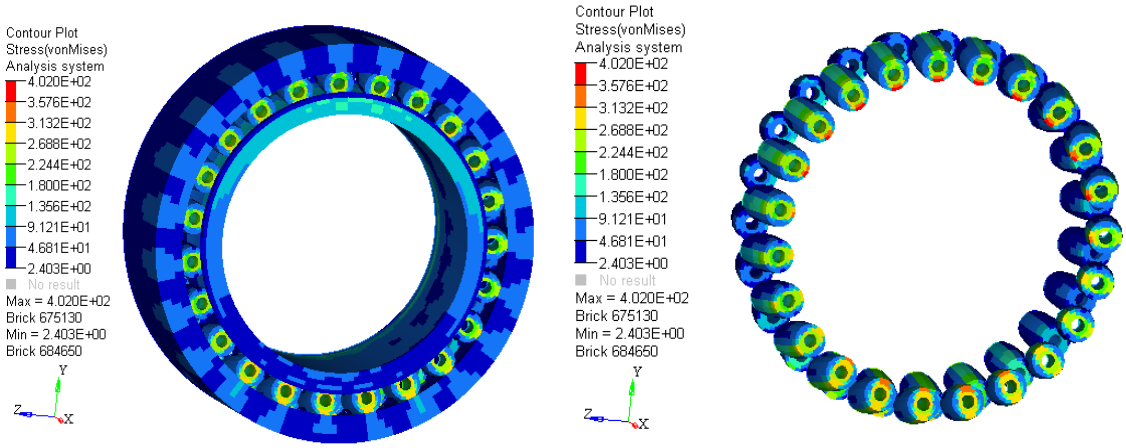

FIGURE 9 The thermal stress field of bearing when the roller hollowness was 40%

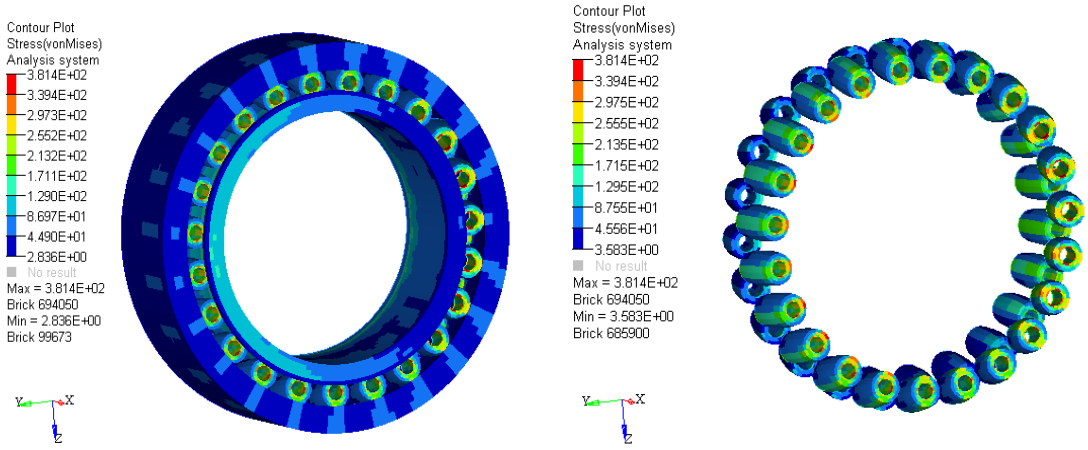

FIGURE 10 The thermal stress field of bearing when the roller hollowness was 50%

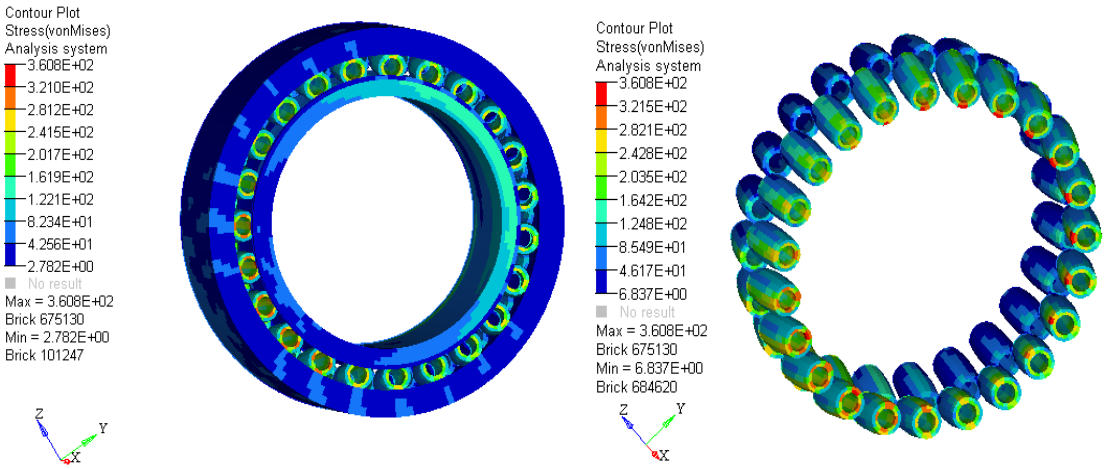

FIGURE 11 The thermal stress field of bearing when the roller hollowness was 60%

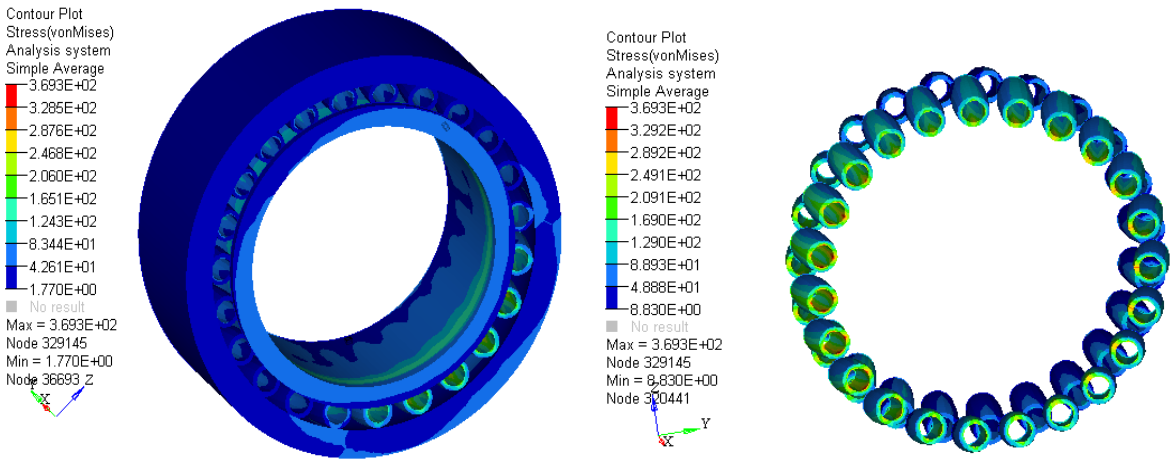

FIGURE 12 The thermal stress field of bearing when the roller hollowness was 70%

By analysing, the maximum thermal stress curve of bearing could be obtained in different roller hollowness. As shown in Figure 13.

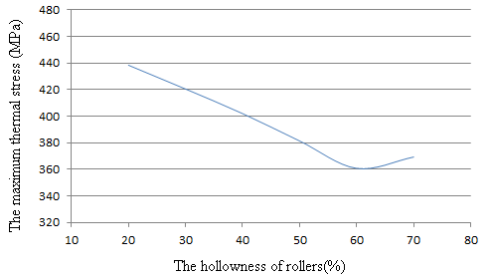

FIGURE 13 The maximum thermal stress curve of bearing roller in different roller hollowness

By observation, it could be seen that the part which the bearing subjected to the maximum stress on the roller. And with the increase of roller hollowness[10], when the roller hollowness was 60%, the bearing subjected to the minimum stress, was 360.8MPa, smaller 50.5MPa than the roller without hollowness. It compared with the allowable stress, in this case the bearing was not easy to failure. Also it could be found that the rolling body stress distribution become uniform, to a certain extent, it also optimized the thermal stress distribution of casting roller bearing and play a role of reference for bearing design.

5 Conclusion

By analysing the stress field of continuous casting roller bearing, it could be found that the maximum stress of bearing was 249.3MPa when the bearing seat was applied cooling water and not applied thermal load, and the coupling stress was 411.3MPa, while the thermal stress caused by temperature was large, the result had been very close to allowable stress of bearing material. At the same time the bearing operating temperature was very high, and the temperature distribution was not uniform, the deformation of bearing different parts caused by different temperature rise of bearing different parts was also inconsistent, affected the bearing accuracy and the rotary bearing capacity of bearing, thus the temperature was the main cause of the failure of continuous casting roller bearing. By altering the hollowness of rolling body from the structure to reduce the stress, and simulated the optimization scheme then the result showed that bearing subjected a minimum stress when the rolling body hollowness was 60%, and the stress distribution was relatively uniform. Thus, it improved the bearing internal heat dissipation and extended the service life of bearing, also played a role of reference for bearing design.

Abstract

Ladle is an important container parts, plays a vital role to storage and operation of steel smelting. The length of the ladle service life directly affects the efficiency of steel production and the cost of production. The service life of the ladle is mainly affected by thermal mechanical stress of ladle lining, thermal mechanical stress is mainly caused by the severe changes of temperature, in order to fully understand the working state of ladle to ensure the safety of the ladle, the ladle temperature monitoring is particularly important. Ladle design of remote monitoring system uses the structured and modular design thought, on the basis of using the LabVIEW virtual instrument platform; realize the collection of ladle temperature data and remote monitoring. Establish ladle remote client monitoring system by TCP communication protocol, realize the ladle monitoring networked. This system uses the real-time waveform display and friendly human-computer interaction interface, greatly enhanced the real-time and visibility of the ladle remote detection system.

Keywords: the ladle, LabVIEW, remote monitoring list

1 Introduction

Ladle is an important fundamental of steel production in the steel mill, each working procedure in the process of steel-making is required to complete with ladle, and the temperature conditions of ladle directly affect the quality problem of the iron and steel production, especially in high efficiency continuous casting production. Ladle will be impacted by high temperature from molten at work, affecting the service life of the ladle, so the collection of temperature of ladle and precise monitoring is very important. The traditional monitoring equipment for ladle is relatively backward in our country, and its security, reliability and precision and automation degree is low, a lot of testing equipment is in need of upgrading [1]. This paper based on the LabVIEW platform will get the ladle temperature data by sensors, then monitor the collected data with the remote monitoring system based on LabVIEW and determine whether the temperature value is in the normal range, this help the remote workers to rule out the fault in production timely, thus avoid the damage of high temperature to ladle lining, can greatly improve the using efficiency of the ladle, improving the steelmaking efficiency of steel.

2 Structure and life of ladle

The ladle model is as shown in Figure 1. The ladle is mainly composed of trunnion, work layer, permanent layer, ladle wall, impact block, vent brick, nozzle bricks and other parts. Ladle wall has a small slope, lift ladle through the trunnion, and complete the movement of the ladle.

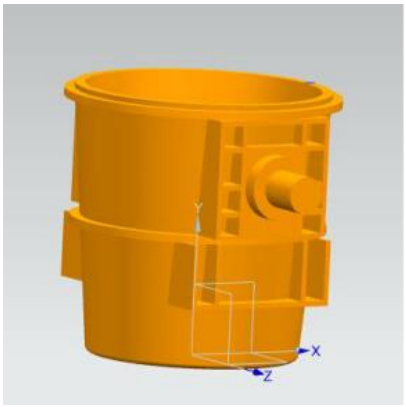

FIGURE 1 Model of the ladle

Figure 2 is the plane view of ladle bottom. There are mainly impact block in the bottom of the ladle, vent brick and runner brick.

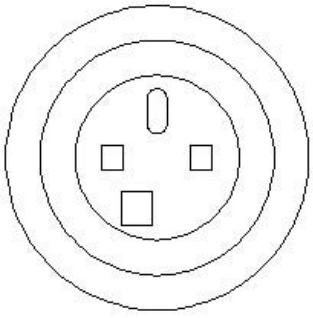

FIGURE 2 Structure figure of ladle bottom

**Corresponding author* e-mail: honghai.liu@port.ac.uk

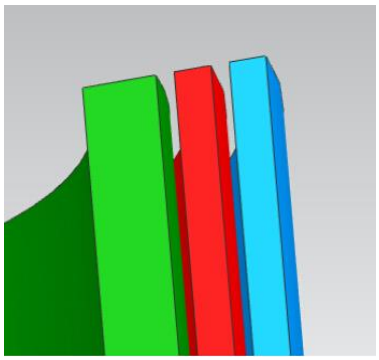

FIGURE 3 Three layer structures of ladle

Ladle generally is consists of three layers, from the inside out are working layer, permanent layer and ladle wall. The material of working layer is commonly alumina and magnesia carbon, material of permanent layer is commonly micro expansion high aluminium, the three layer structure use different materials, so the temperature of ladle is in security.

Ladle life will directly affect the production efficiency of iron and steel and the cost of steel production in steel production. Erosion and burst of refractory lining in the iron and steel production, causing the penetration of liquid steel in the ladle, this is the most common damage in the process of iron and steel production. Thermal mechanical stress and chemical erosion is the main reason of the lining damage. Which the direct reason of resulting the damage of the ladle refractory and the crack of lining layer is the thermal mechanical stress. The damage principle of thermal mechanical stress is that as the temperature of ladle lining layer in a dramatic changes, the produced thermal stress make the micro cracks in the materials gradually spread, eventually led to the fracture and peeling of inner layer material.

The heat transfer phenomenon of temperature in engineering can be roughly divided into three categories: thermal radiation, heat convection and heat conduction. To mainly affect the temperature of ladle are heat convection and heat conduction.

a. Heat convection

Macro relative motion caused by different temperature inside fluid parts caused the heat transfer through mutual movement.

$$q = \lambda \Delta T A, \tag{1}$$

where ΔT – object temperature difference on both sides (K), A – surface area of convective heat transfer $\left(m^2\right)$, λ – surface convective heat change coefficient $\left(W/\left(m^2 * k\right)\right)$.

b. Heat conduction

Each parts with different temperatures or different objects in an object's, through the collision and movement of the microscopic particles in the objects transmitting energy, this way of heat transfer is contacted each other between objects.

$$q = -\lambda A\left(dt/dx\right), \tag{2}$$

where A – area $\left(\left(m^2\right)\right)$, λ – heat transfer coefficient $\left(W/\left(m^2 * k\right)\right)$, t – temperature, x – coordinates on the surface of the heat.

The sharp temperature change of ladle, will make the life of the ladle affect greatly, as the ladle is in the process of working, there happened damage phenomenon, such as lining erosion or burst, ladle needs different levels of maintenance, thus affect the normal production schedule of the steel. Monitoring and displaying every area of the ladle temperature timely, and set the corresponding alarm monitoring, can timely understand the working status of the ladle. Make a corresponding adjustment for the ladle operation according to the monitoring the situation, improving the service life of the ladle.

3 Temperature data collection of ladle

Data collection is a bridge connecting external physical world and the PC, in order to realize the monitoring of ladle temperature signal, first ladle work quantities should be converted into electrical signals of analogy quantities by sensors, then converts processed analogy signals to be the identified digital quantity on ladle remote computer monitoring system, and send to the ladle remote monitoring system [2]. Data acquisition system of ladle obtain needed information from the monitoring objects by sensors, and converts the output signal to the identified digital signal by computer, and then put into the computer to carry on the corresponding processing, get the required data. Ladle data acquisition has a variety of software and hardware combination, can choose appropriate from several combination as the hardware and software of this system.

Good or bad data of acquisition system performance of ladle remote monitoring system is mainly determined by the speed and precision of the ladle data [3]. On the premise of ensuring the accuracy of the collected ladle data, should improve the speed of the ladle data as possible, in order to meet the real-time of ladle data acquisition and processing [4]. Table 1 ladle data acquisition system, generally can be divided into five parts:

TABLE 1 Data acquisition composition of the ladle monitoring system

Sensor	Sensor of monitoring Ladle is a sensor can monitor ladle temperature, and convert the detected signal into the needed signal form to put
Signal	A quantity from a ladle monitoring sensor, signal is transmission medium of ladle data acquisition system, signal usually has two forms, digital and analogy
Signal conditioning	Convert collected temperature signals of ladle to a standard and identifiable signal through a series of transformations
Data acquisition hardware	Data acquisition hardware of ladle monitoring system is the device that convert simulation quantity to digital quantity for ladle monitoring signal
Driver program and application software	The application software of ladle monitoring system is the LabVIEW virtual instrument software and related hardware driver

Data acquisition system of ladle remote monitoring system is shown in Figure 4.

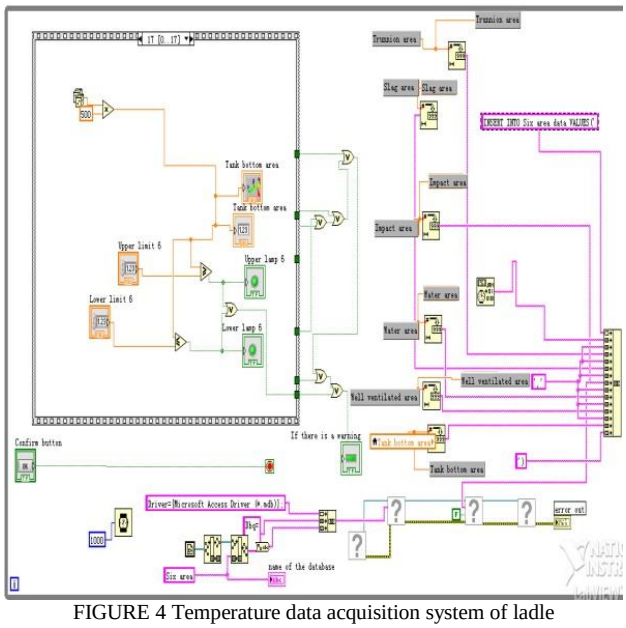

FIGURE 4 Temperature data acquisition system of ladle

The main functions of the data acquisition system are man-machine interface, data acquisition, data display, data storage, printing and output as well as secondary calculating of data shown in the following table.

1) The man-machine interface of ladle data acquisition system.

In the ladle data acquisition, staff dialogue to data acquisition system of the ladle through the mouse, keyboard or touch screen, complete ladle data collection.

2) Data collection of the ladle.

When data acquisition system is working, it will collect for analogy signals into the system or other signals in accordance with the previous ladle collection cycle.

3) Data display of ladle data acquisition system.

The collected temperature data of ladle are displayed in the form of that watchers are convenient for watching, displaying interface is commonly images, forms, trend charts and so on.

4) Storage of the ladle collection data.

Ladle state change is a slow process, set a certain time interval for the storage of collected ladle data, store the collected important data of ladle, and store it to the specified database, convenient for future reference.

5) The ladle data collected printing.

After the ladle data collection, we need to output the data collected to print, in order to understand the performance of the ladle; it will be the required to set a certain time interval to print the data in the form of a graph or table.

6) Secondary calculation of ladle data.

Comparing the collected first data of ladle by the sensor with normal numerical range at work, then making secondary calculation, to identify the running status of the ladle.

4 Ladle temperature remote monitoring

Network communication is an important aspect of Ladle's remote monitoring; the LabVIEW software has a strong network communication function and remote communication function of LabVIEW allow LabVIEW users write remote communication software to realize the remote communication function [5]. Ethernet technology is now widely adopted by the computer network technology, the media access and control mode is adopted by the collision detection of the carrier to listen on multiple accesses. To establish a network publishing of LabVIEW needs to be more than 2 PC through communication lines connected and established communication [6]. So you can through the establishment of communication network to provide resource sharing, communication service, coordination load, data transmission and remote fault diagnosis other functions so on.

From the composition of the entire computer network, which is made up of many WAN and LAN together [7]. Node of the Internet is consisting of the PC, subnet segment, servers and other equipment, which can be established through LAN and telephone line connected to the Internet. Throughout the development of network technology, LAN technology is a focus in the fastest, users can make use of local area network (LAN) in the Internet technology, which brings a lot of convenience [8]. LAN topology structure mainly can be divided into star structure, bus structure, and ring structure and so on. In these several topology types, bus structure is the most simple topological structure, whose local area network (LAN) is based on public information channel [9]. Although this structure is not easy to fault detection, it is easy to be extended and easy to maintenance and installation Each PC machine on the network has an own logo, that is the IP address of the PC, which generally consists of four part numbers. Ladle of network monitoring system is a trend of modern ladle monitoring, combining the Internet and monitoring of the ladle system together, which can make full use of network resources and improve the efficiency of monitoring.

TCP/IP protocol is one of the most basic Internet protocol, TCP and IP forms the core of TCP/IP protocol, both LAN and the Internet are widely adopted, TCP/IP protocol. The application layer, transport layer, network layer, link layer make up the TCP/IP protocol suite. IP is Network protocol, which belongs to Network interconnection layer protocol. In order to transfer the data to the destination, you will need to print data sending into a datagram, and then add the header to datagram and sent to the destination [10]. Because IP layer service is a connectionless service, it is difficult to guarantee the reliability of data in data transferring, which is the reason that seldom directly used IP in LabVIEW programming. TCP is transmission control protocol that is a transport layer protocol, which needs to link first in the data transmission, and most of the network data transmission use TCP transmission control protocol (TCP) now. TCP uses bits of circulation in data transmission and a session needs to be established on the data exchange [11]. In order to guarantee the reliability of data, through the TCP data will be assigned a sequence number. When data in the transmitted is divided

into several small pieces, the receiver can specify whether the data has been received. During the data transfer, the data of the receiver must carry on the confirmation, which realized by sending a reply. When using TCP transmit data, you need to call the IP network protocol, but compared with TCP/IP network protocol, TCP will not repeat or miss data and more reliable in data transmission.

In the use of remote data transmission, TCP client port settings should be consistent with server port, at the same time the client need to specify the right IP address [12]. So as to it can realize correct network interconnection. The design of server-side as shown in Figure 5, TCP server program will first collect the temperature data in the production of the ladle, then write to the TCP server, finally send the data to client.

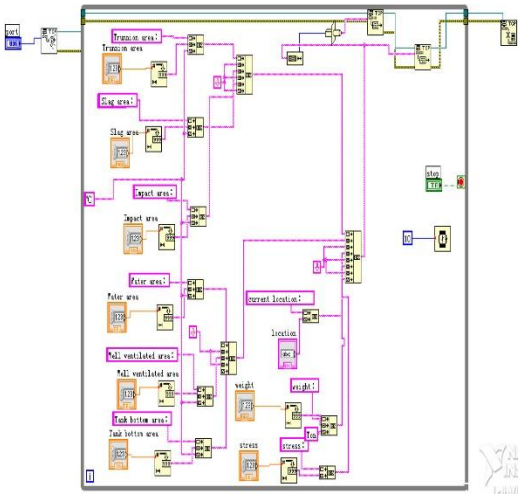

FIGURE 5 The TCP server program

The program diagram of client as shown in Figure 6, The remote monitoring the client program diagram of ladle is programming under the While loop structure, in order to ensure the data writing continuity, with setting the frequency of data writing [13]. In addition to set two attribute node, TextFontSize and Text TextColor, it convenient to observe display window of the front panel data, so that it can read out data transmitting.

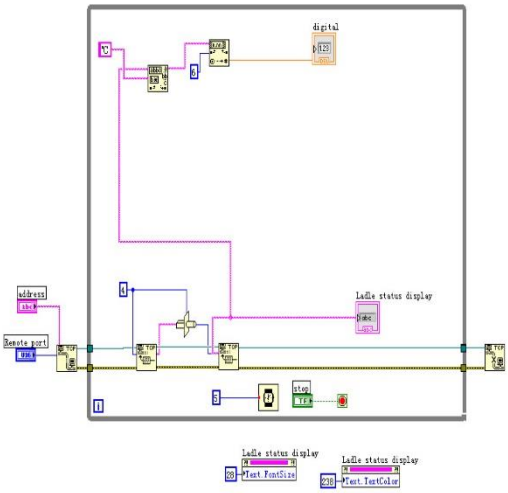

FIGURE 6 The client program of ladle remote monitoring

In the working of ladle, if the temperature status of the ladle is not informed in a timely manner, you will appear many problems, for example:

1) The temperature is too low, so that molten steel solidification needs to be reheated.

2) The temperature of ladle is too low, so the ladle must be heated to a certain temperature before picking up the molten steel.

3) When the ladle is shipping to the continuous casting desktop, too low temperature needs to be reheated.

Because the monitoring object is ladle, system should real-time monitor the ladle temperature data (the temperature of the six, trunnion area, slag zone, under the impact area, the water area, breathable area, and tank bottom area). And count and analysis the acquisition of data, calculate the upper and lower value of collecting data and compare to the setting value, judge whether the working condition of the ladle is normal [14]. It can alert when it is not normal operation, thus reducing the failure rate of the ladle work.

Establish ladle remote monitoring system of remote data transmission module and a remote monitoring server, and then write the data needing to transfer to the remote communication program, which established via TCP communication protocol. To establish a ladle remote monitoring client, you can read the monitoring data of the ladle transmitted from the server, so that to realize remote monitoring [15].

In order to ensure the ladle in production has a good process to produce good quality steel and to study the relationship between temperature field and stress distribution, the need for monitoring the temperature of the ladle six area, trunnion area, slag zone, under the impact area, the water area, breathable area, tank bottom area, is necessary. The temperature monitoring of the ladle front panel diagram as shown in the figure below

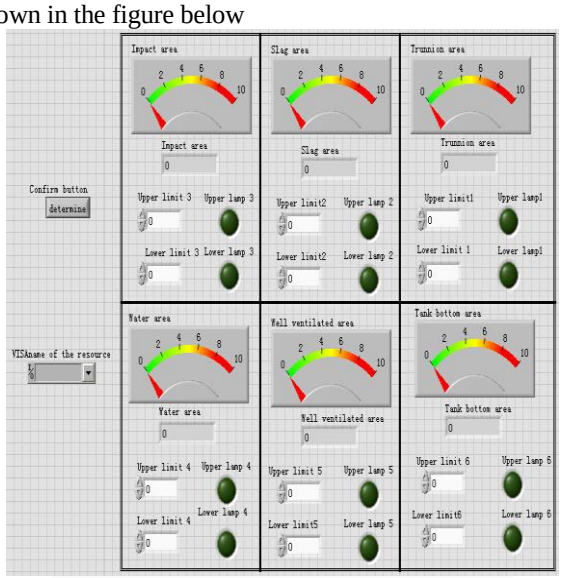

FIGURE 7 The front panel of temperature monitoring

This system is designed to meet the temperature detection, while meet the demand for six area temperature monitoring, in this program using the sequential loop structure to achieve six area through a serial port to read six regional

temperature requirements. Each interval of temperature upper and lower limit value should combine the ladle located automatically to set, which meet the demand of temperature of ladle in any position.

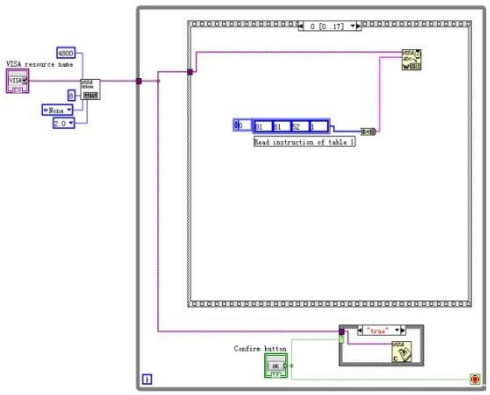

FIGURE 8 Send instruction to the monitoring instrument

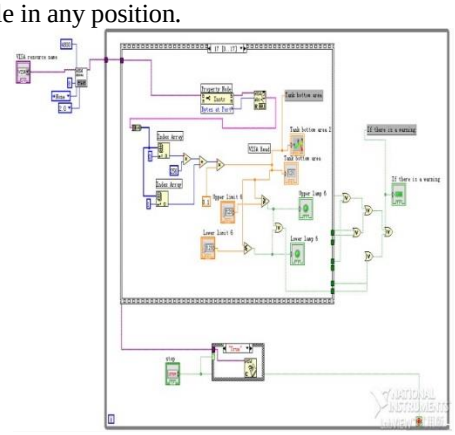

FIGURE 9 Read temperature of six temperature zone

Read the six area temperature value and write temperature data collected through global variables into the database established connection. The temperature monitoring by temperature monitoring module has the six districts, through a serial port of one monitoring module to realize six areas temperature monitoring, that need to be established connection to the temperature acquisition instrument by VISA Write. To judge the collected temperature data with the upper limit and lower limit value, when is greater than the threshold value or less than the lower limit value can change warning light color.

5 Conclusions

The length of the life of the ladle has a vital role on iron and steel production, and the real-time monitoring for ladle production status is conducive to improve the efficiency of steel production. Based on the ladle as monitoring object, this paper starts from virtual instrument technology, then collects and monitories of the temperature parameters of the ladle, next makes a further analysis and research on the data, to ensure that the working temperature of ladle has been in a normal range, thus educes the failure rate, greatly extends the life of the ladle, raises the productivity of the steel.

Abstract

This paper investigates the dynamics and control aspects of the linear motion of a pendulum-driven spherical rolling robot. The dynamic model is deduced for the linear motion of a spherical robot by using the Euler-Lagrange formulation. By appropriate definitions the equations of motion for the robotic system are transformed into the state space form. A novel decoupled sliding mode control approach is proposed to achieve set-point regulation of the linear motion. This approach consists of the construction of a cascade sliding mode controller and the design of a nonlinear reaching law by using a switching component that dynamically adapts to the variations of the controlled system. The asymptotic stability of the robotic system is verified through Lyapunov analysis, and the validity of the proposed approach is illustrated through numerical simulations.

Keywords: spherical robot, linear motion, dynamic model, decoupled sliding mode control, exponential reaching law

1 Introduction

A spherical robot is a robotic device without wheels or legs, which has a single spherical form that scrolls by itself to conduct missions. The spherical shape of this class of mobile robots offers several advantages over other forms of surface-based locomotion such as wheels, tracks or legs. The sphere is a strong shape providing a high level of robustness with no major weakness points on its surface, whereas wheels, tracks or legs can be damaged, potentially disabling the mobility of the robot. The outer shell can also be resilient and serve as a protective barrier between the outside environment and the inside equipments. A spherical robot is by nature non-invertible further limiting the risk of becoming disabled, while most other mobile robot designs are vulnerable to tipping over or becoming stuck on the terrain where their means of locomotion lose contact with the ground. These advantages indicate that a spherical robot is appropriate for many different applications such as surveillance, reconnaissance, hazardous environment assessment, search and rescue, as well as planetary exploration.

Spherical rolling robots can be categorized into different types according to their internal driving mechanisms [1-9]. Compared with other types of spherical rolling robots [1-6], a pendulum-driven spherical rolling robot [7-9] has a simpler structure further making it easier to be manoeuvred. The schematic diagram of a pendulum-driven spherical rolling robot with dual inputs is illustrated in Figure 1. Linear motion is a basic form of locomotion of pendulum-driven spherical rolling robots, and it is realized by moving a motor-controlled pendulum forwards or backwards. In this paper, a new decoupled sliding mode control approach based on a novel exponential reaching law is presented for stable control of the linear motion. In the proposed controller, a double layer structure is used to guarantee the stability of the whole system, and the sub-sliding surfaces are utilized to drive the tracking errors to zero.

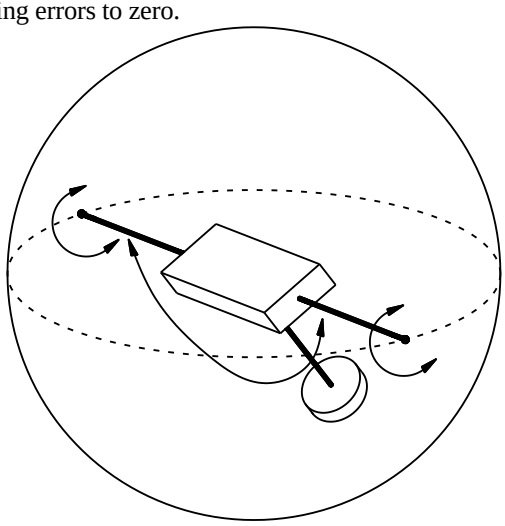

FIGURE 1 Structure of a pendulum-driven spherical robot

2 Dynamic analysis

We start with a simplified planar model, only considering no slip linear motion on flat surfaces. Figure 2 illustrates the simplified model with a side view of a pendulum-driven spherical rolling robot. It represents the spherical shell with its centre of mass *B*, the internal mechanism with its centre of mass *D*, which coincides with that of the spherical shell, and the pendulum (composed of a massless link and a counterweight at its end) with its centre of mass *E* and the axis attached at the centre of the sphere. The definition of the model parameters is listed in Table 1.

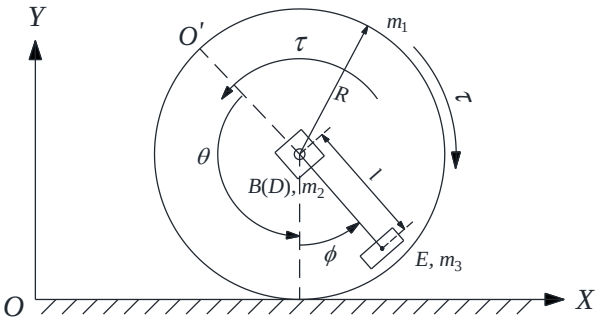

FIGURE 2 Simplified model of the linear motion

TABLE 1 Parameter definition of the planar model

m1, m2, m3	mass of the spherical shell, the internal mechanism and the pendulum, respectively
r, l	radius of the spherical shell and length of the pendulum, respectively
θ, ϕ	roll angle of the spherical shell and sway angle of the pendulum, respectively
I1, I2, I3	moment of inertial of the spherical shell, the internal mechanism and the pendulum, respectively
τ	torque applied to the pendulum

We first choose the roll angle of the sphere θ and the sway angle of the pendulum ϕ as the generalized coordinates of the robotic system, and then we develop the equations of motion by calculating the Lagrangian $L = T - P$ of the system, where T and P are the kinetic energy and potential energy of the system respectively.

The kinetic energy and potential energy of the whole robotic system are given by

$$T = \frac{1}{2} J_1 \dot{\theta}^2 + \frac{1}{2} J_2 \dot{\phi}^2 + m_3 r l \dot{\theta} \dot{\phi} \cos\phi \quad P = -m_3 g l \cos\phi, \tag{1}$$

where g denotes the gravitational acceleration;

$J_1 = M_t r^2 + I_1$, $M_t = m_1 + m_2 + m_3$, $J_2 = m_3 l^2 + I_2 + I_3$.

It is assumed that the viscous friction operates between the sphere and the pendulum. The loss due to the viscous friction is written in an energy dissipation function that depends on the velocities of the system and the damping coefficient ζ associated with the pendulum-sphere bearing.

$$R = \frac{1}{2} \zeta \left(\dot{\theta} + \dot{\phi} \right)^2. \tag{2}$$

Using the Euler-Lagrange Equations [10], the dynamics of the linear motion can be expressed as

$$\boldsymbol{M}(\boldsymbol{q}) \ddot{\boldsymbol{q}} + \boldsymbol{N}(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \boldsymbol{E}(\boldsymbol{q}) \tau, \tag{3}$$

where $\boldsymbol{M}(\boldsymbol{q})$ is the inertia matrix, $\boldsymbol{N}(\boldsymbol{q}, \dot{\boldsymbol{q}})$ is the nonlinear terms, and $\boldsymbol{E}(\boldsymbol{q})$ is the input transformation matrix.

$$\boldsymbol{M}(\boldsymbol{q}) = \begin{bmatrix} J_1 & m_3 r l \cos\phi \\ m_3 r l \cos\phi & J_2 \end{bmatrix}, \quad \boldsymbol{E}(\boldsymbol{q}) = \begin{bmatrix} 1 \\ 1 \end{bmatrix},$$

$$\boldsymbol{N}(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \begin{bmatrix} \zeta \left(\dot{\theta} + \dot{\phi} \right) - m_3 r l \sin\phi \dot{\phi}^2 \\ \zeta \left(\dot{\theta} + \dot{\phi} \right) + m_3 g l \sin\phi \end{bmatrix}.$$

Using the control input $u = \tau$ and the state vector $\boldsymbol{X} = \left(\theta, \dot{\theta}, \phi, \dot{\phi} \right)^T$, we can rewrite Equation (3) as follows

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = f_1(\boldsymbol{X}) + b_1(\boldsymbol{X}) u \\ \dot{x}_3 = x_4 \\ \dot{x}_4 = f_2(\boldsymbol{X}) + b_2(\boldsymbol{X}) u \end{cases}, \tag{4}$$

where

$$f_1(\boldsymbol{X}) = \frac{m_{22} n_1 - m_{12} n_2}{m_{12} m_{21} - m_{11} m_{22}}, \quad f_2(\boldsymbol{X}) = \frac{m_{11} n_2 - m_{21} n_1}{m_{12} m_{21} - m_{11} m_{22}},$$

$$b_1(\boldsymbol{X}) = \frac{m_{22} - m_{12}}{m_{11} m_{22} - m_{12} m_{21}}, \quad b_2(\boldsymbol{X}) = \frac{m_{11} - m_{21}}{m_{11} m_{22} - m_{12} m_{21}}.$$

Here m_{ij} denotes the element in the i-th row and j-th column of the matrix $\boldsymbol{M}(\boldsymbol{q})$, and n_k represents the k-th component of the vector $\boldsymbol{N}(\boldsymbol{q}, \dot{\boldsymbol{q}})$.

3 Controller design

In this section, we investigate the set-point regulation scheme of the linear motion of a spherical robot, and a decoupled sliding mode controller based on a new exponential reaching law is derived to asymptotically stabilize the robot around its desired equilibrium.

Considering the system represented by Equation (4), we first divide the whole system into two subsystems as

$$A: \begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = f_1(\boldsymbol{X}) + b_1(\boldsymbol{X}) u \end{cases}, \quad B: \begin{cases} \dot{x}_3 = x_4 \\ \dot{x}_4 = f_2(\boldsymbol{X}) + b_2(\boldsymbol{X}) u \end{cases}.$$

Then we construct the following first layer sliding surfaces for the two subsystems

$$s_1 = \lambda_1 e_1 + \dot{e}_1, \qquad s_2 = \lambda_2 \phi + \dot{\phi}, \tag{5}$$

where λ_1 and λ_2 are positive constants; $e_1 = x_1 - \theta^d$, and θ^d is the desired value of θ.

We define an intermediate variable z which represents the information from subsystem B, and it is incorporated into the sliding surface s_1. Therefore, the second layer sliding surface S is designed as

$$S = \lambda_1 (e_1 - z) + \dot{e}_1 \quad z = z_u \cdot \tanh(s_2), \tag{6}$$

where z_u is the upper bound of $abs(z)$, $0 < z_u < 1$; $\tanh(\cdot)$ is the hyperbolic tangent function defined as follows $\tanh(s_2) = \dfrac{e^{s_2} - e^{-s_2}}{e^{s_2} + e^{-s_2}}$.

Since z_u is less than one, z presents a decaying signal. As s_2 decreases, z decreases too. When $s_2 \to 0$, we have $z \to 0$, $e_1 \to 0$, and then $s_1 \to 0$, and the control objective will be achieved.

Differentiating Equation (6), we can calculate $\dot{z}$ as

$$\dot{z} = \alpha(s_2, z_u)\cdot \dot{s}_2, \tag{7}$$

where $\alpha(s_2, z_u) = z_u \cdot \sec h^2(s_2)$, $\sec h(s_2) = \dfrac{2}{e^{s_2} + e^{-s_2}}$.

Differentiating Equation (6) and using Equation (7) yields

$$\begin{aligned} \dot{S} &= \lambda_1(\dot{e}_1 - \dot{z}) + \ddot{e}_1 = \\ &\lambda_1 x_2 + f_1 - \alpha\lambda_1(\lambda_2 x_4 + f_2) + (b_1 - \alpha\lambda_1 b_2)u \end{aligned}. \tag{8}$$

Then we can obtain the equivalent control as

$$u_{eq} = \frac{\lambda_1 x_2 + f_1 - \alpha\lambda_1(\lambda_2 x_4 + f_2)}{\alpha\lambda_1 b_2 - b_1}. \tag{9}$$

The control input of the system is assumed to take the following form

$$u = u_{eq} + u_{sw}, \tag{10}$$

where u_{sw} is the switching control.

To construct the switching component u_{sw}, we propose the following exponential reaching law

$$\dot{S} = -\frac{\eta}{N(S)}\operatorname{sgn}(S) - \rho S, \tag{11}$$

where η and ρ are positive constants $N(S) = \delta_0 + (1-\delta_0)e^{-\gamma|S|^p}$.

Here δ_0 is a positive constant that is less than one, p is a positive integer, and γ is also a positive constant.

The proposed ERL given by Equation (11) is composed of a variable rate reaching term [12] and an exponential term. Comparing with the conventional exponential reaching law [13], we can see from Equation (11) that if $|S|$ increases, $N(S)$ approaches δ_0, and therefore $\eta/N(S)$ converges to η/δ_0, which is larger than η. This means that $\eta/N(S)$ increases in the reaching phase, and consequently the attraction to the sliding surface S is faster. On the other hand, if $|S|$ decreases, then $N(S)$ approaches one, and $\eta/N(S)$ converges to η. This means that, when the system state approaches the sliding surface S, $\eta/N(S)$ gradually decreases to reduce the chattering. Therefore, the proposed ERL allows the controller to dynamically adapt to the variations of the switching function S by letting $\eta/N(S)$ vary between η and η/δ_0.

Using Equation (8) to Equation (11), we can obtain the switching control as

$$u_{sw} = \frac{N_\eta(S)\operatorname{sgn}(S) + \rho S}{\alpha\lambda_1 b_2 - b_1}, \tag{12}$$

where $N_\eta(S) = \dfrac{\eta}{N(S)}$.

Substituting Equation (12) into Equation (10), we can obtain the following sliding mode control law

$$u = \frac{\lambda_1 x_2 + f_1 - \alpha\lambda_1(\lambda_2 x_4 + f_2) + N_\eta(S)\operatorname{sgn}(S) + \rho S}{\alpha\lambda_1 b_2 - b_1}. \tag{13}$$

Theorem 1: Supposing that the robotic system represented by Equation (4) is controlled by the sliding mode controller given by Equation (13). Then the system defined by Equation (4) is asymptotically stable.

Proof: Considering the Lyapunov function candidate $V = \dfrac{1}{2}S^2$, then $\dot{V}$ can be given by

$$\dot{V} = S\dot{S} = -N_\eta(S)|S| - \rho S^2 \le -\eta|S| - \rho S^2 \le 0. \tag{14}$$

Integrating both sides of Equation (14), we have

$$\begin{aligned} &V(t) = \frac{1}{2}S^2 \le V(0) < \infty \\ &\lim_{t\to\infty}\int_0^t \left(\eta|S| + \rho S^2\right)\mathrm{d}\sigma \le V(0) < \infty \end{aligned}. \tag{15}$$

According to Equation (15), we have $S \in L_\infty$, $S \in L_2$. According to Equation (14), we have $\dot{S} \in L_\infty$. Consequently, by applying Babalat's lemma we can conclude that the sliding surface S is asymptotically stable, i.e. $\lim_{t\to\infty} S = 0$.

Then the system can be guaranteed to be asymptotically stable.

4 Simulation study

In this simulation, the following physical parameters of the spherical mobile robot [14] and design parameters of the sliding mode controller are used.

$m_1 = 1.2\,\mathrm{kg}$, $m_2 = 1.85\,\mathrm{kg}$, $m_3 = 2.05\,\mathrm{kg}$, $R = 0.15\,\mathrm{m}$, $l = 0.12\,\mathrm{m}$, $I_1 = 0.018\,\mathrm{kg\cdot m^2}$, $I_2 = 0.0017\,\mathrm{kg\cdot m^2}$, $I_3 = 0.0006\,\mathrm{kg\cdot m^2}$, $\zeta = 0.03\,\mathrm{N\cdot m\cdot (rad/s)^{-1}}$, $g = 9.81\,\mathrm{m/s^2}$, $z_u = 0.96$, $\lambda_1 = 4$, $\lambda_2 = 0.6$, $\eta = 3$, $\delta_0 = 0.1$, $\gamma = 10$, $p = 1$, $\rho = 7.8$.

In addition, the initial and desired values of the system states are chosen as $x_0 = (0,\ 0,\ 0,\ 0)^T$, $x^d = (\pi,\ 0,\ 0,\ 0)^T$.

The simulation results are depicted in Figure 3 to Figure 6. As it is theoretically expected, we can find that both the roll angle of the sphere and the sway angle of the pendulum are asymptotically stabilized to their desired values, and the anti-sway control is achieved in a rapid manner after only one oscillation.

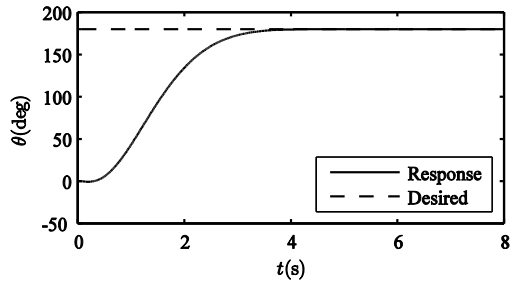

FIGURE 3 Tracking result of the roll angle of the spherical shell

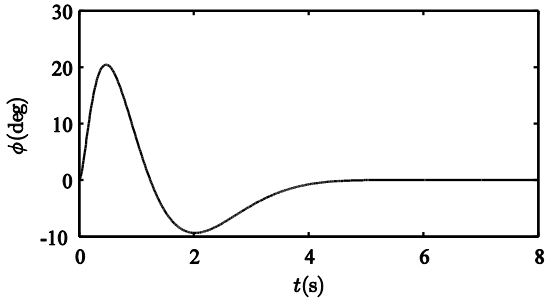

FIGURE 4 Tracking result of the sway angle of the pendulum

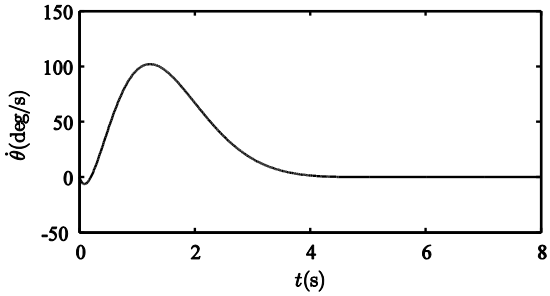

FIGURE 5 Time evolution of the angular rate of the roll angle

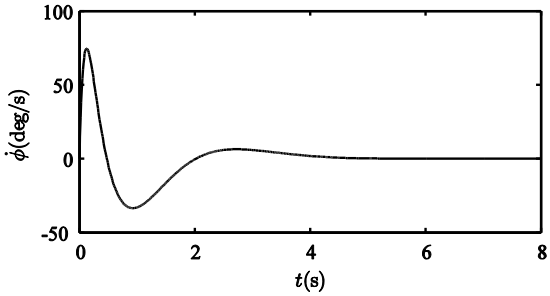

FIGURE 6 Time evolution of the angular rate of the sway angle

5 Conclusions

In this paper, we present a variable structure strategy for set-point regulation of the linear motion of a spherical rolling robot. The control development is based on the construction of a cascade sliding mode controller and a novel exponential reaching law, and the proposed control approach consists of designing a nonlinear reaching law by using a switching term that dynamically adapts to the variations of the system state. The asymptotic stability of the sliding surface of the whole system is theoretically proved, and the simulation results further verify the effectiveness of the proposed controller.

Abstract

According to large scale MEMS united constraints equations, the paper investigates model order reduction (MOR) techniques based on Structure Preserving Reduced-order Interconnect Macro modelling (SPRIM) method, which can be used to generate computationally efficient solutions for multiphasic MEMS simulation. To united constrained model, the high dimensionality of the original system state space is mapped to a suitable low-dimensional subspace, obtained a low-dimensional state sub-space model. A improved algorithms(SPRIM) from Arnoldi algorithms are implemented to extract low dimensional Krylov subspaces from Unified state subspace models for model order reduction, reduced order electro thermal–mechanical models are generated for a MEMS micro beam using the developed programs. Developed programs automatically generate compact structure preserving models and can be used to significantly improve the computational efficiency without much loss in accuracy and model stability for coupled-field MEMS simulation.

Keywords: MEMS (Micro-Electrical Mechanical System), model order reduction, sub-space model, model reflection

1 Introduction

Micro-Electro-Mechanical Systems (MEMS) are the integration of mechanical elements, sensors, actuators, and electronics at the micron-scale or even at nano-scale through micro fabrication technology, which involves the mechanical, electronic, fluid, thermal, optical, magnetic and other disciplines [1]. Most micromechanical devices have some form of nonlinearity, either geometric nonlinearity due to large amplitude deflections or intrinsic nonlinearities due to governing equations, Multi-energy domain coupling effect of MEMS can hardly be described perfectly, because in a micron-scale or even in a nano-scale working room, physical quantities of energy among the different domains interact with each other. So, in MEMS's design process, the comprehensive effects which have been made by a variety of physical phenomena must be taken into consideration. Most MEMS devices are modelled using fully meshed finite-element based dynamic models, such models often require unacceptably long simulation time. As a result, fully meshed dynamical simulation can be computationally lunation time, and as a result, fully meshed dynamical simulation can be computationally infeasible in a typical workstation environment. Such models need to reduce the computation cost without comprising accuracy, thus allowing hundreds or thousands of dynamical simulations necessary to study how a MEMS device actually functions under various input excitations in a reasonable time.

The paper investigates model order reduction (MOR) techniques based on Structure Preserving Reduced-order Interconnect Macro modelling (SPRIM) method, which can be used to generate computationally efficient solutions for multi-physics MEMS simulation. We organized the paper as 4 parts:

1) the preview of MOR method;
2) the principle of SPRIM;
3) the detailed example of MOR based on SPRIM;
4) an application example.

2 Previous work

The basic idea of MOR method of system state space node variable mapping transform based on the PDES dynamics system is controlled by the spatial discretization, get a great degree of freedom of ODES, then using the coordinate transformation method transform the large-scale ODES system into a system with approximation the low dimension ODES, the dynamic characteristic of the approximate system can depict the original system without sacrificing too much precision condition, so as to achieve the state vector of the aim of reducing the number of degree of freedom. Many existing MOR algorithms are basically the reduction of a linear system model, for nonlinear systems, usually use MOR in the vicinity of the operating point linearization, there are three type of the MOR method in general [2-4]:

1) Based on Krylov approximation subspace or moment matching;

2) Based on balanced truncation method (TBR) with approximate Hankel norm;

3) Combined with singular value decomposition (SVD) and the Krylov subspace iterative method. The transient analysis approximate effect of Krylov subspace methods is good,

**Corresponding author* e-mail:gyp@hdu.edu.cn

and its operation is relatively simple, Krylov methods construct a reduced model based on either explicitly or implicitly approximating the transfer function of a full scale model. Asymptotic waveform evaluation (AWE) is an explicit method that has been used to create reduced models; however, AWE has been shown to be a numerically unstable process. The Arnoldi and Lanczos algorithms are implicit methods that generate Krylov subspaces and reduce models by projection onto these subspaces [5, 6]. The Arnoldi and Lanczos algorithms method, which have been widely used to do model order reduction for VLSI interconnects, is used to generate reduced-order models for a linearized fixed-fixed beam microstructure, the method has been proved to be very efficient to generate reduced-order models when the device is operated in the linear regime. However, when the device undergoes large amplitude deflection, the linearized model deviates from the original nonlinear model significantly, suggesting that nonlinear reduced-order models are needed [7, 8]. To solve this problem, the paper presents a new technique by combining the Taylor series expansion and an improve Arnoldi method - SPRIM method, to develop accurate reduced-order models for nonlinear MEMS devices. The main idea of the approach is to devise a state-variable transformation operation from the linearized device system, and use this state-variable transformation operation to project a high-dimensional device nonlinear state-space model onto a low-dimensional form. Simulation of a fixed-fixed electrostatic actuated beam device shows that the reduced-order nonlinear models can accurately capture the original device nonlinear behavior over a much larger range of device deformation than the conventional linearized model.

3 Structure preserving reduced-order interconnect macro modeling (SPRIM) method

Krylov subspace model order reduction method under the condition of certain can maintain the stability of the original system and passive, so to improve the traditional Krylov subspace methods, makes some important attributes order reduction system can keep the original system. Krylov subspace projection methods extract low dimensional Krylov subspaces from models described by ODEs with the desired model reduction achieved by projection of the models onto the subspaces while dynamic characteristics are maintained through a property called moment matching. To illustrate the MOR formulation procedure and moment matching we will take the first order system shown in Equation (1) as an example and rewrite it as follows:

$$\begin{cases} E\dfrac{dx(t)}{dt} = Ax(t) + Bu(t) \\ y(t) = B^T x(t) \end{cases}, \tag{1}$$

where $E = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix} \in R^{n\times n}$, $A = \begin{bmatrix} N & F \\ -F^T & 0 \end{bmatrix} \in R^{n\times n}$, $B = \begin{bmatrix} B_1 \\ 0 \end{bmatrix} \in R^{n\times P}$, M, N and B_1 has the same number of rows, M, H and N is positive semi-definite matrix, at the same time, a given point, as well as the positive integer, specific algorithm is:

Step 1: let: $G = (S_0E - A)^{-1}$, $Q = (s_0E - B)^{-1}$, use Arnoldi block method compute matrix $\hat{V}$, which satisfies: $\text{colspan}\{\hat{V}\} = K_r(G:Q)$;

a) given matrix $A \in R^n, B \in R^{n\times p}$ and QR decomposition of matrix B, let $B = V_0T$;

b) Compute: $\hat{V}_1 = AV_0 - V_0H_{00}$, where, $H_{00} = V_0^TAV_0$, then QR decomposition $\hat{V}_1$, we can get: $\hat{V}_1 = V_1H_{10}$;

c) Compute: $\hat{V}_2 = A_0V_1 - V_1H_{11} - V_0H_{01}$, where: $H_{11} = V_1^TAV_1$, $H_{01} = V_0^TAV_1$, then QR decomposition $\hat{V}_2$, we can get $\hat{V}_2 = V_2H_{21}$;

d) Then compute following parameter intron: $\hat{V}_r = AV_{r-1} - V_{r-1}H_{r-1,r-1} - ... - V_1H_{1,r-1} - V_0H_{0,r-1}$, where: $H_{r-1,r-1} = V_{r-1}^TAV_{r-1}, ..., H_{1,r-1} = V_1^TAV_{r-1}$, $H_{0,r-1} = V_0^TAV_{r-1}$ and QR decomposition $\hat{V}_r$, we can get $\hat{V}_r = V_rH_{r,r-1}$.

Step 2: According to the characteristics of block structure matrix E and A matrix to do division $\hat{V}$: $\hat{V} = \left[V_1^T, V_2^T\right]$, and constructing the corresponding matrix $V = diag\{V_1, V_2\}$.

Step 3: let $\tilde{M} = V_1^TMV_1$, $\tilde{H} = V_2^THV_2$, $\tilde{N} = V_1^TNV_1$, $\tilde{F} = V_2^TFV_2$, $\tilde{B} = V_1^TB_1$, we get the reduced order system:

$$\begin{cases} \tilde{E}\dfrac{d\tilde{x}(t)}{dt} = \tilde{A}\tilde{x}(t) + \tilde{B}u(t) \\ \tilde{y}(t) = \tilde{B}^T\tilde{x}(t) \end{cases}, \tag{2}$$

where: $\tilde{E} = \begin{bmatrix} \tilde{M} & 0 \\ 0 & \hat{H} \end{bmatrix} \in R^{n\times n}$, $\tilde{A} = \begin{bmatrix} \tilde{N} & \tilde{F} \\ -\tilde{F}^T & 0 \end{bmatrix} \in R^{n\times n}$, $\tilde{B} = \begin{bmatrix} \tilde{B}_1 \\ 0 \end{bmatrix} \in R^{n\times P}$.

4 Application example

In order to illustrate the model reduction technique, we give an example of the well-known beam structure in a electrical environment. Figure 1 shows the beam structure, When a voltage is applied, the top plate of the structure bends downward due to the resultant electrostatic force. Also when then beam bends, the pressure distribution of the ambient air under the beam increases. This pressure increase produces a backward pressure force that damps the beam motion. The beam structure has been used in many sensor applications.

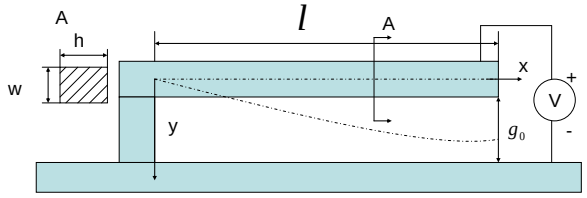

FIGURE 1 Single-ended fixed electrostatic actuating micro beam structure

The beam can be modeled by coupling the Euler beam equation with the electrostatic force and the Reynolds squeeze-film damping equation as:

$$\begin{cases} EI\dfrac{\partial^4 y}{\partial x^4} - s\dfrac{\partial^2 y}{\partial x^2} = -\dfrac{\xi_0 \omega V^2}{2y^2} + \int_0^{\infty}\left(p - p_a\right)dy - \rho\dfrac{\partial^2 y}{\partial t^2} \\ \nabla\cdot\left(y^3 p\nabla p\right) = \dfrac{12\mu}{1+6k}\dfrac{\partial(py)}{\partial t} \end{cases}, \quad (3)$$

where: $y(x,t)$ is the immunity of the z direction, E is young's modulus, $I = \dfrac{wh^3}{12}$ is the moment, ρ is the density, ε_0 is dielectric constant, p is the air damping of the pressure, p_0 is the ambient pressure, μ is the air viscosity coefficient, g is the distance from the plate under initial state, λ is air mean free path (Table 1).

TABLE 1 The parameters of Single-ended fixed electrostatic actuating micro beam structure

Parameters	Value
Length	610 μm
Width	40μm
Thickness	2.2μm
Gap	2.3μm
Young's modulus	149GPa
Density	2330kg/m3
Air viscosity	1.82×10^{-5}kg/(m·s)
Mean-free path of air	0.0064

Let: $\tilde{y} = \dfrac{y(x,t)-g}{g}$, $\tilde{p}(x,t) = \dfrac{p(x,t)-p_0}{p_0}$, substitute them into Equation (3), and in g and p_0 using Taylor series expansion, and take position, speed and pressure as state variables, like: $x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}$, we can get the micro beam for original system state equation:

$$\dot{x} = \begin{pmatrix} \dot{y} \\ \ddot{y} \\ \dot{p} \end{pmatrix} = \begin{pmatrix} x_2 \\ \left(-\dfrac{EI}{\rho}\cdot\dfrac{\partial^4 y_i}{\partial x^4} + \dfrac{s}{\rho}\dfrac{\partial^2 y_i}{\partial x^2} + \dfrac{\varepsilon_0\omega V^2}{g^3\rho}\right)x_1 + \dfrac{p_0}{g\rho}\int_0^{\omega} x_3 dy - \dfrac{3\varepsilon_0\omega V^2}{2g^3\rho}x_1^2 - \dfrac{\varepsilon_0\omega V^2}{2g^3\rho} \\ \left[\left(1+\dfrac{6\lambda}{g}\right)+\left(1+\dfrac{6\lambda}{g}\right)x^3 + \left(2+\dfrac{6\lambda}{g}\right)x_1\right]\dfrac{g^2 p_a}{12\mu}\nabla^2 x^3 - (1+x_3+x_1) \end{pmatrix}. \quad (4)$$

To solve the linearized equation numerically, the Equation (4) should be discretized in space, and then converted into state-space model. We use $(N+1)\times(M+1)$ mesh as shown in Figure 2, where N represents the number of inner grid points in the x direction and M is the number of inner grid points in the y direction. After the mesh is generated, we then project the unknowns $u(x,t)$ and $p(x,y,t)$ onto the mesh points and apply the trapezoidal rule to discretize the special integral operator and the central difference method to discretize the special derivative operators as follows:

$$\frac{\partial^2 y_i}{\partial x^2} = \frac{y_{i+1} - 2y_i + y_{i-1}}{\Delta x^2}, \quad (5)$$

$$\frac{\partial^4 y_i}{\partial x^4} = \frac{y_{i+2} - 4y_{i+1} + 6y_i + 4y_{i-1} + y_{i+2}}{\Delta x^4}. \quad (6)$$

Accelerometer beam clamped at one end, so the boundary conditions are: $y_0 = 0, y_{-1} = y_1$, substitute Equations (5) and (6) into Equation (4) to discrete, then map the n state vector:

$$X = \left[\, y_1 \ \ldots\ y_N \ \frac{\partial y_i}{\partial t} \ \ldots\ \frac{\partial y_N}{t} \ p_{11} \ \ldots\ p_{mn} \,\right]^T$$

to the various nodes, we can convert discrete equations into n dimensional state space Equation (7), where: $n = 2N + NM$.

$$\begin{cases} X(t) = Ax(t) + Bv(t) \\ y(t) = B^T X(T) \end{cases}, \quad (7)$$

where: $E = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix} \in R^{n\times n}$, $A = \begin{bmatrix} N & F \\ -F^T & 0 \end{bmatrix} \in R^{n\times n}$, $B = \begin{bmatrix} B_1 \\ 0 \end{bmatrix} \in R^{n\times P}$.

$y(t)$ is the micro displacement of the beam end, $v(t)$ is the input voltage of the system.

According to the two-dimensional model establishment of beam parameters as shown in the Figure 2. The beam was divided by with 2D quadrilateral element PLANE82, and the air medium was divided with PLANE121, displacement constraints were applied to fix the micro beam anchors in ANSYS, each degree of freedom beam base and left side of beam were restricted, the finite element model as shown in

the Figure 3 then applied effect of voltage on the beam structure. Figure 4 is the displacement of micro-beam.

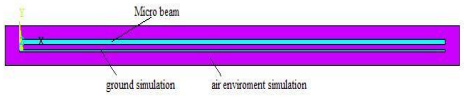

FIGURE 2 Structure Model of Micro Beam

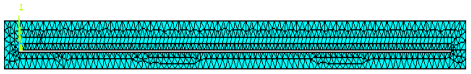

FIGURE 3 Finite Element Model of Micro Beam

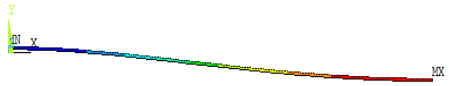

FIGURE 4 The displacement of Micro Beam

Applying the boundary conditions, the finite element model is solved can change the endpoint micro beam under different voltage conditions. The voltage load vector along with the mass and stiffness matrices were extracted and imported into Matlab. For problem simplification, viscous damping was not considered and Rayleigh damping was employed with both proportional damping constants equal to 0.25. Reduced models of size 10 and 30 were generated via the developed SPRIM reduction program. Reduced order models were numerically integrated in Matlab and reduced model solutions were expanded to full scale using Equation (8) to determine the micro beam displacement states. Algorithm stopping criteria were applied similar to those described in the electro structure results section. Figure shows the transient vertical displacement at the lower tip of the micro beam for the reduced and full models. As shown in [5], the simulation results of pull in voltages for the reduced and full models were both nearly in 8.7 V~8.8V, corresponding to relative percent errors of 2.2%.

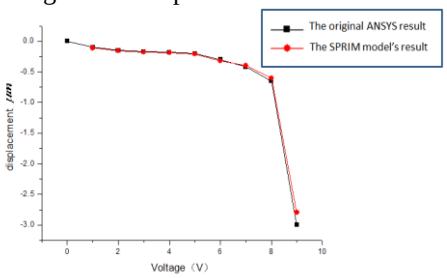

FIGURE 5 the transient vertical displacement of the micro beam for the reduced and full models

The reduced model is applied step signal under the condition of dynamic simulation, the original simulation model and reduced the response curve of the model, the simulation results are shown in Figure 6.

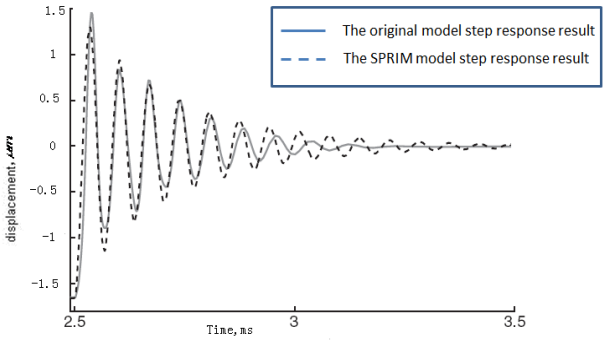

FIGURE 6 dynamic simulation comparison between the SPRIM model and original model

5 Conclusion

Model order reduction methods for coupled metaphysics FEA simulation of a common MEMS device are investigated in this paper. Simulation is performed for various sized reduced models of an electro structure actuated micro beam and compared with the full model simulation. Reduced model comparison illustrates that the reduction methods greatly increase the efficiency of FEA simulation with SPRIM models achieving simulation time reductions 84%, respectively, while SPRIM efficiency improvement was slower than PRIM model, but models experiencing relative errors of 2.2% is least. The relationship between accuracy and reduced model size is demonstrated by an increase in accuracy as model size increases.

Wireless monitoring system for temperature and humidity based on ZigBee

Jianjun Chen*

Shaoxing University Yuanpei College, Shaoxing, Zhejiang, 312000, China

Received 1 March 2014, www.cmnt.lv

Abstract

Traditional methods of environmental monitoring have the shortages including difficult network layout and low intelligent of node. A monitoring system for temperature and humidity was designed based on ZigBee (wireless network), with SHT11 (temperature and humidity integrated sensor) and CC2430 (wireless radio frequency module integrated with MCU). Data of temperature and humidity, collected at some acquisition terminals in SHT11 and CC2430, were displayed on monitoring host via centre node. By using solution of single chip ZigBee, the system was optimized with high precision, low power dissipation and simple equipment.

Keywords: CC2430 wireless network; monitoring temperature and humidity

1 Introduction

Environmental temperature and humidity are monitored in fields of biopharmaceutics, food processing, paper making and so on. Functions of current integrated intelligent sensors including such as linearization treatment, automatic temperature compensation and humidity calibration, provide favourable conditions for development of temperature and humidity monitoring system [1]. Wireless network can be easily built with ZigBee technology. Data are secure and stable during transmission with little influence from the terrible circumstance such as outside noise and strong magnetic field. In this work a wireless monitoring system for temperature and humidity was built with CC1010 (ZigBee wireless radio frequency module) and SHT11 (temperature and humidity sensor module). Measuring signal of local sensor is sent to monitoring terminal without setting quantities of temperature cables in conservatory. The system was optimized with real-time performance, high precision and overall treatment of nodes' temperature, as well as simplified installation and cost reduction.

2 Overall plan of temperature and humidity monitoring system

A star-like wireless sensor network was built with several ZigBee acquisition terminals and a ZigBee centre node (coordinator). Temperature and humidity sensor in the acquisition terminals collected environmental temperature and humidity data. The data were corrected by 8051 MCU embedded in ZigBee wireless radio frequency module [2]. Then, the corrected data were sent to centre node by wireless chips via ZigBee wireless network. All acquisition terminals have the same functions and implementation methods. Centre node was composed of a ZigBee wireless radio frequency chip and a USB module. As a network coordinator, the chip was responsible for generation, management and maintenance of the network. In detail, its duty included network address distribution for new equipment, access and departure of nodes, distribution and update of network security keys, etc. Furthermore, the chip should upload collected data to monitoring host, and send out orders from the host.

Monitoring host accepted all data of temperature and humidity and displayed them on PC screen for monitoring. The host periodically read serial port buffer and put data of from centre node into cache. Then, temperature and humidity data were extracted and decomposed by host. ID in each data packet was used to confirm data source. After that, the host displayed temperature and humidity information in real time. The host needed to judge residual energy through working voltage of acquisition terminal nodes. If the voltage was too low, the reliability of sensor data would be greatly reduced. And in that case there would be an alarm of battery replacement. Figure 1 shows structure of overall network.

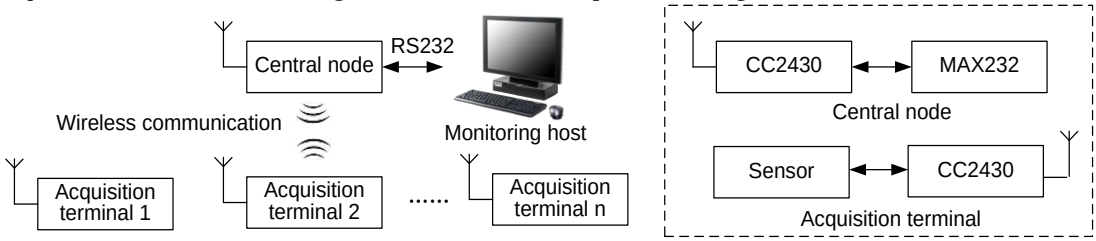

FIGURE 1 Overall design of the monitoring system

3 Hardware of temperature and humidity monitoring system

3.1 DESIGN OF ACQUISITION TERMINAL HARDWARE

Acquisition terminal is composed of microprocessor module (with internally-integrated wireless radio frequency module), temperature and humidity data acquisition module and power module. Temperature and humidity data measured by sensor are processed by microprocessor chip and sent to centre node via wireless radio frequency. Figure 2 shows the structure of acquisition terminal. Instead of utilizing the combination of microcontroller and ZigBee, terminal with single ZigBee chip is optimized with high precision, low power dissipation and simple equipment.

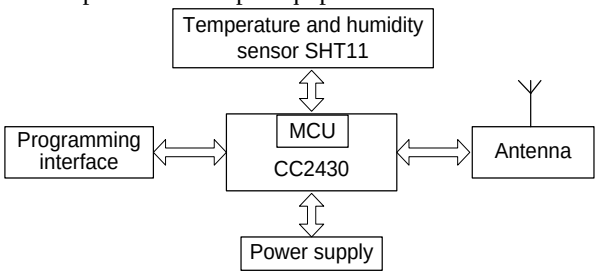

FIGURE 2 Overall block diagram of the acquisition terminal

3.1.1 Wireless RF transceiver chip CC2430 [3]

As core of acquisition terminal, CC2430 is a radio frequency chip produced by Chipcon, with low power dissipation and multiband. It is internally integrated with a 2.4 GHz RF transceiver of direct sequence spread spectrum, as well as an enhanced industrial microprocessor 8051. Microprocessor 8051 has an 8 KB RAM, a programmable flash memory, several timers (including a watchdog timer), a collaborative processor, a 32 KHz crystal oscillator sleep timer, 21 I/O connectors, power detection circuit and power on reset circuit.

CC2430 is also used in wireless radio frequency chip of centre node. Register RFMAIN determines receiving or transmission mode of chip. Seventh RXTX of 8-RXTX RAMAIN can be used to set modes: 0 as receiving mode and 1 as transmission mode.

3.1.2 Temperature and humidity sensor SHT11

SHT11, designed by Swiss Sensirion, is an integrative temperature and humidity sensor with two-wire serial interface. A capacitive polymer humidity sensor can detect the humidity, and energy gap temperature device is for temperature detection. Devices transform temperature and humidity information into weak electrical signals. Signals are amplified by operational amplifier and then directly sent into A/D converter, outputting digital signals via two-wire serial interface bus.

For convenience, debugging and calibration of data are implemented within chip. Besides, users can set measurement accuracy with resolution up to 8, 12 or 14 bits. CRC checking in chip ensures the accuracy of data transmission. Figure 3 shows the hardware connection diagram of SHT11 and MCU. Besides, DATA cable should be externally connected with pull-up resistor. Clock line SCK is used for communication between microprocessor and SHT11. SCK has no limitation of minimum frequency because its interface contains a whole static logic. If working voltage was higher than 4.5 V, frequency of SCK will be up to 10 MHz; else, maximum frequency of SCK will be only 1 MHz.

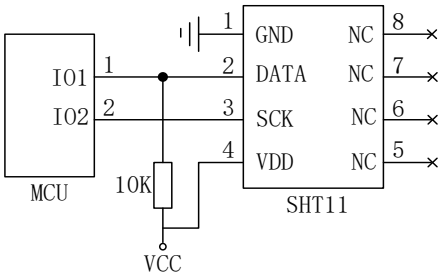

FIGURE 3 MCU connected with SHT11

3.2 HARDWARE OF CENTRE NODE

Centre node is composed of a ZigBee wireless radio frequency CC2430 and a USB MAX232. As a network coordinator, CC2430 can build, maintain and cease ZigBee wireless network [4]. CC2430 is connected with thirteenth pin $R1_{IN}$ and fourteenth pin $T1_{OUT}$ of MAX232 serial module with two serial lines - TXD0 and RXD0. Data are periodically sent to monitoring host via MAX232 USB (see Figure 4).

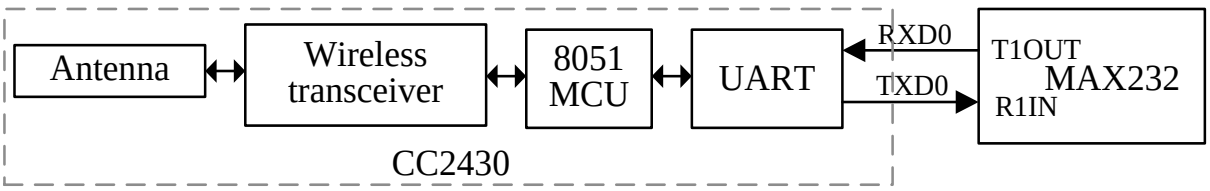

FIGURE 4 Block diagram of central node

CC2430 is regarded as the wireless module for acquisition terminal and centre node because it has four low power modes - PM0, PM1, PM2 and PM3. Largest power dissipation is on PM0 mode, while least power dissipation on PM3 mode. On normal state (PM0), wireless communication module will keep monitoring wireless channel to checks whether data have came. Wireless communication module is closed on other low power modes. Largest energy dissipation emerges on receiving state in normal work, while

slightly less on delivery state. Least energy dissipation results from dormant state. Therefore, system can enter dormancy as soon as possible for low power dissipation, with needless communication [5].

4 Design of system software

Software of system should have functions including building a ZigBee wireless LAN, collection, revision and delivery of temperature and humidity data, packaging, transport and display of each acquisition terminal data. Software design includes three parts, namely the design of acquisition terminal software, centre node software and upper computer system software.

4.1 SOFTWARE OF TEMPERATURE AND HUMIDITY DATA COLLECTION

After acquisition terminal is power on, it will initialize hardware module and ZigBee protocol stack. Then, node searches ZigBee network nearby for accession. Once accessed, terminal turns into low power mode.

Collection of temperature and humidity information included two types – automatic and manual collection. Automatic collection was based on timer at terminal. Timer started after setting an initial value. It would cause interruption when time came to the set value, and the measurement of temperature and humidity began. After measuring, data were sent out via radio frequency, with terminal entering low power mode. Timer was reset for next timing. Thus, automatic collection can be achieved with such circulation.

In manual collection, monitoring host will send out query demand to appointed terminal. Sensor started to collect and process temperature and humidity data once terminal identified the instruction. Then, data were immediately uploaded to monitor host, achieving manual collection. Figure 5 shows the collection flow.

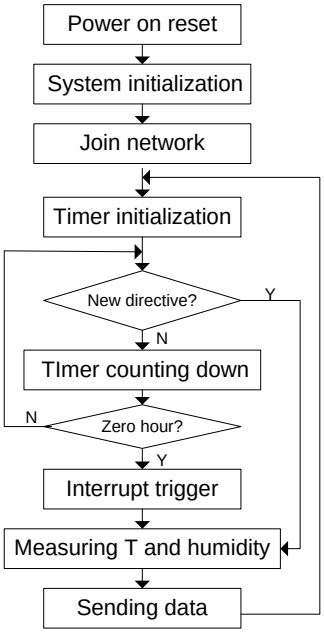

FIGURE 5 Flow chart of acquisition

SHT11 is a temperature and humidity integrated sensor with two measurement commands: 03H for temperature and 05H for humidity measurement. Temperature and humidity data, transferred from SHT11 to CC2430, were nonlinear relative value. The data was sent to centre node after linear compensation by using 8051 MCU embedded in CC2430 chip. Without correction and compensation, the data can be directly used by centre node, saving time on the correction of relative value. Humidity data of 12 bit was converted to actual humidity value. Relative humidity data N can be compensated with Equation (1).

$$RH_L = (-4 + 0.0405N - 2.8*10^{-6} N^2)\%, \quad (1)$$

where N is collected humidity data, and RH_L the transferred humidity value. For temperature's influence on humidity sensor, temperature correction for humidity sensor should be considered when actual temperature was far from 25°C (-77°F). Equation (2) was used for calculation of actual humidity value (represented as RH_T) with temperature compensation.

$$RH_T = RH_L + (T - 25)(0.01 + 0.00008N)\%. \quad (2)$$

Environment or other factors have little effect on SHT11 for its excellent linearity. Digital output of SHT11 can be directly transferred to temperature value with Equation (3). Value of d_1 was determined by working voltage of sensor, while value of d_2 was determined by resolution of sensor [6].

$$Temperature = d_1 + d_2 * SO_T. \quad (3)$$

4.2 SOFTWARE DESIGN OF CENTRE NODE

Software with star-like network topology was designed for centre node. As a coordinator, centre node had two major functions. One was to build a ZigBee wireless network. Web beacons were sent to domain spaces by CC2430 via antenna, so as to inform bound terminal nodes of establishment of wireless network.

Besides, acquisition terminal nodes should receive and reply requests for accession of network. PANid of request equipment was judged. If PANid was concordant, entrance of acquisition terminal was authorized, with an assigned unique 16 bit short address in network.

After ZigBee wireless network was built, acquisition terminal periodically sent temperature and humidity data to centre node via ZigBee wireless network. Useful information, such as temperature and humidity data and the unique short address, were extracted by centre node with accession of data packet. All the information from terminal nodes was processed to be a data packet with structure form. Then, data were then sent to monitoring host through MAX232 serial module. Figure 6 shows the process.

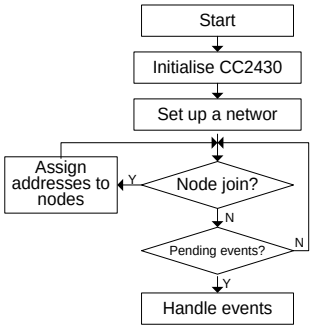

FIGURE 6 Flow chart of the main program in coordinator

4.3 SOFTWARE OF UPPER COMPUTER

PC was used as upper computer, mainly accepting data from centre node via serial port. Moreover, friendly human-machine interface should also be provided for real-time display of data, as well as storage management. Software of upper computer was developed by using VC++6.0 with Mscomm communication control. This control provided all functions of serial communication and achieved data reading or writing via serial port.

With simple programming and convenient debugging, the control encapsulated underlying operation procedure in the process of communication. Users only needed to set up and monitor properties and events of control. Asynchronous serial communication between users and applications can be easily achieved. Figure 7 shows the partial interfaces of monitoring software.

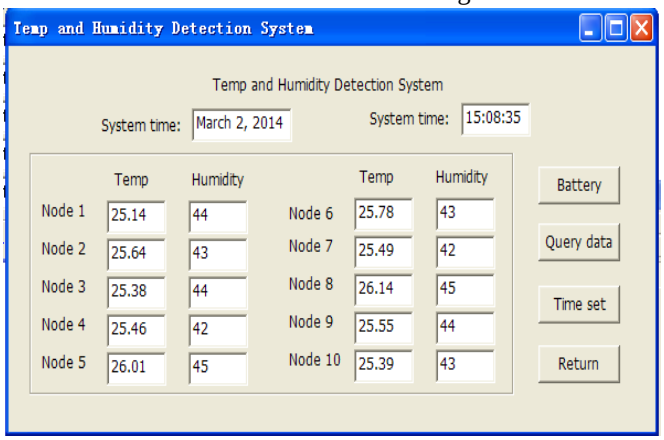

FIGURE 7 Temperature and humidity detection system

Temperature and humidity data management database was established with Microsoft Access 2003 in background. The database covered information of nodes number, temperature, humidity, acquisition time, etc. Table 1 was established in Access for the record and management of nodes formation.

TABLE 1 The node's information

Node number	Temp	Humidity	Battery power	Acquisition time
01	21	65%	48%	10:18:30

Data management of temperature and humidity acquisition terminal became convenient with the database design in this system. With friendly interface display, all databases of this system had functions such as adding, deleting and inquiry.

5 Experimental results

Two 1.5V batteries supplied power for centre node and ZigBee in the experiment. Different programs for centre node and ZigBee acquisition terminal nodes were downloaded by simulator before experiment. Ten acquisition terminals located in 10 different sites, with direct communication to centre node. Centre node was connected with computer via serial port, uploading received data to the computer.

Table 2 shows experimental data of 10 nodes. Test results showed that effective communication distance was about 50 meters in outdoors without obstacle. If there was an obstacle, communication in indoor was stable in 20 meters.

6 Conclusions

A ZigBee wireless network was built with ZigBee radio frequency chip CC2430. Data are sent and received on wireless, achieving point-to-multipoint data transmission and receiving. System can be utilized in many occasions to ensure the accuracy of data. With the same functions of wired temperature and humidity monitoring system, wireless system avoids the limitation of wiring, with low power consumption and high reliability. In empty place without obstacles, communication distance can reach as far as 50 meters, satisfying temperature and humidity monitoring.

Analyses on flow and heat transfer performance and of heat exchanger with continuous helical baffles

Jiazhu Zou, Fengwei Yuan*, Qian Deng

College of Mechanical Engineering, University of South China, Hengyang 421001, Hunan, China

Received 1 October 2014, www.cmnt.lv

Abstract

A numerical simulation for heat exchanger with continuous helical baffles was carried out. The study focuses on the effects of helix angle on flow and heat transfer characteristics, and heat exchanger performance is evaluated by entropy generation number based on the analysis of the second law of thermodynamics. The results show that both the shell-side heat transfer coefficient and pressure drop decrease with the increase of the helix angle at certain mass flow rate. The latter decreases more quickly than the former. The tangential velocity distribution on shell-side cross section is more uniform with continuous helical baffles than with segmental baffles. The axial velocity at certain radial position decreases as the helix angle increases in the inner region near the central dummy tube, whereas it increases as the helix angle increases in the outer region near the shell. The heat exchange quantity distribution in tubes at different radial positions is more uniform at larger helix angel.

Keywords: continuous helical baffles, heat exchanger, helix angle, entropy generation, numerical simulation

1 Introduction

The conventional shell and tube beat exchange most used in the arch baffles, and the shell side fluid flows along the side with large pressure. There are the flow and heat transfer dead regions in the shell side. It is not only easy scaling, but that the high velocity easily induced vibration of heat exchange tube and shorten the service life. For this kind of situation, from the Angle of the change of baffle plate arrangement, put forward the thought of the spiral baffle plate heat exchanger, the application in the shell side of the heat exchanger along the axial of the spiral baffle plate structure, made fluid helical plunger flow. Flow uniform stability, thus overcome the bow baffle plate heat exchanger of the above shortcomings. Existing research shows that compared with the bow baffle plate heat exchanger, spiral baffle plate heat exchanger when the shell side of the same flow unit pressure drop of the heat transfer coefficient is higher, especially for the high degree of double fluid, its advantage is more outstanding.

Most of current research of the spiral baffle plate heat exchanger to apply a set of method and the heat exchange tube axial Angle of fan-shaped certain plane board to lap, approximate spiral surface formation, called the continuous helical baffle plate. Although it is easy to manufacture installation, but this kind of structure because of the discontinuity of the baffle plate and the triangular space is formed between two adjacent frames. The shell side fluid in the region will form a short circuit leakage flow, lead to flow deviation from the ideal spiral flow, thus affecting the performance of heat transfer in the heat exchanger.

To make the shell side fluid to achieve relatively smooth continuous spiral flow, baffle plate should be continuous spiral curved surface, called continuous helical baffles. Baffle plate in the shell on the formation of the spiral curve tangent with the angle β between the cross section is defined as the continuous helical baffle helical angle.

$$\beta = \arctan\left(\frac{H_s}{\pi D_s}\right)_{\varphi}. \tag{1}$$

The shell side of the helical angle determines the Angle between the direction of fluid flow and heat exchange tube bundle, boundary layer thickness and the flow characteristics and so on, in the shell inside diameter must, helical angle determines the cross-section of the shell side of the pitch and circulation, directly affect the shell side heat transfer and resistance properties. So, helical angle is reflecting the continuous helical baffle heat exchanger thermal performance of the important parameters.

Experimental study of continuous helical baffle heat exchanger is made the high installation costs, cycle is long, and not easy to get the distribution of the shell side quantities, this paper established the continuous helical baffle heat exchanger of three-dimensional physical model. A numerical simulation for heat exchanger with continuous helical baffles was carried out by using commercial codes of ANSYS CFD 12.0. The study focuses on the effects of helix angle on flow and heat transfer characteristics, and heat exchanger performance is evaluated by entropy generation number based on the analysis of the second law of thermodynamics.

2 The physical model and geometric dimensions

The continuous helical baffle heat exchanger shell side application, because in the actual processing baffle plate screw

surface tangent direction of the centre and the shell axial Angle is very small, drilling difficulties, usually equipped with centre false tube helical surface centre position, no false tube fluid flow, the numerical simulation model of heat exchanger is applied with centre of false tube structure. Continuous helical baffle heat exchanger the calculation area physical model as shown in Figure 1, the basic structure size reference GB 151-151, as shown in Table 1.

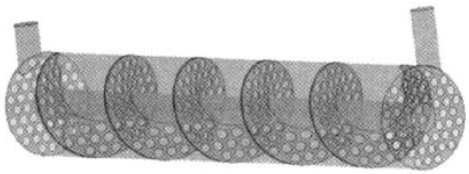

FIGURE 1 Physical model calculation area

3 Mathematical model and numerical simulation method

3.1 TURBULENCE MODEL AND THE CONTROL EQUATION

Continuous helical baffle heat exchanger shell side turbulent pulsating flow with spiral flow interaction, to show high levels of anisotropy and sensitivity to the streamline curvature, so numerical simulation using RNG k model, its strong streamline curvature, the vortex and has good performance of rotating calculation, at the same time in close to the constant application of standard wall function method.

General control equation for related physical quantities

$$div(\rho U\varphi) = div\left(\Gamma_{\varphi} grad\varphi\right) + S_{\varphi} . \quad (2)$$

Substituting different general variables ϕ, Equation (2) to show the continuity equation, momentum equation and energy equation and the equation of $k-\varepsilon$, the generalized diffusion coefficient Γ_{ϕ} and generalized the values S_{ϕ} in the source term is corresponding to each equation.

3.2 WORKING MEDIUM FLOW AND BOUNDARY CONDITIONS

Shell side working medium for heat conduction oil, its steady turbulent flow in the shell side channel. Because of heat conduction oil, the degree of value changing with temperature is bigger, it is a function of temperature to the fitting $\mu = 5.18125\times10^{-6}T^2 - 3.69\times10^{-3}T + 0.66233$, the rest of the physical parameters of constant. In the working medium is water passes and physical parameters are constant. Both gravity, thermal buoyancy lift and clear heat dissipation.

To determine the appropriate boundary conditions on the physical model of simplified. A given shell side inlet mass flow rate M_s, temperature $T_{s,i} = 353.15k$ and turbulence intensity I = 5%; Tube side population rate constant, $\upsilon = 1.5m\cdot S^{-1}$ define temperature $T_{s,i} = 353.15k$ and turbulence intensity I = 5%. The shell side and tube side exports are pressure outlet boundary, given the recycling of static pressure and the appropriate conditions. No sliding surface is defined as the heat exchange tube impermeable solid wall, the application of coupling boundary conditions of cold and hot fluid heat transfer FGC calculation; Baffle plate and shell wall impermeable solid wall is defined as adiabatic without sliding.

3.3 MESHING WITH NUMERICAL SIMULATION METHOD

The shell side of the continuous helical baffle heat exchanger internal structure is complex, so the application of tetrahedron and pyramidal unstructured meshing; in the application passes hexahedron mesh. Selected unit number is respectively 11.82 million, 14.92 million, 17.78 million, 3 sets of grid independence test, when $M_s = 10Kg\cdot S^{-1}$, the spiral Angle of 40°of continuous helical baffle heat exchanger by the 3 sets of the grid to calculate the shell side of heat transfer coefficient and pressure drop, respectively in the import and export $446.1W\cdot m^{-2}\cdot K^{-1}$, $70164.1Pa$,$452.2W\cdot m^{-2}\cdot K^{-1}$ and $65891Pa$,$456.5W\cdot m^{-2}\cdot K^{-1}$ and 65035. 9Pa, after the 2 sets of grid computing results are within 2%. Considering calculation accuracy and efficiency, choose 2 sets of grid computing.

Finite volume method was applied to calculate area and control equations are dispersed and solving, define the convergence condition of the equation of average residual error absolute value is less than 1.0×10^{-5}.

3.4 NUMERICAL SIMULATION VALIDATION

Applying the method of continuous helical baffle heat exchanger are simulated, and the results were compared with the experimental data. Figures 2 and 3 shows the shell side pressure drop simulation value and experiment value deviation for 13. 800-21.2%, the shell side heat transfer coefficient of deviation for the simulation value and experiment value 7.8% - 8%, deviation in a reasonable scope, the validity of the numerical simulation method presented in this paper.

Besides inevitable error of measurement, numerical simulation of the heat exchanger of simplified model and boundary conditions may cause the deviation between the numerical simulation results with the experimental data, for example, numerical simulation of the model ignores the baffle plate and shell and the leakage flow between heat exchange tube, baffle plate and shell wall is simplified to adiabatic boundary condition, etc.

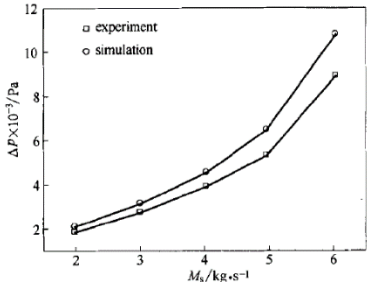

FIGURE 2 Shell side pressure drop experimental value compared with the simulation values

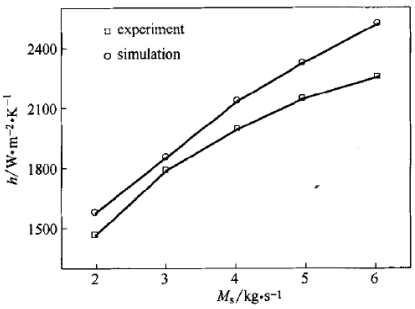

FIGURE 3 Shell side heat transfer coefficient of the experimental value and simulation value comparison

The effect of leakage flow and significantly with the increase of shell side flow, so the deviation between the simulated results with the experimental data with the flow rate increases.

4 The results of numerical simulation and analysis

4.1 SHELL SIDE SCREW CHANNEL AXIAL DISTRIBUTION OF CONVECTIVE HEAT TRANSFER

Continuous helical baffle heat exchanger shell side fluid in the shell, baffle plate, centre pipe and heat exchange tube wall of channel flow, heat transfer along the flow direction of the development process, with the development of the fluid mechanics was conducted at the same time. To high pr, such as heat conduction oil fluid, in fully developed section, heat transfer rate have also been fully developed. So, the shell side of the can from cross section along the axial distribution of local heat transfer coefficient on the shell side of the judgment convective heat transfer full development period of spiral channels.

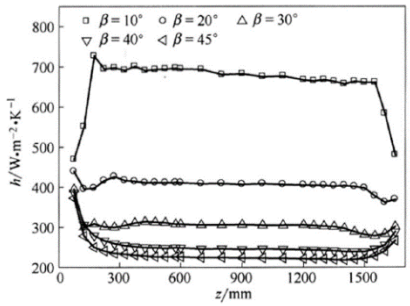

FIGURE 4 Screw channel and the distribution of local heat transfer coefficient along the axial direction

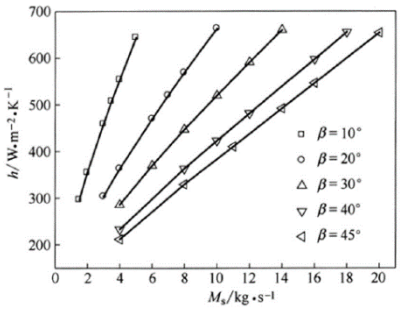

FIGURE 5 Shell side heat transfer coefficient changing with the flow

To decorate with continuous helical baffle and processes do not include the shell The shell side of the outlet pipe of the channel for the screw channel, can see from Figure 4, the shell side mass flow rate is equal to ($M_s = 4Kg \cdot S^{-1}$). The screw channel and local heat transfer coefficient *h* and decreased with the increase of helical Angle. This is because the spiral Angle increases means that the circulation of the shell side of the pitch increases, sectional area increase, results in the decrease of flow velocity, *h* is reduced.

Helix Angle is not at the same time, the axial distribution of *h* is very different: the spiral Angle of 10°, *h* decreased slightly after a sharp increase is seen at the inlet section of the first, and then its value changed little, marked the convective heat transfer into the full development stage, in the export section h drastically reduced; Spiral Angle of 20° and 30°, h in the inlet and outlet section shows the trend of increase with the decrease of, after first; Spiral Angle of 40° and 45°, *h* in inlet and outlet, respectively is the decrease and increase the monotonicity of the trend. This is because of the inlet and outlet of the spiral channel flow at the inlet and outlet of the cross-sectional area by the baffle plate and tube plate of the distance between the decision, and fully development period of the circulation of sectional area is determined by the baffle plate pitch, when the helix Angle is small, the former is greater than the latter, made of import and export as full development period of high flow velocity, and can lead to the development of import and export of *h* is less than fully; with the increase of helical Angle, the situation is the opposite.

In the comprehensive analysis, fluid flow people screw channel after about 1 times the length of the pitch of the part is import section, flow channel is about 0.75 times the length of the pitch before the part of the period for export, import and export for the part between the convective heat transfer full development period.

4.2 FULL DEVELOPMENT PERIOD OF HEAT CONVECTION OF SHELL SIDE HEAT TRANSFER AND RESISTANCE PERFORMANCE

As shown in Figures 5 and 6, the shell side of the same mass flow, the shell side heat transfer coefficient of convective heat transfer full development period of h and pressure drop per unit length Δp_m are reduced with the increase of helical Angle. When $M_s = 4Kg \cdot S^{-1}$ compared with the spiral

Angle of 10°, h and Δp_m decrease respectively 34.4% and 87.9% at 20° and respectively lower 48.3% and 96.5% at 30°, respectively reduce 57.9% and 98.6% at 40°, respectively 61.7% and 99.1% at 45°, the lower the trend will be increased with the increase of flow rate is more and more significant.

This is because, on the one hand, the shell side of the pitch and circulation area increases with the increase of helical Angle, reduce with traffic flow and h and Δp_m so reduce. The shell side of the small spiral Angle, on the other hand, closer to the fluid flow form horizontal tube bundle, same velocity when the heat transfer effect is better. But also inevitably bring large pressure loss. Because along with the increase of helical Angle, Δp_m lower margin than h, significantly, Figure 7 shows the shell side heat transfer and resistance performance will increase along with the increase of helical Angle.

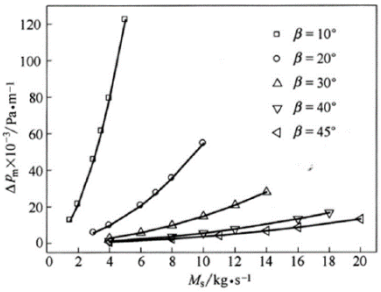

FIGURE 6 Shell side pressure drop per unit length along with the change of flow rate

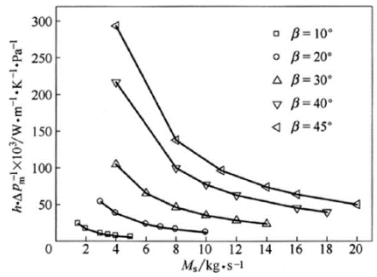

FIGURE 7 Shell side comprehensive performance along with the change of flow

4.3 THE SHELL SIDE VELOCITY DISTRIBUTION

Fluid in the shell side channel spiral flow, the velocity can be broken down for the axial velocity υ_a and tangential velocity υ_θ and radial velocity υ_r. υ_a produce longitudinal from the effect of heat exchange tube bundle, υ_θ produce the effect of horizontal sweep bundles, υ_r that secondary flow is generated by the bundle disturbance. the shell side of the three component makes the function of flow between the longitudinal flow and transverse flow, both of the two characteristics: compared with the longitudinal flow, spiral flow of the tangential component of the shell side fluid velocity gradient along the shell radius direction, destroyed the boundary layer on the surface of the heat exchange tube bundle, enhanced heat transfer; Compared with horizontal flow, spiral flow axial component of the plunger shape is closer to the fluid flow, improve the heat transfer temperature difference.

The shell side of the Figure 8 for the spiral Angle of 40° when convective heat transfer full development period of the velocity vector distribution on cross section. Can see that, because of the continuous helical baffle diversion, formed on the shell side of the fluid in the cross section of regular rotation flow, the distribution of υ_θ is evener, compared with the traditional bow baffle plate, eliminates the flow dead zone, and to reduce the impact of the fluid exchange heat pipe bundle.

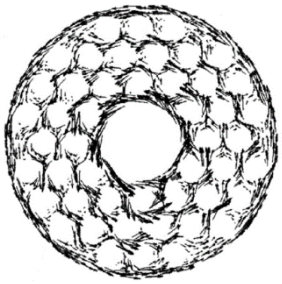

FIGURE 8 The velocity vector distribution on cross section

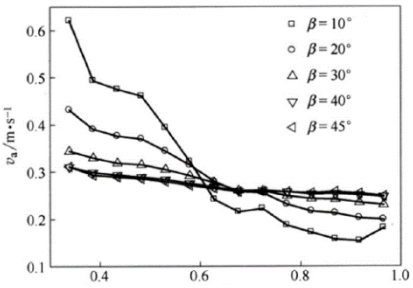

FIGURE 9 Radial distribution of axial velocity along the shell

Bundle between the medial and centre false wall surface and bundle the wall between the lateral and shell because of the heat exchange tube bundle of turbulence effect influence is weak, low flow resistance, fluid showed more significantly than control internal rotation, formed by the spiral flow in two places.

Figure 9 shows the shell side mass flow rate is equal to ($M_s = 4Kg \cdot S^{-1}$), the different spiral Angle υ_a. And decreased with the increase of the radial position δ ($\delta = 2r / D_s$), centre near false tube υ_a is greater than other location. Spiral Angle at 10, υ_a radial along the shell to reduce the sharpest, centre near false tube of shell wall near 4 times, poor distribution uniformity. Gradually, with the increase of helical Angle υ_a along the radial distribution even, $\beta \geq 40^\circ$, the radial distribution uniformity along the shell is better. Shell side spiral channels of distribution can be divided into two areas, near the centre of false tube inner regions, the same radial location along with the increase of helical Angle, and the area near the wall of the outer shell, the same radial position is increased along with the increase of helical Angle.

4.4 SURFACE OF HEAT EXCHANGE TUBE HEAT TRANSFER PERFORMANCE OF THE DISTRIBUTION

Equals the Figure 10 for shell side mass flow rate ($M_s = 4Kg \cdot S^{-1}$), different radial position of the surface of the heat exchange tube Q^* , the change rule of dimension 1 in heat $Q^* = Q_\delta / Q_{\delta=0.42}$. Can see, the spiral Angle is not the change rule of similar at the same time, in addition to the false tube closest to the centre of heat exchange tube, the rest of the radial position of the heat exchange tube are less than 1, indicates that the most close to the centre of the fake tubes due to heat exchange tube bundle inside between the centre of false wall surface and side stream, the influence of surface heat exchange tube in the heat more.

With the increase of radial distance, Q^* downward trend, close to the shell by heat exchange tube bundle of the lateral wall and the influence of the side stream of the shell wall, there will be a certain degree of rise. The smaller spiral Angle, change the magnitude of the more severe, the radial heat exchange tube in different radial positions at this time in exchange for heat distribution inhomogeneity between the stronger, the thermal stress is, the greater the this is the problems that should be paid attention to in the design and use of heat exchanger. When $\beta \geq 30^\circ$ the heat transfer between the heat exchange tube in different radial positions distribution uniformity is better.

4.5 ENTROPY GENERATION ANALYSIS

The second law of thermodynamics, points out that all the actual process in the nature are not reversible. Continuous helical baffle heat exchanger as energy transfer device, the heat transfer process is a typical irreversible process, the energy of the irreversible process will inevitably lead to the loss of available energy. The irreversible loss in the heat exchanger is divided into the irreversible loss caused by finite temperature difference heat transfer and fluid flow in the process of overcoming friction resistance caused by irreversible loss, the sum of the total irreversible loss in the heat exchanger.

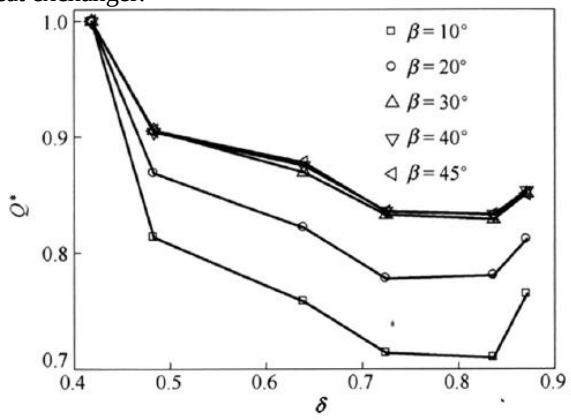

FIGURE 10 Surface of heat exchange tube dimension 1 heat transfer along the radial distribution

The irreversible loss in the heat exchanger can use entropy generation, production rate of heat transfer caused by the entropy is:

$$\dot{S}_{gen,\Delta T} = (Mc_p)_s \mathrm{In}\frac{T_{s,o}}{T_{s,i}} + (Mc_p)_t \mathrm{In}\frac{T_{t,o}}{T_{t,i}}. \quad (3)$$

For incompressible fluid, Resistance to flow caused by the production rate for entropy is:

$$\dot{S}_{gen,\Delta p} = M_s \frac{\Delta p_s}{\rho_s}\frac{\mathrm{In}(T_{s,o}/T_{s,i})}{T_{s,o}-T_{s,i}} + M_t \frac{\Delta p_t}{\rho_t}\frac{\mathrm{In}(T_{s,o}/T_{s,i})}{T_{s,o}-T_{s,i}}. \quad (4)$$

Total entropy yield:

$$\dot{S}_{gen} = \dot{S}_{gen,\Delta T} + \dot{S}_{gen,\Delta p}. \quad (5)$$

Be-Heat transfer caused by the entropy generation and the ratio of the total entropy generation Can be said in the heat exchanger caused irreversible loss caused by heat transfer and flow resistance of the relative importance of the irreversible loss:

$$Be = \frac{\dot{S}_{gen,\Delta T}}{\dot{S}_{gen}}. \quad (6)$$

As shown in Figure 11, when the different helix angle, Be increased with the increase of shell side mass flow is reduced, show that heat transfer caused by irreversible loss percentage of total irreversible loss. In this paper the simulation range, Be less than 0.75, in most cases in 0.9 above, that irreversible loss in the total heat transfer dominates in the irreversible loss. Under small flow rate, the five kinds of helix angle Be were similar, with the increase of flow rate, $\beta = 10^\circ$ when Be falling fastest, $\beta = 20^\circ$ comes second, $\beta \geq 30^\circ$ when Be Dropping lowest. Equals the visible shell side mass flow rate, the smaller helix angle make less of an effect the irreversibility of heat transfer.

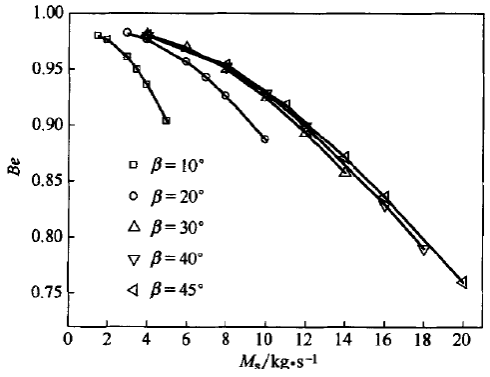

FIGURE 11 Be along with the change of flow rate

For the convenience of comparison of different type of heat exchanger performance under different working conditions, the application needs to be frequently during entropy generation outline 1, entropy generation by the outline 1 is:

$$N_s = \frac{\dot{S}_{gen}}{(Mc_p)_{\min}}. \quad (7)$$

Entropy generation number is smaller, which indicates that irreversible loss is smaller, the better the performance of heat exchanger.

5 Conclusion

1) The helical Angle is not at the same time, the shell side convective heat transfer in helical channel along the shell axial distribution of different. helical channel after about 1 times the pitch to import export before about 0.75 times as part of the pitch, for the full development period of heat convection.

2) The shell side mass flow rate is equal, the shell side heat transfer coefficient and pressure drop per unit length are along with the increase of helical Angle decreases, and the decrease of the amplitude is greater than the former, the shell side heat transfer and resistance along with the increase of helical Angle and improve the comprehensive performance.

3) Shell side cross-sectional tangential flow distribution more uniform, but in the centre of the heat exchange tube bundle and false wall between the tube and shell will be formed by the spiral flow in two places.

Numerical simulation on winding CFRP pipe axial compression stability

Bo Nan*, Yue Wu

School of Civil Engineering, Harbin Institute of Technology, Harbin 150090, China

Received 1 October 2014, www.cmnt.lv

Abstract

Because of the requirements of strict weight, airship structures are usually built by high strength and light-weight CFRP composite truss, CFRP composite tube is the basic unit of it. Winding CFRP tube ultimate bearing capacity has been further improved by combinations of various fiber directions, while stable bearing capacity is an important indicator that could influence the bearing characteristics. It concludes the destruction and deformation characteristics, as well as the relationship between stability factor Φ and slenderness λ, through analysing different CFRP tubes of slenderness ratio with The arc-length method, and drawing the Load-displacement curve, which provided a theoretical basis to better the truss design, and discussed the laws of how component defects affect its stability capacity via a large number of parameters.

Keywords: carbon fiber-reinforced plastic (CFRP), the arc-length method, stability coefficient, slenderness ratio

1 Introduction

Truss structure is a traditional form of large support structure, which is using rod or pipe to transfer load statically, because of big stiffness and saving material, which is a highly efficient structure form of supporting. From the use of material types, the existing truss structures are made of steel, aluminum alloy and CFRP composites, etc. Steel truss by the weight of material density, which cannot meet the requirements of aerospace lightweight structure; Quality of aluminum alloy truss structure is lighter and has been widely used in various kinds of large support structure in the field of aerospace. Along with the development of the large airship and space technology, advanced CFRP composite truss structure because of its significant weight loss effect and excellent mechanical properties have also been more and more applied to the satellite, airship, etc all kinds of aerospace structure (as shown in Figures 1 and 2).

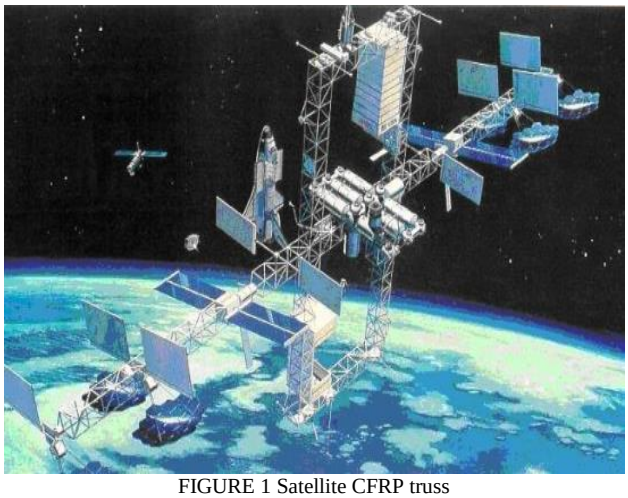

FIGURE 1 Satellite CFRP truss

FIGURE 2 Airship CFRP skeleton

In the composite truss structure, CFRP composites pipe components is the basic composition, and the stability of axial compression bearing capacity is the key to affect the whole structure stability. However, at present the study on stable of long tube CFRP are rare, and the research on bigger slenderness CFRP axis compression member is more rare. But the stability of the long tube from other materials research methods mainly can be divided into the following kinds:

Theoretical derivation:

The earliest Study of aluminum bending member overall stability is researched by Hill and Clark [1, 2], the stable theory research is Mainly done in solid rectangular section, box and i-section section aluminum alloy extrusion profiles component. And the related formula of axial force and bending moment was put forward.

Experimental study:

Aluminum alloy axial compression member is researched by Shen Zuyan, Guo Xiaonong [3], Qian Ruojun, Li Ming [4], etc. Cross section forms include circular pipe and "H" type of section, the test results show that members are bent instability. And for glass fiber reinforced composites (GFRP) pipe compression members, Qian Peng, Ye Lieping [5,6] get the basic parameters of the mechanical properties of GFRP pipe through short pipe compression test firstly,

***Corresponding author** e-mail: nb2003ccc@163.com

then select 4 different slenderness ratio of 12 GFRP long pipe to do experiment to study its stability.

Numerical analysis:

Compared to these two materials, Steel constitutive relationship has been relatively mature, Shi Yongjiu, Wang Yuanqing et al. [7, 8] using ANSYS finite element software, calculate overall stability capacity of High-strength steel welded box-section axial compression column, accurately simulate residual stress and geometric components of the initial defect. The results are in good agreement with the experimental results.

The above method has the following disadvantages: if the material model is simple, Stability capacity of members can be obtained accurately both the theoretical analysis and simulation; if the material model is complex (FRP composite material), results are obtained through the test method, and can only get a small amount of results.

Different angle of winding short CFRP pipe was analysed, then choose a better layer, and establish effective stress strain model, get its nominal yield strength according to Ramberg-Osgood equation; then through different slenderness ratio CFRP components axial compression, derived relationship Stability factor between the slenderness ratio, Finally, large number of parameters was analysed to discuss the law for components of the initial defect affecting its stability capacity.

2 Numerical simulation for short winding CFRP pipe axial compression

2.1 HASHIN PROGRESSIVE FAILURE CRITERIA

CFRP composite laminated structure mainly has 5 kinds of common failure criteria: yhe maximum stress theory, the maximum strain theory, Tsai-Hill criteria, Hoffman criteria, Tsai-Wu criteria. Failure criterion is single directional plate fiber by using a variety of the strength of the composite material under different load conditions; these theories do not consider the injury accumulation before the damage completely. The Hashin failure criterion [9] is a material consideration cumulative injury, damage evolution to achieve the criteria.

The basic principle of this theory includes fiber tensile fracture, compression buckling under transverse tensile and shear fracture when matrix under transverse compression and shear failure such as crushing, mainly includes the following forms:

Fiber tension ($\hat{\sigma}_{11} \geq 0$):

$$F_f^t = \left(\frac{\hat{\sigma}_{11}}{X^T}\right)^2 + \alpha\left(\frac{\hat{\tau}_{12}}{S^L}\right)^2. \tag{1}$$

Fiber compression ($\hat{\sigma}_{11} \leq 0$):

$$F_f^c = \left(\frac{\hat{\sigma}_{11}}{X^C}\right)^2. \tag{2}$$

Matrix tension ($\hat{\sigma}_{22} \geq 0$):

$$F_m^t = \left(\frac{\hat{\sigma}_{22}}{Y^T}\right)^2 + \left(\frac{\hat{\tau}_{12}}{S^L}\right)^2. \tag{3}$$

Matrix compression ($\hat{\sigma}_{22} \leq 0$):

$$F_m^c = \left(\frac{\hat{\sigma}_{22}}{2S^T}\right)^2 + \left[\left(\frac{Y^C}{2S^T}\right)^2 - 1\right]\frac{\hat{\sigma}_{22}}{Y^C} + \left(\frac{\hat{\tau}_{12}}{S^L}\right)^2, \tag{4}$$

X^T is axial tensile strength. X^C is axial compressive strength. Y^C is transverse compression strength. Y^T is transverse tension strength. S^L is axial shear strength. S^T is transverse shear strength. α is the coefficient of shear stress for fiber tensile failure $\hat{\sigma}_{11}$, $\hat{\sigma}_{22}$, $\hat{\tau}_{12}$ are the component effective stress $\hat{\sigma}$. $\hat{\sigma}$, which assess the initial damage equation:

$$\hat{\sigma} = M\sigma, \tag{5}$$

where σ is the nominal stress, M is the damage factor:

$$M = \begin{bmatrix} \frac{1}{(1-d_f)} & 0 & 0 \\ 0 & \frac{1}{(1-d_m)} & 0 \\ 0 & 0 & \frac{1}{(1-d_s)} \end{bmatrix} \times d, \tag{6}$$

d_f, d_m, d_s for the internal damage variable of shear characterization of fiber, matrix. They are derived from the previously mentioned four damage model related damage variable d_f^t, d_f^c, d_m^t, d_m^c:

$$d_f = \begin{cases} d_f^t \_if\_\hat{\sigma}_{11} > 0 \\ d_f^c \_if\_\hat{\sigma} < 0 \end{cases}, \tag{7}$$

$$d_m = \begin{cases} d_m^t \_if\_\hat{\sigma}_{22} > 0 \\ d_m^c \_if\_\hat{\sigma}_{22} < 0 \end{cases}, \tag{8}$$

$$d_s = 1-\left(1-d_f^t\right)\left(1-d_f^c\right)\left(1-d_m^t\right)\left(1-d_m^c\right). \tag{9}$$

Before the injury occurred, M is unit matrix, so $\hat{\sigma} = \sigma$. Once the injury began, it evolved at least one kind of mode above, injury began to occur, $\hat{\sigma}$ represents the real bearing capacity.

2.2 NUMERICAL SIMULATION OF SHORT PIPE AXIAL COMPRESSION BASED ON LAYERED SHELL ELEMENT

2.2.1 Layer Angle

Fiber is called the longitudinal direction, expressed with an "*x*", in vertical direction (sometimes have woven fiber, fiber content less) called lateral, expressed with "*y*", Thickness direction with "*z*", *tk is* the thickness of single layer. θk is angle between Fiber and principal axis direction (as shown in Figures 3-5).

Size	L=150mm, D=50mm
thickness	4mm
Number of layer	8
Element type	S4R
Element number	2400
Boundary conditions	One end fixed, one end free
Load	2mm displacement
Diameter-thick ratio	12.5

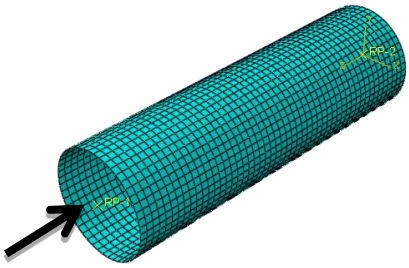

FIGURE 3 Model grid partition map

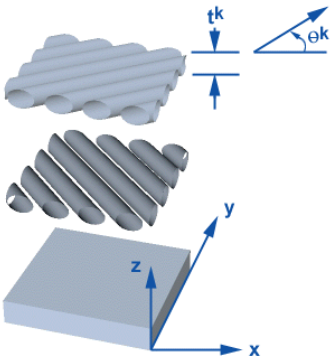

FIGURE 4 Fiber layer directions

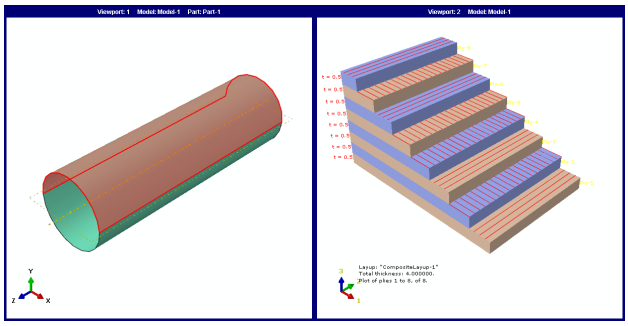

FIGURE 5 90/0/90/0/90/0/90/0 layer angle

2.2.2 The calculation results

Through to the mechanical properties of layer angle analysis of CFRP pipe, the strength of 90/0/90/0/90/0/90/0 orthogonal layer is high, but it belongs to brittle failure, if accompanied by plus or minus 45° layer can achieve very good effect (Figure 6).

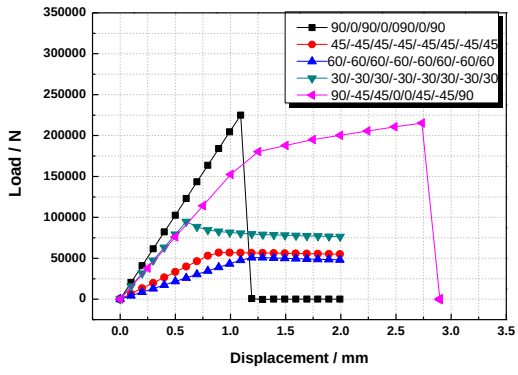

FIGURE 6 Load - displacement curve for each layer angle

2.3 THE EQUIVALENT STRESS AND STRAIN CURVE

According to the load-displacement curve, we found that 90/-45/45/0/0/45/-45/90 angle is the best. Select the layer mode as the research object, using the homogenization thought the macro components of load-displacement curve into material such as microscopic stress-strain curve, the following equation:

$$\sigma = \frac{F}{A} = \frac{F}{\frac{\pi}{4}(D^2 - d^2)}, \tag{10}$$

$$\varepsilon = \frac{\Delta l}{l}. \tag{11}$$

The equivalent of the stress-strain curve as follows:

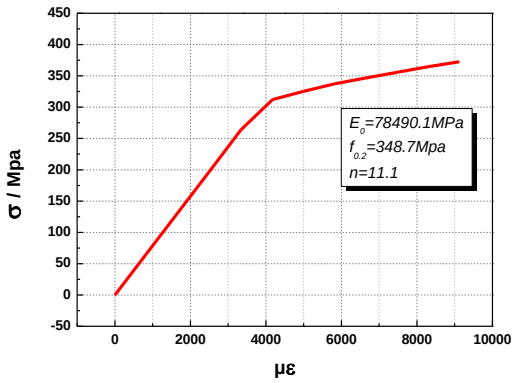

FIGURE 7 Equivalent stress - strain curve

Stress-strain curve of CFRP has no obvious yield platform, Ramberg - Osgood [10] formula was used to describe that:

$$\varepsilon = \frac{\sigma}{E_0} + 0.002\left(\frac{\sigma}{f_{0.2}}\right)^n, \tag{12}$$

E is material elastic modulus. f0.2 is nominal yield strength. *n* is used to describe the strain hardening material, Its value can be calculated according to 0.1% and 0.2% nominal yield strength.

$$n = \frac{\ln(2)}{\ln(f_{0.2} / f_{0.1})}. \tag{13}$$

The equivalent material parameters such as Table 1.

TABLE 1 Material parameters

Material	E0 (MPa)	f0.1 (MPa)	f0.2 (MPa)	fu (MPa)	n
CFRP	78490.1	327.5	348.7	372.4	11.1

3 Research on winding CFRP long pipe stable performance

Calculating ideas of long pipe stable are as follows. The real component is modeled using finite element software. First linear modal analysis was done, a first-order modal L/1000 was extracted as the initial defect component to be applied to the original member. Then the arc method was used to do nonlinear finite element calculation considering the effect of large deformation (Figures 8-10).

FIGURE 8 Modal analysis

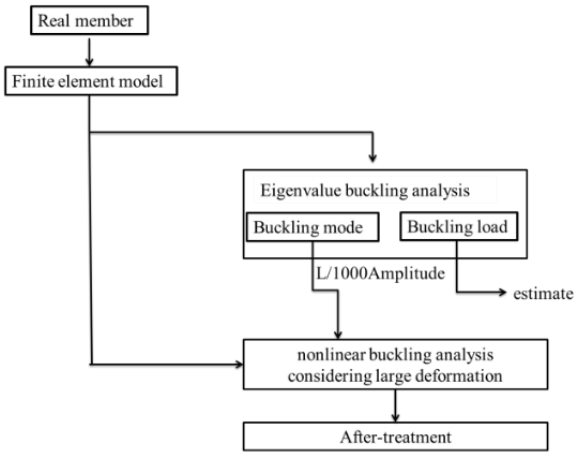

FIGURE 9 Calculation process

FIGURE 10 Nonlinear finite element calculation

3.1 LOAD - DISPLACEMENT ANALYSIS

In order to avoid local buckling, select section for Φ70×10 pipe [11], and calculate the pipe of slenderness ratio of 40, 60, 80, 100, 120, get the whole process of load – displacement curve (as shown in Figure 11) and load – mid-span deflection curve (as shown in Figure 12).

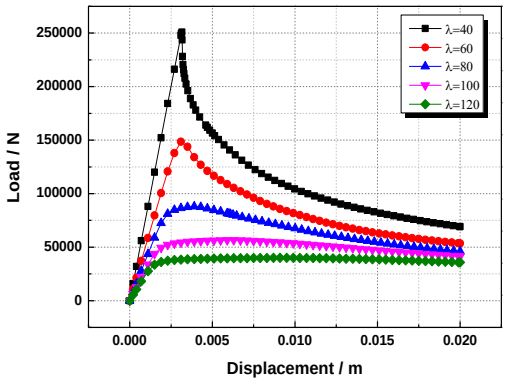

FIGURE 11 Load 3 – displacement curve

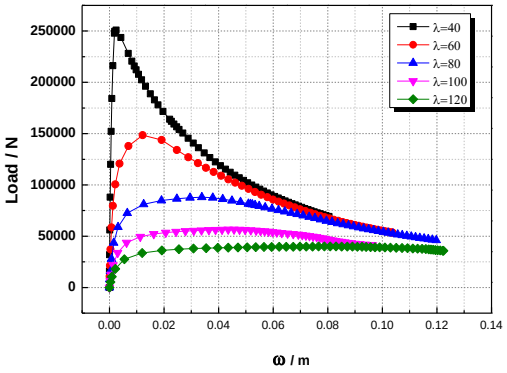

FIGURE 12 Load - deflection curve

As shown in Figure 11 along with the increase of slenderness ratio, compression stability bearing capacity of pipe falling; Slenderness ratio λ of 40 and 60, the shape of load – displacement curve is sharp, brittle failure mode, Mainly because CFRP is brittle material When λ is 80, 100, 120, the shape corners disappear into a smooth gradient inflection point, it shows overall instability of the structure.

As shown in Figure 12, for slenderness smaller components, load - mid span deflection curves presents "tip" is brittle failure, less deformation span; for slenderness relatively large components, load - mid span deflection curve is smooth, elastic deformation, the larger the amount of deformation span.

3.2 STABLE FACTOR – SLENDERNESS RATIO CURVE

The Figure 11 shows the extraction the stability bearing capacity of the whole process load - displacement curve and the stability bearing capacity of the corresponding displacement are listed in the table below.

TABLE 2 List of stable bearing capacity - slenderness ratio

Slenderness ratio λ	Stable bearing capacity (N)	The stability bearing capacity of displacement (mm)
40	250842	2.8
60	148483	3.1
80	88027	3.9
100	56520	5.9
120	39975	9.5

In order to facilitate the comparison of component stability bearing capacity of different sizes, stable factor is introduced; stable factor φ can be calculated through the following equation:

$$\varphi = \frac{F_u}{F_{0.2}}, \tag{14}$$

where F_u for buckling load, $F_{0.2}$ for the product of nominal stress and the cross section (Figure 13).

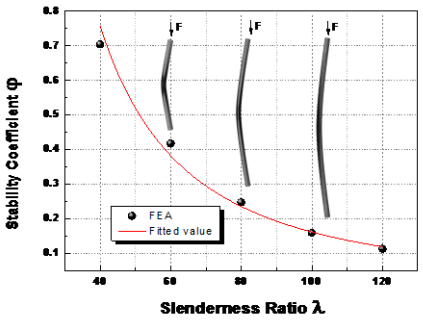

FIGURE 13 $\bar{\lambda} - \varphi$ curve

According to $\lambda - \varphi$ curve, stability coefficient decreases with the increase of slenderness ratio, by fitting curve can be ensure stable factor of slenderness ratio of 50 at 0.5.

3.3 INFLUENCE OF INITIAL DEFECTS

In order to investigate the initial defects of different cross section and the influence of different elastic modulus components, regularization slenderness ratio could be calculated to achieve it, specific methods are as follows:

$$\bar{\lambda} = \sqrt{\frac{F_{0.2}}{F_E}}, \tag{15}$$

$$F_{0.2} = Af_{0.2}, \tag{16}$$

$$F_E = \frac{\pi^2 E_0 I}{L_e^2}, \tag{17}$$

where A is term cross-sectional area, $f_{0.2}$ is nominal buckling strength, E_0 is initial elastic modulus, I is moment of inertia, L_e is calculated length, $F_{0.2}$ is load yield, F_E is Euler critical force (Figure 14).

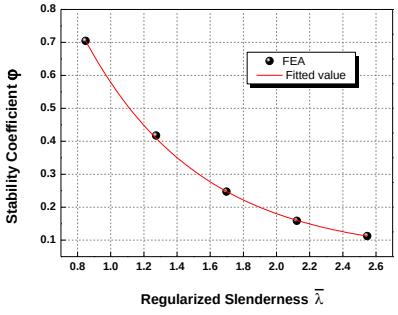

FIGURE 14 $\bar{\lambda} - \varphi$ curve

In this paper, the overall magnitude of bending the initial defect was analysed, includes 6 kinds of conditions, L_e/500, L_e/800, L_e/1000, L_e/1500, L_e/2000, L_e/3000, the results as shown below (Figure 15):

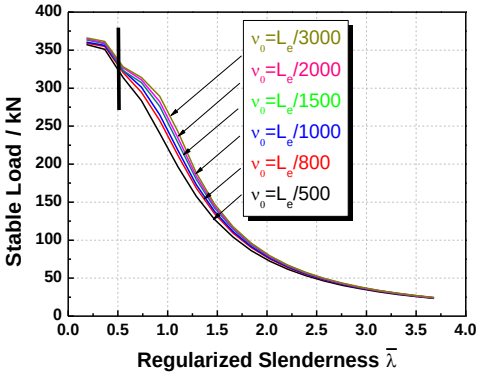

FIGURE 15 Sensitivity analysis of initial defect

The calculation results show that, the length of the smaller member ($\bar{\lambda} < 0.5$) is the intensity of damage, others are overall instability. in the whole range, buckling load of member decreases with the increase of the amplitude of the initial defect, initial defect has the larger the effect on member of the regularization slenderness ratio ($0.5 \le \bar{\lambda} \le 2.0$), when slenderness ratio ($\bar{\lambda} = 1$), Buckling load is most sensitive to changes in the initial defect, has Little effect even negligible when $\bar{\lambda} > 2.0$.

4 Conclusion

1) The compression of short tube is analysed based on the progressive failure criteria (Hashin Criterion) to get the optimal layer angle 90/-45/45/0/0/45/-45/90, and equivalent relationship of stress and strain is obtained to define this layer material.

2) Before instability, CFRP winding pipe appears linear elastic characteristics, brittle characteristics when destroyed, and the length of the smaller member ($\bar{\lambda} < 0.5$) is the intensity of damage, length of middle and long pipe ($\bar{\lambda} > 0.5$) is overall bending instability.

3) According to the $\lambda - \varphi$ relationship curve, stability factor decreases with the increase of slenderness ratio.

4) Initial defect has the larger the effect on member of the regularization slenderness ratio ($0.5 \le \bar{\lambda} \le 2.0$), when slenderness ratio ($\bar{\lambda} = 1$), Buckling load is most sensitive to changes in the initial defect, has Little effect even negligible when $\bar{\lambda} > 2.0$.

Exploratory development of ancient village based on the low carbon travel development model

Jifei Zhang*

School of Business and Management, Hebei Normal University of Science & Technology, Hebei, 066000, China

Received 2 September 2014, www.cmnt.lv

Abstract

This paper summarized basic theory of low carbon travel and the functional mechanism of the low carbon economy to improve the village tourism development by analyzing its conception, and development status and existing problem of the ancient village tourism in the low-carbon tourism development mode of our country nowadays is put forwarded. Combining with actual situation, this paper aims to propose the emission reduction countermeasures in allusion to these problems above, in order to provide certain reference to the development of ancient villages low carbon tourism.

Keywords: Low carbon concept; Low carbon travel; Ancient village travel; Emission reduction countermeasure

1 Introduction

With the increasing attention to the climatic variation worldwide, "low carbon" enters into view and is brought to the forefront. At the same time, with the voice of developing the low carbon economy, energy conservation and emission reduction, the low carbon travel becomes the fashionable tourism rapidly. Ancient village is a kind of traditional human settlement space, and it unites the most traditional life custom, social structure and thousands of years of farming culture of our country. A new tourism development mode has been built by combining the low carbon travel with ancient village travel development. The spiritual enjoyment of people can be satisfied when they are traveling, and at the same time, the healthy ecosystem can be guaranteed. The environmental friendly and energy-saving travel has a positive meaning to promote the development of the ancient village and protect the integrity of the ancient village [1-4].

2 Overview of the low carbon travel

2.1 CONCEPTION OF THE LOW CARBON TRAVEL

The low carbon travel in our country is not clearly defined because it starts late, and scholars have put forward their own viewpoint of the low carbon travel: Cai Meng et al [1] defined the low carbon travel as the carbon sequestration mechanism and low carbon consumption patterns through the low-carbon technology, in order to get higher quality of tourist experience and tourism economy. The core idea of it was to obtain greater economic, social and environmental benefits with less carbon emissions of tourism development; Qu Bao [2] thought that the low carbon travel was a deeper green tourism with low power consumption, low pollution, lower carbon footprint and carbon dioxide emissions; Hou Wenliang et al [3] thought that fundamental purpose of low carbon travel was to reduce greenhouse gas emissions with the premise of guaranteed satisfaction, and realized the new travel mode and management concept of low carbon economy development through the different ways and the humanized system; this was a new kind of management philosophy, the essence of it was a new tourism consumption with low carbon intensity and its objects were all categories of tourist activities. Making a general survey of each scholars' viewpoint, although the low carbon travel is not clearly defined, all of them agree that low carbon tourism is a new type of tourism, and the traveling experience can be higher in the case of reducing carbon emissions through the new type "energy conservation and emissions reduction" technology and tourist's "low carbon consciousness" [5].

2.2 THE THEORETICAL BASIS OF LOW CARBON TRAVEL

The theoretical basis of low carbon travel is mainly about low carbon economy theory, tourism sustainable development theory and ecological tourism theory [5]. The low carbon economy refers to change development pattern from extensive development pattern to new development model with low pollution, low energy consumption, low emissions through a series of means, including technology, institutional innovation, new energy development, etc; innovation and change are the core essentials, and final goal is to achieve sustainable development. Sustainable tourism development follows its basic concept, that is, meet the need of contemporaries and do not threaten the capacity of future generations to their needs. It balances and coordinates the relationship between travel and nature, economy, culture and harmonious development. Besides respecting the integrity of local natural travel and protecting traveling, ecological tourism also involves the interpretation and education of the natural.

* ***Corresponding author*** e-mail: zjfhbqhd@163.com

3 The development mechanism of ancient village travel based on the low carbon travel development model

The low carbon economy promotes the development of ancient village travel in aspects of low carbon concept, low carbon technology and low carbon policy, and it is a comprehensive function mechanism. The function mechanism of the low carbon economy to promote the development of ancient village travel [5] is shown in the Figure 1.

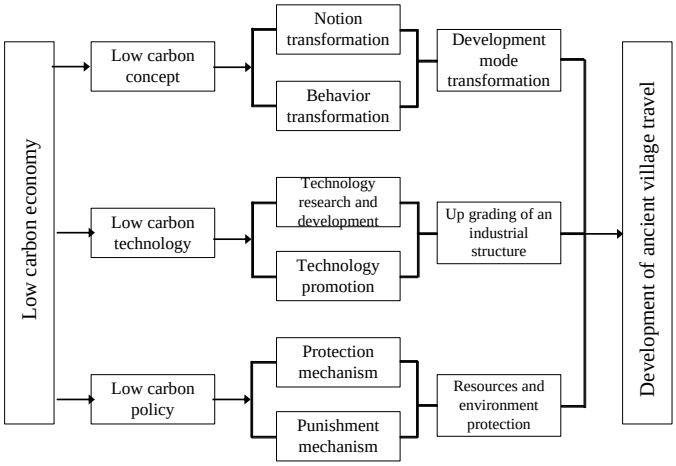

FIGURE 1 Action mechanism of the low carbon economy to promote the development of ancient village

Low carbon concept changes the concept and behaviours of participant and promotes the transformation of development pattern into low pollution, low energy consumption and low emissions in pursuing travel [5]. Most of ancient villages are in the ecological sensitive zone or reserves. The production of the low carbon concept can realize the transformation of development pattern by changing the ecology and resource utilization pattern, and the tourists are boosted to produce low carbon behaviours, and at the same time the ancient villages operators, enterprise, etc can receive self-discipline by calculating the carbon emissions; the low carbon technology provides the support to the low carbon travel, and then upgrade of tourism industry structure of ancient village is promoted. The low carbon technology steady or reduce the demand of non-renewable high carbon fossil energy by improving energy efficiency in each link of each industry in the process of ancient village travel such as eating (food tourism), living (Tourist hotel industry), behaviours (Tourist transportation), travelling (Tourism landscape), purchase (Tourism businesses), amusement (Tourist entertainment industry), etc. The cleaner production and thrift is proposed, and the virtuous cycle and harmonious development of ecology and economy of ancient village is realized by strict control of wastes and emissions; the cleaner production and thrift is proposed, and the virtuous cycle and harmonious development of ecology and economy of ancient village is realized by strict control of wastes and emissions. The low carbon policy provides the safeguard mechanism to low carbon travel by protection mechanism and punishment mechanism in the process of the development of the ancient village travel. It is easy to produce tour order disorder because of the continuously extended ancient village tourism industry scale, which will produce adverse impact to sensitive local ecological environment and resource utilization. Effective utilization of the environment and resources is realized by policy guidance and protection mechanism. The establishment of punishment mechanism can hit the behaviours of environment damage and resources waste to some extent. These two supplement each other, and the objective of ancient village tourism environment protection can be realized under the action of the dual mechanism.

4 The development status of ancient village travel based on the low carbon travel development model

On account of the different national conditions, there has a significant difference between ancient travel development at home and abroad based on the low carbon travel development model [3, 5-7]. First, the research contents of low carbon travel abroad concentrate on tourists' behaviours choice, tourism carbon emissions and reducing travel emissions. The research perspectives of domestic scholars of low carbon travel concentrate on the conceptual framework of low carbon travel, development research and systematic study of low carbon travel. Research focuses at home and abroad have big difference. The research key point at home is low carbon tourism basic theory and gradually tend to study evaluation system of low carbon tourism and the development strategy; abroad study is more tend to measure the tourist traffic emissions through quantitative calculation, at the meanwhile, the corresponding measures of carbon reduction are put forward based on it. By comparison, the value of research results at abroad is generally higher than that at home in terms of science and credibility. The study of travel and protection of ancient village at foreign countries has certain reference significance to our country. Secondly, the history of tourism development research abroad is longer; therefore they have larger advantages compare with our country in the involved field and results. The study of ancient village travel abroad unfold in three aspects, ancient village tourism stakeholders, sustainable development and community participation in tourism, in order to form a virtuous circle of travel development in multiaspect. The study in this aspect at home is still on the exploratory stage, and the points of view in

our study are the problems in the process of tourism, protection and development of ancient villages and stakeholders. Although the involved fields of the theoretical research at home are being extended, lots of them are still rest on the principle and strategy, especially the study of new travel development mode of ancient village travel is rare. Therefore, guidance of the theory and practice is needed in the sustainable development of the ancient village.

The sustainable development of the ancient village is discussed starting from the view of low carbon economy. This paper put forward a technical route framework based on the research and analysis of the low carbon tourism development at home and abroad, in order to provide a certain reference to the study in this aspect. Research on ancient villages' technology roadmap under low carbon economy is shown on Figure 2.

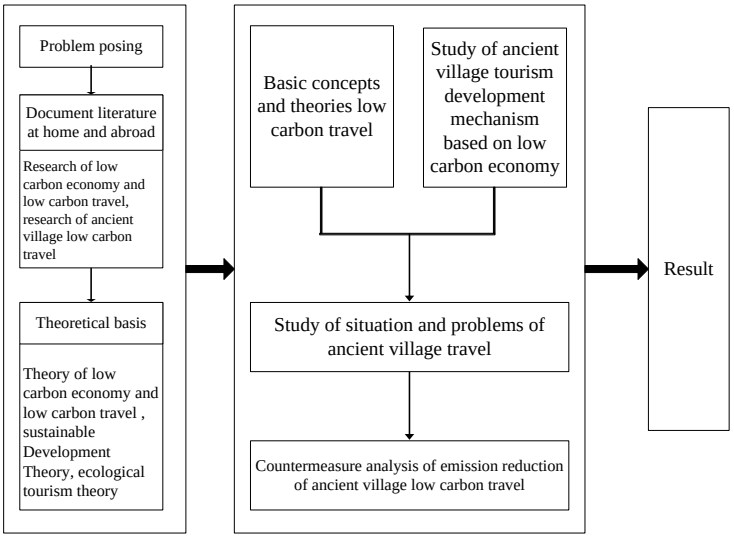

FIGURE 2 Research on ancient villages' technology roadmap under low carbon economy

5 Emissions reduction countermeasures of ancient village tourism development based on low carbon tourism development pattern

The ancient village travel in our country is still in the initial exploration stage; therefore, we should draw on the advanced experience abroad. The environment at home and abroad is different, therefore, how to use the experience for reference is still an issue needed to be researched. The consciousness of low carbon concept is built up from the aspects of "carbon source", "carbon sink" and industrial restructuring. Industry system of ancient village low carbon travel is supported by low carbon technology and guaranteed by low carbon policy, and then the ancient village low carbon travel can realize. The relative countermeasures are shown below:

5.1 ENHANCE THE LOW CARBON CONSCIOUSNESS, AND STRUCTURE INDUSTRIAL SYSTEM OF ANCIENT VILLAGE LOW CARBON TRAVEL

The economy of ancient village is lag behind relatively and the development is slow, which are influenced by its sealing and conservatism. Another study found that domestic tourists did not know completely about the low carbon travel. New knowledge should be increased and the concept should be changed in order to change this phenomenon [5, 7]. We must increase publicity of low carbon tourism consciousness, and the tourism environmental protection concept of "low carbon tourism" should be promoted to the village residents and tourists actively, in order to cultivate and establish a public awareness culture of environmental protection. At the same time, the relative tourist enterprises should devote themselves to forge the low carbon tourism products with local characteristics and guide green and energy-saving consumption. The covers of the tourist industry are very wide, and the tourist industry of low carbon travel is structured by vertical and horizontal industry chain.

5.2 POPULARIZE THE LOW CARBON TECHNOLOGY, AND STRUCTURE THE CLEAN AND EFFICIENT ENERGY SUPPLY SYSTEM

Promotion and application of the low carbon technology is the key to develop the ancient village travel. Comprehensive benefits of ancient village travel can be realized through measures including increasing the invest capital to low carbon travel, completing supportive polices of low carbon travel development, popularizing the development patterns of local ecological agriculture and recycling economy. The commonly used methods for further refinement include many new technologies like carbon capture and sequestration technologies, reduction, recycling, energy utilization technology and so on, and we should promote using proportion of clean energy and process contaminant, which is generated in the production, and live.

5.3 CONSUMMATE THE LOW CARBON POLICY, AND BUILD THE LONG-TERM MECHANISM OF ANCIENT VILLAGE LOW CARBON TRAVEL

The local government should play a leading role to guide the behavioral pattern of enterprise, resident, tourist under the

guidance of sustainable development and low carbon concept. We should formulate the target responsibility, appraise check-up system, develop strategic step combine with the local practical, and make scientific plannings. The rational distribution of local low carbon travel should be bulit. In addition, the experience and lessons of low carbon enconomy and low carbon travel development abroad can be used for reference in building the suitable marketing system and policy system for the development of ancient village low carbon travel. The low carbon travel is regarded as the capital projects of ancient village, and then a sound long-term mechanism will be built.

5.4 ENCOURAGE THE ENTERPRISE TO TAKE PART IN ACTIVELY, AND FORM THE ECONOMICAL PRODUCTION SYSTEM

One of the basic requirements of low carbon travel is to reduce the energy consumption in the production processses and use the clear energy. "Green operation" needs the cooperation of enterprise. Nowadays, the usage rate of ancient village travel enterprises to use low carbon technology and clear energy is not ideal. The enterprise should be initiated to do green consumption and cultivate the low carbon tourism awareness of employees, and production system with scientific, forward-looking and environment friendly should be chose. We can make full use of natural high carbon sinks tourism resources, and the low carbon resources of culture and intangible cultural heritage resources should be excavated and protected in order to realize the ancient village tourism low carbonization.

5.5 EXCHANGE THE CONSUMPTION MODEL OF TOURIST, AND BUILD LOW CARBON CONSUMPTION PATTERNS

Tourists are the subject in the tourist activity. The common consumption model of tourist with resources wasting and increased emissions pollution should be translated into low carbon consumption model, from the aspects of eating, eating, living, behaviours, purchase. The tourists can enjoy a healthy ancient village tourism environment and protect the healthy environment of ancient village at the same time, and the benign development of ancient village travel can be promoted.

5.6 EXERT THE USE OF CARBON SINK, AND STRUCTURE THE CLEAN DEVELOPMENT MECHANISM

Definition of carbon sink is: the course, activity and mechanism of the forest vegetation fix the carbon dioxide in organisms by photosynthesis and reduce the concentration of carbon dioxide in the atmosphere [5]. Ancient villages reduce carbon emissions from the carbon source and pay attention to the carbon sink function of forest, grassland, wetland ecological land etc by using local ecological resources. Therefore, the utilization efficiency of agrarian and the protection of ecologically fragile area should be intensified in the ancient village travel.

6 Conclusion

The ancient village low carbon travel is a new type of tourism sustainable development facing to the increasing climatic variation and environmental resources pressure. It can not only realize the objective of energy conservation and emission reduction but also can quicken the upgrade industries of the tourist industry, and the energy consumption and operation cost of the tourist industry can be reduced, at the same time, the returns can be increased. The tourist industry can develop with dimension and collectivization [3, 5]. At present, it is in the booming period. Based on the further analysis of development mode of ancient village low carbon tourism, this paper started with the research on this aspect of the relevant literature and development mechanism research based on low carbon tourism development at home and abroad, comprehended the research status of ancient village low carbon travel at home and abroad and proposed relative research technology roadmap. On the above basis, we put forward countermeasure of emission reduction from the aspects of "carbon source", "carbon sink" and industrial restructuring, and positively promote the destination construction of low carbon travel.

Abstract

In the last few years, with the growing of multimedia in Internet, MP3 music become one of the most popular types. Some of the MP3 music collections available are approaching the scale of million tracks and this has posed a major challenge for searching, retrieving, and organizing music content. In this paper, we proposed a method to retrieve the MP3 lossy compression format music by using MFCC features. The Kullback-Leibler Divergence and Earth Mover's Distance (EMD) are used to compute music similarity. Experiments show that the retrieving probability of our design can achieve high recall values of 95% out of a total of 1951 tracks in the database.

Keywords: content-based music retrieval, MP3, MFCC, kullback-leibler divergence, EMD

1 Introduction

In the last few years, with the growing of multimedia in Internet, MP3 music become one of the most popular types. Some of the MP3 music collections available are approaching the scale of million tracks. Therefore, it's become increasingly difficult when people classify and manage these massive musical date only by his own hand. We need to query the music information quickly, accurately and efficiently, the traditional approach that query by the text has been far from satisfying the user's search request for such resources. Besides the traditional way, which is using keyword-based mode to retrieve the song information to obtain the desired song, people also want to query it just by the characteristics of the music itself. The CBMR (Content-based Music Retrieval) is an important technique in recent years in handling massive multimedia data in a network environment, together with image retrieval and video retrieval it is today's hotspot in content-based retrieval research field [1].

The work of CBRM research began in the 1990s, the initial research is mostly about the humming retrieval system. Ghiaset [2] carried out pioneering research in Single-track MIDI music humming retrieval system, they use time-domain autocorrelation algorithm to extract pitch information, then by using a fast approximate string matching algorithm they implemented monophonic music retrieval. Tomonariet [3] using span and pitch information as search clues, adopt both dynamic threshold determination and coarse-to-fine matching for matching. Kosugi [4] proposed using pitch direction and distribution at the same time to improve the system performance. They developed a Sound Compass system, it contains 10086 audios, and people must humming coordinate with musical beats while using this system. Seungminet [5, 6] improved the pitch-tracking algorithm, they added the fundamental frequency index function to the traditional tracking algorithm, and by using genetic algorithm-based relevance feedback schemes they signify-cantly improved the retrieval accuracy.

In recent years the audio fingerprint-based fast retrieval technique, which is using binary number to represent the audio features, has becoming the key technology of audio retrieval engine [7-9]. Audio fingerprint extraction first proposed by Philps Institute in Holland, they proposed a global information based audio fingerprints extraction method. This method segment the audio spectrum into many frames, each frame represented by a 0 or 1, thus the whole audio spectrum can be expressed by a binary numbers sequence, the advantage of this method is the whole audio spectrum can be recorded. Another way is proposed by Shazam Company, this UK company try to find some feature points from the audio spectrum, they usually are peak points, and make them be Peak-Pairs, then use the sequence of the Peak-Pairs as the audio fingerprint of this frame. This method centralize the effective messages and got a good noise immunity.

Query by Humming allows the users to find a song by humming part of the tune, use the melody and rhythm to retrieval, make it convenient for the user to find a song compare to the traditional way which use the song title, artist and other text information to retrieval. However, the key part of this way is humming, this make it little meaningful to the user. Audio fingerprints is a better way to retrieval, classify and sorting music for users, but its shortcomings are the feature information is not typical and the noise immunity is also not good enough. Since the general users prefer MP3 format and MP3 as a lossy compression format is designed to significantly reduce the data size of an audio, when we use the audio fingerprint to retrieval a MP3 music it's hard to achieve high accuracy, but for most user's listening experience the reproduction acoustics and the original sound almost in the same level.

This passage proposed a MP3 retrieval system which is using MFCC (Mel-frequency Cepstral Coefficients) to characterization the audio signal. MFCC is based on the human

***Corresponding author** e-mail: xluo@dhu.edu.cn

auditory characteristics, it's a non-liner relationship with the Hz frequency. Through the 1951 Chinese and other language songs retrieval experiment we proved the effectiveness of the proposed method.

2 Proposed audio retrieval

Our proposed way is use MFCC as the audio features. MFCC is the determinants of the spectrum modeling, therefore it can reflects the tone of an audio for a certain degree. We extract MFCC vector sets from each audio and classify them as cluster sets, then calculate the distance between each cluster, use the nearest result as the similar retrieval result.

2.1 RETRIEVAL SYSTEM FRAMEWORK

In this section we review the audio retrieval system flow. The search processes, as shown in Figure 1, can be summarized in the following phases: first, extract MFCC features from all songs in MP3 music database and establish a MFCC feature database. The length of the MFCC feature is the 30 seconds in the middle of the front half of the corresponding song. Next, compress the extracted MFCC features by LBG Design Algorithm, then use k-means cluster them. When to retrieve a song, first extract the MFCC feature MF from query music, and then calculate the similarity distance between MF and the MFCC feature database using KL divergence function or EMD distance function, finally sort the distance in ascending order, output the top 100 songs as final retrieval results.

Details about the feature extraction and distance calculation are given in Figure 1.

2.2 MFCC FEATURE EXTRACTION

Mel frequency cepstrum coefficient just like the cepstrum is the feature, which is used to represent the channel characteristics. Cepstral analysis is mainly to get the audio spectral envelope by Fourier transformation, but, the human auditory perception experiments showed that human auditory perception only focus on certain areas, rather than the whole spectral envelope. The human auditory system is a special non-linear system, MFCC consider the characteristics of human hearing, first, it mapped a linear spectrum to Mel nonlinear spectrum based on auditory perception, and then convert it to cepstrum. Logan et al [10] through music modeling verified the effectiveness of MFCC feature in speech and music field.

The MFCC extraction algorithm performs as follow:

Step 1: Pre-emphasis the voice signal with a pre-emphasis filter, magnify the high frequency part. By doing so, make the channel characteristics more clearly. The pre-emphasis filter is determined as:

$$y(n) = x(n) - px(n-1), \tag{1}$$

$x(n)$ is the waveform of the voice, p is the pre-emphasis coefficient.

Step 2: To reduce the edge effect, apply Hamming window to each frame whose waveform have already attached pre-emphasis filter, calculate the amplitude of the vector by FFT(Fast Fourier Transform).

Step 3: Use Mel Filter Bank compress the Amplitude Spectrum. The filter bank consists of 33 triangular shaped band-pass filters. The focus here is to generate Mel-Frequency. The dimension of Mel is the horizontal axis which is used to reflect the human auditory characteristics, its unit is mel. The lower the frequency, the narrower the interval, the opposite is also true, the higher, the wider. The human ear in the subtle low frequency sound could feel the pitch different, but in the high frequency sound, its goes harder.

Step 4: Transform the compressed values by DCT to remove the correlation between the signals in different dimension, map the signal into low dimensional space.

Step 5: Using the low dimensional composition of the obtained cepstrum as MFCC feature values.

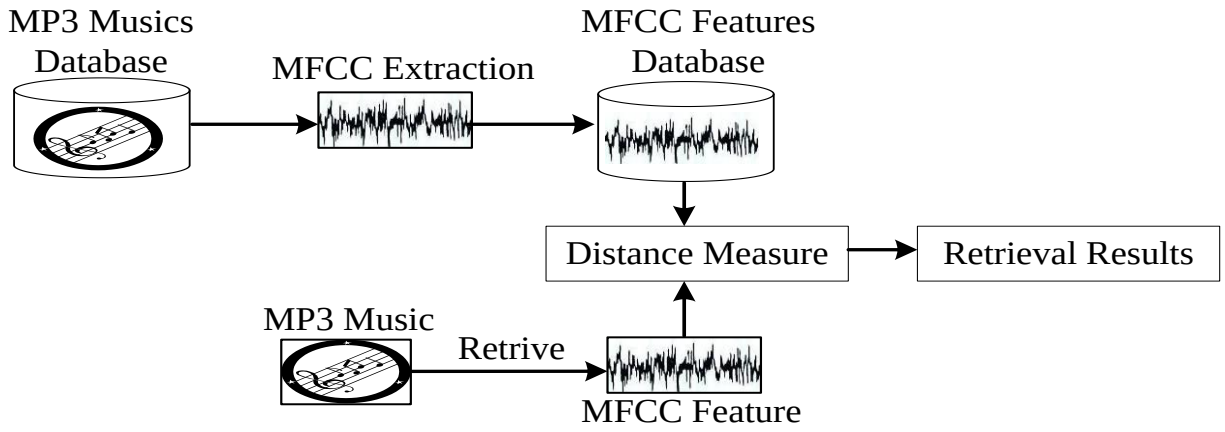

FIGURE 1 Flow of proposed method

This way, a music can be described by a series of spectrum vectors, and each vector is the MFCC feature vector of each frame.

The block diagrams for calculating MFCCs is given as Figure 2.

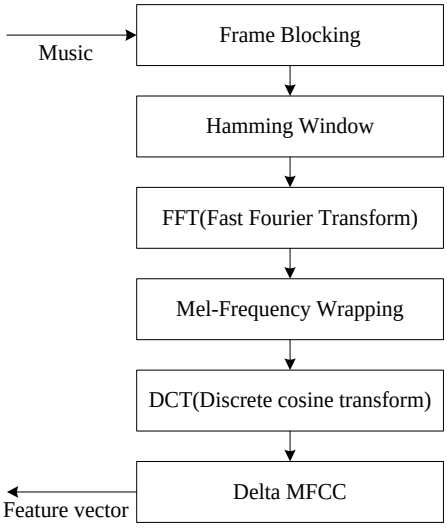

FIGURE 2 MFCC feature extraction processing

2.3 METHOD FOR SIMILARITY DISTANCE CALCULATION

In pure feature vector, the distance between each feature values can be expressed by Euclidean distance. But in audio retrieval, the feature value is not the vector but the normal distribution, that's why we cannot use a simple Euclidean distance.

2.3.1 KL Divergence

KL Divergence, a distance measure index of normal distribution, is the abbreviation of Kullback-Leibler Divergence, also known as Relative Entropy. It measures the difference between two probability distributions in the same sample space. According to the KLD, the definition of Kullback-Leibler Divergence between Normal distribution *N*1 and *N*2 (respectively, the mean vector, variance – covariance matrix) is:

$$D_{KL}(N_1 \| N_2) = \frac{1}{2}\left(tr(\sum_2^{-1}\sum_1) + (\mu_2 - \mu_1)^T \sum_2^{-1}(\mu_2 - \mu_1) - \ln\left(\frac{|\sum_1|}{|\sum_2|}\right) - k \right), \quad (2)$$

where *k* is the dimension of the mean vector. Usually the Kullback-Leibler Divergence is not symmetry, the value of $D_{KL}(N_1 \| N_2)$ and $D_{KL}(N_2 \| N_1)$ are not the same. However, this will not achieve our goals, so we use the Kullback-Leibler Divergence in symmetry case, that is:

$$0.5(D_{KL}(N_1 \| N_2) + D_{KL}(N_2 \| N_1)), \quad (3)$$

in this way we can ensure its symmetry.

2.3.2 The Earth Mover's Distance (EMD)

In computer science, the Earth Mover's Distance (EMD) is a measure of the distance between two multi-dimensional distributions in some feature space where a distance measure between single features. These distributions can be summarized with clustering algorithms, which reduce the feature space in a fixed number of bins. Each cluster c_j is associated with a weight w_j that indicates the size of the cluster (e.g. the occurrences of features in each cluster). The EMD describes the cost that must be paid to transform one distribution (considered as a mass of earth spread in space) into the other (considered as a collection of holes in the same space). The EMD measures the least amount of work needed to fill the holes with earth, considering that a unit of work corresponds to transporting a unit of earth by a unit of distance (ground distance). The EMD evaluation is based on the solution of the transportation problem, which consists in finding the least expensive flow from one distribution to another according to some constraints.

In a more formal way we can express the transportation problem as follows[11].

Let $P = \{(p_1, w_{p1}), ..., (p_m, w_{pm})\}$ be the first distribution with m clusters, where p_i is the cluster representative and w_{ij} is the weight of the cluster. $Q = \{(q_1, w_{q1}), ..., (q_n, w_{qn})\}$ the second distribution with n clusters; and $D = [d_{ij}]$ the ground distance matrix where d_{ij} is the ground distance between clusters p_i and q_j.

The flow $F = [f_{ij}]$ that minimizes the overall cost is computed by Eq. (4) where f_{ij} is the flow between p_i and q_j.

$$WORK(P, Q, F) = \sum_{i=1}^{m}\sum_{j=1}^{n} f_{ij} d_{ij}, \quad (4)$$

and it is subject to the following constraints:

$$f_{ij} \geq 0, 1 \leq i \leq m, 1 \leq j \leq n, \quad (5)$$

$$\sum_{j=1}^{n} f_{ij} \leq w_{pi}, 1 \leq i \leq m, \quad (6)$$

$$\sum_{i=1}^{m} f_{ij} \leq w_{qj}, 1 \leq j \leq n, \quad (7)$$

$$\sum_{i=1}^{m}\sum_{j=1}^{n} f_{ij} = \min\left(\sum_{i=1}^{m} w_{pi}, \sum_{j=1}^{n} w_{qj}\right). \quad (8)$$

The first constraint indicates that the items can be moved only from *P* to *Q* and not vice versa. The next two constraints are related to the amount of mass which can be sent from the elements in *P* (it must not exceed the weight values) and to the amount which can be received by elements in *Q* (again limited by the weights). The last constraint forces to move the maximum amount of mass as possible. After solving the transportation problem and computing the total flow *F*, the EMD is defined as the work normalized by the total flow:

$$EMD(P,Q)=\frac{WORK(P,Q)}{\sum_{i=1}^{m}\sum_{j=1}^{n}f_{ij}}. \quad (9)$$

The EMD is a robust method to compare multidimensional distributions of features. It is a true metric if the ground distance is metric and if the total weights of the two signatures are equals

3 Experiment and Evaluation

3.1 CONDITION FOR MFCC FEATURE VALUES EXTRATION

Extraction feature values from the entire song will lead the data amount being too large, to reduce calculation, Pampalket [12] proposed choosing the centred 30 seconds of each song as a proposing target. What's more, according to the characteristics of the song, usually the first half of a song can reflect its characteristic most, and for a considerable part of the song, the second half of them is usually repeating the first half. For this reason, in our experiment we use the MFCC feature extracted from the middle 30 seconds in the first half of a song as its processing target.

Table 1 shows the 30 seconds MFCC feature vectors of song A, sampling frequency 16Hz, shift width 160 samples.

One row in Table 1 represent 20 dimensional vectors of a frame, and a 30 seconds audio include 3000 frames, that's 6000 dimensional vectors in total, the calculation can be pretty big. To reduce this, we use LBG Design Algorithm which proposed by Lindeet [13] to compress it. After clustered 6000 dimensional vectors by this algorithm, we classify the similar vectors to the corresponding class, and assume all classes are normal distribution to calculate its mean vector and covariance matrix, using the result as the new feature value, therefore the feature value of audio *A* can be described as:

$$A=\left\{\left(\mu_{A1},\Sigma_{A1},w_{A1}\right),...,\left(\mu_{Am},\Sigma_{Am},w_{Am}\right)\right\}, \quad (10)$$

where *m* is the number of classes.

Using *k*-means as cluster algorithm. By clustering, we can get the reduced-dimensional vector:

$$A_{MFCC}=CA_i\sigma_i, \quad (11)$$

A_i is the mean vector of each class, σ_i is the covariance matrix, *C* is the number of classes. In this experiment *C* taken 16, 32 and 64 respectively. By using this equation, when the feature vector of audio A using 16 as the number of classes, a 30 seconds MFCC feature vector can be compressed to 6720 from 60000 dimensions.

3.2 DATASETS

To verify retrieval results, our experiments collected 1951 MP3 audios and songs in Chinese and other languages. We manually classified these audio files by its types and kept them in different folders, details are shown in Table 2.

3.3 RESULT AND EVALUATION

Our experiment evaluate the retrieval system from two aspects.

Let us do a brief review of this experiment at first. First choose 10 audios from each class, there are 6 classes, so its 60 audios in total, use these audios for querying and calculate the effectiveness of the retrieval system. While retrieving, extract the MFCC feature MF from the middle 30 seconds in the first half of the query music, calculate the EMD distance between MF and the MFCC feature database, outputs the top 100 songs as final results.

TABLE 1 MFCC Features of Song A

–5.36	–0.20	–0.92	...	–1.40	–1.78	1.40	–0.66	22.44

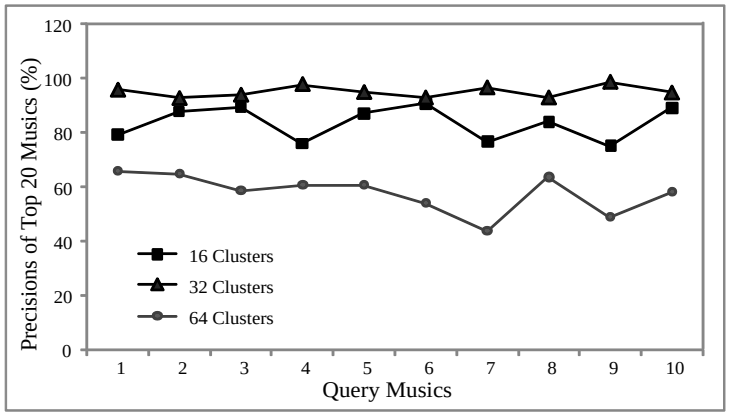

FIGURE3 The retrieval accuracy in using datasets with different classes cases.

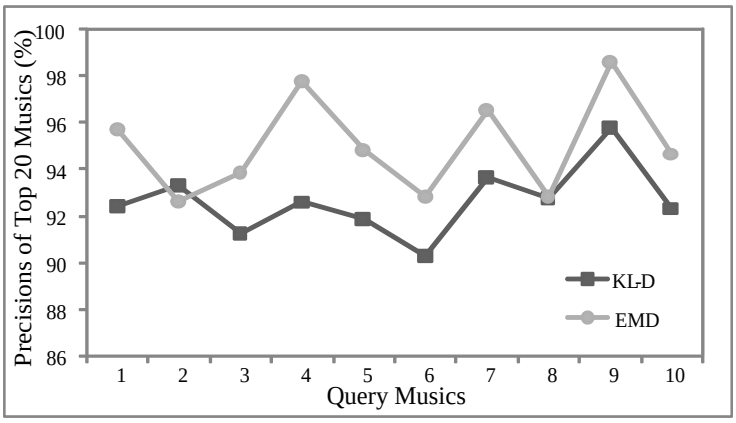

FIGURE 4 The retrieval accuracy by using different distance calculation method

We chose 10 most representative music to do this experiments, each retrieved 3 MFCC datasets (including 16, 32 or 64 classes) respectively. According to the retrieval results, select top 20s to compare with the corresponding class, calculate the precision to compare their accuracy. Our retrieval results show that in a MFCC datasets have 16 classes the accuracy is 83.28%, the accuracy is 95.05% in a 32 classes datasets and 57.85% in a 64 classes datasets. Therefore, the MFCC datasets which have 32 classes can get a better retrieval precision, the larger the number of classes, the lower the accuracy of query and the longer the calculation time. The results are shown in Figure 3.

And after that, for these 10 query music, we use KL divergence and EMD distance respectively to retrieve the MFCC datasets in 32 classes. Results shows as Figure 4.

From the experimental results, we can see that EMD is better than KL divergence under the same conditions.

4 Conclusion and prospects

This passage proposed an audio retrieval system, which is based on MP3 audio compression format, the audio feature values use MFCC and the retrieval distance use KL-D and EMD respectively. The proposed method are mostly focused on the first half of an audio, because the latter part usually repeat the previous section. Therefore we extract MFCC features from the middle 30 seconds of the first half to construct the feature vector datasets, and use LBG design algorithm compress the extracted features, then reduce dimension by using cluster algorithm.

In order to test and verify the effectiveness of our experiments, we collected 1951 different types MP3 music and songs in all kinds of languages. We tested MFCC feature datasets in 16, 32 and 64 classes. Experiment results show that when the class number is 32 the retrieval result is the best. When the number of class goes to 64, the retrieval amount becoming bigger, time consuming more, even the accuracy goes worse.

The proposed method only applies to MFCC feature, and because MFCC is based on human auditory characteristics, it is worked not very well on the low frequency area, which is sensitive to human ear. Our future work will focus on how to extract audio features more efficient. In addition, because the music features are usually got a large amount, in the future we will do more works on how to enhance the retrieval speed and reduce the calculation.

Finally, this experiment using a small MP3 music database, the future we will do further experiments in high-speed retrieval effectiveness aspect on the use of a large-scale database.

Inversion strategy research of travel time tomography with sparse rays

Yali Guo*, Yan Han, Linmao Liu

National key laboratory of Electronic test Technology in North University of China, Taiyuan, Shanxi, China

Received 1 October 2014, www.cmnt.lv

Abstract

The incomplete data travel time tomography with sparse rays can result in the ill-posed inverse problem in practical engineering, so the inversion strategy is very important in order to obtain reasonable inversion result. In this paper, the generalized inverse theory is taken and the influences are discussed which the system layout, initial model and prior information will impose on the inversion. The indexes of system optimal layout, the selection principle of initial model and regularization methods are presented in this paper. A velocity model of explosion is imitated and the inversion results are compared. A conclusion can be gained that system optimal layout, initial model rational selection and regularization methods utilization can help to improve inversion precision farthest in practical project.

Keywords: sparse rays, inversion strategy, regularization methods

1 Introduction

Computerized tomography is one of the non-destructive testing methods [1]. We can achieve the distribution of physics parameter existing in detected target by laying sensors outside the detected target and resolve the engineering and technology problems [2-4]. Computerized tomography technology has already used in medical and industrial fields widely.

Elastic wave travel time tomography is one of the important methods of engineering physics survey, it has played an important role in industry testing and resources prospecting [5]. It is necessary that there are enough detecting rays through the target in order to achieve high accuracy image information inside the target, however, which will increase the practical project difficulty and improve the cost. The data of elastic wave computerized tomography in practical project is usually incomplete owing to the insufficient driving sources and detectors. This engineering problem results in the incomplete tomography data inevitably.

Incomplete data tomography has the problems of sparse inverse data and low inversion accuracy and the inversion result is determined by a good many factors [6]. This paper aiming at the problems of travel time tomography with sparse rays, analyses the influences that the system layout, initial model and prior information imposed on the inversion by numerical experiment. In practical project, we can improve inversion accuracy by system optimal layout, initial model rational selection and utilization of regularization methods.

2 Inversion strategy analysis

For travel time tomography, there is the equation below:

$$DS = T, \tag{1}$$

where $T = (t_1, t_2 \cdots t_m)'$ is the m-dimension column vector of travel time; $S = (s_1, s_2 \cdots s_n)'$ is an unknown *n*-dimensional column vector, it expresses unknown discrete element slowness value in discrete cell; D is the distance matrix of $m \times n$ and its element is d_{ij}.

2.1 SYSTEM LAYOUT OPTIMIZATION

2.1.1 Mesh generation

The tested area is divided into numbers of regular meshes and each mesh has a uniform wave velocity. The more meshes are generated, the higher resolution of computed tomography will be achieved and the more uncertain solutions will be achieved too. Mesh generation should accord to the tested area size, the prior information (such as velocity distribution characteristic, abnormal body size, sampling position etc.), reconstruction accuracy, the number of driving sources and detectors.

2.1.2 Optimal distribution of sensors and judgment indexes

When designing sensors position, we should meet the following principles: extensive coverage and uniform distribution of rays, reduced number of zero elements in distance matrix. In order to make the tested area covered by rays as much as possible and achieve the effective detection, we should have a rational distribution of the sensors according to the follow factors: the ray density, orthogonality and the condition number of matrix D.

The ray density represents the number of rays passing through each mesh. The ray orthogonality is measured by maximal sine value of angle between rays [7]. The greater

***Corresponding author** e-mail:guoyali@nuc.edu.cn

the ray density is and the better the orthogonality is, the smaller inversion error will be achieved.

The tomography inversion is to solve the ill - posed Equation (1). The inversion stability is determined by the condition number of matrix *D*. The bigger condition number can result in poor inversion stability. Supposing that observed data *T* has a minor change, the variation of solution is δS Equation (1) has the relation:

$$D(S+\delta S)=T+\delta T\ . \tag{2}$$

Then:

$$\delta S=D^{-1}\delta T\ . \tag{3}$$

According to the property of subordinate norm, there is the relation: $\|\delta S\|\le\|D^{-1}\|\|\delta T\|$ and $\|T\|\le\|D\|\|S\|$, so $\frac{\|\delta S\|}{\|D\|\|S\|}\le\frac{\|D^{-1}\|}{\|T\|}\|\delta T\|$. That is:

$$\frac{\|\delta S\|}{\|S\|}\le cond(D)\frac{\|\delta T\|}{\|T\|}\ . \tag{4}$$

Then,

$$cond(D)=\|D\|\|D^{-1}\|, \tag{5}$$

where $cond(D)$ is the condition number of matrix *D*. Rational distribution of the sensors can reduce the condition number and we can receive the more stable solutions.

2.2 THE INITIAL MODEL SELECTION

When the rays through the target are sparse, the inverse results depend on the initial model severely. If the deviation of initial model and true model is small, we can obtain better results, otherwise, the results aren't true.

This paper calculates the correlation degree of initial model and true model by correlation coefficient; analyses the change trend of correlation coefficient with inversion error and obtains the dependence degree of inversion result on initial model.

For two groups data of x_i and y_i , $i=1,2,\cdots n$, the correlation coefficient is defined as[8]:

$$r=\frac{\sum_{i=1}^{n}(x_i-\bar{x})(y_i-\bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\bar{x})^2\sum_{i=1}^{n}(y_i-\bar{y})^2}}\ . \tag{6}$$

The absolute value of *r* is closer to 1, the two groups data have higher correlation degree. We can set reasonable initial model by prior information and experience. We should analyse the character of model according to prior information before inversion. Experience formula is also a good way to set initial model. In a word, we should improve the correlation degree of initial model and true model as far as possible, only thus can we improve the inversion accuracy.

2.3 APPLICATION OF REGULARIZATION METHODS

Incomplete data travel time tomography with sparse rays makes the $n>m$ in Equation (1) and represents underdetermined problem in mathematics. In this condition, the inversion results have multiple solutions and credibility is poor. An effective way to resolve the underdetermined inversion problem of multiple solutions is adopting regularization methods to constrain the inversion process and the inversion results by prior information. At the same time, regularization methods make an important role in perfecting ill-conditioned problem.

The application of regularization methods includes: damping the asymmetrical covering of rays, damping the inaccuracy of observed data, tight constraint for true data, setting the value range of some parameters in the iterative procedure and so on. The ways of regularization adding have addition and multiplication. This paper presents some regularization methods as described below.

2.3.1 Damping the asymmetrical covering of rays

The ray coverage will affect the inverse results. The damping regularization methods aiming at the asymmetrical covering of rays is model covariance matrix, which weights different value in different mesh according to ray coverage. Generally, rays is denser, the inversion results are more accurate. Therefore, the meshes through by more rays have more information and should weight a larger value.

2.3.2 Damping the inaccuracy of observed data

The observed data contains noises. The data in different acquisition channel has different noises and the noises will be amplified in inversion. So, the data should have different weighting according to its accuracy. The damping matrix is data covariance matrix. For travel time tomography, the waveform signal is weakening with the transmission distance. The ray path is shorter, the signal to noise ratio is higher, so the smaller travel time should weight a larger value.

2.3.3 Tight constraint of true data

In practical application, we can measure the velocity of this position by individual sampling point in interested area and treat it as the prior information. Equivalent to increase the constraint equations in the linear Equation (1) with:

$$WS=S'\ , \tag{7}$$

where *W* is a $h\times n$ matrix. *h* is the number of sampling point. And the $w_i=[000\cdots10]$, the position of constrained parameter is 1, others are 0. S' is the observed data of sampling points. So the Equation (1) is rewritten as:

$$\begin{bmatrix} D_0 \\ W \end{bmatrix} \cdot S = \begin{bmatrix} T_0 \\ S' \end{bmatrix}, \tag{8}$$

where D_0, T_0 are the distance matrix and travel time matrix without prior information. Rewrite above equation becoming $DS = T$ and make calculation.

2.3.4 Setting the value range of some parameters

We can obtain the value range of some parameters by the prior information sometimes. Constraining the results by the value range of some parameters in the iterative procedure helps to improve the inversion precision.

3 Weighted generalized inversion algorithm

Solving the discrete inversion Equation (1) by matrix is the same as solving inverse matrix of D. However, in practical project, the problem of incomplete data owing to the insufficient number of driving sources and detectors makes Equation (1) become into a sparse, morbid, underdetermined, incompatible linear equation set [9]. The coefficient matrix-D in general is a singular matrix and its inverse matrix does not exist obviously. So it is necessary to adopt the generalized inverse theory to solve matrix-D.

Thinking of the regularization methods, we adopt model covariance matrix and data covariance matrix to damp the asymmetrical covering of rays and the inaccuracy of observed data. The weighted generalized inversion method is the generalized inversion algorithm combining with the regularization methods.

Given $A \in C^{m \times n}$, P and Q are positive definite matrix of $m \times m$ and $n \times n$ respectively. If $X \in C^{n \times m}$, satisfying:

$$\begin{cases} AXA = A, XAX = X \\ (PAX)^T = PAX \\ (QXA)^T = QXA \end{cases}. \tag{9}$$

Then X is defined as weighted generalized inverse of A: A_{mn}^{+}, A_{mn}^{+} is expressed as [10]:

$$A_{mn}^{+} = Q^{-1}(PAQ^{-1})^{+}P. \tag{10}$$

The data covariance matrix and model covariance matrix are P and Q, the diagonal element of P and Q is defined as:

$$diag\{P\} = T^{-1}, \tag{11}$$

$$diag\{Q\} = K. \tag{12}$$

T is the M-dimension vector of travel time of current model, the element of which is $t_i = \sum_{j=1}^{n} d_{ij} \cdot s_j$, $i = 1,2,3,\cdots,m$. K is the N-dimension vector, the element of K is $k_j = \sum_{i=1}^{m} d_{ij} \cdot v_j$ ($j = 1,2,3,\cdots,n$). v_j is velocity in mesh of No. j.

Consequently, travel time tomography based on weighted generalized inverse is rewritten as:

$$S = Q^{-1}(PDQ^{-1})^{+}P \cdot T. \tag{13}$$

4 Numerical simulation experiments

4.1 TESTING MODEL

The model is a velocity model of explosion field as shown in Figure1. The tested area is divided into 10×10 meshes, and bomb is placed in the centre of test area as shown in Figure 2. With the principle of symmetry, we only need make velocity inversion in the 1/4 area. The sensor number is no more than 20. This is a typical model of travel time tomography with single driving sources and sparse rays.

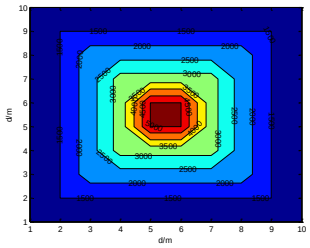

FIGURE 1 The velocity model of explosion field

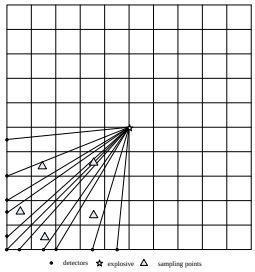

FIGURE 2 The tested area layout

Defining, the number of regular meshes is n, The relative velocity error in the No. j mesh is defined:

$$\delta_j = \frac{v_j - v_j'}{v_j'}, \tag{14}$$

where v_j' is the true velocity value in No. j grid , v_j is the inversion result.

The average relative error in all meshes is defined:

$$\bar{\delta} = \frac{1}{N}\sum_{j=1}^{N}\left|\delta_j\right| = \frac{1}{N}\sum_{j=1}^{N}\frac{\left|v_j - v_j'\right|}{v_j'}. \tag{15}$$

4.2 SIMULATION OF SENSORS DISTRIBUTION

We select the sensors number is 13; two different sensor layouts are presented in Figure 3. The first sensor layout is symmetrical as shown in Figure 3a, the second is optimized layout by the judgment indexes in this paper as shown in Figure 3b.

The ray density and orthogonality distribution in the whole tested area in the two layouts are in Figure 4 and Figure 5. The condition number of matrix D in the two layouts are $2.74 \cdot 10^{16}$ and 35.61 respectively. We can see that the second layout has more reasonable ray distribution, the better orthogonality and smaller condition number. The initial model is in Figure 6. We make velocity inversion and the relative errors in each mesh are in Figure 7, the average relative errors are 8.47% and 3.32%. The inversion results are in Figure 8. We can see that the inversion errors are smaller and inversion result is approaching the true model with the optimized sensors layout in this paper.

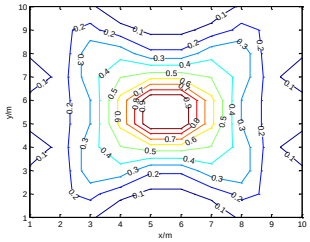

FIGURE 5a The first orthogonality distribution

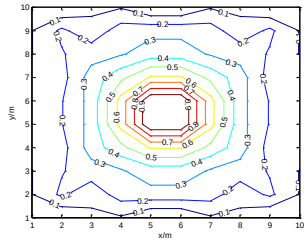

FIGURE 5b The second orthogonality distribution

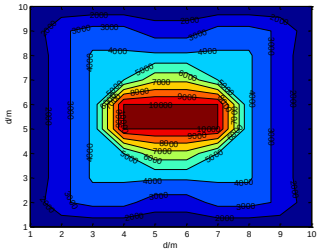

FIGURE 6 The initial model

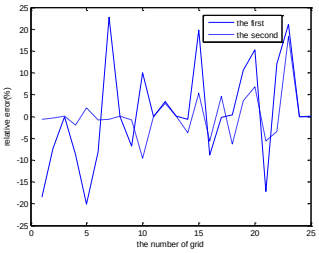

FIGURE 7 The relative error in each mesh

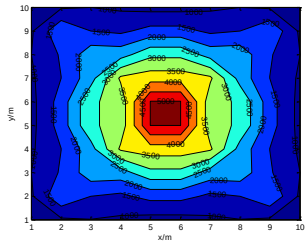

FIGURE 8a The first inversion results

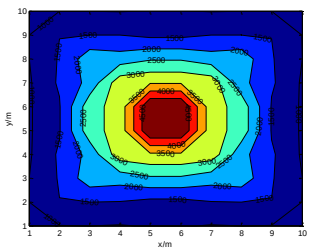

FIGURE 8b The second inversion results

4.3 INFLUENCE OF INITIAL MODEL

We generate the initial model by adding a certain proportion of random noise to true model and make the correlation coefficient of initial model and true model change from 0 to 1. We adopt the same weighted generalized inverse algorithm to simulate above model with different initial model. The relationship curve of correlation coefficient with inverse average relative error is in Figure 9. We can see that the correlation coefficient of initial model and true model is closer to 1, the inverse average relative error is smaller. Figure 10 is the relative error in each mesh when the correlation coefficient is 0.97, 0.75, 0.54 and the initial model is even velocity.

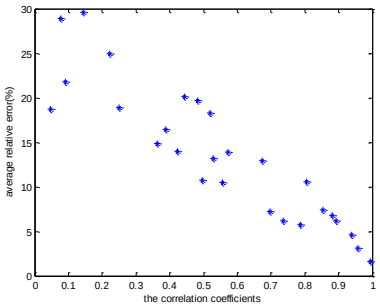

FIGURE 9The relationship curve of correlation coefficient with inverse average relative error

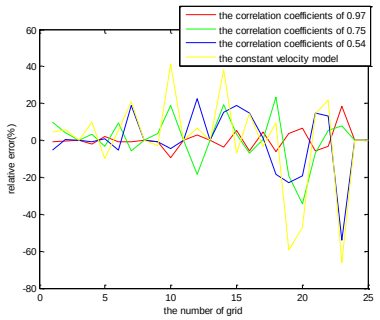

FIGURE 10 The relative error in each mesh with different correlation coefficient

From above analysis, we can conclude that inverse results depend on the initial model severely in the same condition. Selection reasonable initial model is very important for incomplete data travel time tomography with sparse rays.

4.4 INFLUENCE OF PRIOR INFORMATION

We make velocity inversion by generalized inversion algorithm with regularization methods. Figure 11 shows the different results of generalized inversion algorithm with regularization methods and without regularization methods. The average relative errors in all meshes are 4.2% and 19.81% respectively.

Figure 12 shows the influence of tight constraint of true data on inversion. When the number of sampling points is respectively 3, 5, 6, the relative errors in each meshes are shown in Figure 12. We can see that the relative error decreases with the number increase of sampling points.

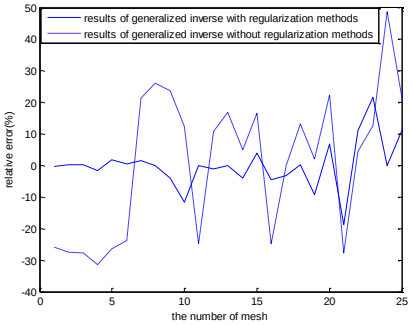

FIGURE 11 Inversion relative error in each mesh

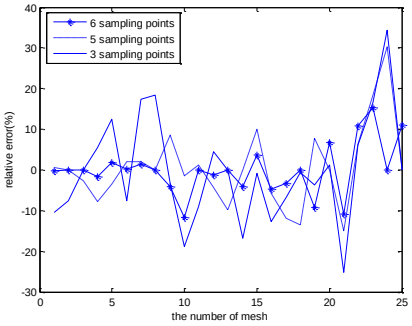

FIGURE 12The influence of tight constraint of true data on inversion

5 Conclusions

The particularity and complexity of the detected target result in the incomplete distribution of sensors. The travel time tomography owing to the insufficient driving sources and detectors is an incomplete data travel time tomography with sparse rays. This paper aiming at the problems of travel time tomography with sparse rays, analyses the influences that the system layout, initial model and prior information imposed on the inversion. We obtain the conclusions as follows:

In the condition of sparse rays, system optimal layout helps to improve the inversion accuracy. The indexes of system optimal layout are presents;

When the rays through the target are sparse, the correlation degree of initial model and true model is higher, the results are more accurate. We can set reasonable initial model by prior information and experience.

We can adopt regularization methods by prior information to overcome the underdetermined inversion problem of multiple solutions.

In practical project we can improve inversion accuracy by system optimal layout, initial model rational selection and utilization of regularization methods.

Abstract

Using the Monte Carlo simulation, we investigate the three-dimensional fractal growth of a magnetic diffusion-limited aggregation (MDLA), which consists of magnetic particles interacting with an exponential potential βCe-αr. The cluster morphology, fractal dimension and magnetic susceptibility of this MDLA are analysed with respect to the range facto rα and the coupling energy βC. In the case of long-range ferromagnetic interaction, our results show that the cluster morphology grows to be a hexagonal symmetry as the coupling energy increases, which is different from the two-dimensional simulation. For a proper coupling energy, the fractal dimension takes the maximal value and the cluster morphology becomes more compact. In the case of short-range interaction, the critical value of the cluster specific magnetic moment is much larger than the simulation result in the MDLA with the interacting potential of power law.

Keywords: diffusion limited aggregation, magnetic particle, exponential decreasing potential

1 Introduction

Since the "diffusion limited aggregation" (DLA) model was introduced by Witten and Sander [1] in 1981, it has been extensively studied for the cluster fractal growth simulation and applied in various fields such as the viscous fingering [2], the electrochemical deposition [3] and the thin film growth [4]. Among the simulation efforts are DLA models that have been proposed to investigate the influences by different physical conditions on the cluster growth [5-10]. Hassan et al. [11] investigated a simple model, which described the aggregation kinetics of two-component (two-different-size) particles with stochastic self-replication. The particle anisotropy and particle shape are also discussed by Liu et al. [12] and Li et al. [13]. Vandewalle and Ausloos [14] introduced the spin degree of freedom for the aggregating magnetic particles. They studied the dependence of the fractal growth on the nearest neighbor coupling among the magnetic dipoles as well as the external magnetic field. Indiveri et al. [15] studied the morphology and symmetry of a two-dimensional cluster growing in the long-range interaction scenario with the power law potential $r^{-\alpha}$ (r is the distance between any two-grid points in the system, α is a positive constant). Furthermore, Xu et al. [16] studied the two-dimensional cluster morphology when the power law function interaction exists among magnetic particles. Their results show that, for the long-range ferromagnetic interaction and when βC takes appropriate values, the cluster morphology appears four-degree symmetry.

In many physical systems, the interaction potential appears the exponential function with respect to the distance between two objects. In ion chemistry, some atomic and molecular repulsive forces and hydrophobic forces decay as $e^{-\alpha r}$ [17]. In the direct electrochemistry of proteins, the reaction rate of the electro active substance on the electrode decreases exponentially with respect to the distance between the electron donor and acceptor [18]. In condensed matter physics moreover, the interactions among some electric dipoles and magnetic dipoles decay exponentially with their distances. In some correlative many body systems, the exponential potential $e^{-\alpha r}$ is often used as an approximation of the practical interaction [19]. Tomohiko et al. [20] using the Yukawa potential $r^{-1}e^{-\alpha r}$ to study the phase diagram of the Pd-Mn alloy. By means of the Fourier transformation.

This paper discusses the magnetic diffusion limited aggregation (MDLA) with magnetic particles diffusing in the three-dimensional space. The dipole-dipole coupling between magnetic particles is assumed to decay exponentially with the distance $\beta Ce^{-\alpha r}$. Using the Monte Carlo method, we study the fractal growth dynamics. The cluster morphology, the fractal dimension, and they are analysed with respect to the decay rate α and the coupling strength βC.

2 Modeling and simulation methods

Based on the well-known DLA model, the MDLA model introduces the spin degree of freedom [21], where each particle is a two-level system with $\sigma = +1$ standing for spin-up and $\sigma = -1$ standing for spin-down. The cluster is assumed to grow on a three-dimensional cubic lattice. The simulation algorithm is as follows:

***Corresponding author** e-mail: shyshgl@163.com

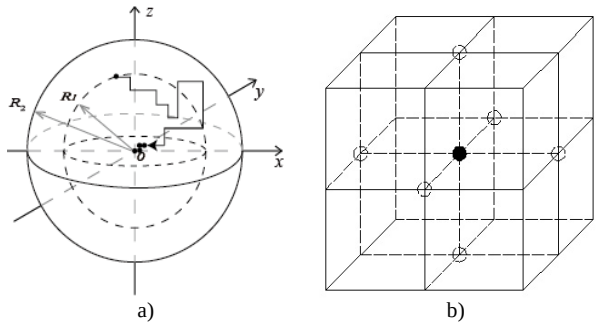

FIGURE 1 a) Illustration of the MDLA model and b) the six neighbor sites for a particle from the initial position diffusing

1) A seed particle with an initial spin state is placed at the centre of the cubic lattice (seed site).

2) Let the radius of the cluster aggregation is R_0, a diffusing particle with spin up or down is randomly generated on the spherical surface of radius $R_1 = R_0 + 20$, centred on the seed site.

3) The diffusing particle moves in the lattice according to the probability, which is determined by the change of the system energy with respect to the position and spin orienttation. Considering the Ising coupling among the spins and their potential energy in the outer magnetic field, the dimensionless system energy can be defined as follows:

$$\begin{aligned} &\beta E = -\sum_{\langle i,j \rangle} J r_{(i,j)} \sigma_i \sigma_j - \sum_i \beta H \sigma_i \\ &J\left(r_{i,j}\right) = \beta C e^{-\alpha r_{i,j}},\ \alpha \geq 0, \end{aligned} \quad , \qquad (1)$$

where $J(r_{i,j})$ is the coupling energy which is related to the distance $r_{i,j}$ between the particles *i* and *j*, βH is the outer magnetic field, and σ_i is the spin variable of the *i*-th particle. βC is the coupling strength related to temperature and α reflects the decay rate of the exponential function with the distance.

As illustrated in Figure 1, there are six neighbour sites where the diffusing particle from the initial site can move. The probability of moving to the *m*-th site is given by

$$P_m = \frac{\exp(-\Delta\beta E_m)}{\sum_{k=1}^{6} \exp(-\Delta\beta E_k)}, \quad m,k = 1,2,\cdots,6, \qquad (2)$$

where $\Delta\beta H$ is the energy difference induced by the change of the position and spin orientation. Using the roulette algorithm [22], we can select the location of the particle diffusion and spin orientation.

If the particle diffuses to the site connected to the condensed cluster, the particle will adhere to the cluster, and the spin orientation of the particle will be frozen. If the particle moves outside the spherical surface of radius $R_2 = R_0 + 30$, centred on the seed site, the particle disappears. In either case, one returns to the second step for another diffusing particle. The diffusing processes are repeated until a fractal cluster of *N* particles is formed.

3 Results and discussion

As an extension of the classical DLA model, the energy difference in the MDLA model is jointly determined by the diffusing particle's position and spin orientation. By tuning the parameters βH, βC and α, we can simulate the growth process of condensed clusters in the situation of different magnetic fields and temperatures. For simplicity, we consider the case of magnetic field strength $\beta H = 0$ in this paper. The spin of the seed particle is set to be spin-up. The two spin states, up and down, are illustrated by blue color and red color respectively. According to the energy Equation (1), we can know that, when βH and βC are close to zero, the energy difference before and after the particle diffusion is approximately zero. Therefore, the probabilities of the particle diffusing to different nearest neighbors are same. The motion is approximated to the uniform random walk process, and the formed cluster morphology is similar to the DLA model.

3.1 FRACTAL MORPHOLOGY OF THE LONG RANGE MAGNETIC INTERACTION SYSTEM

When the parameter α is small, the coupling energy between the magnetic particles damps slowly with their distance, and hence there is a long range interaction between the magnetic particles. Figure 2 shows the cluster morphologies with fixed $\alpha = 0.2$ and various $\beta C = -10, -1, 0.01, 0.18, 0.22, 200$.

Figures 2a and 2b show that when βC is negative, the cluster grows by the antiferromagnetic way. The cluster morphology becomes looser as $|\beta C|$ increases. The spin states of the magnetic particles present a regular crosswise distribution as shown in Figure 3a.

When βC is positive, the cluster grows by the ferromagnetic way. With the increasing βC, the cluster morphology becomes more and more regular as a six-degree symmetry structure distribution. As shown in Figure 1(f), the six-degree symmetrical structure corresponds to simple cubic lattice structure. In fact, the similar structure of six-degree symmetry widely exists in the systems (e.g., $\alpha = 0.1, 0.25, 0.3, 0.4$) of long range magnetic interactions.

When βC varies from 0.1 to 0.5, influenced by the random Brownian walking, the spin distributions of dominant up and dominant down appear alternately as shown in Figure 2c and 2d. However, when βC takes values greater than 0.8, the spins in the cluster are completely magnetized to the up state like the seed particle. This means that the force of the cluster imposing on the diffusing particle is increasing. The diffusing particles take the same spin states for the lower system energy. The certainty factor of the spin interaction plays a major role; while the effect the random factor is weaken.

3.2 FRACTAL DIMENSION OF THE LONG RANGE INTERACTIONS SYSTEM

In Figure 4, the fractal dimension of the cluster is plotted with respect to βC. In the case of antiferromagnetic growth, as $|\beta C|$ increases, the fractal dimension D_f gradually reduces to about 1.79. When βC reduces to - 100, the cluster no longer maintains the DLA fractal structure, but shows a broadband-like morphology.

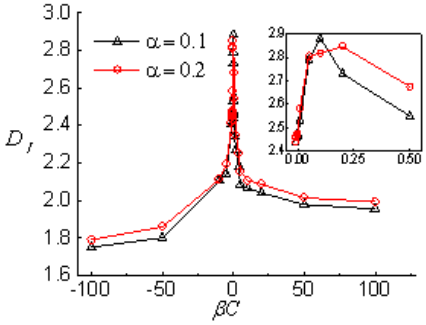

FIGURE 4 Aggregation clusters fractal dimension of different parameter βC when $\alpha = 0.1$, 0.2

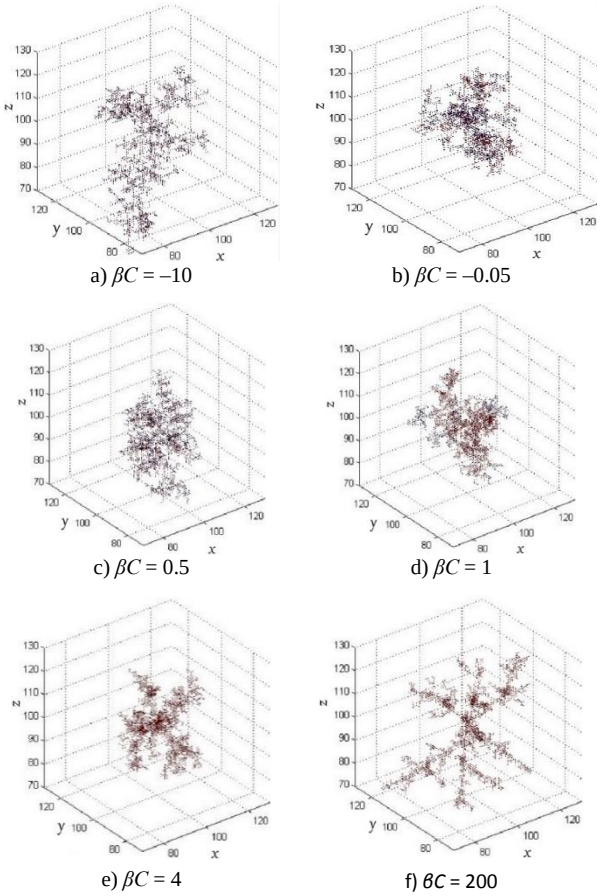
In the case of $\beta C = 0$, clusters of fractal dimension is about 2.47. In the case of ferromagnetic growth, the value D_f of the cluster changes significantly with the increase of βC. Especially for the system of $\alpha = 0.1$, the value D_f has a maximum peak value of 2.88. In the system of $\alpha = 0.2$, D_f, also has a maximum peak close to 2.84. However, as βC continues to increase, the fractal dimension decreases sharply. As shown in Figures 2d and 2e, the morphologies of the clusters are relatively tight, and the system energies are the smallest, which means the systems are stable. With $|\beta C|$ increasing, the morphology varies similarly to the case of $\alpha = 0.1$, except that the value D_f drops relatively slow.



a) $\beta C = -10$ b) $\beta C = -0.05$ c) $\beta C = 0.5$ d) $\beta C = 1$ e) $\beta C = 4$ f) $\beta C = 200$

FIGURE 5 The the cluster morphology in different parameter βC but fixed $\alpha = 1$

3.3 FRACTAL MORPHOLOGY OF THE SHORT RANGE MAGNETIC INTERACTION SYSTEM

When the parameter α is large, the coupling energy between the magnetic particles damps quickly with their distance, and hence the magnetic particles have the short-range interactions with each other. Only when closing to the aggregation cluster, does the diffusing particles can be affected by the cluster heavily. Figure 5 shows the growth morphology of the clusters with $\alpha = 1$ and $\beta C = -10, -0.05, 0.5, 1, 4, 200$.

Figures 5a and 5b show that, when βC is negative, the clusters grow in the antiferromagnetic way. Similar to the long range interaction system, as $|\beta C|$ increases, the morphology of aggregation cluster is more and more loose, and the spin state presents a crosswise distribution as shown in Figure 3b. But under the long range interaction system, the morphology gets sparse relatively faster.

When βC is positive, aggregation clusters grow in the ferromagnetic way. Unlike the long rang interaction system, the cluster morphology does not vary obviously and won't appear the six degrees of symmetrical structure even though βC is very large. For the larger $\alpha(\alpha > 1)$, the branch tips of the cluster are forked. The cluster tends to be unstable and the morphology is not compact like that in Figure 2b any more. The reason is that, in the short range interaction system, when the diffusing particle is far away from the cluster, the influence made by the cluster to the diffusing particle is approximate to zero. Only when the diffusion particles move close to the aggregation clusters, does the magnetic interaction between the particles has a significant impact. However for the long range interaction system, from the beginning of its movement, the diffusing particle is affected by the cluster, and when βC takes appropriate values, the magnetic particles agglomerate more closely so that the cluster energy will be less and the system will be more stable.

When $\beta C < 1$ the spin-up particles and the spin-down particles appear in the aggregation cluster at the same time. But as βC increases, the number of spin-up particles increases. When $\beta C > 4$ all condensational particles are magnetized to spin-up state. In short-range interaction systems, the value of βC that magnetizes all aggregation clusters to spin-up state is much larger than that in the long range interaction systems.

3.4 THE FRACTAL DIMENSION IN THE SHORT RANGE INTERACTION SYSTEMS

Figure 6 shows the cluster fractal dimension curve with respect to βC when $\alpha = 1, 3$. We can see that when βC is negative, the cluster grows in the antiferromagnetic way. when $\alpha = 1$ with $|\beta C|$ increasing, the fractal dimension decreases gradually to about 2.13. When $\alpha = 3$, as $|\beta C|$ increases, the fractal dimension of clusters decreases gradually to about 2.4. When βC is positive, the cluster grows by ferromagnetic way. As βC increases, when $\alpha = 3$, $100 > \beta C > -100$, D_f, the fractal dimension distributes between 2.4 to 2.58 and does not appear the maximum peak that similar to the maximum peak in the long-range interaction systems. When βC is smaller, the value of D_f is about 2.48, and it is similar to the classic DLA model. With βC increasing, D_f, decreases gradually and tends to a stable value about 2.4. For short range interaction system, magnetic particles near the aggregation clusters determine direction of spin particles, therefore, regardless of ferromagnetic or antiferromagnetic growth way, it has a small influence to the cluster morphology, and the difference of its fractal dimension change is not obvious.

3.5 SPECIFIC MAGNETIC MOMENT

In order to study the evolution of the spin state under different forces, we analysed the dependence of the specific magnetic moment M of aggregation clusters on the parameter βC. The specific magnetic moment M of the cluster is the ratio between the total spin and the total number of the particles, where the total spin indicates the difference between the numbers of spin-up particles and the spin-down particles.

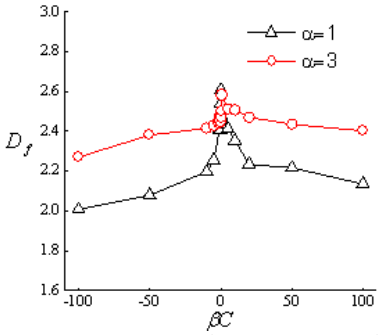


FIGURE 6 Aggregation clusters fractal dimension of different parameter βC when α = 1;3

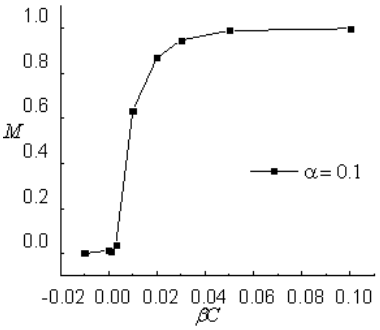

FIGURE 7 The curve of M changing with βC when α = 0.1

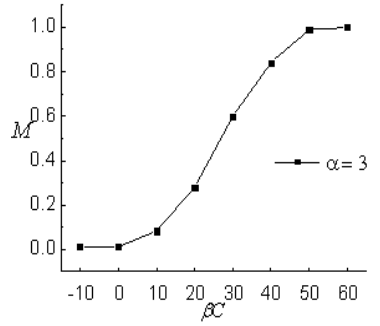

FIGURE 8 The curve of M changing with βC when α = 3

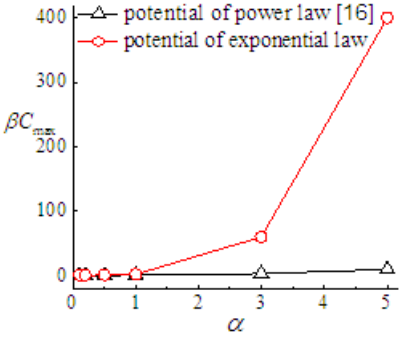

FIGURE 9 The curve of the critical value βC_{max} changing with different forcing process parameters α

As shown in Figures 7 and 8, in both cases of the long range interaction and the short range interaction, when βC is negative, the specific magnetic moment of aggregation clusters decreases and tends to 0 with $|\beta C|$ increasing. In the case of long range interaction $\alpha = 1$, the specific magnetic moment increases rapidly with βC increasing, and to the saturate value 1 as βC increases beyond 0.05. In the case of short range interaction $\alpha = 3$, the specific magnetic moment increases slowly with βC increasing, and when βC goes beyond 60. All of the aggregation particles are magnetized to spin-up state i.e., the specific magnetic moment $M = 1$. In the short-range interaction force, although the particle spin- flip probability is small, but once the spin flip, subsequent particle also will spin flip, resulting magnetization fluctuation phenomena.

For a given interaction range factor α, one can always find the threshold βC_{max}, which leads to the complete magnetization $M = 1$. Figure 9 shows the magnetization threshold βC_{max} as a function of the range factor α. In the case of long range interaction, the interaction between the particles did not change significantly with their distance, the magnetization threshold βC_{max} various slowly with the range factor [16]. As α increases to the short range interaction cases, the interaction strength between particles decays rapidly with their distance. The value of βC_{max} under the power law interaction is significantly greater than that under the exponential interaction. The influence that βC made to the specific magnetic moment in the power law interacting particles is far less than that made to the specific magnetic moment of exponential law interacting particles.

4 Conclusion

Using the MDLA model and assuming that the magnetic interaction force between the particles decays exponentially with their distance, we simulated the dynamic behavior of cluster fractal growth for different physical parameters. When the cluster grows in the antiferromagnetic way, the spin states of magnetic particles under different forces are in a crosswise distribution. Along with the decrease of the parameters of α and βC, the morphology of aggregation clusters gets more sparse, the fractal dimension decreases continuously, and the specific magnetic moment of aggregation clusters tends to be zero. When the cluster grows in the ferromagnetic way, for long range interaction systems, the cluster morphology and fractal dimension change significantly with the physical parameters. The cluster morphology evolves to regular six-degree symmetric structure from the ordinary DLA morphology, and there are also dense forms appear in the middle range. The specific magnetic moment M increases rapidly from 0 to 1 as the parameter βC increases. For short-range interaction systems, the cluster morphology and the fractal dimension change slowly with the physical parameters. Moreover, the compact structure and six-degree symmetric morphology does not appear. The specific magnetic moment M also increases slowly from 0 to 1 as the parameter βC increases. This conclusion provides a reference for explaining the related phenomenon of physics experiments and studying the fractal growth mechanism of magnetic particles, etc.

Abstract

This paper applied computational fluid dynamics (CFD) method to investigate the internal multiphase flow filed in a 75 mm hydrocyclone. The Reynolds stress model (RSM) and VOF model were employed in the numerical simulation. This study discussed the velocity and pressure distribution in the hydrocyclone, and analysed the formation and development mechanism of air core. The numerical simulation results showed that the flow field was very unstable in the region of the air core. The axial velocity gradient reached its maxima, and the turbulent fluctuation was strongest in the simulation region. This study provided theoretical basis on further research of the air core effect on separation efficiency and pressure drop.

Keywords: numerical simulation, multiphase flow, hydrocyclone, CFD

1 Introduction

Hydrocyclone is a typical device that is used to separate non-uniform multiphase fluids. Owing to its advantages of small space requirement, simple structure, high separation efficiency, large separation capacity, low maintenance costs, and no moving parts, it has been widely used in various industries such as chemical engineering, oil/gas, and ore dressing. Although the structure of hydrocyclone is simple, the inner flow field is very complex and the flow characteristics are complicated. High speed rotating turbulent flow, interaction between multiphase flows and interruption of the air core increase the challenge to the study of internal flow field in hydrocyclone [1-3]. For many years researches on hydrocyclone were typically carried out in experimental ways. For example, Kesall [4] applied light-speed microscopic measurement system, Knowles et al. [5] used imaging velocimetry system, and Hsieh et al. [6] employed a LDV to study the internal velocity distribution of hydrocyclone, in which small amount of tracing particles were added to the water. However, these methods require delicate experimental conditions, high cost, long working period, and have disadvantage of difficult measurement and non-universality. With the development of computation fluid dynamics (CFD) and continuous improvement of turbulent models, numerical simulation becomes research hot points in hydrocyclone studies. Through simulation, the internal flow field and velocity distribution can be clearly detailed, which provides important guide to structural design and optimization of hydrocyclones. This paper applied a CFD software, FLUENT, to simulate the internal two-phase flow field in a hydrocyclone. This study correctly reflected the internal flow field in the hydrocyclone, obtained the velocity and pressure distribution, and especially focused on the formation and development mechanism of the air core.

2 Construction of the model

Structural model This paper aimed at the standard hydrocyclone that was proposed by Hsieh, [6] where the structural dimension is shown in Figure 1.

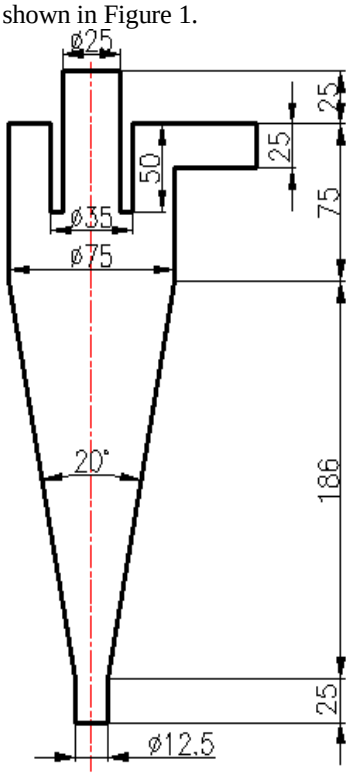

FIGURE 1 Geometry of the hydrocyclone

The diameter of cylindrical section Φ is 75mm, and the length is 75mm. The cone section is 186mm long, and the length of the underflow section is 25mm. The inner depth of the overflow section is 50mm. The overflow tube thickness

**Corresponding author* e-mail: lpk710128@163.com

is 5mm and the diameter of the overflow and underflow tubes is 25mm and 12.5mm, respectively. The inlet section area is 25×12.5mm, and the cone angle is 20°. The mesh was generated through ICEM with structural hexahedral mesh. The mesh in the central axis and wall area was refined, which is shown in Figure 2.

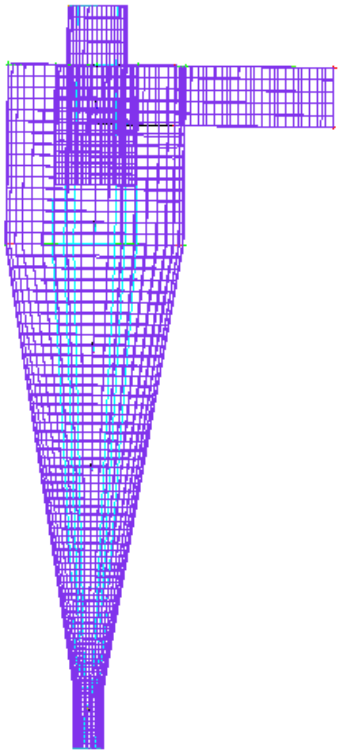

FIGURE 2 The mesh of the hydrocyclone

Determination of the turbulent and multiphase flow models Due to the complexity of turbulent flow, its generation mechanism has not been fully understood. Bhaskar et al. [7] used experimental studies to compare k-ε turbulent model, k-εRNG turbulent model and RSM model on the numerical simulation of hydrocyclone flow. The results indicated that the RSM model could provide the smallest error compared to the experimental data, because RSM model completely considers the rapid change of streamline curve, rotation and tension, which can well predict anisotropic turbulence. Therefore, it is very suitable for the study in hydrocyclone flow where the flow is highly rotational. Considering the flow in the hydrocyclone is two phase or multiphase flow, this paper applied volume of fluid (VOF) model to study liquid-air two phase flow. This study solved a set of momentum equation and analysed the VOF of two phase flow through the computational domain, which can well simulate the un-dissolved fluid distribution of air and water in the hydrocyclone.

Boundary condition and controlling parameters Boundary condition is the key to determine the exact solution of the governing equation. The governing equation and boundary condition constitute the complete mathematical description of the flow process of a physical variable. FLUENT provides various boundary conditions. In this study, the boundary condition was set as follows:

Inlet condition: the primary phase was set to be water. The temperature is constant, density of water is 998.2kg/m^3, viscosity is 0.001Pa·s, volume fraction is 1. The secondary phase was set to be air, the temperature is also constant, density is 1.225kg/m3, viscosity is 0.00001 Pa·s and volume fraction is 0. The velocity of water at inlet was 2.28m/s and the turbulent characteristics were determined based on the combination effect of hydraulic diameter and turbulent level.

Pressure outlet: Both overflow and the underflow exits were set exposed in the air, where the relative pressure was zero. The backflow coefficient of air was set to be 1. In this regard, the backflow of fluid would be air, if negative pressure presented at the flow outlet.

Wall condition: The wall condition was treated as non-slip boundary condition, where the boundary layer turbulence was determined according to the standard wall function.

3 Simulation results and discussion

The residual was set to be 10^{-5} and the time step was 1×10^{-4}s. The velocity field, pressure field, and the formation and development of the air core were determined through iteration. The results and discussion are presented as follows.

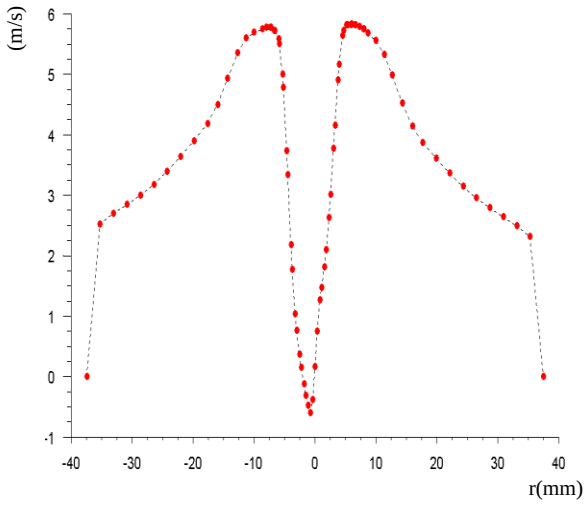

FIGURE 3 The tangential velocity distribution

Tangential velocity distribution in the hydrocyclone, tangential velocity has great influence on the separation efficiency. Large tangential velocity has great centrifugal force, and therefore high separation efficiency. From the tangential velocity distribution (Figure 3), tangential velocity varied clearly along the axis, where the minimum tangential velocity was at the wall. With the gradual decrease of radius, the value of tangential velocity increased continuously. After reaching the maximum value at the air core edge, the tangential velocity tended to decrease gradually. The distribution of the tangential velocity had the characteristics of combined vortex. An obvious transition area existed between forced vortex and free vortex, which agreed well with the research results of Kelsall [4] in 1952.

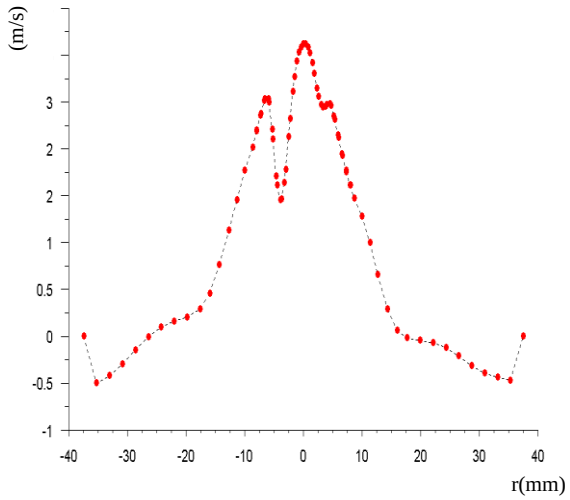

FIGURE 4 The distribution of axial velocity

Axial velocity distribution: during the separation process of the hydrocyclone, axial velocity directly affects the retention time of the fluid in the flow field, and determines the distribution relationship of fluid between overflow and underflow. Hsieh [6], Kelsall [4], and Bradley et al [2] conducted detailed experimental studies of axial velocity in hydrocyclone. Using experimental data, Xu [8] applied mathematical regression method to fit the mathematical equations for axial velocity distribution of fluids in the area under the overflow tube of hydrocyclone. The distribution of axial velocity in this study is shown in Figure 4. The direction of flow in the tube was downward close to the wall, towards the underflow exit. Towards the axial direction in the tube, the axial velocity decreased with the decrease of radius. The axial velocity was zero at the location of approximately half radius. After this zero point, the axial velocity changed to upward direction, i.e., the flow was towards the overflow exit, and increased with the decrease of radius. There was always a point with zero axial velocity at different cross-sections. Therefore, a contour surface shaped like a cone can be named locus of zero vertical velocity (LZVV), shown in Figure 5. This LZVV divided the axial velocity of fluids in the hydrocyclone into two parts: The flow direction of fluids outside of the zero axial velocity envelope plane was downward, forming outer helical flow; In contrast, the flow direction of fluids inside of the zero axial velocity envelope plane was upward, forming internal helical flow. Figure 6 gives axial velocity gradient of hydrocyclone flow. It can be seen that the gradient close to the wall was smallest. With the decrease of radius, in the area of air core, the gradient increased rapidly until reaching a certain value and then decreased fast, forming a hump-like distribution. It indicates that turbulence in the centre area of the hydrocyclone was very intense, and the flow field was extremely unstable. However, the turbulent level was weakest in the area of hydrocyclone wall, where the flow field was relatively mild.

FIGURE 5 The locus of zero vertical velocity

Pressure distribution: The pressure distribution in hydrocyclone is very important to separation efficiency and separation size, which is the primary basis for calculation of productivity and energy loss. Through the two-phase numerical simulation, the pressure distribution in the hydrocyclone is obtained and shown in Figure 7. It can be seen that the static pressure in the hydrocyclone gradually decreased from the wall towards the axis. The static pressure of the fluids was zero at the location of the air core interface. Afterwards, the negative pressure became stronger as closer to the axis, and decreased to the minimum value at the underflow and overflow exits.

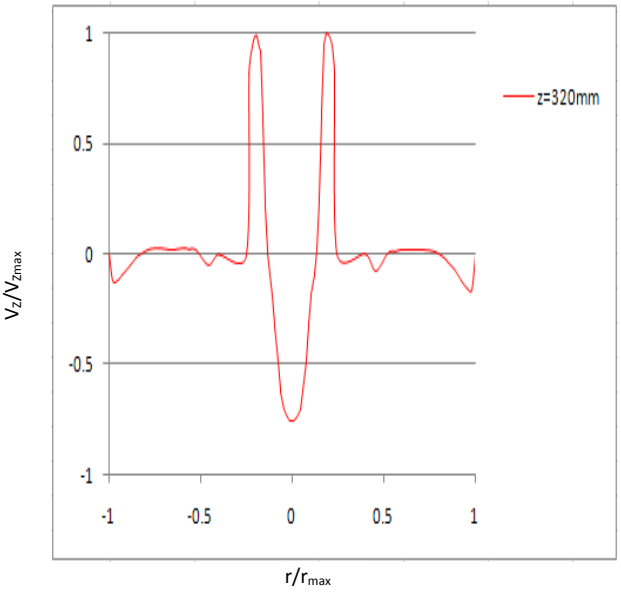

FIGURE 6 The axial velocity gradient of the hydrocyclone

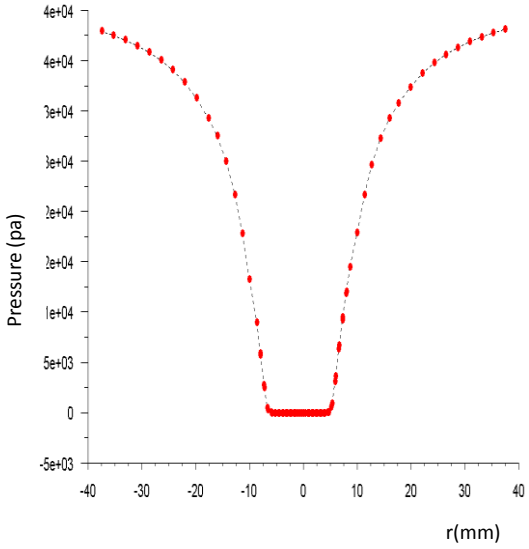

FIGURE 7 The pressure distribution of the hydrocyclone

Formation and development of the air core Figure 8 shows the formation and development of the air core in the hydrocyclone. In the figure, blue color represents air, whereas red part is water. At the initial time, the hydrocyclone is filled with air. With the evolution of the flow field, the volume of air in the hydrocyclone decreased gradually, and the ratio of water phase volume to total volume increased. When the time is about 1.1s, water occupied the whole internal area of the hydrocyclone. With the increase of time, air core initially formed under the overflow tube, and then in the area of underflow exit. The two air core grew and moved towards each other until they merged to a single air core. It is evident from this numerical simulation that, because the underflow and overflow tubes were directly connected to air, the fluids entering into the hydrocyclone rotated strongly as spiral vortices. When the tangential velocity reached a certain value, the negative axial pressure formed, and air entered into hydrocyclone. Under the effect of this negative pressure, the air core developed and reached the stable condition. The size and shape of the air core changed with the development of the flow field. Even when the flow condition reached stable, the sizes of the air core at different axial locations were not the same. The axial change of diameter of the air core is shown in Figure 9. The maximum diameter of the air core located at the bottom of the overflow tube, which is 15.57 mm. The diameter of the air core decreased to 9.91 mm with the decreasing height of the hydrocyclone, which was induced by structural change of bottom section of the overflow tube. In the cone section, the diameter of the air core varied irregularly at different locations in the hydrocyclone. The characteristics of the air core in the underflow tube were similar to that in overflow tube. The diameter at bottom of the underflow tube is maximum, i.e., 9.8 mm. The diameter changed suddenly to 8.91 mm at the interface between underflow tube and the cone section.

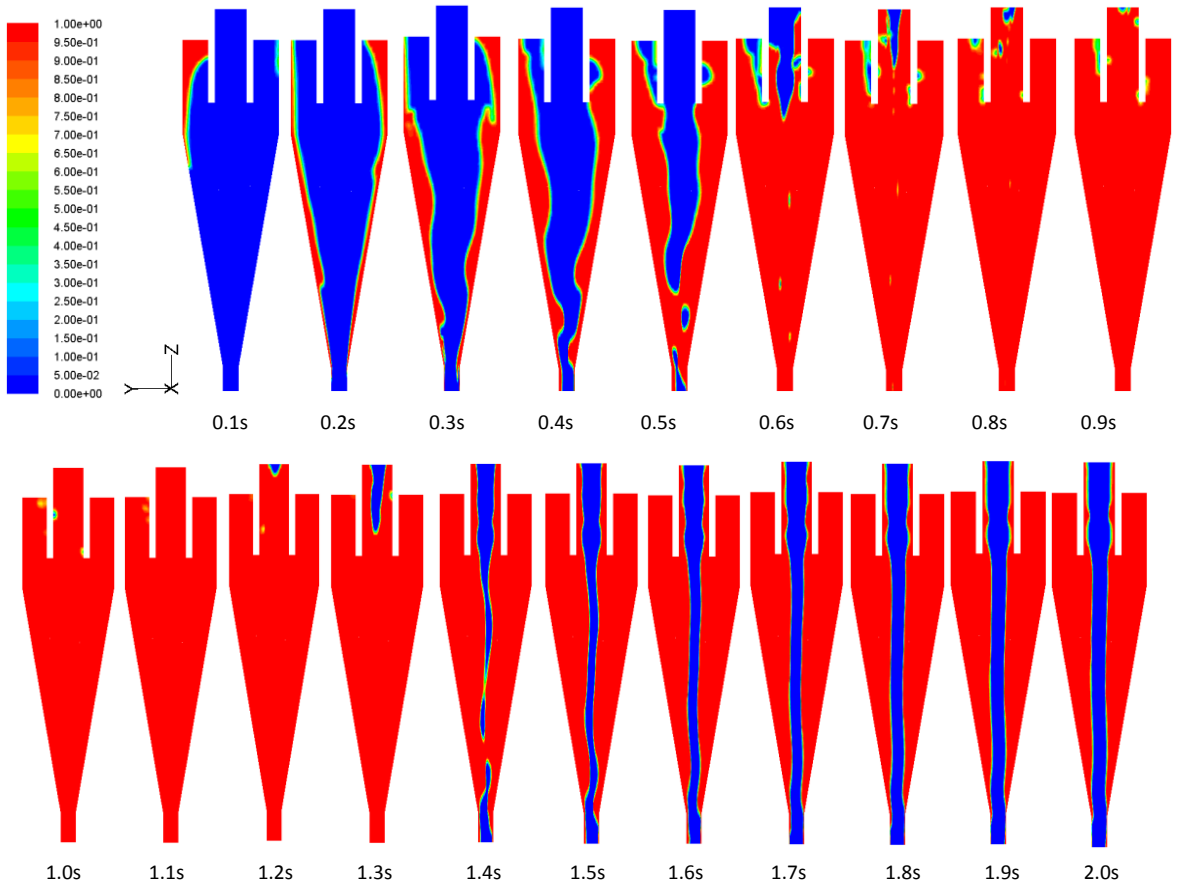

FIGURE 8 The development of the air core in the hydrocyclone obtained from CFD simulations

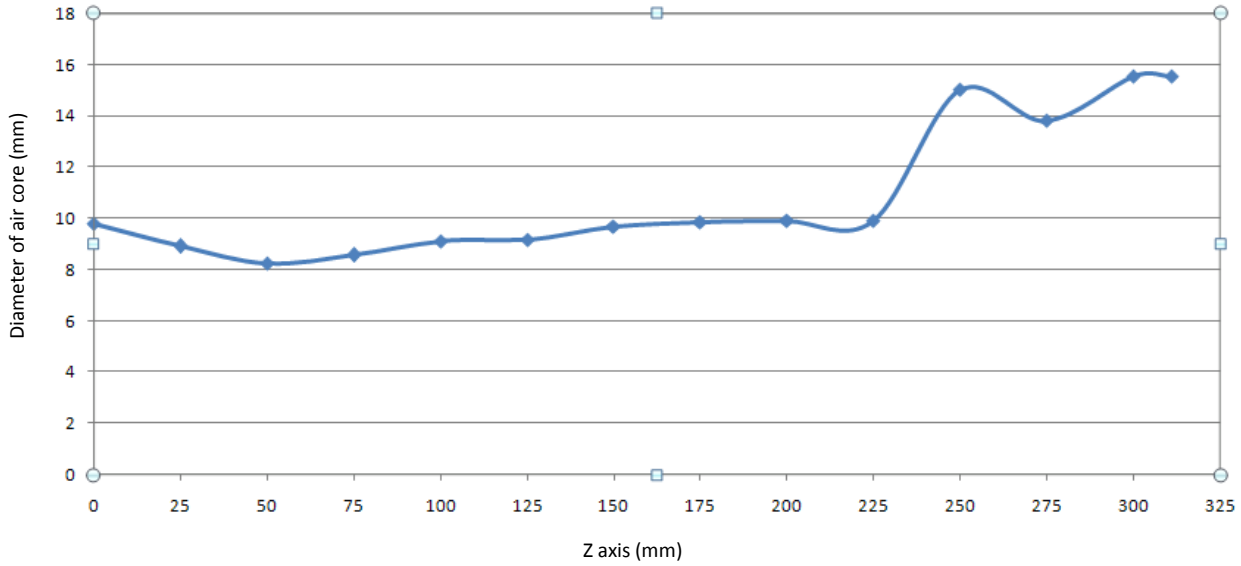

FIGURE 9 The axial change of diameter of the air core in the hydrocyclone

4 Conclusions

This paper used FLUENT and applied RSM and VOF models to simulate the two phase flow field in a hydrocyclone. The results of this study were consistent with the previous theoretical and experimental studies. The results explored the internal flow field in the hydrocyclone. This study emphasized the formation and development of the air core. The numerical results showed that the flow field was highly unstable in the area of the air core, with the largest axial velocity gradient and strongest turbulent fluctuation. This study also provides the theory basis of further investigation of air core effect on the separation efficiency and pressure drop.

Abstract

MIMO systems, also known as multiple-input multiple-output, can effectively improve the capacity and reliability of wireless communication. Antenna selection (AS) is a low-cost low-complexity attractive approach in MIMO systems that capture many advantages of these systems. In this paper, we comprehensively review and describe various kinds of AS schemes in MIMO systems. First, we discuss the techniques of antenna selection from the perspective of different channel environments. Analysis results show that exploiting the AS technique can avoid sending redundant information and improve the channel capacity in the low rank and correlated channel conditions. Then the applications of AS systems in spatial diversity and spatial multiplexing are considered. In order to reduce the complexity of AS algorithm, we propose a novel joint transmit and receive AS scheme in MIMO systems. The results of simulations demonstrate that the proposed AS method of performance outperforms other methods, and the proposed algorithm can significantly reduce computational complexity compared to the optimum algorithm. Finally, we summarize some conclusions about the antenna selection.

Keywords: MIMO, antenna selection, spatial diversity, spatial multiplexing

1 Introduction

Using multiple input, multiple output (MIMO) systems is one of the most significant technical breakthroughs in modern wireless digital communications. Compared with single inputs single output (SISO) systems, the capacity and reliability of a wireless communication system can be improved dramatically by employing multiple antennas at the transmitter and/or receiver without increasing bandwidth and transmit power [1]. MIMO technology has been drawn significant research interests recently due to its advantages. Most importantly, the standard for the third-generation cellular phones (3rd generation partnership project, 3GPP) has joined the MIMO technology. The MIMO technology has been widely applied to Beyond 3G and 4G systems. We can foresee that the mobile communication systems in the future, including the 5G system, will be implemented by massive MIMO technology [2].

It is shown that in an independent and identically distributed (i.i.d.) Rayleigh fading channel, the capacity of a MIMO system with N_T transmit antennas and N_R receive antennas scales almost linearly with the $min(N_T, N_R)$ in the high signal-to-noise ratio (SNR) regime [1]. The MIMO wireless communication systems have now demonstrated the potential for increased capacity and reliability in rich multipath environments, without any increase in bandwidth or transmit power. However, the application of multiple antennas has been restricted by the hardware cost and power consumption of the RF chains. Because it requires the same number of RF chains at the transmitter and receiver. The RF chains include amplifiers, up-down converters, as well as the analog-to-digital-to-analog (A/D/A) conversions. The cost and hardware complexity of the RF chains is often much higher than the antenna array. How to reduce the hardware complexity and at the same time maintain most of the advantages of MIMO systems is an important research topic. A MIMO system with antenna selection (AS) has been shown to significantly outperform a system exploiting the same number of RF chains without AS. Therefore, the AS approach that chooses a subset of the available transmit and/or receive antennas is an attractive low-cost and low-complexity technique. The MIMO technology improves the wireless communication system performance from two aspects, spatial multiplexing and spatial diversity. First, from the point of view of spatial diversity, MIMO systems can improve the signal-to-noise ratio (SNR) and the robustness of the communication links in terms of BER (Bit Error Rate) by collecting multipath signals between the transmitter and receiver. On the other hand, spatial multiplexing, which makes full use of independent space degrees of freedom between the transmitter and receiver can dramatically improve the capacity and the speed of data transmission of the communication system.

The remaining sections of this paper are organized as follows. We will introduce MIMO systems with AS techniques and discuss AS schemes in various kinds of operation environments of actual channel in Section II. AS systems based on both spatial diversity discussed and analysed In Section III. Section IV studies mainly the AS criterions based on spatial multiplexing, and analyses the complexity of various kinds algorithms. Section V describes the simulative results and discussion. Finally, the prospection and conclusions are included in Section VI.

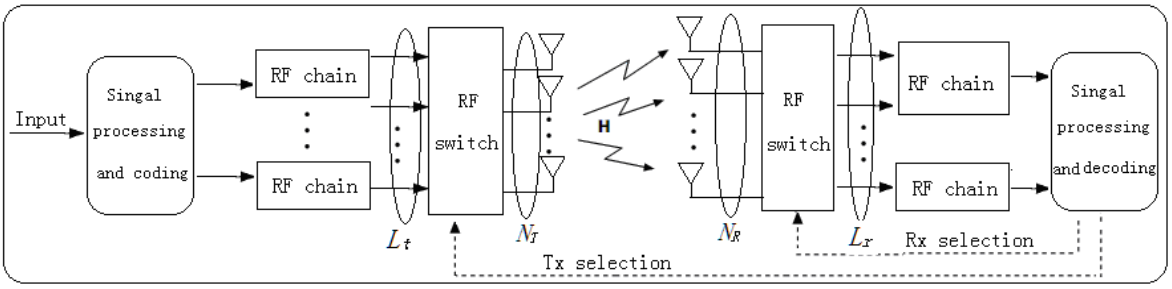

FIGURE 1 Antenna selection in MIMO system

2 Antennas selection of channel model

2.1 MIMO SYSTEM CHANNEL MODEL

Figure 1 shows the MIMO systems with N_T transmit antennas and N_R receives antennas. The transmitter includes an STBC encoder, RF chains, and a switch that connects the RF chains to select L_t out of N_T transmit antennas according to the message of *Tx* selection through feedback channel from the receiver. Likewise, at the receiver, a switch connects the RF chains to select L_r out of N_r receive antennas according to the message of Rx selection from the signal processing unit, in which during a period of the received signals process the channel state information (CSI) of MIMO systems is estimated. Assuming all N_T transmit antennas and N_R receive antennas are selected, the complex envelope of the received signal at the antenna array after matched filtering is given by:

$$y=Hx+n, \tag{1}$$

where x is a N_T dimensional column vector of the transmitted signals, and n is a N_R dimensional complex noise vector where each component is a complex white Gaussian noise sample with zero mean and variance σ_n^2. The channel matrix is defined in Equation (2)

$$H=\begin{pmatrix} h_{11} & h_{12} & \cdots & h_{1N_T} \\ h_{21} & h_{22} & \cdots & h_{2N_T} \\ \vdots & \vdots & \vdots & \vdots \\ h_{N_R1} & h_{N_R2} & \cdots & h_{N_RN_T} \end{pmatrix}, \tag{2}$$

where matrix H is a $N_R \times N_T$. It is assumed that the matrix H is independent complex Gaussian random variables with zero mean and unit variance, namely, all of the transmitted signals experience frequency selective flat Rayleigh fading channel. The element h_{ij}, i=1,2,…N_R; j=1,2,…N_T, of the matrix H represents the complex channel gain between the j-th transmit antenna and the i-th receive antenna.

2.2 THE EFFECT OF CHANNEL SITUATIONS ON AS

The capacity of wireless communication system has been severely influenced by the channel situations [3]. A lot of AS schemes on MIMO systems have been discussed in the different channel conditions [4-11]. Under the flat Rayleigh fading channels, assuming that MIMO wireless channels are mutually independent, the references [4-8] presented some AS schemes. These results indicated that AS technique can capture most of the advantages of MIMO systems and at the same time reduce the hardware complexity. If the wireless channels are independent, we can be sure that the performance of the system will be deteriorated in the correlated channels. The fact that the channel is correlated implies that some rows/columns in the channel matrix can be expressed as a linear combination of the others. This means that the information in these rows/columns is in some way redundant and does not contribute to capacity. It is thus clear that redundant information is easily produced in the correlated channel situation. To do this, a fast AS algorithm based on Frobenius norm and correlation coefficient was proposed in [7]. This algorithm chooses two rows of the channel matrix, which carry identical information, since they own similar signal components, one of them will be deleted in this scheme. In addition, the two rows have different powers, or rather squared Frobenius norm of the row, the corresponding row with higher power will be selected in the algorithm. When there are no two rows of identical information, the algorithm in [9] choose two rows of the channel matrix, which have higher correlation factor, and the corresponding row with lower power will be deleted. In a word, it allows us to obtain a sub-channel matrix whose rows are minimally correlated and have maximum powers. Further, in a low rank and correlation matrix channel, it is easy to send redundant information, which does not contribute to the channel capacity. It is necessary to select a set of antenna in a low rank channel conditions, so that the total transmission power may be allocated to a small amount of transmit antennas to improve the capacity of the system. An optimal AS algorithm in the low rank matrix channel was proposed in [10]. It has shown that AS in the low rank matrix channel can still improve the capacity of the channel. And in the seriously frequency selective fading channel, it has been shown that the effect on AS is very little. However, when the bandwidth of the system is greater than the correlated bandwidth of channel, an additional degree of diversity which is generated by AS is not prominent. Even so, the advantages of antenna selection are still reflected in a general frequency selective fading channels. According to reports in the [11], it shows that CDMA signals, in a general frequency selective channels, can be exploited to maximize the SNR at the receiver based on both generalized combined, in which combined multiple copy signals, and pre-coding technique as well, at the same time it can reduce the complexity of the transmitter and receiver.

3 AS systems based on spatial diversity

MIMO technique can greatly improve the performance of the wireless communication systems by exploiting the independence of the channel space. Namely, it takes advantage of the degrees of freedom provided by multiple antennas and the technique of time/spatial diversity to improve the performance and reliability of wireless communication. Diversity refers to two or more random fading signals are merged to reduce the fluctuation of signal level. As Figure 2 shows a block diagram of conventional receive diversity. All of the transmit signals experience a different fading channel with complex valued coefficient $h_i(t)$ and additional noise signal $n_i(t)$. Due to multiple fading paths are statistically independent, it is unlikely that they appear synchronous fading phenomenon. At any moment, the probability of all uncorrelated fading signals simultaneously in a deep fading is small. Therefore, diversity can significantly reduce fading degree of the combined signals. At present, diversity has been widely exploited in wireless communication systems to against the multipath fading.

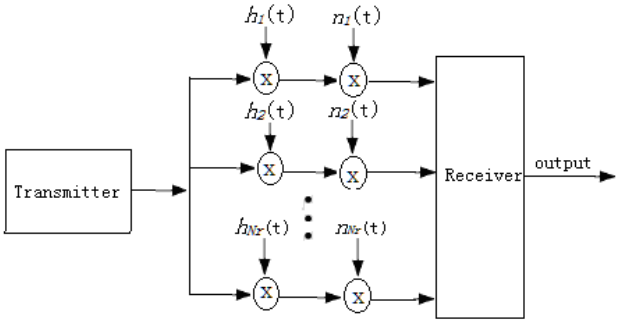

FIGURE 2 Block diagram of receive diversity

3.1 THE TRADITIONAL DIVERSITY

Figure 3 shows a generalized receive antenna selection diversity system, which is an extension of the conventional receive diversity. The independent signals after the antenna selection must be combined at the receiver to improve the signal-to-noise ratio (SNR) of the system. Diversity combining can be classified into three categories by the different ways of signals combination. They are maximal ratio combining (MRC), equal gain combining (EGC) and selection combining (SC). Although the implement of MRC would be relatively complicated, it is still an optimal technique of diversity combining which gives a better performance of the system. With the development of semiconductor and signal processing techniques, MRC technique now has been widely exploited in communication systems. A rapid incremental AS approach, in which at each step a new antenna is added to the selected antenna subset based on the maximum output SNR strategy, for MIMO diversity systems using maximum ratio transmit (MRT) at the transmitter and MRC at the receiver was proposed by Duan Hong, and Liu Feng in [12]. It shows that the MIMO AS systems can keep most of the diversity gain, and do not need too many RF chains. In addition, the performance analysis of a kind of reduced-complexity transmit/receive diversity systems and SNR and bit error rate (BER) of hybrid SC/MRC systems are discussed respectively in [13, 14], study results show that it shows that the system performance is obviously improved.

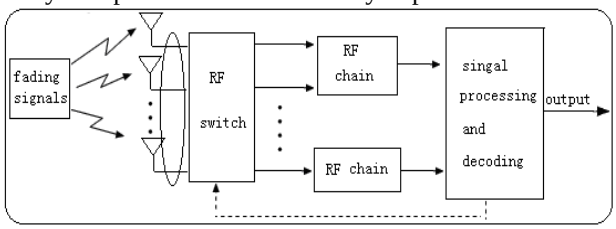

FIGURE 3 Block diagram of generalized receive AS diversity system

3.2 THE SPACE-TIME DIVERSITY

As mentioned above, through hybrid the AS technology and traditional MIMO diversity, we can greatly boost the diversity gain, thus output SNR and BER performance of the communication systems are obviously increased and improved. However, in the actual operating environments, it may bring the mutual interference of transmitting antennas by exploiting the multi-antenna. In order to reduce mutual interference of transmitting antennas, an optimal AS with space-time block coding was proposed in [15]. Research shows that MIMO AS systems with the space-time coding can obtain certain additional diversity advantages. The input serial data from signal constellation are performed series-to-parallel to multiplex parallel data streams, and then the processed data employing space-time coding are transmitted in sequence over the selected antennas. So transmit diversity advantage will be produced by space-time two dimensional coding in the transmitter. It shows that transmit antenna selection with space-time block coding (STBC) can greatly improve the performance of BER in communication systems [16]. At the same time, [17] shows that antenna selection combined with quasi-orthogonal STBC can improve the diversity gain and coding gain to reduce BER. The investigation results in [18] indicate that quasi-orthogonal STBC systems with AS can increase the capacity of the channel and improve the transmission rate of the system. [19] points out that the diversity gain and closed loop gain of the system can improved greatly by combining V-BLAST and antenna selection algorithm.

Finally, we can conclude that MIMO systems combining with space-time code will be a key technology in the future high-speed transmission communications. Employing MIMO AS systems not only can reduce tremendously the system implementation complexity and cost, but also provide a higher diversity gain and enhance the SNR magnitude. The following section, we will verify MIMO AS systems can increase effectively the channel capacity and improve the rate of transmission as well.

4 AS systems based on spatial multiplexing

As we known, MIMO can greatly improve the channel capacity and the rate of data transmission of the system by exploiting spatial multiplexing. With the increase of number of transmit and receive antennas, the channel capacity of

MIMO systems will increase linearly. As shown in the Figure 1, the MIMO system equips with N_T transmit antennas and N_R received antennas. Assume that the MIMO wireless channel is modelled as a Rayleigh fading distribution. Based on spatial multiplexing, the AS criteria of MIMO system is to select an antenna subset, in which subset can achieve the maximum channel capacity. On the basis of the channel matrix H, L_t out of N_T transmit antennas and L_r out of N_R receive antennas are selected from MIMO system, let the selected sub-matrix be denoted by $\tilde{H}$. Assuming that the system transmission power is evenly allocated to each of the transmitting antennas, thus the channel capacity of MIMO system can be expressed as [1]:

$$C_{\text{full}} = \log_2[\det(I_{N_T} + \frac{\rho}{N_T} H^H H)], \quad (3)$$

where ρ denotes the average signal-to-noise ratio (SNR), H is the $N_R \times N_T$ channel matrix. I_N denotes a $N \times N$ identity matrix. The superscript H denotes the conjugate transpose.

The channel capacity of sub-matrix $\tilde{H}$ corresponding to the optimal antenna subset can be written as:

$$C_{\text{sel}} = \underset{S(\tilde{H})}{max}\{\ \log_2[\det(I_{N_T} + \frac{\rho}{N_T} \tilde{H}^H \tilde{H})]\}. \quad (4)$$

However, the computational load required for an optimal selection through an exhaustive search over all possible antenna subsets grows exponentially with the total number of the antennas available. This is a computationally prohibitive problem. High-speed communications systems demand an efficient AS scheme with lower complexity, so the investigation of the sub-optimal AS algorithms is of great practical as well as theoretical interest.

4.1 RECEIVE ANTENNAS SELECTION

The Receive antennas selection (RAS) system based on spatial multiplexing is choosing the channel matrix to maximize the channel capacity in the receiver. The simplest RAS algorithm is norm-based selection (NBS), which was proposed in [4]. Selection criteria of NBS is that the row of channel matrix with the maximal Frobenius norm is chosen in each step selection algorithm. Due to lower computational complexity, NBS is the most suitable for low SNR or only a RF link at the receiver. However, NBS is not necessarily optimal in other scenarios. The lower complexity of NBS, the more losses of channel capacity, in order to reduce the losses of channel capacity, a fast antenna selection is proposed in [5]. The algorithm begins with the full channel matrix, and then removes one antenna per step. So the AS criteria is based on the antenna with the lowest contribution to the system capacity is removed per step. In contrast to [5], an incremental antenna selection algorithm is proposed [6,7]. The computational complexity is much lower than the algorithm of [5]. The algorithm starts with an empty antenna subset and adds one antenna per step to this subset. At each step, the objective is to select one antenna, which leads to the highest contribution to the channel capacity. Although the computational complexity of the algorithm [6, 7] will be lower than AS algorithm [5], there are still some losses of channel capacity. These algorithms [5-7] can substantially reduce the computational load in the AS systems, however, they are still restricted by so called local searching shortcomings. These local searching strategy, though reduce the computational load, give rise to the loss in optimality simultaneously. A kind of global and fast receiver antenna selection for MIMO systems was proposed [8], it takes into account the number of RF chains is the same both at the transmitter and receiver. It allows to finding the sub-matrix with the greatest determinant for a high SNR scenario. It shows that the fast AS algorithm can achieve almost the same capacity performance as the optimal selection method.

In order to illustrate the performance of the antenna selection, the channel capacities of different algorithms are simulated with 1000 random number seed by Monte Carlo method. Figure 4 shows that comparison of the channel capacity the incremental algorithm [6, 7], decreasing algorithm [5], global and fast antenna selection method [8] for $L_r = N_T = 3$, $N_R = 6$, and the value range of SNR is 0*dB* to 20*dB*. It can be seen that, obtain almost the same capacity performance as the optimal selection method. While the NBS [4] has a certain losses of channel capacity compared to the optimal algorithm. Table 1 shows the complexity of antenna selection algorithms. It shows that the complexity of NBS selection algorithm is smallest. While the complexity of global and fast antenna selection method [8], the incremental algorithm [6, 7] are smaller than decreasing algorithm [5].

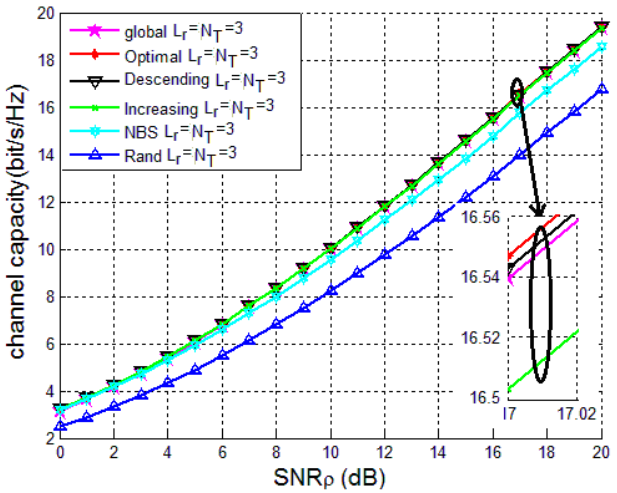

FIGURE 4 The channel capacity versus SNR

TABLE 1 Comparison of computational complexity for AS algorithms

Descending [5]	Increasing [6]	Global [8]	NBS [4]
$N_R^2 N_T^2$	$max\{N_T,N_R\}N_T L_r$	$N_R N_T^2$	$N_R N_T$

4.2 TRANSMIT ANTENNAS SELECTION

In the same way, transmit antenna selection (TAS) performs to select the optimal transmit antenna subset at the MIMO transmitter employing full or partial channel state information (CSI). However, TAS implementation is more difficult

than RAS. This is because TAS MIMO systems need a dedicated feedback channel to feed the CSI from the channel estimator unit at the MIMO receiver. In order to ensure performance of TAS system, known perfect CSI at the transmitter is very important. In practical scenario, the wireless channel is random variation, achieving perfect CSI is very complicated. Therefore, it is inevitable to receive a small fraction of the error CSI. Effect of imperfect CSI on the channel capacity of the MIMO systems with TAS is obvious. Like the RAS systems, compared to without TAS, the capacity performance of MIMO systems with TAS will be greatly improved [20].

4.3 JOINT TRANSMIT AND RECEIVE ANTENNA SELECTION

Figure 1 shows the MIMO system equips with N_T transmit antennas and N_R received antennas. There are L_t and L_r RF chains at the receiver and transmitter, respectively. Assuming all N_T transmit antennas and N_R receives antennas are selected. The object is to select the best L_r out of N_R antennas at the receive side and the best L_t out of N_T antennas at the transmit side so that the resulting system capacity is maximized. The channel matrix H is an $N_R \times N_T$ complex valued matrix. The ideal antenna selection technique chooses $\tilde{H}$ (is an $L_r \times L_t$) out of H. The optimal subset selection which can always be obtained by fully searching overall the possible row and column combinations of the channel matrix H. The performance of systems that using the optimal subset selection has much higher than that of the systems using the same number of antennas without any selection. However, the complexity of the optimal algorithm is $C_{N_R}^{Lr} \cdot C_{N_T}^{Lt}$, which may not be feasible. The joint transmit and receive antenna selection algorithm [21] was first proposed to decouple the joint antenna selection problem into separate transmit and receive antenna selection and carried out the exhaustive search. So the algorithm requires computing $C_{N_R}^{Lr} + C_{N_T}^{Lt}$ determinants of size $L_r \times L_t$ sub-matrices for the exhaustive search. In order to select the appropriate subset of antennas, antenna subset selection problems have been intensively studied in the [22-29], a similar decoupling strategy has also been used in the separable transmit/receive successive selection [22]. The selection algorithm adopted the fast incremental successive selection algorithm [7] for both transmit and receive side selection in the decoupled problem. The complexity of this algorithm is $max\{N_T, N_R\}^2 L^2$. It results in the huge complexity reduction compared to the algorithm [21]. But, it has a loss of performance compared to the optimal selection.

Although the decoupling-based strategies can reduce the computational burden of the problem of joint transmit and receive antenna selection, the complexity of this decoupling-based strategies is still large. To reduce the computational complexity, the successive joint transmit and receive antenna selection algorithm is proposed in [23-26]. The algorithms start with the empty set of selected antennas and add one pair of antenna per step to this set. At each step, the objective is to select one pair of antenna, which leads to the highest contribution to the system capacity. The joint transmit and receive selection strategies by exploiting stochastic optimization algorithms such as the genetic algorithm [27, 28] or particle swarm optimization [29] have also been investigated to find the subset of the antenna to achieve maximum instantaneous channel capacity. It is assumed that $N_T = N_R = N$. Then, the complexity of CJAS [25] is $N^2L^3/2$. It is large when the number of the selected antennas is more than $N/2$. A novel joint transmit and receive antenna selection algorithms is proposed. It is calculating the capacity reduce instead of the whole subsystem capacity when selecting a new candidate pair of antenna at each step. In each step, our objective is to select one pair of antenna, which leads to the lowest contribution of the capacity. The complexity of the proposed algorithm is $3\times N^4/4 - 3\times (N-L)^4/4$. Table 2 shows the complexity of three antenna selection algorithms, we can find that the computational complexity of the proposed antenna selection algorithm is far less than the optimal antenna selection algorithm. When the number of selected antennas is more than $N/2$, the complexity of the proposed algorithm is less than CJAS [25]. So it is suitable for more number of selected antennas.

TABLE 2 The complexity comparison for transmit and receive antenna selection algorithms

algorithm	**complexity**	***N*=8, *L*=2**	***N*=8, *L*=3**	***N*=8, *L*=4**	***N*=8, *L*=5**	***N*=8, *L*=6**
optimal algorithm	$C_N^L C_N^L L^3$	6272	84672	313600	392000	169344
proposed algorithm	$\frac{3}{4}N^4 - \frac{3}{4}(N-L)^4$	2100	2603	2880	3011	3060
CJAS	$\boldsymbol{N^2L^3/2}$	256	864	2048	4000	6912

5 Results and discussion

In this section, we consider the MIMO AS systems channel model as mentioned before, the elements of H are represented by independent complex Gaussian random variables with zero mean and unit variance. The simulation results will be vastly presented to compare the proposed algorithm with other joint transmit/receive AS algorithms, such as optimum selection (OS), NBS, and CJAS [25]. In order to illustrate more clearly the performance of the proposed algorithms and other AS approaches, we will plot a large number of graphs to describe the channel capacity and the cumulative distribution function (CDF), they are the curves of channel capacity as a function of SNR and different selected antenna numbers, and CDF as a function of channel capacity and SNR. These curves are plotted by computer Monte

Carlo simulation using a certain random number data (e.g., 1000, or 2000).

Figure 5 shows the comparison results of five algorithms with L_r=L_t =2, N_T=N_R=5, and the value range of SNR is 0*dB* to 20*dB*. In order to get these curves, in the two figures at each value of SNR, we average statistically to 1000 simulating values. It can be observed that the performance of our proposed algorithm is better than CJAS [25]. The figure also indicates that the proposed algorithm has almost the same performance with optimum AS. The reason is that our proposed algorithm removes the antenna serial number, which leads to the smallest contribution of channel capacity and yields a negligible lossed to channel capacity, compared to the optimal selection. Figures 5 and 6 show that the more number of selected antennas at the transmitter and receiver, the greater channel capacity of MIMO systems. This is because MIMO wireless systems have the potential for increased capacity in rich multipath environments.

Figures 7 and 8 show the CDF curves as a function of system channel capacity for the case of SNR = 8*dB* and 20*dB* with L_r=L_t=3, N_T=N_R=7. It can be observed that our algorithm also obtains closer curve to the optimal one with higher SNR. From the simulation results we can observe that our proposed algorithm perform better performance of channel capacity than CJAS [25], in addition, it can reduce computational cost significantly compared with OS scheme. So our proposed algorithm is an effective method, at the same time, it has multiple antenna diversity advantage.

6 Conclusions

This paper presents an overview of antenna selection in MIMO systems. It focused on the spatial diversity and spatial multiplexing system. It shows that AS can reduce system implementation complexity and hardware cost, and achieve full diversity gain, and enhance the channel capacity and transfer rates. A novel joint transmit and receive antenna selection algorithm is presented in this paper. Our proposed algorithm is suitable for more number of selected antennas. Computer simulations show that the proposed algorithm can achieve near optimal channel capacity performance, while the overall complexity of the proposed algorithm is signifycantly lower than that of the optimal exhaustive search. However, there are still several problems in antenna selection, such as the problem of sub-optimal joint transmit and receive AS algorithm is still worth researching. How to evaluate performance of AS algorithms when there is a delay of feedback channel state information. At present, antenna subset selection problems have been intensively studied in Rayleigh fading channels, and Nakagami fading channels still needs more research.

Abstract

Starting from the analysis of the measuring principle of atmospheric pressure altitude and the necessity of the pressure sensor temperature compensation, this paper presents the design and realization of an atmospheric pressure altitude measuring system with high performance which use FPGA as the data processor and with the pressure sensor temperature compensation design. Article discusses in detail the hardware circuit design of the measuring system, and the internal structure of FPGA software design. At last, the results of system test verify the feasibility and effectiveness of the atmospheric pressure altitude measuring system. Because of the FPGA's characteristics of high reliability, strong data processing ability, high speed and so on, and the effective combination of temperature compensation design, the atmospheric pressure altitude measuring system has the advantages of high measuring precision, high reliability, good real-time and low power consumption.

Keywords: atmospheric pressure altitude, FPGA, temperature compensation algorithm, measuring system

1 Introduction

Atmospheric pressure altitude data is an important flight parameters of aircraft, it can guarantee the safety of the flight and ensure the ground command and control personnel to properly guide the flight to complete mission. The development of modern microelectronics technology and computer technology greatly promotes the development of aviation testing technology, and makes the development of aviation testing equipment to high precision, strong anti-interference, small size, and low power consumption [1].

The FPGA (Field Programmable Gate Array) is a programmable processor, it has strong data processing ability, high reliability, high speed, flexible design, intelligent development tools advantages etc, and it is more and more popular in the field of high-speed hardware electronic circuit design [2]. With the characteristics of FPGA, this paper introduces the design and implementation of a kind of high precision and real-time pressure measuring system with pressure sensor temperature compensation method.

2 Measuring principle of atmospheric pressure altitude

According to international standard ISO25332, which was developed by the international organization for standardization, we can get the relation formula between the geopotential altitude H (often referred to as the standard atmospheric pressure altitude) and the atmospheric pressure PH in 2000m to 80000m altitude range, and this relationship is shown in Equation (1):

$$H = \frac{T_b}{\beta}\left[\left(\frac{P_H}{P_b}\right)^{-\beta R/g_n} - 1\right] + H_b. \quad (1)$$

In Equation (1), *R* is the air special gas constant and the value is $287.05287\,m^2/\left(K\cdot s^2\right)$, g_n, is the free fall acceleration of gravity and the value is $9.80665\left(m/s^2\right)$, β is the rate of vertical temperature change and the value is dT/dH; T_b, H_b and P_b are the lower limiting value of atmospheric temperature, standard atmospheric pressure altitude and atmospheric pressure in the corresponding altitude range that are used by international standard atmosphere [1], and their values are shown in Table 1.

TABLE 1 Atmospheric temperature, temperature gradient and altitude stratified

standard atmospheric pressure altitude H_b(km)	temperature T_b(K)	vertical temperature change β(K·km^{-1})	atmospheric pressure P_b(Pa)
-2.00	301.15	-6.50	127 774
0.00	288.15	-6.50	101 325
11.00	216.65	0.00	22 632

Making these parameters what are in Table 1 into the Equation (1), we can obtain the single value functions of atmospheric pressure and atmospheric pressure altitude in different altitude stratified [3], and these functions are shown in Equation (2) and Equation (3).

In the range of -2000 to 0m altitude

$$H = -46330.8\left[\left(\frac{P_H}{127774}\right)^{0.190263102} - 1\right] - 2000. \quad (2)$$

***Corresponding author** e-mail: paul-2308@hotmail.com

In the range of 0 to 11000m altitude

$$H = -44330.8\left[\left(\frac{P_H}{101325}\right)^{0.190263102} - 1\right]. \quad (3)$$

3 Error analysis and compensation design

3.1 ERROR ANALYSIS

Piezoresistive pressure sensor is one of the most widely used sensors, but because the sensitivity of the semiconductor physics properties on temperature, the output of piezoresistive pressure sensor used in this measuring system will not only change with pressure but also change with the temperature. This phenomenon leads to the accuracy of the whole measuring system is reduced greatly, so a kind of software temperature compensation method for error correction used in FPGA processor is adopted to improve the accuracy of measuring system.

The idea of the temperature compensation method is to adjust the output values of pressure sensor at different environmental temperature to the output values at 25°C. The linear relationship between input p and output U of the pressure sensor at 25°C and t°C are shown in Equation (4) and Equation (5).

$$U_0 = a_0 + b_0 \times p, \quad (4)$$

$$U_t = a_t + b_t \times p, \quad (5)$$

a0, at, b0 and bt in Equation (4) and Equation (5) are zero position and sensitivity coefficient at normal temperature 25°C and t°C.

The output of pressure sensor with temperature compensation at t°C can be obtained by making the Equation (5) into the Equation (4) and it is shown in Equation (6).

$$U_t' = a_0 + \left(\frac{U_t - a_t}{b_t}\right) \times b_0. \quad (6)$$

System testing selects six groups of different atmospheric pressure value provided by the pressure pump for pressure sensor and six groups of different temperature value provided by high and low test temperature box for temperature sensor, the output values of pressure sensor without temperature compensation at different temperatures and pressures are shown in Table 2.

TABLE 2 Pressure sensor output values without compensation

Pressure/p_a	The output voltage/mV					
	-40°C	*-20°C*	*0°C*	*25°C*	*50°C*	*60°C*
49154.5	39.207	38.892	38.300	38.186	38.048	38.009
57728.3	46.023	45.661	44.975	44.849	44.688	44.645
67474.9	53.752	53.337	52.551	52.404	52.221	52.169
78513.1	62.526	62.049	61.146	60.981	60.771	60.711
90970.1	72.396	71.852	70.822	70.629	70.390	70.320
104981.0	83.529	82.908	81.727	81.512	81.238	81.158

It is obvious from Table 2 that the change magnitude of the pressure sensor output varies with temperature under the same pressure is large, and the maximum change amount under constant pressure output is 2.017 mV, to result in the decrease of sensor accuracy significantly [4].

3.2 COMPENSATION ALGORITHM DESIGN.

According to non-compensated pressure sensor data in Table 2, the linear relationship between the output *Ut* and the input pressure *p* of the sensor can be gotten by the linear interpolation algorithm using MATLAB software at different temperature, and these linear relationships are shown in Table 3.

TABLE 3 The relationships between input and output of sensor

Temperature	The linear relationship between sensor output and pressure
-40°C	$U_t = 0.19435 + 7.9379 \times 10^{-4} \times p$
-20°C	$U_t = 0.14724 + 7.8832 \times 10^{-4} \times p$
0°C	$U_t = 0.07012 + 7.7782 \times 10^{-4} \times p$
25°C	$U_0 = 0.04876 + 7.7596 \times 10^{-4} \times p$
50°C	$U_t = 0.02914 + 7.7354 \times 10^{-4} \times p$
60°C	$U_t = 0.02867 + 7.7278 \times 10^{-4} \times p$

According to the linear relationships between the output U_t and the input p of the pressure sensor at different temperature. The zero point data and sensitivity coefficient data of the pressure sensor at different temperature can be gotten, and then to use quadratic curve fitting formula with these data by MATLAB software to get zero point Equation (7) and sensitivity coefficient Equation (8).

$$a_t = 0.07143 - 2.17494 \cdot 10^{-3} \cdot t + 2.56347 \cdot 10^{-5} \cdot t^2 \quad (7)$$

$$b_t = 7.80122 - 2.6002 \cdot 710^{-3} \cdot t + 2.40446 \cdot 10^{-5} \cdot t^2 \quad (8)$$

Finally, the temperature compensation algorithm, which is shown in Equation (9), can be obtained by making the Equation (7) an Equation (8) into the Equation (6).

$$U_t' = 0.0487 + \frac{10000U_t - 0.256347t^2 + 21.7494t - 7143}{2.40446t^2 - 260.027t + 780122.0} \cdot 77.596 \quad (9)$$

4 Circuit design of measuring system

The circuit design of atmospheric pressure measuring system mainly consists of pressure sensor, temperature sensor, signal adjusting circuit, dual-channel A/D converter and FPGA processor, its working principle block diagram is shown in Figure 1.

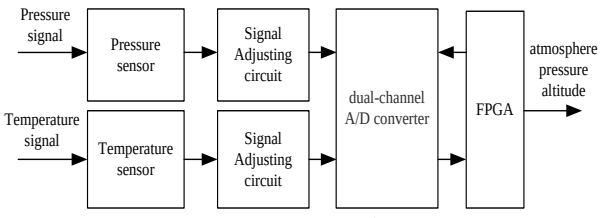

FIGURE 1 Principle diagram of system circuit

The output voltage signals of the pressure sensor and temperature sensor will be transmitted to the A/D converter through signal amplification, filtering and zero regulation of

the signal regulation circuit. Then the A/D converter will convert pressure and temperature analog signals into digital pressure value and temperature value, finally the FPGA processor will read the digital pressure and temperature value from the A/D converter, and output the atmospheric pressure altitude value by the calculation of the temperature compensation algorithm and atmospheric pressure altitude formula [5, 6].

4.1 SENSOR CIRCUIT

The pressure sensor used in this measuring system circuit is an absolute pressure sensors of NPC-1210-015A type made by GE NovaSensor company, it has the measuring range of 0Pa to 103425Pa, and the output voltage of the pressure sensor is in the range of 38.009 mV to 83.529 mV when the pressure sensor is tested in the pressure range of 49154.5Pa to 104981Pa.

The temperature sensor is AD590 made by AD Company, its measuring temperature range is the range of 55°C to150°C and the temperature coefficient is 1uA/K. The output current of the temperature sensor is in the range of 233.2uA to 333.2uA when the temperature sensor is tested in the temperature range of -40°C to 60°C If the output circuit of the temperature sensor connects an external 10k resistor, the sensor output voltage is the range of 2.332V to 3.332V.

4.2 SIGNAL ADJUSTING CIRCUIT

The signal adjusting circuit of the measuring system mainly completes the work of signal amplification, filtering and zero regulation of the sensor's output analog voltage signal.

The amplifier circuit is designed by AD620 made by AD Company which is low power consumption, low noise and high precision instrumentation, its use is very convenient that just connect a resistance R_G between pins 1 and pins 8 on a chip to adjust the amplification factor of amplifier, the Equation of amplification factor is shown in Equation (10).

$$G=49.4\ k\Omega/R_G+1. \quad (10)$$

Due to the reference voltage of the A/D converter is set to 1v, so the sensor output voltage range need to adjust the sensor voltage range of 0v to 1v, the value of resistance R_G can be calculated by Equation (10), the R_G resistance selection of 2.355kΩ resistance, magnification is about 21.968 times. In order to get more accurate output voltage range, one trimming resistor can be connected in parallel with R_G resistance.

Zeroing circuit in the system is implemented by anti-adder that is constituted by MAXIM OP07 operational amplifier. The role of zeroing circuit is to adjust the output voltage signal of pressure sensor and temperature sensor what are amplified to the 0 to 1V range in system testing scope [7, 8].

4.3 A/D CONVERTER

A/D converter used in the system circuit is AD7705 made by AD Company; it is a 16-bit dual-channel Sigma - Delta converter with 500Hz maximum sampling frequency and a three line serial communication port. AD7705 can work on two voltage range of 2.7V to 3.3V and 3.3V to 5.25V, in order to match with the working voltage of FPGA chip, the design choose 3V working voltage, and the reference voltage of AD7705 is VREF - 0V and VREF +1V.

The working status of AD7705 is set mainly by its 4 internal function registers which are communication registers, setting registers, clock registers and data registers. The communication register is used to select the register type will be working, the setting registers is used to set the AD7705 operating polarity and buffers, the clock register is used to select the AD7705 operating the master clock frequency and the sampling frequency, the data register is used to store finished converting 16 bit binary data, read these features and conversion data register settings are done through the FPGA control [3]. The connection diagram of AD7705 and FPGA chip is shown in Figure 2.

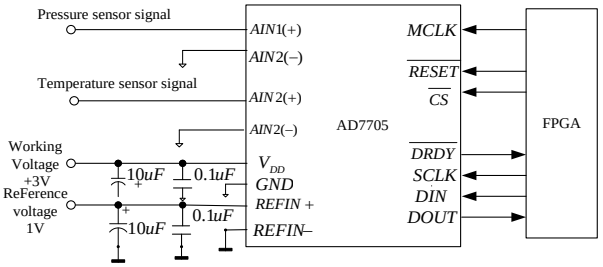

FIGURE 2 Connection diagram of AD7705

4.4 FPGA CIRCUIT

The type of the FPGA chip used in measuring system is Strax EP1S25F780C5 processor made by Altera Company, with an external crystal oscillator of 80MHz. FPGA is a core part of system control and data processing, to complete the work of reading the data from the A/D converter, implementing temperature compensation algorithm and calculating atmosphere pressure altitude.

5 Design of FPGA processor

The FPGA processor is designed by VHDL hardware description language using the QuartusII integrated development environment, the function structure of FPGA includes frequency dividing module, data reading and writing module, compensation calculating module and altitude calculating module.

5.1 FREQUENCY DIVIDING MODULE

The frequency dividing module plays a role of providing the clock signals that are required in FPGA control, A/D converter working and the serial port communication from main

clock signal, which is 80MHz. The internal structure of the frequency dividing module is shown in Figure 3.

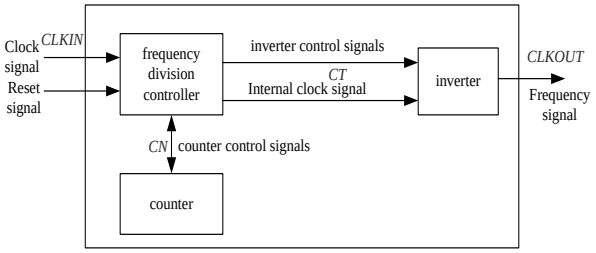

FIGURE 3 Inside block diagram of the frequency dividing module

As the system resets, the frequency division controller clears the counter through counter control signal *CN*, and then the counter starts counting according to the Rising edge of master clock *CLKIN* signal. When the counter reaches the frequency counts, a reverser control signal *CT* is sent to reverser by frequency division controller, and make the output clock signal *CLKOUT* reverse, at the same time counter will reset, so repeatedly.

5.2 DATA READING AND WRITING MODULE

Data reading and writing module mainly controls the working status of the A/D converter through the $\overline{CS}$ and $\overline{RESET}$ pins of AD7705, and sets the running status of A/D converter through the serial communication port, and ensures the FPGA reading the converted digital pressure value and temperature value fast and accurately. The internal structure of data reading and writing module is shown in Figure 4.

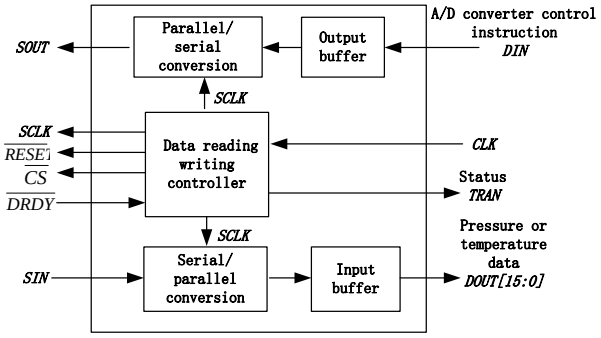

FIGURE 4 Inside block diagram of data reading and writing module

After the system resets, data reading and writing controller makes the A/D converter into working status through setting the $\overline{CS}$ and $\overline{RESET}$ signals, sends the operating status register command which has made parallel/serial conversion to A/D converter. Then monitors the status of pin *DRDY* in A/D converter, when *DRDY* status is valid, data can be read from the data register of A/D converter, and converts the serial data into parallel data [9].

5.3 COMPENSATION CALCULATING MODULE

Compensation calculating module is used to calculate the digital pressure value compensated according to the pressure sensor temperature compensation algorithm. The internal structure of compensation calculating module is shown in Figure 5.

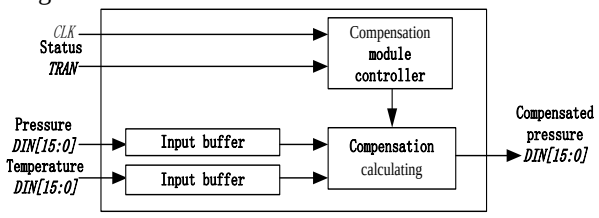

FIGURE 5 Inside block diagram of compensation calculating module

Calculating module controller monitors the value of *TRAN* at the trigger edge of the clock *CLK*, and reads pressure and temperature data when the value of *TRAN* is valid and calculates the pressure value with the temperature compensation algorithm.

5.4 ALTITUDE CALCULATING MODULE

The function of altitude calculating module is to calculate the atmospheric pressure altitude value according to the Equation (2) and Equation (3). In order to simplify the calculation for improving calculating efficiency, the linear interpolation method is adopted to make approximate treatment for atmospheric pressure altitude Equation. According to the error formula of the linear interpolation method, which is shown in Equation (11), and the precision requirements of the system design, we can calculate the maximum step length of the interpolation and the minimum interpolation section number in measuring range.

$$|R(x)| = \left|\frac{f''(\delta)}{(2)!}\omega(x)\right| \leq \delta. \tag{11}$$

At each interpolation interval, we can use Equation (12) to make approximate calculation, and the interpolation parameters y_i, k_i, x_i in Equation (12) can be calculated in advance and stored in memory.

$$y = y_i + k_i(x - x_i). \tag{12}$$

The internal structure of altitude calculating module is shown in Figure 6.

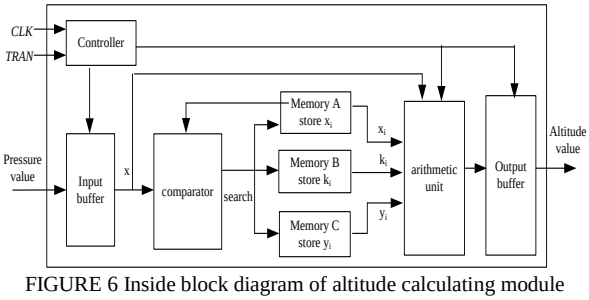

FIGURE 6 Inside block diagram of altitude calculating module

When TRAN value is valid, the controller will read the pressure value, which is compensated into input buffer. First of all, by comparing the pressure value decide the interpolation interval, and then the corresponding interpolation parameters can be got from the FPGA memory, finally to calculate the atmospheric pressure altitude value according

to the Equation (10). In order to improve the search efficiency and the computational efficiency, the binary search algorithm can be adopted when to search interpolation interval.

6 FPGA simulation and system testing

6.1 FPGA SIMULATION

After accomplishing program edit of FPGA using VHDL language, the functional simulation can be performed by Modelsim SE 6.0 software to verify the circuit function whether to meet the design requirements. The functional simulation picture of data reading and writing module is shown in Figure 7.

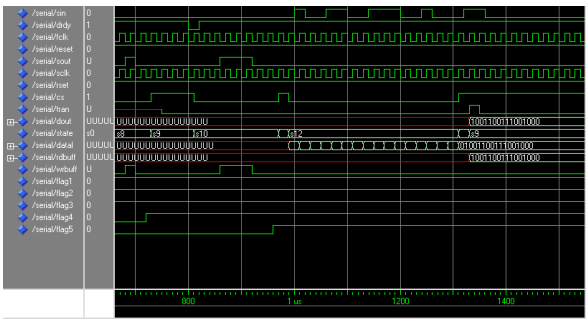

FIGURE 7 Functional simulation map of data read module

If every functional simulation of the FPGA's functional blocks is correct, the integrated design can be performed by QuartusII software to get the connection diagram of the basic logic units. The logic connection diagram of compensation algorithm is shown in Figure 8.

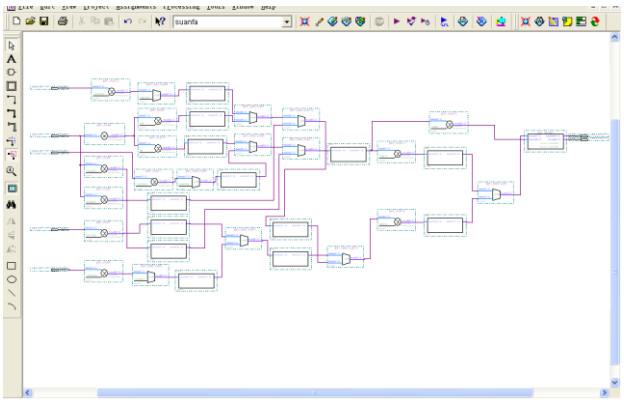

FIGURE 8 Logical connection diagram of compensation algorithm

FPGA's timing simulation is implemented after the completion of the placement and routing design in the FPGA, this kind of simulation contains the most comprehensive and accurate delay information, and reflect effectively the actual working state of the FPGA chip [10, 11]. The simulation diagram of compensation algorithm is shown in Figure 9.

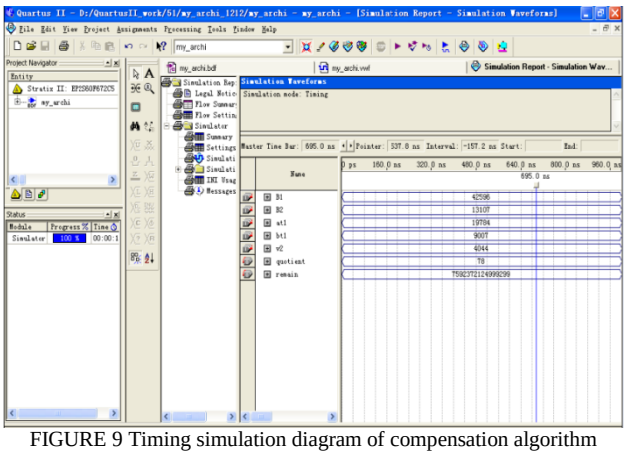

FIGURE 9 Timing simulation diagram of compensation algorithm

6.2 SYSTEM TESTING

After the FPGA simulation, the configuration file generated by source code program can be downloaded to the FPGA chip, and then connect FPGA chip to the whole measuring system. The measuring system is tested with the six groups of atmospheric pressure and three kinds of temperature, and the results of testing are shown in Table 4.

Table 4 The results of measuring system with compensation

atmospheric pressure (p_a)	theory altitude (m)	measuring altitude (m)		
		-20°C	*25°C*	*50°C*
49154.5	5700	5701.6	5700	5700.7
57728.3	4500	4497.9	4498.8	4501.1
67474.9	3300	3300.7	3300.5	3301.8
78513.1	2100	2097.7	2098.6	2102.6
90970.1	900	897.8	898.9	900.9
104981.0	-300	-297.5	-299.4	-298.6

As can be seen from Table 4, the maximum error of measuring system tested at different atmospheric pressure and temperature is 2.6m, and it is proven that this measuring system has the very high precision. Factors lead to error are the following:

1) Calculation error of FPGA data calculation.

2) The precision of reference voltage used in A/D converter.

3) Inherent quantization error of A/D converter.

4) External error of system test, such as the accuracy of the test equipment, human error, etc.

7 Conclusions

In this paper, a kind of atmospheric pressure measuring system is designed and implemented with temperature compensation design based on FPGA processor. Because FPGA has the advantageous characteristics of high reliability, high speed, strong processing capacity, small volume, low power consumption and so on, so this measuring system has a better performance in terms of stability, real-time, power consumption and so on, and the data processing time is only about 9us. The combination with the temperature compensation design in system also improves greatly the precision of the measuring system on the whole.

Abstract

The frequency response and energy conversion efficiency are the critical issue for vibration energy harvester. In this paper, a vibration energy harvester with suspended piezoelectric beam is proposed. This harvester structure is composed of a discrete support beam in the bottom and a suspended piezoelectric beam on top. This suspended beam structure is beneficial to the higher response frequency and the energy conversion efficiency by applying the tension on the shear mode piezoelectric layer. An analytical bending model of suspended piezoelectric beam is developed, based on the actual deformation: rotational and translational movement modes. The characteristic of suspended piezoelectric beam is also analyzed by Finite element method. Finally, a 1000:1 prototype is fabricated and measured. The optimums acquired experiment results show that it is matching well with the model. The maximum of output voltage is 6.5 V.

Keywords: energy harvester, vibration, suspended piezoelectric beam, piezoelectric layer

1 Introduction

Energy harvester is the device, which can convert environment energy, such as vibration, temperature, solar energy, etc., into useful electrical energy [1-6]. And with the development of NMES/MEMS technology, and wireless network sensors, the micro-scale energy harvester can generate electric energy at milli watt level. At the same time, the power consumption of wireless sensors drastically reduced to milliwatt and even nanowatt level. Thus, the micro-scale energy harvester is popular to power sources. Among the different energy forms, the vibration energy is a good choice due to its widespread existence. The vibration harvester can harvest vibration energy via different materials and structure [7-11]. And among different structure of vibration energy harvesters, the cantilever-mass structure is regarded as a promising structure due to the small size, little power consumption, low cost, and compatibility with integrated circuits [12-16].

However, the lower energy efficiency and lower response frequency limit the cantilever-mass energy harvester further application. To resolve these problems, several approaches were chose.

Firstly, selecting suitable material such as PZT, PMNT, and PDVF, etc. is a useful method to enhance efficiency [17].

Secondly, increasing the thickness of the piezoelectric layer is also a good choice since the normal strain experienced by the piezoelectric layer is proportional to its thickness [18, 19].

Thirdly, using the proper coupling mode of piezoelectric material is also worth considering, since the different coupling mode relate to the different electrode pattern [20]. Finally, choosing novel configuration such as tapered cantilever beam, L-shaped beam and so on can affect the frequency of harvester [21-24].

This paper reports an energy harvester with suspended piezoelectric beam for d31 mode. The cantilever structure is composed of a discrete support beam in the bottom and a piezoelectric beam on top. And a gap is forming between the top beam and the bottom beam. The electrode mode is selected as d31 mode based on the distribution of strain. To achieve more accurate analysis, the frequency formula of the suspended piezoelectric beam is derived, considering the two actual deformation modes. Furthermore, it also discussed how the geometrical parameters of suspended piezoelectric beam affect harvester's performance. This model is verified by a prototype and experiments afterwards.

2 Modeling analyses

The conventional mass-cantilever structure is shown in Figure 1, it consists of three parts, the piezoelectric layer, the support layer and the proof mass. And the piezoelectric layer is often attached on the support layer.

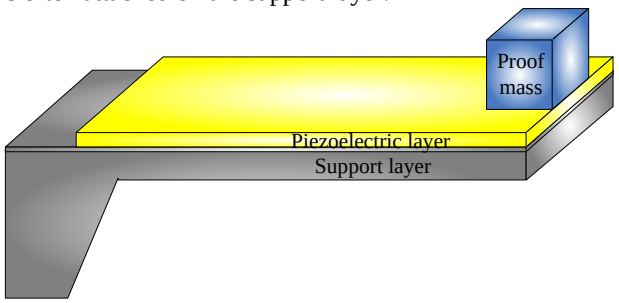

FIGURE 1 Conventional cantilever structure

[*]***Corresponding author*** e-mail: chiucj@hlju.edu.cn

Different from conventional mass-cantilever structure, the suspended piezoelectric beam energy harvester is constructed as Figure 2.

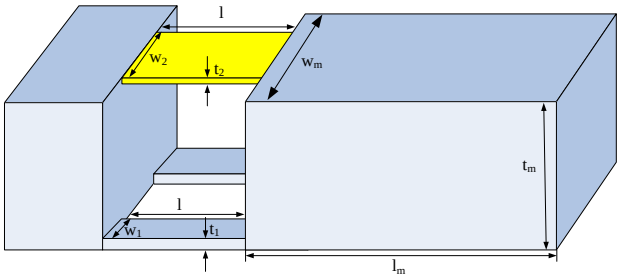

FIGURE 2 Structure of energy harvester with suspended piezoelectric beam

And the piezoelectric material operates in the d_{31} mode to enhance the output charge. The energy harvester is composed of a discrete support bottom beam and a piezoelectric top beam, so the gap structure exists between the top beam and bottom beam. And the discrete support bottom beam is composed of two small parallel beams, the geometric dimension of two parallel beams is same. The dimensions (width × thickness × length) of the bottom support beams, the piezoelectric top beam, and proof mass are $2\times w_1\times t_1\times l$, $w_2\times t_2\times l$, and $w_m\times t_m\times l_m$, respectively.

Cross-sectional view of suspended piezoelectric beam energy harvester is shown in Figure 3.

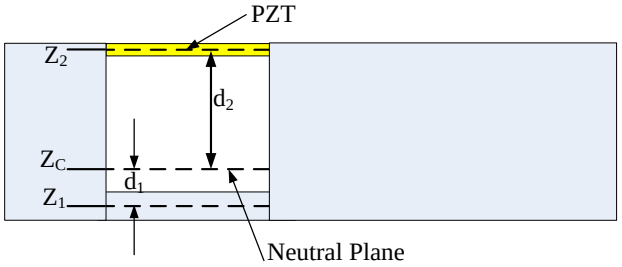

FIGURE 3 Cross-sectional view of energy harvester with suspended piezoelectric beam

Z_1 and Z_2 are the middle planes coordinates of the bottom and top beams respectively, and Z_C is the coordinate of neutral plane. In mechanics, the neutral plane is a conceptual plane where the stress is zero. When an inertial force is applied, the cantilever bends so that one surface of cantilever is in compression and the other surface of that is in tension. d_1 is the distance between the Z_1 and Z_C, d_2 is the distance between the Z_C and Z_2. Accordingly, the neutral plane coordinate Z_C of suspended piezoelectric beam can be expressed as:

$$Z_c = \frac{E_1A_1Z_1 + E_2A_2Z_2}{E_1A_1 + E_2A_2}. \tag{1}$$

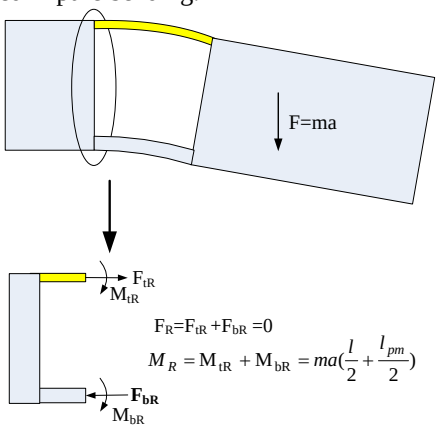
E_1, E_2, A_1 and A_2 are respectively defined as the Young modulus and cross-sectional area of bottom beam and top beam. A_1 is equal to the product of width $w1$ and thickness t_1 of bottom beam. A_2 is the product of width w_2 and thickness t_2 of top beam. Thus, the formulations of d_1 and d_2 can be expressed as:

$$\begin{cases} d_1 = \dfrac{E_2A_2(Z_2 - Z_1)}{E_1A_1 + E_2A_2} \\ d_2 = \dfrac{E_1A_1(Z_2 - Z_1)}{E_1A_1 + E_2A_2} \end{cases}. \tag{2}$$

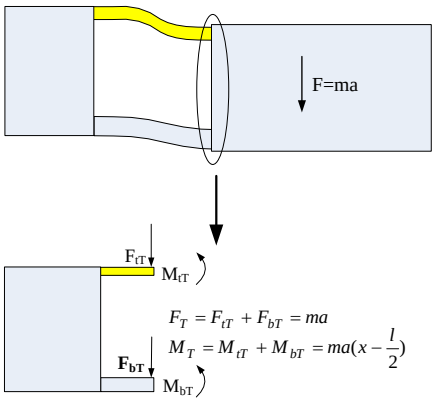
Since the thickness of PZT film prepared by Sol-Gel is generally less than 4 um, and then the bottom should be thick enough to support the big proof mass. As a result, the location of neutral plane will be shift down to close to the bottom beam. From the Equation (2) and Figure 3, the distance d_2 can approximately equal to the gap distance when considering the thickness of top beam and bottom beam.

Next the analysis model is discussed. The Euler-Bernoulli beam theory based on Kirchhoff's assumption is not accurate for the suspended beam structure. Therefore, it is necessary to establish a new model to describe this structure. In practice, we can observe two deformation modes: rotational movement and translational movement, shown in Figure 4. In our analysis, the beam's mass and the proof mass deformation are ignored.

For the rotational movement, the bending moments M of beam is constant and the shear force of beam is zero. Thus, the deformation of suspended piezoelectric beam can be considered in pure bending.



a) Rotational movement mode



b) Translational movement mode

FIGURE 4 Two movement modes

From the theorem of multilayer structure cantilever, rotary inertia of parallel axis is obtained by $I_R = I_i + A_i(d_i)^2$.

The bending rigidities of rotational movement can be expressed as:

$$(EI)_R = E_1 I_b + E_2 I_t + E_1 A_1 d_1^2 + E_2 A_2 d_2^2 . \quad (3)$$

For the translational movement, the mass remains in horizontal direction after deforming, this means the bending moment is a linear function of the horizontal position and the bending moment at the middle of the beam is zero, the shear force is constant. The bending rigidity of translational movement is $(EI)_T = E_1 I_b + E_2 I_t$.

Thus, the total bending rigidities of suspended piezoelectric beam is:

$$(EI)_Z = \frac{4(EI)_R}{[3\gamma^2 + \mu]}, \quad (4)$$

where $\gamma = \frac{l + l_{pm}}{l}$, $\mu = \frac{(EI)_R}{(EI)_T}$.

Finally, the resonant frequency of vibration energy harvester with suspended piezoelectric beam can be expressed as:

$$f = \frac{\pi}{11.24}\sqrt{\frac{(EI)_R}{ml^3(3\gamma^2 + \mu)}} . \quad (5)$$

Equation (5) describes the length of cantilever and the mass of proof mass as the function of frequency.

From the energy perspective, the piezoelectric layer was expected to store as much stretching energy as possible to transform into the electric energy from the total mechanical energy applied. Thus, the energy conversation efficiency should be discussed. As shown in Figure 4, the force F_{tR} of rotational mode stretch the piezoelectric layer, which means the strain is generated. But the force F_{tT} translational modes don't contribute the strain. As a result, the rotational mode is domain in contributing the strain of whole structure. Thus, the energy of rotational mode is composed of bending energy and normal stretching/compress energy. The value η defined as ratio of stretching energy stored in the top piezoelectric layer to the total mechanical energy, and η can be expressed as:

$$\eta = \frac{E_2 A_2 d_2^2}{(EI)_R} . \quad (6)$$

Finally, the output voltage and charge also can be considered. To generate as much output voltage as possible, the piezoelectric layer should be experience the maximized stretching stress accordingly. But the shear force of translational movement cannot contribute any stretching/compress strain for the top piezoelectric layer. Thus, the mainly electric energy is generated in the rotational movement and the contribution of translational movement can be negligent.

The output voltage and charge under d_{31} mode can be expressed as:

$$\begin{cases} V = \dfrac{F_{tR} \cdot d_{31}}{\varepsilon_{33} \cdot \varepsilon_0 \cdot w_2} \\ Q = -F_{tR} \cdot A_{elec} \cdot d_{31} \end{cases}, \quad (7)$$

where ε_{33} is the dielectric constant, A_{elec} the electrode area [25]. Substituting F_{tR} shown in Figure 4 into Equation (7), the output voltage and charge can be expressed as:

$$\begin{cases} V = \dfrac{ma \cdot (l + l_m) \cdot d_2 \cdot E_2 \cdot A_2 \cdot d_{31}}{2 \cdot (EI)_R \cdot \varepsilon_{33} \cdot \varepsilon_0 \cdot w_2} \\ Q = -\dfrac{ma \cdot (l + l_m) \cdot d_2 \cdot E_2 \cdot A_2^2 \cdot d_{31}}{2 \cdot (EI)_R \cdot \cdot w_2} \end{cases} . \quad (8)$$

3 Optimum design

To obtain the better performance, some parameters of suspended piezoelectric beam structure should be considered, especially in MEMS scale. The Figure 5 shows the relationship between frequency and the cantilever length and the proof mass length. The frequency is range from 1.5 KHz to 308 KHz. And the length of proof mass is from 10 um to 50 um and that of suspended piezoelectric beam of is 1 um to 50 um, respectively.

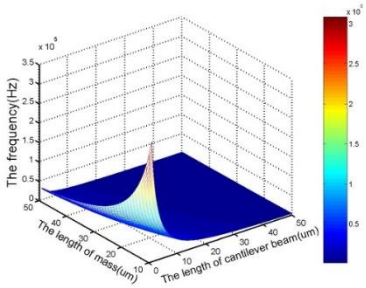


FIGURE 5 The frequency depending on the length of mass and that of cantilever

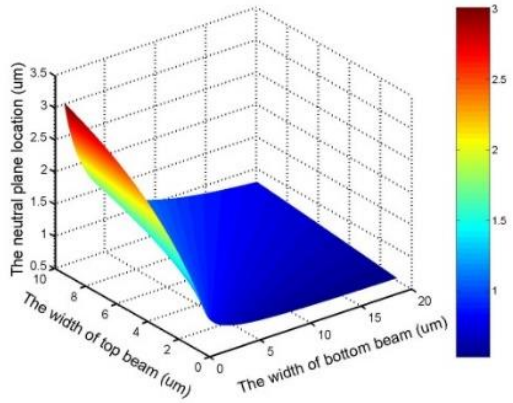
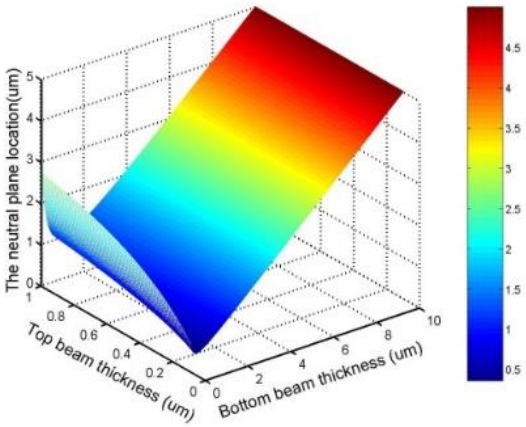
As shown in Figure 5, the smaller length of suspended beam and proof mass can lead to the higher frequency. Giving the width, the thickness, and the density, the length of proof mass can represent the mass. Thus, a conclusion can be derived that the frequency of suspended beam structure is affected the mass of proof mass and the length of suspended beam.

The neutral plane also should be discussed. From Figure 3 and Equation (1), the location of neutral plane is linked with the Young modulus, the width and the thickness of bottom beam and top beam. For conventional cantilever, the neutral plane should be far away the PZT layer, which can generate strong output voltage. This case is suitable for suspended beam structure. The relationship of neutral plane and width of top beam and bottom beams is shown in Figure 6a. The location of neutral plane is distinctly dropped with the decreasing of top width, but there is tiny change to the bottom beam. As shown in Figure 6b, the similar conclusion on the neutral plane and thickness of the top and bottom beams is derived. The thinner top beam generates the lower neutral plane location. But the relationship between the

thickness of bottom beam and neutral plane location isn't the linear function. And the neutral plane location is lowest when the bottom beam thickness is 1 um.



a) The relationship of neutral plane and thickness



b) The relationship of neutral plane and width

FIGURE 6 The parameter relationship: a); b)

Next, the optimum energy conversation efficiency should be considered. The relationship between the width ratio of two beams and energy efficiency is shown in Figure 7. It is obvious that the greater width of top beam can improve efficiency. When the width ratio is approximately equal to 0.5, the optimum efficiency is 87.5%. Similarly, the relationship between different thickness ratio of two beams and efficiency is shown in Figure 8, the optimum thickness ratio is 0.5.

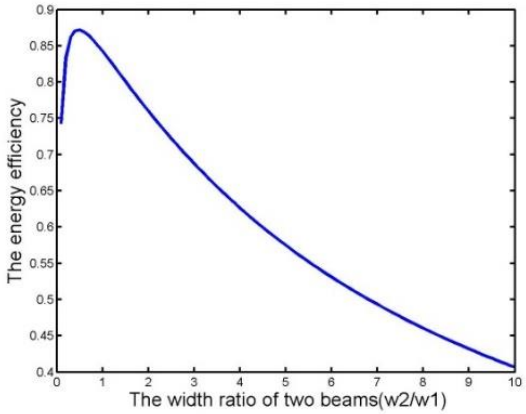


FIGURE 7 Relationship of width ratio and efficiency

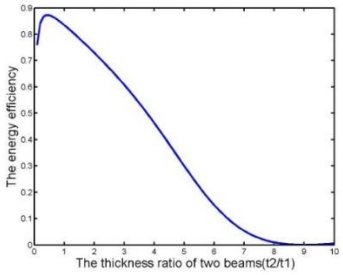

FIGURE 8 Relationship of thickness ratio and efficiency

Finally, the performance comparison of suspended piezoelectric beam structures and conventional structure is given in Table 1 based on Equation (5) and Equation (6). From the Table 1, we can observe that the suspended beam structure has the better performance than the conventional structure. Thus, a conclusion can be derived that the suspended beam helps to improve the resonant frequency and enhance the energy conversation efficiency.

TABLE 1 Comparison of suspended piezoelectric beam and conventional beam (l=8 um, w1=20 um, t1=1 um, w2=10 um, t2=0.5 um, L=40 um, wm=30 um, T=5 um)

	Suspended beam structure	**Conventional structure**
Frequency	372(K Hz)	102(K Hz)
Conversation efficiency	83.4	58.6

4 Measurement

In order to verify the analysis model and simulation results, the millimeters lever prototype is fabricated, and the dimension of prototype is a 1000:1 time than simulation parameter in Table 1.

To obtain the similarly performance compared with the silicon-based device, some candidate material should be considered. The bottom beam and proof mass is fabricated with 45# steel, since its mechanical property is very similar to that of silicon, and its Young modulus is 209 GPa.

The measurement system picture is shown in Figure 9. The device was fixed to a Vibrator (SINOCERA JZK-2), which is used to generate mechanical vibrations. Sinusoidal signals were applied to the vibrator at various frequencies. The voltages from the energy harvesting device were monitored by an Oscilloscope (YOKOGAWA DL850) at the same time, and the non-contact Doppler Vibrometer (Vibroducer V1002) is used to measure the contrastive voltage. The experiment frequency is 376.0 Hz, and the peak output voltage is 25.9 V, shown in Figure 10, which agrees well with the analysis frequency of 372 Hz.

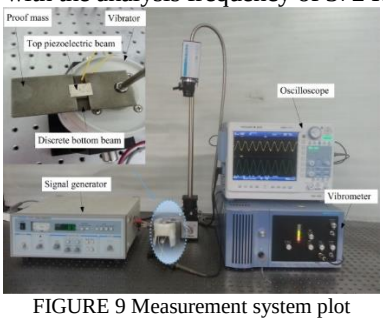

FIGURE 9 Measurement system plot

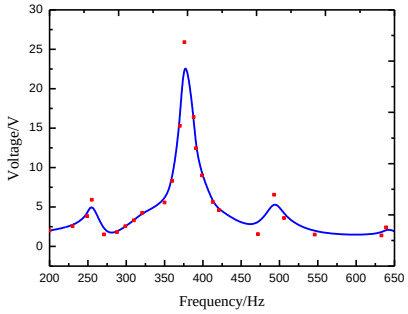

FIGURE 10 Frequency response of the suspended piezoelectric beam

Also, the plot of charging voltage/power is shown in Figure 11, the value of the capacitor was 100 μF. The capacitor voltage collected from the energy harvester is 6.5 V. Providing $E = \frac{1}{2}CV^2$ and $E = P \times t$, the 29.5 μW maximum power is derived.

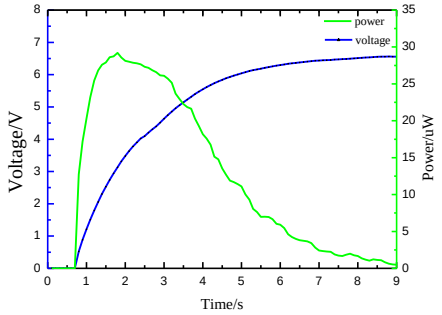

FIGURE 11 Plot charging voltage/power of the capacitor

5 Conclusions

The research on energy harvester with suspended piezoelectric beam, including structure design and optimum, modeling analysis, prototype fabrication and measurement are discussed in this paper. Considering the actual deformation in rotational and translational movement modes, the formulation of resonant frequency of suspended piezoelectric beam is derived. Furthermore, some parameters are considered to optimum the design. Accordingly, the acquired 1000:1 scale prototype is assembled. The prototype can generate the 6.5 V output voltage and 29.5 μW output power. The experiment frequency is 376.0 Hz that match well with 372.0 Hz of calculated frequency.

Compared to conventional cantilever, suspended beam structure can firstly enlarge the response frequency due to the existing gap which is affected the bending rigidities of system. The second advantage of suspended piezoelectric beam is the improvement of energy conversion efficiency by matching heavier mass, which improve output charge by stretching the piezoelectric layer. The finally advantage lies in the technology feasible of device fabrication [26].

Abstract

The electrolytic capacitor is one of the most critical components in the switching power supply, in actual use of the power supply, the ripple is an important factor that leads to failure of the electrolytic capacitor. The research on the ripple's effect on the service life of the electrolytic capacitor is significant to the stability of the switching power supply. This paper designed a controllable circuit generating ripples of different phases, tested the electrolytic capacitors' changes in capacitance with ripples of different phases, analysed the reason of the changes in the capacitance, selected the fastest change, and used three prediction models of support vector regression, radial basis function and kernel-based partial least-squares algorithm to predict the change trends of capacitance of electrolytic capacitor with ripples of this phase. The results showed that compared with radial basis function and support vector regression model kernel-based partial least-squares algorithm can more accurately predict the service life of the electrolytic capacitor.

Keywords: electrolytic capacitor, ripples, different phases, prediction of capacitance, capacitor life

1 Introduction

The electrolytic capacitor is one of the most critical components in the switching power supply, and the service life of the electrolytic capacitor directly determines the service life of the power supply and other electronic devices [1]. In actual use of the power, the ripple is an important factor that leads to failure of the electrolytic capacitor [2]. Ripples of different initial phases reflect different circumstances of electrolytic capacitor failure. In the actual production process, the sampling method is often used to test quality of mass capacitors. In this paper, three prediction models of radial basis function, kernel-based partial least-squares algorithm and support vector regression can be used to test the failure time of mass capacitors to evaluate the applicability of the product. RBF network, that is, radial basis function neural network can approximate any nonlinear function, can handle the difficult regularity within the system, and has good generalization ability as well as quick learning and convergence rate, so it can be well used in the time series analysis in this experiment [3]. KPLS introduces RBF as a kernel function into partial least-squares regression, maps through the kernel function the input data into high-dimensional characteristic space, and then operates in the space, so that the nonlinear relationship between input and output variables can be established [4]. In SVR, RBF is used as the kernel function instead of the linear term in the linear equation, so that the non-linear regression can be achieved. At the same time, the kernel function is introduced to achieve the purposes of dimension rising, and increased adjustable parameters make the over-fitting still in control [5].

2 Experiment principle

2.1 EQUIVALENT FIGURE OF ELECTROLYTIC CAPACITOR

Figure 1 is the equivalent figure of electrolytic capacitor [6].

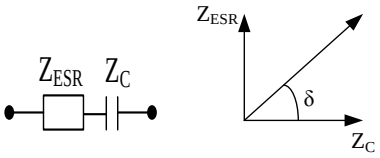

FIGURE 1 Series equivalent circuit and vector diagram

Where, Z_{ESR} is impedance of the equivalent series resistance ESR, Z_C is capacitance value of the electrolytic capacitor, and δ is the loss angle.

2.2 LOSS FACTOR OF ELECTROLYTIC CAPACITOR

Loss factor, i.e., the loss tangent, is defined as the ratio of ESR and capacitive impedance, as shown in the following Equation (1):

$$D = \tan\delta \times 100\% = \frac{ESR}{\frac{1}{\omega \times C}} = \frac{ESR}{\frac{1}{2\pi f \times C}} = 2\pi f \times ESR . \quad (1)$$

3 Experimental method and design

The experiment was carried out at room temperature. Due to room temperature for general projects, it was difficult to

* ***Corresponding author*** e-mail: chenxj@wzu.edu.cn

control the temperature. The experiment lasted one hour. The experimental subject was JAKEC electrolytic capacitor, +105°, 50V withstand voltage, 47uF. The experimental instruments used were YD2817 broadband LCR meter (to measure capacitance) and Tektronix TP2024B four-channel separated oscilloscope (to observe waveform). The frequency of ripple was 50Hz, more easily accessible, the peak value was 24V (effective value), and the ripple was not superposed on the DC component, with the effect of the DC component removed.

After each experiment, the measurement could not be done before the electrolytic capacitor was cooled to room temperature, about 2 hours. In the experiment A, five capacitors were measured for each phase, and two capacitance values were measured each time for the mean value to reduce the impact of errors. In experiment B, 20 capacitance values were measured for the mean value, and this is because as time progresses, the capacitance may vary to a small extent.

Figure 2 shows the experimental circuit. The adjusted ripple was actually the current obtained from the electric supply after transformed and half-wave rectified, whose initial phase was controlled by a single chip microcomputer. Figure 3 shows ripple voltages at different phases displayed by the oscilloscope, respectively 20°, 90° and 160°, with other circumstances omitted.

4 Results and discussion

4.1 VARIATION OF ELECTROLYTIC CAPACITOR CAPACITANCE WITH DIFFERENT PHASE RIPPLES

First, we will study the variation of electrolytic capacitor capacitance with different phase ripples, that is, loss of the electrolytic capacitor at different phases. Five capacitors were measured for each phase. The histogram (Figure 4) of the variation of electrolytic capacitor capacitance with different phase ripples can be obtained on the basis of results. Similarly, ESR of the capacitor in this case can be obtained, which is not stated here.

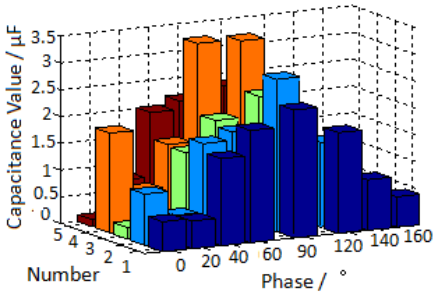

FIGURE 4 Histogram of variation of electrolytic capacitor capacitance with different phase ripples

Figure 4 shows that the ripple at 90° phase has the greatest "harm" to the electrolytic capacitor, embodied in maximum attenuation of the electrolytic capacitor of 90° in the same duration [7]. Compared to other special phases, such as 0° phase with the longest ripple duration and 160° phase with the shortest ripple duration, it is clear that at 90° phase with the highest ripple variation rate, that is, the maximum value of du/dt, rich harmonics components results in a rapid decrease of electrolytic capacitor capacitance [8, 9].

Then, we will study the ripple phase with most harms (i.e. 90° phase), and find out the variation of harm to the electrolytic capacitor with time. Figures 5 and 6 demonstrate the variation of the electrical capacitance with time.

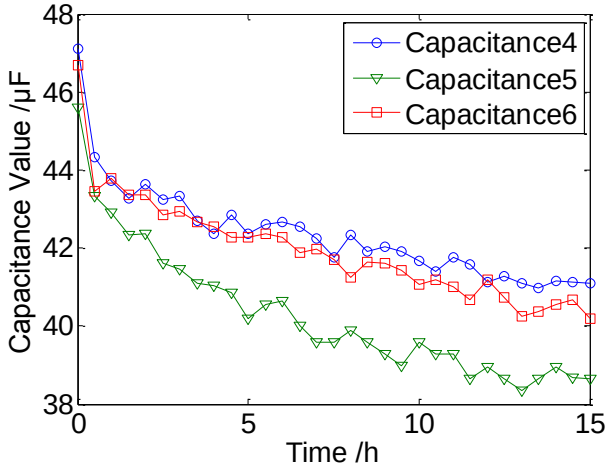

FIGURE 5 Variation of capacitance 4, 5, 6 with time (time interval of half an hour)

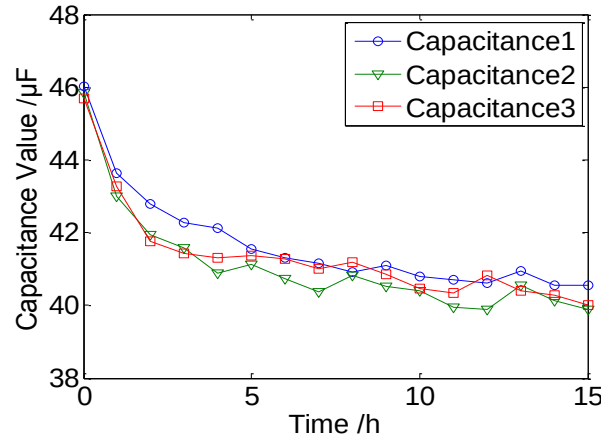

FIGURE 6 Variation of capacitance 1, 2, 3 with time (time interval of an hour)

Figures 5 and 6 show that with the ripple effect the overall trend of the electrolytic capacitor capacitance is gradual decrease, because the electrolyte repairs and thickens the oxidation film, the capacitance decreases, and ESR increases. Hydrogen generated at the cathode accelerates the volatilization of the electrolyte, resulting in degradation of the electrolytic capacitor [8]. In the early degradation, as time goes, the decrease of the capacitance becomes slow. But in the late degradation, the electrolyte has more loss and thickens, causing rise of resistivity and significantly increased loss of the capacitor [9]. But here we only study the impact of the capacitance failure in early degeneration on the circuit.

4.2 PREDICTION MODEL OF ELECTROLYTIC CAPACITOR CAPACITANCE

Figure 4 illustrates that the ripple at 90° phase has the greatest impact on the electrolytic capacitor capacitance. Figure 5 and 6 show the variation of the harm to electrolytic capacitor with time at 90° phase ripple with time, and then, we will study this trend and establish the prediction model. Capacitance 1, 2, 3 are taken as training data, Capacitance 4, 5, 6 are taken as predicted data.

First, data pre-treatment:

As in Equation (2), normalization is carried out.

$$S_{ij} = \frac{C_{ij}}{\max\limits_{j}\left(C_{ij}\right)}, \quad i = 1,2,3,4,5,6, \tag{2}$$

where, i and j are respectively the number and the moment of the capacitor sample, C_{ij} is the capacitance of the i-th capacitor at the j-th moment, $\max\limits_{j}\left(C_{ij}\right)$ is maximum value of C_{ij}, that is, the initial capacitance C_{i1} of the sample, and S_{ij} is the value of normalized C_{ij}.

As in Equation (3), equalization is carried out.

$$\bar{S}_j = \frac{\sum\limits_{i} S_{ij}}{n}, \tag{3}$$

where, n is the number of capacitor samples.

Second, as in Equation (4), by function $f(t)$ training, the data of one-hour time interval are used to train and fit the model $\bar{S}$:

$$\bar{S} = f(t), t > 0. \tag{4}$$

The training data used are $\bar{S}_j$, $j = 1, \cdots, 16$.

$\overline{s_j}$ is the value of $\bar{s}$ predicted by the fitting model at the moment j, as in Equation (5), the corresponding predicted value of the capacitor is:

$$C_{ij} = C_{i1} \times \hat{S}_j, \ i = 4,5,6, j \geq 0. \tag{5}$$

4.2.1 Neural network model

Capacitance 1, 2, and 3 are taken as modeling data, and the RBF network is applied. RBF network has two layers, the first is the implied radial basis layer, and the second is the linear output layer. Theoretically, RBF can approximate any nonlinear function.

4.2.2 KPLS model

KPLS introduces RBF as a kernel function into partial least-squares regression, maps through the kernel function the input data into high-dimensional characteristic space, and then operates in the space, so that the nonlinear relationship

before input and output variables can be established. The radial basis kernel function is selected as the kernel function.

4.2.3 SVR model

The support vector regression algorithm mainly after the dimension raising constructs in high-dimensional space a linear decision function to achieve linear regression. As e-insensitive function is used, it is mainly based on the e-insensitive function and kernel functions algorithm. If the fitting mathematical model is used to express a curve in multi-dimensional space, it, according to the results obtained by e-insensitive function, includes the curve and the "e-pipe" of the training point. In all sample points, only the sample points distributed on the "pipe wall" determine the position of the pipe. These training samples are called "support vector". To accommodate the nonlinearity of the training sample set, the traditional fitting method usually adds the higher-order term after the linear equation. Admittedly this method is effective, but the increased adjustable parameters accordingly increase risk of over-fitting. The support vector regression algorithm uses the kernel function to solve this contradiction. The kernel function is used instead of the linear term in the linear equation to make the original linear algorithm nonlinear, i.e., the nonlinear regression. At the same time, the introduction of the kernel function achieves the purpose of dimension raising, and the increase of adjustable parameters makes the over-fitting still in control. As in Equation (6), kernel functions in the above three methods are all radial basis functions and the kernel parameter is:

$$\sigma^2 = 1. \tag{6}$$

Figures 7, 8 and 9 respectively apply three prediction models of RBF, KPLS and SVR to predict the capacitance of the three capacitors of capacitor 4, 5, and 6.

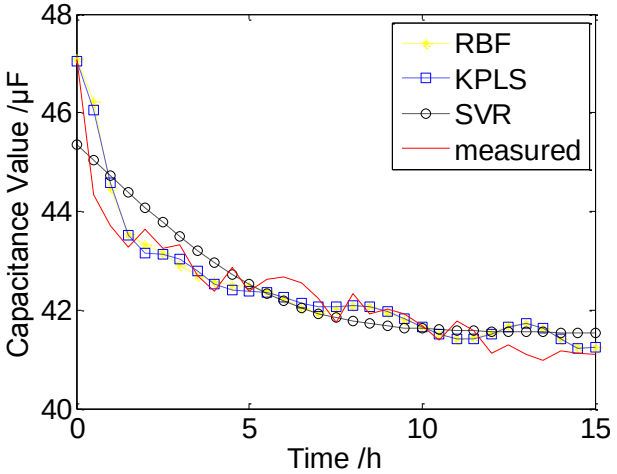

FIGURE 7 Capacitance of capacitor 4 predicted by models of RBF, KPLS and SVR

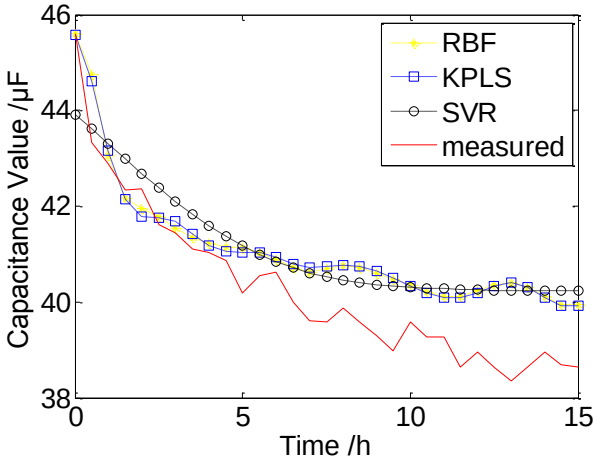

FIGURE 8 Capacitance of capacitor 5 predicted by models of RBF, KPLS and SVR

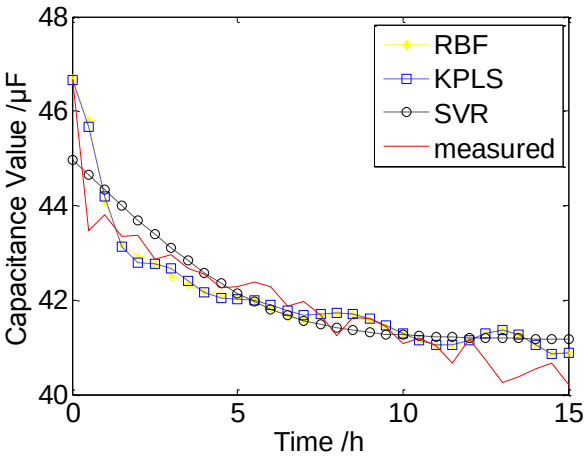

FIGURE 9 Capacitance of capacitor 6 predicted by models of RBF, KPLS and SVR

Table 1 shows mean absolute percentage error, root-mean-square error and correlation coefficient error between capacitance and measured value of the three capacitors in the three prediction models of RBF, KPLS and SVR. From Table 1, as can be seen, the root-mean-square error of KPLS is minimum.

TABLE 1 Errors of the three prediction models of RBF, KPLS and SVR

No. of capacitor	Mean absolute percentage error			Root-mean-square error			Correlation coefficient		
	RBF	KPLS	SVR	RBF	KPLS	SVR	RBF	KPLS	SVR
4	0.010	0.007	0.010	0.538	0.453	0.557	0.937	0.941	0.897
5	0.045	0.022	0.024	1.902	1.030	1.067	0.946	0.947	0.965
6	0.009	0.009	0.010	0.581	0.560	0.574	0.908	0.914	

5 Conclusion

The ripple at 90° phase has the greatest "harm" to the electrolytic capacitor, embodied in maximum attenuation of the electrolytic capacitor of 90° in the same duration. Compared to other special phases, such as 0° phase with the longest ripple duration and 160° phase with the shortest ripple duration, it is clear that at 90° phase with the highest ripple variation rate, that is, the maximum value of du/dt, rich harmonics components results in a rapid decrease of electrolytic capacitor capacitance. At the same time, we studied the curve of loss with time in case of the maximum loss. We then estimated the trend of the curve based on the above three algorithms models and found that these three models have high accuracy, KPLS is slightly better than SVR and RBF, which provides certain reference to the specific failure of the electrolytic capacitor.

Abstract

Doppler scale estimation is one key module in underwater acoustic (UWA) orthogonal frequency division multiplexing (OFDM) communication. In this paper, null subcarrier based blind Doppler scale estimation is considered, which is an extremal problem. The cost function is constructed of the total energy of null subcarriers through DFT. The frequencies of null subcarriers are calculated according to non-uniform Doppler shifts at each tentative scaling factor. Then it is proofed that the cost function can be fitted as a quadratic polynomial near the global minimum. So the accurate location of the global minimum can be achieved through polynomial interpolation. This theory is a basement of developing new methods of Doppler scaling estimation and is verified through an experiment conducted in shallow water.

Keywords: orthogonal frequency division multiplexing (OFDM), underwater acoustic (UWA) communication, polynomial interpolation, Doppler scale estimation

1 Introduction

Underwater acoustic (UWA) orthogonal frequency division multiplexing (OFDM) communication has been under extensive investigation in recent years [1-5]. Unlike the radio channel, which has relative short delay spread and slow time variation, underwater acoustic channels suffer from exhibit long delay spread and fast time variation. The latter brings significant Doppler effects to UWA communication systems, so estimation of the Doppler scaling factor is of critical importance [6-9].

As an extension of the blind carrier frequency offset (CFO) estimation method [10], using the energy on the null subcarriers to find the best fit becomes a popular Doppler scaling factor estimation method in UWA OFDM communication [11-15]. The key is an extremal problem on the cost function constructed of energy of the null subcarriers. In [11] a two-step approach was used. First resample the received signal according to the Doppler scaling factor roughly measured by preamble and postamble, followed by resolution of residual Doppler, which is considered to be uniform. The rough measurement leads to a poor real-time performance and residual Doppler could not be considered to be uniform when the carrier frequency is low to achieve long range communication. In [12] the total energy of frequency measurements at null subcarriers of the block resampled with different tentative scaling factors and huge computational complexity is need. As an improvement, in [15] the cost function is sampled sporadically to find the rough place of the global minimum, and then get an accurate estimation by the method of steepest descent.

In this paper, the cost function is constructed of the total energy of null subcarriers through DFT. The frequencies of null subcarriers are calculated according to non-uniform Doppler shifts at each tentative scaling factor. DFT is more convenient and with much less computational complexity than resampling. Then the cost function is investigated and proofed that it can be fitted as a quadratic polynomials near the global minimum. So the accurate location of the global minimum can be achieved through polynomial interpolation, as a new method of Doppler scaling estimation. To verify the theory, an experiment was conducted in shallow water, whose results confirm its validity.

2 Cyclic prefix OFDM with non-uniform Doppler shifts

Let denote the OFDM symbol duration and T_g the cyclic prefix. The total OFDM block duration is $T + T_g$.

The frequency spacing is $\Delta f = 1/T$. The k -th subcarrier is at the frequency

$$f_k = f_c + k\Delta f \ , k = -\frac{K}{2}, \cdots, \frac{K}{2} - 1, \tag{1}$$

where f_c is the carrier frequency and K subcarriers are used so that the bandwidth is $B = K\Delta f$.

Consider one CP-OFDM block. Let $d(k)$ denote the information symbol to be transmitted on the k-th subcarrier. The non-overlapping sets of active subcarriers S_A and null subcarriers S_N satisfy $S_A \cup S_N = \{-K/2, \cdots, K/2 - 1\}$. The transmitted signal in passband is then given by

$$s(t) = \left[\sum_{k \in S_A} d(k) e^{jk2\pi\Delta ft} \right] e^{j2\pi f_c t} \ , t \in \left[-T_g, T \right]. \tag{2}$$

[*]***Corresponding author*** e-mail: chenyang.heu@163.com

Consider a multipath underwater channel that has the impulse response

$$c(\tau,t)=\sum_p A_p(t)\delta\left(\tau-\tau_p(t)\right), \quad (3)$$

where $A_p(t)$ is the path amplitude and $\tau_p(t)$ is the time-varying path delay. To develop our receiver algorithms, this paper adopt the following assumptions.

A1) All paths have a similar Doppler scaling factor a such that

$$\tau_p(t)\approx\tau_p-at. \quad (4)$$

In general, different paths could have different Doppler scaling factors. The method proposed in this paper is based on the assumption that all the paths have the same Doppler scaling factor. When this is not the case, part of useful signals is treated as additive noise, which could increase the overall noise variance considerably. However, we find that as long as the dominant Doppler shift is caused by the direct transmitter/receiver motion, as it is the case in our experiments, this assumption seems to be justified.

A2) The path delays $\tau_p(t)$, the gains $A_p(t)$, and the Doppler scaling factor a are constant over the block duration.

The received signal in passband is then

$$\tilde{y}(t)=\sum_p A_p\sum_{k\in S_A} d(k)e^{jk2\pi\Delta f\left(t+at-\tau_p\right)}e^{j2\pi f_c\left(t+at-\tau_p\right)}+\tilde{n}(t), \quad (5)$$

where $\tilde{n}(t)$ is the additive noise.

Base on the expression in (5), each subcarrier experiences a Doppler-induced frequency shifts $(f_c+k\Delta f)a$, which depends on the frequency of the subcarrier. Since the bandwidth of the OFDM signal is comparable to the center frequency, the Doppler-induced frequency shifts on different OFDM subcarriers differ considerably; i.e., the narrowband assumption does not hold.

3 Quadratic polynomial fitting of total energy of null subcarriers

The total energy of the null subcarriers is used as the cost function. Assume that coarse synchronization is available from the preamble. After truncating each CP-OFDM block from the received signal, CP is removed. The energy of null subcarriers whose frequency is measured according to tentative scaling factors are achieved by DFT as in (6).

$$Y\left(\gamma_\kappa\right)=\frac{1}{T}\int_0^T\tilde{y}(t)e^{-j2\pi\left(f_c+\kappa\Delta f\right)(1+a+\hat{a})t}dt,\kappa\in S_N \ , \quad (6)$$

where $\gamma_\kappa=(f_c+\kappa\Delta f)(1+a+\hat{a})$ is frequency of null subcarrier, $\tilde{a}=a+\hat{a}$ is a tentative scaling factor, a is the Doppler scale factor, $\hat{a}$ is the deviation of the Doppler scale factor and the tentative scaling factor.

The sum of the energy of null subcarriers is used as the cost function for the Doppler scale estimation.

$$J(\tilde{a})=\sum_{k\in S_N}\left|\frac{1}{T}\int_0^T e^{-j2\pi(f_c+k\Delta f)(1+\tilde{a})t}\tilde{y}(t)dt\right|^2, \quad (7)$$

$$\bar{a}=arg\ min J(\tilde{a}) \ , \quad (8)$$

where $\bar{a}$ is the estimation of a.

The Equation (6) can be transformed as follows:

$$Y\left(\gamma_\kappa\right)=\frac{1}{T}\int_0^T\sum_p A_p\sum_{k\in S_A}d(k)e^{j2\pi\left(f_c+k\Delta f\right)\left(t+at-\tau_p\right)}$$

$$e^{-j2\pi\left(f_c+\kappa\Delta f\right)(1+a+\hat{a})t}dt+\frac{1}{T}\underset{a\ll1,\left(f_c+\kappa\Delta f\right)\hat{a}T\ll1}{=}-$$

$$\frac{\left(f_c+\kappa\Delta f\right)\hat{a}T}{1+a}\sum_p A_p\sum_{k\in S_A,k\neq\kappa\pm1} \quad , \quad (9)$$

$$d(k)e^{-j2\pi\left(f_c+k\Delta f\right)\tau_p}+\frac{1}{T}\int_0^T\tilde{n}(t)e^{-j2\pi\gamma t}dt$$

$$=\alpha_\kappa\hat{a}+\beta_\kappa$$

where $\beta_\kappa=\frac{1}{T}\int_0^T\tilde{n}(t)e^{-j2\pi\gamma t}dt$,

$\alpha_\kappa=-\frac{(f_c+\kappa\Delta f)T}{1+a}\sum_p A_p\sum_k d(k)e^{-j2\pi(f_c+k\Delta f)\tau_p}$.

Then the cost function is:

$$J(\tilde{a})=\sum_{\kappa\in S_N}Y\left(\gamma_\kappa\right)Y^*\left(\gamma_\kappa\right)=$$

$$\sum_{\kappa\in S_N}\left(\alpha_\kappa\hat{a}+\beta_\kappa\right)\left(\alpha_\kappa\hat{a}+\beta_\kappa\right)^*= \quad . \quad (10)$$

$$\hat{a}^2\sum_{\kappa\in S_N}\left|\alpha_\kappa\right|^2+\hat{a}\sum_{\kappa\in S_N}\alpha_\kappa\beta_\kappa^*+\beta_\kappa\alpha_\kappa^*+\sum_{\kappa\in S_N}\left|\beta_\kappa\right|^2$$

Considering the irrelevance of signal and noise, $\sum_{\kappa\in S_N}\alpha_\kappa\beta_\kappa^*+\beta_\kappa\alpha_\kappa^*\to0$ when κ is large enough, thus $J(\tilde{a})$ becomes

$$J\left(\tilde{a}\right)=\hat{a}^2\sum_{\kappa\in S_N}\left|\alpha_\kappa\right|^2+\sum_{\kappa\in S_N}\left|\beta_\kappa\right|^2=$$

$$\left(\tilde{a}-a\right)^2\sum_{\kappa\in S_N}\left|\alpha_\kappa\right|^2+\sum_{\kappa\in S_N}\left|\beta_\kappa\right|^2 \quad . \quad (11)$$

From Equation (11) it can been seen that the cost function is a quadratic polynomial of the tentative scaling factor $\tilde{a}$, and minimized when $\tilde{a}=a$.

There are two conditions need in the derivation of (9):

$$a\ll1, \quad (12a)$$

$$(f_c+\kappa\Delta f)\hat{a}T\ll1\Rightarrow\hat{a}\ll\frac{1}{\left(\frac{f_c}{\Delta f}+\kappa\right)} \quad . \quad (12b)$$

In UWA communication, the Doppler scale factor is normally about the order of 10^{-3}, so (12a) is always meted. The condition (12b) indicates that the cost function can be fitted by a quadratic polynomials only when the tentative scaling factor being limited in a small range around the Doppler scale factor.

Based on (11), a Doppler scale factor estimating method can be proposed. First find the fitting function with several

sample of the cost function around its minimum, and then calculate the exact position of the minimum through the fitting quadratic polynomials function as the estimation of the Doppler scale factor.

4 Experimental results

An experiment was conducted in Lianhua lake of Heilongjiang province in September, 2010. The water depth was around 40 m, the transmitter was located at a depth of about 5 m and the receiver submerged at a depth of about 7 m. The receiver boat was anchored and the transmitter boat could move around. The range between the receiver boat and the transmitter boat was 2~3 km. OFDM signals were transmitted while transmitter boat was moving towards the receiver boat in the first voyage and away from in the second voyage.

The bandwidth of the OFDM signal is 4 kHz, and the carrier frequency is 6 kHz. The transmitted signal thus occupies the frequency band between 4 and 8 kHz. CP-OFDM with a CP of 85.3 ms per OFDM block. The number of subcarriers is 341. The subcarrier spacing is 11.72 Hz, and the OFDM block duration is 85.3 ms. QPSK modulation is used. Block-type pilot is adopted and a null subcarrier is inserted in every 4 subcarriers. So the number of active subcarriers is 256 and the number of null subcarriers is 85, as illustrated in Figure 1. Every frame transmitted contains 50 blocks. The transmitter is moving at a speed of up to 5 kn, at which the Doppler shifts of 8 kHz is 13.36 Hz, which is larger than the OFDM subcarrier spacing.

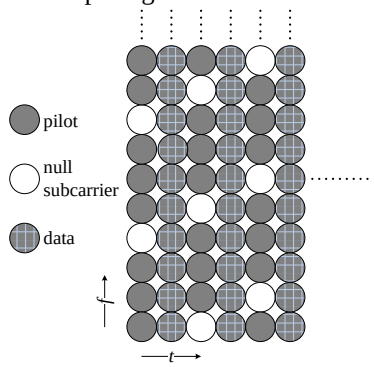

FIGURE 1 Illustration of pilot and null subcarrier pattern

Figure 2 depicts the cost function of one OFDM block. Three samples are made around the minimum, according to which a quadratic polynomials function is fitted. Zoom in Figure 2 to see the details as in Figure 3. The cost function $J(\tilde{a})$ has several minimums but just one unique global minimum, and can been fitted as a quadratic polynomial function around the global minimum. The position of the global minimum is the Doppler scale factor. Figure 4 depicts the errors between the cost functions and the corresponding fitting functions of different OFDM blocks. The error is expressed as $\left(J_p(\tilde{a}) - J_c(\tilde{a})\right)/J_c(\tilde{a})$, where $J_p(\tilde{a})$ is the quadratic polynomial function of (11) and $J_c(\tilde{a})$ is the cost function of (7). In this experiment, the area of accurate fitting is about $[-1.5 \times 10^{-4},\ 1.5 \times 10^{-4}]$, which is matched with (12*b*).

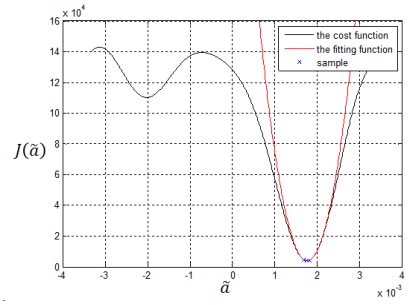

FIGURE 2 The fitting of the cost function of one OFDM block

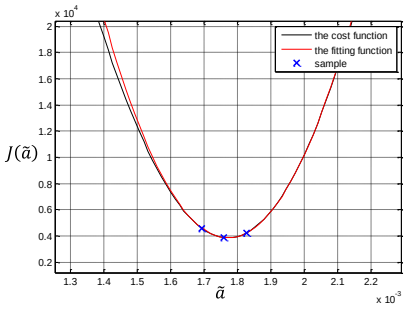

FIGURE 3 Zoom in around the global minimum

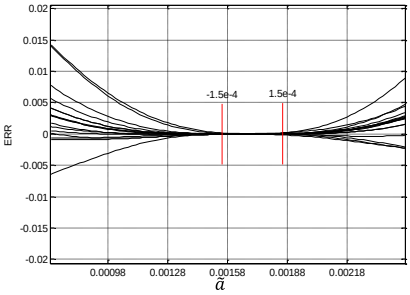

FIGURE 4 The errors between the cost functions and the corresponding fitting functions of different OFDM blocks

5 Conclusions

In this paper, a new cost function of total energy of null subcarriers measurement method is proposed in UWA channels with non-uniform Doppler shifts, which is of less computational complexity. The cost function has several minimums but just one unique global minimum whose position is the Doppler scale factor, and can been fitted as a quadratic polynomial function around the global minimum. To verify the theory, an experiment was conducted in shallow water, whose results confirm its validity.

Based on this theory, new methods of Doppler scaling estimation through polynomial interpolation will be investigated in future research, to develop simple and effective Doppler scaling estimation for UWA OFDM communication systems.

Research of the vibrating infrasonic sensor based on Fiber Bragg Grating

Haohua Liu, Zhou Wan*, Yiyang Li, Zhunen Chen

College of Information Engineering and Automation, Kunming University of Science and Technology, Kunming 650500, China

Received 1October 2014, www.cmnt.lv

Abstract

Current research on infrasound more extensive and in-depth, the sensor is essential prerequisite for infrasonic detection, in order to overcome some lack of current infrasound sensor for detecting the infrasound, paper innovative design a vibrating wire sensor structure, and make it capable of receiving a full rang infrasound, range adjustable, easy installation, etc. and use fiber Bragg grating which has obvious advantages in terms of low-frequency detection as the sensing element. Test the performance of the sensor and the results show that the average of the sensor is 6.11%, within 1 Hz-20 Hz range, the sensor has good linearity and small error, has practical value.

Keywords: Fiber Bragg grating; vibration wire; infrasonic sensor

1 Introduction

In the acoustic frequency, frequency of less than 20Hz of the band called infrasonic wave. Infrasound has the particularity of low frequency, long wavelength, and has spread far, strong penetrating power, small interference characteristics. Infrasound exists widely, for example: the storm at sea, earthquake, volcano eruptions and other natural disasters are likely to produce infrasonic wave [1]. Our life is often accompanied by infrasonic wave, for example: Ohashi Ko, car racing, even audio and mixer at hone will produce [2] infrasound wave. At present there are many countries are devoted to the study of infrasonic wave, infrasound weapons, infrasonic wave exploration, infrasonic wave forecasting and warning are the recent hot, there must be foresee that future of infrasonic wave will have broader applications. Therefore, there will be great practical value and scientific significance to detect infrasound, existing for infrasound detection of infrasonic sensor have some shortcomings such as low sensitivity, frequency range is small, large volume, inconvenient installation and high demands on the environment, the fiber grating sensor has high sensitivity, wide dynamic range, without electromagnetic interference, corrosion resistance, small volume, light weight and other advantages [3]. Based on this, this paper designs a vibrating sound sensor based on fiber Bragg grating.

2 The measuring principle

2.1 THE SENSING PRINCIPLE OF FIBER BRAGG GRATING

Fiber grating wavelength of reflection or transmission peak concern with the refractive index modulation of the grating period and the core refractive index, and when a broadband light source is incident to the Bragg grating, refraction, transmission or reflection due to refractive index change occurs, the reflection need to meet Bragg condition, namely the reflection wavelengths of light to meet the optical [4] equations:

$$\lambda_B = 2\Lambda n_{neff} . \tag{1}$$

Type (1): λ_B as the center wavelength of fiber Bragg grating; n_{eff} as the core region of the fiber refractive index; Λ as the Bragg grating period.

By the Equation (1) shows, the Bragg center wavelength of fiber Bragg grating λ_B changes with the change of the n_{eff} and Λ, or change any physical quantity of n_{eff} or Λ will lead to reflection or transmission peak wavelength of fiber Bragg grating drift. Through the detection of Bragg wavelength reflection or transmission spectrum peak wavelength, also is the detection of the central fiber Bragg grating wavelength, can detect the corresponding variables.

When the fiber grating under strain and strain is uniform, on one hand, external strain induced grating period changes [5]:

$$\Delta\Lambda / \Lambda = \varepsilon . \tag{2}$$

On the other hand, photoelastic effect caused by the change of effective refractive index:

$$\Delta n_{eff} = \frac{n^3_{eff}[P_{12} - \nu(P_{11} + P_{12})]}{2}\varepsilon . \tag{3}$$

Type (3), P_{11} and P_{12} are the fiber optic strain tensor components, ν is the Poisson's ratio.

Changes of these two aspects led to the change of the wavelength of the fiber grating, by Equation (1) can be obtained:

* ***Corresponding author*** e-mail: liuhaohua@126.com

$$\Delta\lambda_B = 2n_{eff}\Delta\Lambda + 2\Delta n_{eff}\Lambda . \quad (4)$$

The types (2) and (3) into type (4) have

$$\Delta\lambda_B = 2n_{eff}\Lambda\{-\frac{1}{2}n_{eff}{}^2[P_{12} - \nu(P_{11} + P_{12})]\}\varepsilon + 2n_{eff}\Lambda\varepsilon . \quad (5)$$

Valid elastic optic constants of optical fiber P_e is defined:

$$P_e = \frac{n^2{}_{eff}}{2}[P_{12} - \nu(P_{11} + P_{12})] . \quad (6)$$

Then type (5) can be simplified as:

$$\Delta\lambda_B = (1 - P_e)\lambda_B\varepsilon = K_\varepsilon\varepsilon = K_\varepsilon\frac{\Delta\Lambda}{\Lambda} . \quad (7)$$

Equation (7) expresses the relationship between the wavelength shift and the external when the fiber Bragg grating strains uniformly. In Equation (7), K_ε is the strain sensitivity coefficient of fiber grating sensor. Its value is closely related to the size of the optical fiber material, by the decision of the effective refractive index of optical fiber, elastic-optic coefficient and Poisson's ratio. Therefore, When the materials of the fiber is determined, K_ε is a constant so the change of the fiber grating wavelength is determined by the change of the fiber Bragg grating period, in the other word, which is determined by fiber Bragg grating lattice spacing changes. When the lattice spacing changes at a high frequency, the change frequency of the center wavelength is also high. But the rapid changes of the center wavelength are not conducive to the detection. On the contrary, for small frequency strain, the change of the fiber Bragg grating lattice spacing frequency is small; its centre wavelength change frequency is also small, which is easier to be tested. Therefore, optical fiber Bragg grating has obvious advantages in detection of low frequency and ultra-low frequency.

2.2 WORKING PRINCIPLE OF THE SENSOR

As designed in this paper, the Vibration Wire infrasound sensor based on the fiber Bragg grating, using vibrating string as a receiving component, can receive a full range of infrasound and vibration. The vibration is transmitted to the elastic diaphragm through the string bridge. Elastic diaphragm produces strain due to the vibration, driven the fiber Bragg grating wavelength attached to the elastic diaphragm to shift.

At this point, the vibration is converted into the center wavelength shifting of the fiber Bragg grating. The center wavelength shift values of the fiber Bragg grating are obtained by the use of demodulation instrument, thus the corresponding relation of the vibration frequency and wavelength. In addition, the effective length of the vibrating wire is determined by two string bridges, one of the two can move within a certain range, so that the effective length of the vibrating string is adjustable, so the range of the designed sensor in this paper is adjustable.

3 Structure and design of the sensor

The structure of the sensor is shown in Figure 1, In order to be able to receive the full range of infrasound, this design uses a using vibrating string as a receiving component. Vibrating strings are fixed by the clamp device on both ends of the bracket. In order to make the range of the designed sensor adjustable, the effective length of the vibrating string must be adjustable. The vibrating wire length between the two string bridges is the effective length of the vibrating wire. So install a guide rail on the base plate of the right said of the fixed bracket to make the string bridge on the right side move on the guide rail to transform the effective length of the vibrating string. The string bridge on the left side can transmit the vibration of the vibrating wire. So, install the left side string bridge on center of the elastic diaphragm and paste the fiber Bragg grating under the elastic diaphragm then design a circular section on the left side of the fixed bracket to fix the elastic diaphragm.

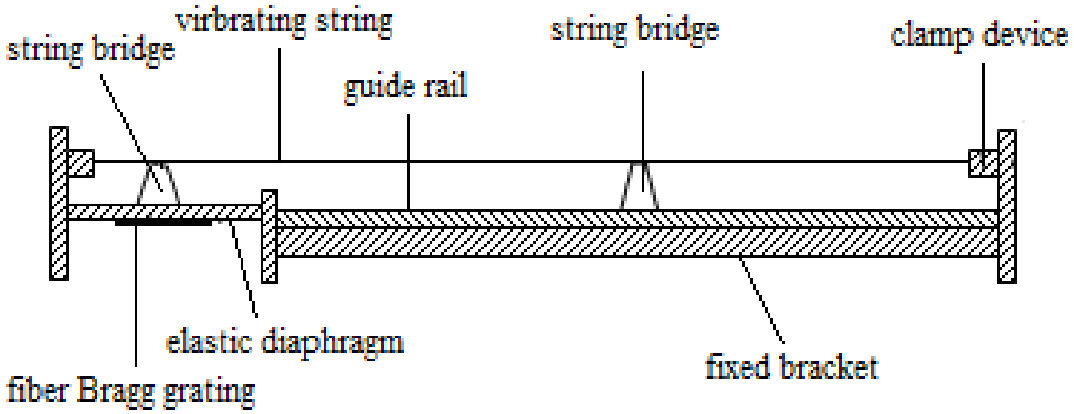

FIGURE 1 The structure of the vibrating wire infrasound sensor based on fiber Bragg grating

For the fixed strings at each end, the correspondent nth vibration displacement generated by receiving the infrasound of a series of frequencies is [6]:

$$y_n = B_n \sin\frac{n\pi}{l} x\cos(2\pi f_n t - \varphi_n) . \quad (8)$$

In Equation (8), B_n and φ_n are the correspondent undetermined coefficients of the n-th vibration. f_n is the frequency of the n-th vibration, and l is the length of the vibrating wire.

The fundamental frequency vibration is the most stable form of vibration. That is, in Equation (1), when n=1, the frequency is:

$$f = \frac{1}{2l}\sqrt{\frac{T}{\delta}} = \frac{1}{2l}\sqrt{\frac{E\varepsilon}{\rho}} \ . \tag{9}$$

In Equation (9), T - vibrating string tension, δ - vibrating wire density, $\delta = \rho s$, ρ means the vibrating wire material density, s means the cross-sectional area of the vibrating string, t - time, l - vibrating string length, E - vibrating wire elastic modulus; ε - the internal stress of vibrating. By increasing the length of the vibrating string, increasing the radius of vibrating strings can reduce the frequency of vibrating wire, thereby increasing sensor's sensitivity to low-frequency. At the same time, we can also know that the bigger elastic modulus of the material is helpful to improve the sensitivity of the sensor, Therefore, we chose the experimental calculated Young's modulus of E=200Gpa, a density of ρ=OCr$_{18}$Ni$_9$ 7.93g/cm3, the chord diameter of 1.20mm, the chord length is 1000mm stainless steel vibrating string.

By the Equation (9) shows that the longer vibrating wire means the better characteristics of low-frequency, but it is represented by the Equation (8) shows that the longer vibration string will get very small strain when receiving the low frequency infrasound. So it is not suitable for the fiber Bragg grating pasted directly on the vibrating string, In this paper an innovative structural design makes vibrating accept vibration, the vibration through the bridge to the elastic diaphragm. This put the vibration focus on the elastic diaphragm, the diaphragm can produce relatively large strain, to facilitate detection.

While the elastic diaphragm not only played the role of isolation and protection, but also increase the damping effect of sensor system. An ideal sensor should be an ideal linear time invariant system, namely the sensor output can be linear to truly reflect the input signal. Specifically, should make the output amplitude is to maintain a constant for all the frequency of the measured signal, to ensure that the harmonic components are the same amplification, and the output phase is linear to the all measured frequency, to ensure the phase shift that each harmonic component is directly proportional to the frequency. This requires sensors with larger bandwidth, and the bandwidth depends largely on the system's natural frequency and damping ratio. When the damping ratio is too large, with the increase of frequency amplitude frequency characteristic curve decreased rapidly, while the damping ratio is too small, with the increase of frequency amplitude frequency characteristic curve will rise, in the above two cases, the amplitude frequency characteristics flat areas are narrow, therefore, appropriate damping ratio can make the sensor has a wide operating frequency range. The sensor is designed in this paper, and the effective length of string vibration adjustable makes the sensor range adjustable, thus the need for a larger operating frequency range. After testing, this design uses the polyester film as diaphragm can enable the sensor has the appropriate damping ratio and wide operating frequency. The elastic diaphragm is round, the radius of R=120mm, thickness of h=0.3mm. The bridge is made of wooden materials, the bottom surface of radius r0=30mm.

According to the principle of the elastic mechanics, when the uniform pressure of perpendicular to the circular diaphragm clamped films, film will produce bending deformation. The center (R=0) of the maximum deformation, the deformation of the diaphragm can be expressed as a Equation:

$$Y_{\max} = \frac{3(1-\mu^2)\mathrm{P}}{16Eh^3}R^4. \tag{10}$$

In the Type (10), E, μ, h and R respectively refers to Young's modulus of the polyester film, Poisson's ratio and thickness and the effective radius.

Analysis of elastic diaphragm were carried out by the finite element software ANSYS [7, 8], circular flat diaphragm radial strain distribution in the diameter direction of the Figure 2:

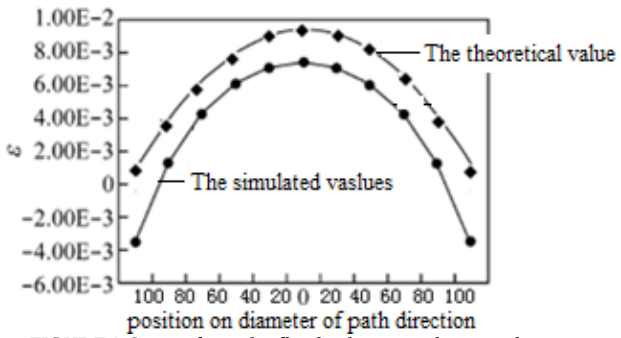

FIGURE 2 Strain of circular flat diaphragm in diameter direction

We can see from Figure 2 strain at the center of the diaphragm is maximum, and at about 1/2 in radius radial strain have another turning point, combine type (10), so as to determine the paste position of fiber Bragg grating on the membrane should be at 1/2 in the diaphragm to the radius of the center. Figure 3 is the schematic diagram of circular flat diaphragm sticking position of fiber Bragg grating.

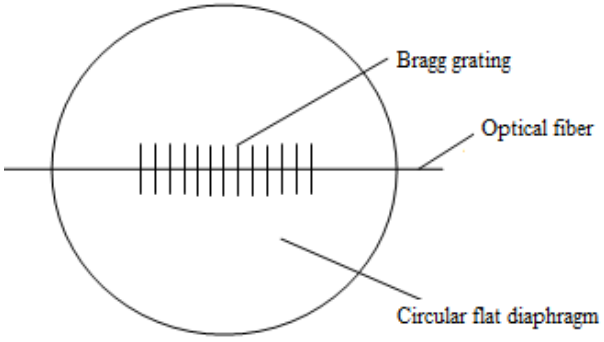

FIGURE 3 Paste position of fiber Bragg grating in the round flat diaphragm

4 Test data and analysis

Produce 0-20Hz sine excitation signal by signal generator, amplified by the power amplifier and speaker produce infrasound wave, the cut-off frequency to the 21Hz test will be low pass filter, 10 tests were carried out for each test frequency, test results, by the Equations (11) and (12) to calculate the average value, the result in Table 1.

$$\bar{f} = \frac{1}{n}\sum_{1}^{n} f_i , \tag{11}$$

$$\bar{\lambda} = \frac{1}{n}\sum_{1}^{n} \lambda_i . \tag{12}$$

4.00	4.16	0.040	20.00	19.74	-0.013

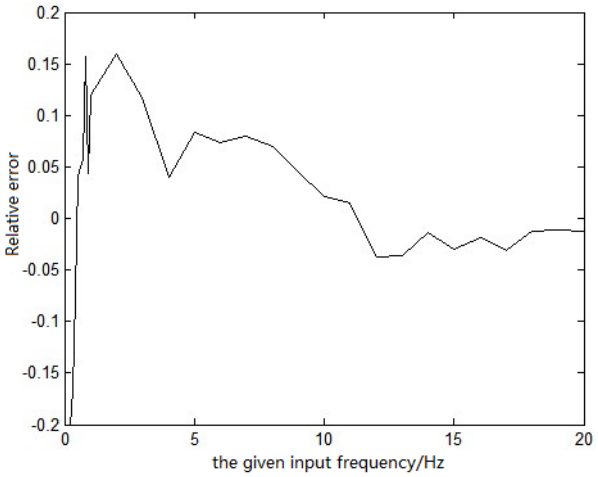

FIGURE 6 Curves of relative error

According to the Equation (13), using the data in Table 2 dawn relative error curves plotted as in Figure 6. We can see from Figure 6, with the increase of the test frequency, the error will be gradually reduced, the average error is E=6.11%. According to Figure 4 and Figure 6 shows, the sensor in the range of 0 Hz-1 Hz designed in this paper, the measurement results is not very stable, the error is large, but in the 1 Hz-20 Hz range, the sensor has good linearity and small error, the result show that the design of the sensor is of practical value.

5 Conclusions

This paper design the vibrating string type infrasonic sensor based on fiber Bragg grating, the sensor using optical fiber Bragg grating as the sensitive element and structure design innovation make the sensor has the advantages of convenient installation, electromagnetic interference resistance, suitable for high temperature, corrosive environment, also can receive infrasound in full range, the measuring range can be adjusted according to the actual situation, so as to improve the sensitivity of the sensor, avoid reducing the sensitivity by using the same range to measuring different frequencies , analysis the test data, and the results show that the sensor error is small, high precision, and has great practical value.

Abstract

How to enhance the accuracy and range is a typical issue in the ultrasonic position technology. The position accuracy depends on the hardware architecture and the detecting methods. This paper designs a hardware platform called Hexagon-Buck with six transceivers around. For the inherent property of TDOA (Time of Difference of Arrival) ranging, the RF synchronous time and embedded software processing time are two inevitable factors that leads to the distance error. At the same time, the ultrasonic velocity is sensitive to the environment temperature. The paper considers both the temperature compensation and Least Squares Linear Regression to enhance the ranging accuracy. By taking the physical test data to identify the linear regression model, we can estimate the real distance. The validity of the method has been proved by the final experiment.

Keywords: ultrasonic ranging, TDOA, least squares linear regression, hexagon-buck

1 Introduction

Each node how to locate themselves in the large sensor network systems has become a challenging subject. According to the measuring distance and the angle information, the wireless location technology can be classified into two types: the range-based technology and the range-free technology. Although range-free technology has advantages in the power consumption and hardware cost, its measured accuracy can not meet the requirement of WSN (Wireless Sensor Networks), such as DV-Hop [1] and APIT [2]. On the contrary, range-based technology like TOA (Time of Arrival) [3], TDOA (Time of Difference of Arrival) [4, 5], AOA(Angle of Arrival) [6, 7], RSSI(Received signal strength indication) [8, 9] and TOF(Time of Fly) [10] is more commonly used in engineering.

TDOA technology is used to range the distance between the sender and receiver by the time difference, which has been widely proposed as a necessary ingredient in WSN self localization systems. Compared with other range technologies, TDOA works without the network time synchronization, which can significantly reduce the resource calculation cost and hardware expenditures. In order to ensure the ranging accuracy, the paper takes TDOA to calculate the distance between two nodes and adopts the Least Squares Linear Regression model to revise the measured error. The hardware called Hexagon-Buck with six transceivers around the board is also implemented to test the ranging performance.

The ultrasonic based TDOA leads to the nodes distance but not the nodes position. This paper also discusses the multi-dimensional scaling positioning algorithm based on the nodes' distance matrix [11]. Theoretically, if the nodes ranging is zero-defection, then the position is zero-error. So we are pursuing an error eliminating method, and concerns how to enhance the ranging accuracy by means of software algorithm optimizing as well as the hardware improvement.

2 System architecture

In this paper, the Hexagon-Buck which is a novel ultrasonic platform featured with six transceivers is presented. The hardware architecture is shown as Figure 1.

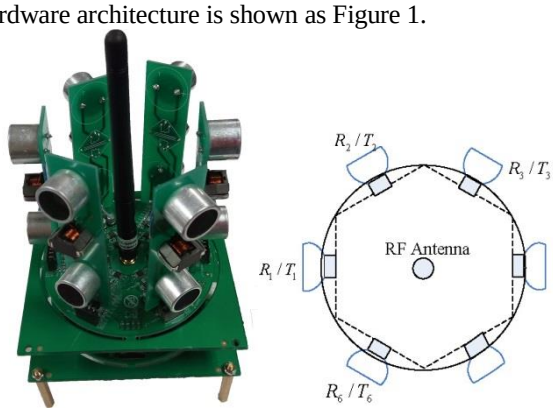

FIGURE 1 Hexagon-Buck platform with six transceivers around (the board has a diameter of 8 centimeters)

Since the radio transmitting time is measured by the local clock of the host node, and the arrival time is calculated on the ultrasound board, so it is important that the clock drift between the two microcontrollers keeps minimal. Thus the time synchronization among the sending nodes and the receiver nodes is necessary. For our hardware platform, the ad-hoc network is constructed by two layers: the physical layer with IEEE 802.15.4 and the network layer with Zigbee. The core of Hexagon-Buck is a dedicated micro-controller to control the ultrasonic transmission, receive signals, as well as manage the Zigbee stack and network application. The MCU of Hexagon-Buck is JN5148 produced by NXP. It is combined with an IEEE802.15.4 compliant transceiver on chip. JN5148 also integrates a temperature sensor. By providing the absolute measure of

[*]***Corresponding author*** e-mail: huyansu@163.com

the device temperature, we can easily amend the sound velocity according to Equation (3).

Typical ultrasonic transceiver is directional. In order to realize the omni-directional detection, we equip six transceivers around to solve the limited beam angle problem, just like the previous platforms (e.g. the SpiderBat nodes [7] and the AHLoS nodes [12]). 40C16T/R-1 Ultrasonic Sensor produced by OSENON is designed as the transceiver. The centre frequency is 40kHz and the bandwidth is 2kHz. The ultrasonic transmission is cone shaped with the angle of $60\pm15^{\circ}$. So six 40C16T/R-1 transceivers can cover 360° omni-direction. Further more, the separate ultrasound transmitters and receivers can reduce the complexity without switching the circuits between receive and transmit mode.

1) The transmission circuit is driven by the square wave with 50% duty ratio and 40kHz frequency. The square wave is operated by the Pulse Width Modulation (PWM) of the micro controller. DC-DC module as power amplifier provides $5V$ and $\pm10V$ voltage to 40C16T/R-1.

2) Since the receiver signal is only a few millivolt, it needs to be amplified for reliable detection. As shown in Figure 2, the first amplification stage provides 40dB amplification. The second amplification stage equipped with a digital potentiometer is to adjust the detection threshold and prevent the saturation of the sampled signal. This detection signal is then to compare with a reference voltage, which is also can be adjusted by a digital potentiometer. If the signal exceeds the reference voltage, the comparator will trigger an electrical level change captured by the micro controller, which leads to hardware interrupt.

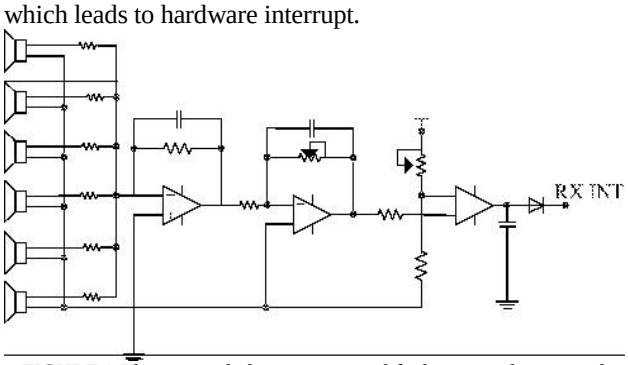

FIGURE 2 The received ultrasonic is amplified twice and compared with a reference voltage

3 Temperature and frequency feature of ultrasonic

3.1 TEMPERATURE FEATURE

Like other acoustic wave, the ultrasonic velocity is about $340.2\,m/s$ in the air at the condition of normal pressure and temperature (NPT). But actually it is affected by the status of transmission medium such as the moisture, pressure and density. Compared with the moisture and pressure, sound velocity is more sensitive to the temperature. The propagation velocity in normal atmosphere can expressed as bellow:

$$v(t)=\sqrt{\gamma RT/\mu},T=273+t, \tag{1}$$

where $\gamma=1.4$ is the air specific heat ratio. R is the perfect gas constant, and the value in the air is $R=8.134kg\cdot mol^{-1}\cdot K^{-1}$. $\mu=0.00283kg\cdot mol^{-1}$ is the air molar mass and t is the centigrade temperature. The Taylor Series Expansion of Equation (2) is as bellow:

$$v(t)=\sum_{n=0}^{\infty}\frac{v^{(n)}(0)}{n!}t^n=v(0)+v'(0)t+\frac{1}{2!}v''(0)t^2+\cdots+\frac{1}{n!}v^{(n)}(0)t^n+\frac{1}{(n+1)!}v^{(n+1)}(\xi)t^{n+1}, \tag{2}$$

where $\xi\in(0,t)$. Omit the higher order term:

$$v(t)\approx331.5+0.607t(m/s). \tag{3}$$

According to Equation (3), the velocity increases about $0.607\,m/s$ along with every additional centigrade. Later we will take Equation (3) to correct the ultrasonic velocity.

3.2 FREQUENCY FEATURE

On one hand, the sound intensity is damping along with the transmission for the energy keeps decreasing during the wave diffusion, reflection and scattering. When the frequency is higher, the intensity declines faster.

On the other hand, the directivity of ultrasonic also changes with the frequency, which is described by the index of half-power beam width (the angle of two half-power point with -3dB damping). The sound energy dumps along with the axial direction and fades out on both sides. If the frequency is higher, the half-power beam width is smaller and the directivity is better.

So the balance between a better directivity and a lower sound intensity decline must be considered when choose the ultrasonic frequency during the hardware design. This paper selects 40 kHz ultrasonic for its better robust and anti-interference.

4 Accuracy deterioration factors

The ultrasound ranging is unidirectional. The sender node initiates a single measurement by broadcasting a radio packet and indicates a time stamp. While the nodes nearby listen for the incoming ultrasound waves. During the procedure, there are several factors which may cause the accuracy deterioration.

4.1 SYNCHRONOUS TIME ERROR

In Figure 3, the coordinator and router are taken as the sender and receiver respectively to show the error schematic. t_{rf} is the RF transmission time and δt_{rp} is the synchronization signal processing time at the receiver. After receiving a synchronization signal, the receiver sends an ACK signal back to the sender and starts a hardware timer to count the ultrasonic fly time. As soon as the sender node gets this ACK, it starts a PWM wave to drive 40C16T/R to generate

an ultrasonic. The processing time at the sender is marked as δt_{sp}. The measured fly time of ultrasonic counted by receiver is marked as t_{uf}, and the theoretical fly time is t'_{uf}.

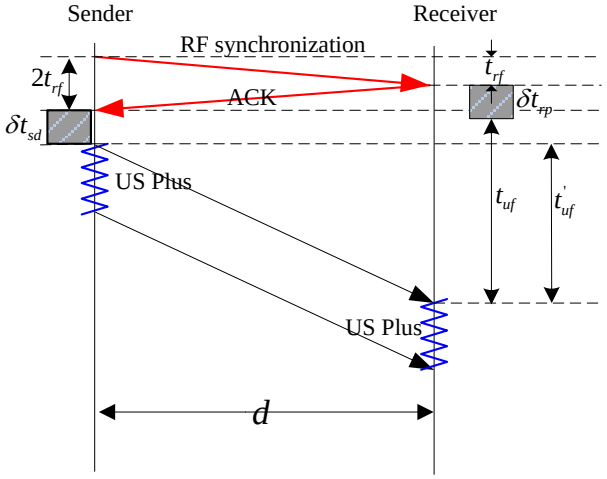

FIGURE 3 Schematic of time synchronization error

As shown in Figure 3, there is the equation: $2t_{rf} + \delta t_{sp} + t'_{uf} = t_{rf} + \delta t_{rp} + t_{uf}$.

Define $\Delta t = t'_{uf} - t_{uf}$, then the Equation above can be rewritten as:

$$\Delta t = \delta t_{rp} - \delta t_{sp} - t_{rf} . \quad (4)$$

Because of the tremendous transmission velocity of RF signals and the span limitation of $20m$, its maximum transmission time is only $0.07us$, during which the ultrasonic only travels $0.0024cm$. So t_{rf} can be omitted during the calculation. But no matter the sender node or the receiver node, the software procession time and hardware start-up time are inevitable and immeasurable. So t'_{uf} must be estimated by t_{uf}:

$$t'_{uf} = t_{uf} + \Delta t \approx t_{us} + (\delta t_{rp} - \delta t_{sp}) . \quad (5)$$

4.2 ULTRASONIC DETECTION ERROR

At the receiver node, the ultrasonic should firstly be transmitted into the voltage signal and then be amplified and filtrated. Next the voltage signal will be compared with a specified threshold to identify if the ultrasonic has reached the receiver node. When the voltage amplitude is greater than the threshold, the comparator triggers a hardware interrupt to tell the MCU that an ultrasonic pulse has been detected and ready to enter the interrupt service routine.

The ultrasonic detection error is because there is time delay t_{sw} before the ultrasonic amplitude reaches the threshold. This delay changes along with the ranging distance. For example, this time is nearly $112.3us$ in our platform and the corresponding distance is about $3.8cm$.

4.3 THE SHAPE ERROR OF HEXAGON-BUCK

As previous mentioned Hexagon-Buck has six parts of transceivers around. In Figure 4, d' is the theoretically transmitting distance. But we need the central to central distance d in practice. So the shape caused error is: $d_{hw} = d - d'$.

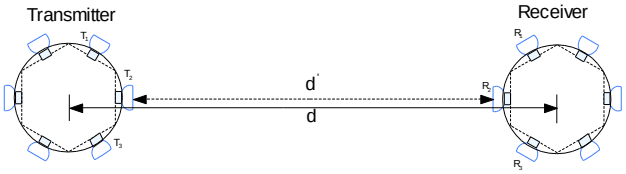

FIGURE 4 Schematic of shape caused error

4.4 ENVIRONMENT EFFECT

If the environment moisture is random distribution in 10~90%RH, the maximum normalized velocity error is only 1.5×10^{-3}, which means that there is only $3cm$ bias at the maximum measure range (about $20m$). This accuracy is enough for the implementation, so need no compensate.

As we discussed in section 3.1, the ultrasonic velocity is more sensitive to the temperature. Define Δv_{temp} be ultrasonic velocity error caused by the temperature. In the following section, the velocity compensation is only based on temperature without considering the environment moisture.

5 Ranging errors correction

5.1 TEMPERATURE COMPENSATION

Use the following equation to calculate the ultrasonic velocity compensation for the distance measurement:

$$d^* = \left(v + \Delta v_{temp}\right) \cdot \left(t_{us} + (\delta t_{rp} - \delta t_{sp})\right) + d_{hw} . \quad (6)$$

Combined the Equation (5), there is: $d^* = v_{temp}\Delta t + d_{hw}$.

The experiments are designed to test the ranging performance of Hexagon-Buck with only temperature compensation. The distance moves every $1m$ and is corrected according to Equation (6). Take the average value of 50 data at each distance. Figure 5 shows the results of ranging error.

The maximum range is about $15.8m$ and the ranging data is stable at $13m$. The average error is about $28.6cm$ and the extreme is $33.6cm$. The phenomenon is because there is no consideration on the RF synchronization error t'_{uf}, the ultrasonic detection error t_{sw}, and the shape error d_{hw}. In order to enhance the accuracy, use Least Square method to correct to error affected by other factors.

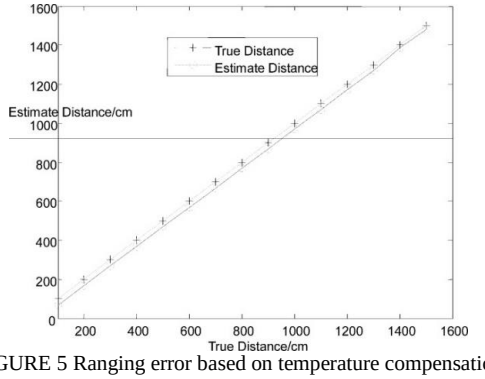

FIGURE 5 Ranging error based on temperature compensation

5.2 LSF CORRECTION

The ranging data correction is a typical liner regression problem: $D_n(x) = \mathbf{AX} = a_n x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0$.

Define $\{(x_i, D_n(x_i)) \mid i = 1, 2 \ldots m\}$ to approximate the actual ranging data $\{(x_i, y_i) \mid i = 1, 2 \ldots m\}$, where x_i is the measured ranging data corrected by the temperature compensation, and y_i is the actual distance between the sender and receiver. Considering the CPU processing ability, take first-order least square regression to estimate the value of constant a_0 and a_1.

$$E = \sum_{i=1}^{m} (y_i - a_1 x_i - a_0)^2 . \tag{7}$$

In order to minimize the variance E, calculating the partial differential of Equation (7):

$$\begin{cases} \dfrac{\partial E}{\partial a_1} = -2\sum_{i=1}^{m} x_i (y_i - a_1 x_i - a_0) = 0 \\ \dfrac{\partial E}{\partial a_0} = -2\sum_{i=1}^{m} (y_i - a_1 x_i - a_0) = 0 \end{cases} .$$

Solve the equation, there is:

$$a_0 = \frac{\sum_{i=1}^{m} x_i \sum_{i=1}^{m} x_i y_i - \sum_{i=1}^{m} x_i^2 \sum_{i=1}^{m} y_i}{\left(\sum_{i=1}^{m} x_i\right)^2 - m\sum_{i=1}^{m} x_i^2}, \tag{8}$$

$$a_1 = \frac{\sum_{i=1}^{m} x_i \sum_{i=1}^{m} y_i - m\sum_{i=1}^{m} x_i y_i}{\left(\sum_{i=1}^{m} x_i\right)^2 - m\sum_{i=1}^{m} x_i^2}, \tag{9}$$

where x_i is the average value of 50 measured data at specific distance, and the distance is increased every 1*m*. Because the maximum range is about 15.8*m*, so the regression only effective in 15*m*, etc. *m*=15. The regression model expression is:

$$D(x) = 0.9922 d^* + 0.347 . \tag{10}$$

Figure 6 is the comparison of the measured distance calculated by regression model and the actual distance. The average bias is only about 3*cm*.

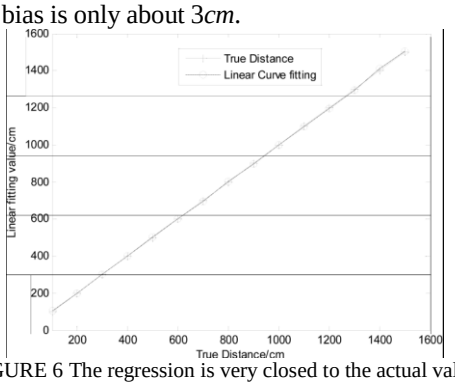

FIGURE 6 The regression is very closed to the actual value

5.3 EXPERIMENT VALIDATION

A further experiment is implemented to evaluate the validity of the linear regression model with the ultrasonic velocity compensation. The experiments are operated twice: first only with the temperature compensation (UN-Calibration) and second considering both the temperature compensation and LSF correction (Calibration). The ranging is also in the range of 15*m* and changes every 1*m*. Figure 7 shows the results. In the condition of only velocity calibration, the average bias is 29.8*cm* and the extreme is 35.3*cm*. However, it is noteworthy that the LSF correction with velocity calibration can greatly reduce the ranging error. The average bias is only 3.5*cm* and the extreme is 8.4*cm* (at the distance of 9*m*).

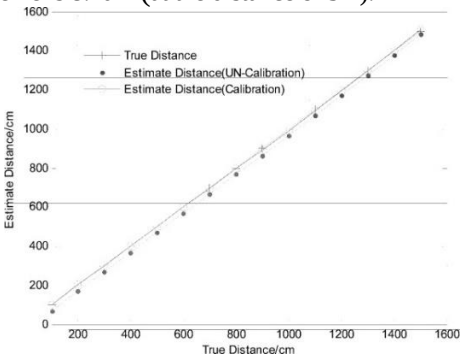

FIGURE 7 The ranging error correction with two methods

6 Conclusions

The paper designs and implements the Hexagon-Buck to enforce the node ranging and position. Considering the ultrasonic velocity error caused by the temperature and the RF synchronous time error caused by TDOA, the paper adjusts temperature compensation and least squares linear regression model to enhance the ranging accuracy. First design the physical experiment and liner regression model to match the unknown parameter, and then calculate the real distance. The experiments show the validity of this method.

Beyond these, the further study will continue consider the impact of ranging error distribution as well as the WSN nodes distribution to the position estimating.

Abstract

On the basis of analyzing the characteristics of harmonic signals, the inter-harmonic detection algorithm of quasi-synchronous sampling is introduced in this paper. This algorithm pre-processes the original sampled signal and separates all the harmonics and inter-harmonics of the reconstructed signal with designed comb FIR filters, to restrain the mutual interference between them, and finally achieve accurate measurement of harmonic and inter-harmonic in power system. At last, the validity of this algorithm is verified with harmonic and inter-harmonic signal generated from standard signal source.

Keywords: quality of electric energy, inter-harmonics, quasi-synchronization, comb FIR filter

1 Introduction

With higher demand on power quality, the inter-harmonics in power quality monitoring is more and more concerned. Nevertheless, due to the uncertainty of inter-harmonic frequency and much smaller amplitude with respect to fundamental and harmonic waves, the spectrum leakage in the process of harmonic signal sampling may cause serious impact on inter-harmonic measurement, or even annihilating of inter-harmonic signal in serious case.

Thus, the current sophisticated algorithms for harmonic detection (such as FFT, etc.) can hardly locate inter-harmonics in the spectrum accurately, and even mistake spectrum leakage or noise interference as inter-harmonics [1, 2].

It is difficult to achieve the desired complete synchronous sampling in practice considering the fluctuation of fundamental wave and non-integer ratio between harmonic frequency and fundamental frequency in actual electric power signal. However, in actual asynchronous sampling process, the reciprocal serious interference among sub-harmonics and neighbor inter-harmonics on the spectrum can influence final measure results. Therefore, the harmonics and inter-harmonics of signal must be first separated, then, their respective parameters are calculated and the parameters of harmonics and inter-harmonics are obtained accurately.

In order to reduce mutual interference between harmonics and inter-harmonics, the quadratic measurement can be adopted to increase accuracy, i.e. the entire measurement process is divided into two stages: first, the harmonic component is extracted from original signal and parameters are calculated; then, the various parameters of inter-harmonics are calculated. In this method, because the harmonics interference has been wiped out before calculating parameters of inter-harmonic signal, so the accuracy of inter-harmonic measurements can be effectively increased [3].

The method of reducing mutual interference through separating harmonics and inter-harmonics of signal, can increase the accuracy to some extent, but the ignorance of inter-harmonics' influence on harmonics when harmonic signals are extracted directly and subtracting them from original signal makes this method incomplete. Due to the mutual interference between harmonics and inter-harmonics, a better way to calculate their parameters should be to separate them precisely from the original signal before calculating their respective parameters [4, 5].

Undoubtedly use comb filter can be ideal separation between the harmonic and harmonic signal, but the comb filter is suitable for the synchronous sampling signal processing, in order to enable it to application in asynchronous sampling condition, must be the actual asynchronous sampling signal accurate synchronization processing to meet the needs of a comb filter for synchronous sampling.

2 Detection model of quasi-synchronous sampling and inter-harmonic

Synchronous sampling requires that the number of signal cycles T_0 contained N sample sequences must be integer, namely: $N \cdot T_S = P \cdot T_0$.

Wherein, T_S is the sampling period; for synchronous sampling, P is an integer; in the asynchronous sampling, P is not an integer. And comb filter requires p to meet integer condition, T_S can be adjusted to make the equation take holds, set the adjusted quasi-ampling period λ_s satisfies [6]:

$$\lambda_s = \frac{P \cdot T_0}{\mathrm{K}}, \tag{1}$$

wherein, K is the sampling points in P sampling periods, usually an integer. According to Equation (1), quasi-sampling period λ_s can be calculated. Then the interpolation

[*] ***Corresponding author*** e-mail: hnxxzxf@126.com

calculation is carried out among K sampling points with equal interval λ_s, a group of new signal sample sequence $K\lambda_s$ with a total length of K can be obtained. P sampling periods are contained in this sequence, so it is the desired quasi-synchronous sampling sequence, and DFT operation or some other operations applied will not result in spectral leakage.

In this case, by simply setting the space width of comb filter according to different situations (usually the fundamental frequency), the harmonic and inter-harmonic signal components can be separated from signal.

3 Measurement of fundamental frequency from inter-harmonic signal

In accordance with IEC61000-4-7, due to the uncertainty of inter-harmonic frequency, at least 10 cycles of fundamental signal sequence are analysed in order to obtain a more accurate calculation value of fundamental cycle. Meanwhile, in order to ensure that the sample sequence after the reconstruction is no shorter than the sum of the length of both the comb filter and the analysis window, 20 cycles of sample sequence will be taken and it's mean value will be operated to obtain a more accurate value of the fundamental cycle [6-8].

$$\mathrm{T}^*_{\mathrm{MEAN}} = \frac{1}{20}[(k_{n+20} - k_n)T_s + (I_{n+20} - I_n)]. \tag{2}$$

Quasi-sampling period is: $\lambda_s = \dfrac{20T^*_{mean}}{L^*}$.

The reconstitution of sampling results after Newton interpolation is:

$$\mathrm{P}(m) = x(g_u T_s) + \tau_m \Delta f_0 + \frac{\tau_m(\tau_m - 1)}{2!}\Delta^2 f_0 + \cdots + \frac{\tau_m(\tau_m - 1)\cdots(\tau_m - 4 + 1)}{4!}\Delta^4 f_0 . \tag{3}$$

4 The design of equiripple comb FIR filter

Comb filters are generally divided into FIR and IIR filters. In the same filter performance parameters requirement, although IIR filter has lower order, its nonlinear and stability of phase characteristics does not meet the requirements of the inter-harmonic measurement; therefore, comb FIR filter will be chosen [9].

Supposing FIR filter with order Mi, if Mi is odd, then the transfer function can be expressed as:

$$H(z) = \sum_{m=0}^{2K} h(n)z^{-m} = z^{-K}[h(K) + 2\sum_{K=1}^{2K} h(K-m)\frac{1}{2}(z^m + z^{-m})] . \tag{4}$$

According to the first species of Chebyshev polynomials $T_n(\omega) = \cos(n \cdot \arccos(\omega))$, $\omega \in [-1,1]$ $\omega = \left(z + z^{-1}\right)/2$, then:

$$\mathrm{T}_{\mathrm{n}}(\omega) = \frac{z^n + z^{-n}}{2}, \tag{5}$$

$z = e^{j\omega}$.

The transfer function can be reduced as

$$H(z) = z^{-k}\sum_{m=0}^{k} a(m)T_m(\omega) . \tag{6}$$

Considering the impact of the filtering effect and filter order on the computational efficiency, design parameters of comb FIR filter with inter-harmonic detection algorithm will be selected. As mentioned earlier, first, the sample sequence with length of 20 fundamental cycles is selected; after reconstructing the sampling sequence, fundamental cycle is determined as 50.1 Hz, and sampling points 102. Then, the filter order of Chebyshev polynomial series is obtained through experiment. The amplitude-frequency response of designed comb FIR filter is shown as Figure 1 [10-12].

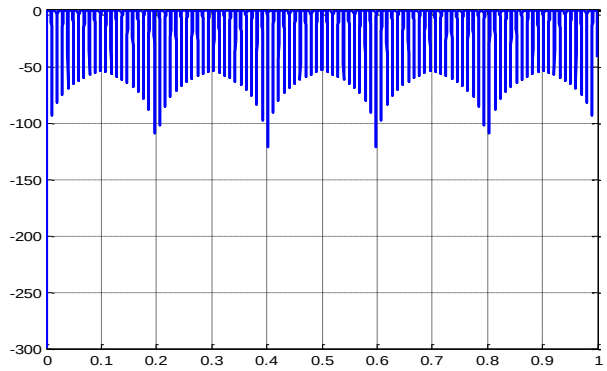

FIGURE 1 Amplitude-frequency Response of Comb FIR

In the harmonic measurement, impulse response effect needs to be considered, the impact of the filter impulse response is shown in Figure 2 [13, 14].

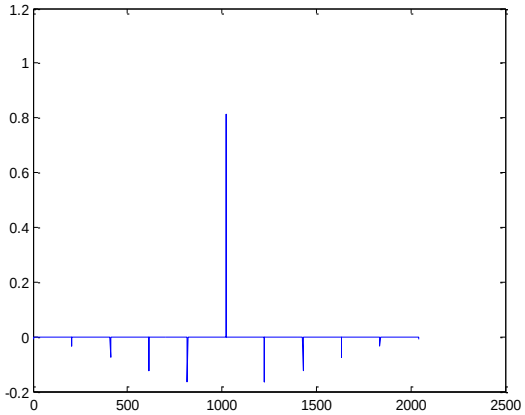

FIGURE 2 Impulse Response of Comb FIR Filter

5 Hardware structure diagram of harmonic and inter-harmonic analyzer

Hardware Structure Diagram of Harmonic and Inter-harmonic Analyser are shown in Figure 3. Three parts are

mainly included: data sampling module, the data processing module data management module [15] based on DSP and ARM.

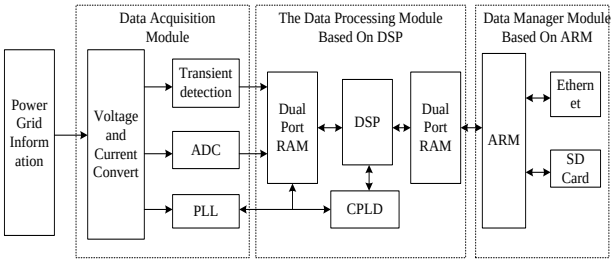

FIGURE 3 Hardware Structure Diagram of Harmonic and Inter-harmonic Analyzer

Among them, the data sampling module includes voltage and current transmitter, PLL, analog to digital converter (ADC) and transient detection and other components, which is mainly responsible for collecting original signal; data processing module is in charge of processing the collected power system voltage, current data, and transient information, meanwhile calculating power quality parameters, which is the core part of analyzer; data management module implements the function of data storage, management, human-computer interaction and supporting network communication.

For inter-harmonic detection, it needed to separate harmonics from inter-harmonics with comb FIR filter, which is a relatively large amount of data processing, and due to the power quality analyser's high requirements of accuracy, the high-performance TMS320C6713 DSP chip produced by TI will be chosen as the arithmetic unit to improve system performance.

In order to achieve inter-signal synchronization between phase position and frequency, a phase locked loop (PLL) circuit is used to automatically adjust the sampling frequency so, as to correspond to the synchronous measurement.

6 Experimental results

In order to carries on the analysis comparison, using the device on the analog signal test and analysis. The experiment uses FLUKE 6100A standard electrical power to produce a distorted signal as a test signal. The actual output signal is as shown in Equation (7):

$$x(t) = 10sin(49.9\omega t) + 0.6sin(99.8\omega t + 0.3) + 0.05sin(149.7\omega t - 0.15) + 0.2sin(75.5\omega t) + 0.05sin(154.5\omega t) \quad (7)$$

In the above Equation, the first three are the fundamental wave and second and third harmonics, the last two are inter-harmonics. The fifth inter-harmonic and third harmonic frequency are closer, and are prone to mutual interference, which can cause some difficulties to accurate measurement of inter-harmonics. The specific waveform is shown in Figure 4:

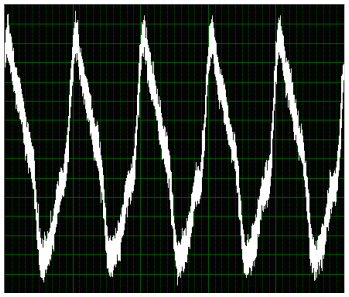

FIGURE 4 The measured signal waveform

Under the proposed IEC standard, the analysis window length should be 200 ms (approximately 10 cycles). The sampling frequency of inter-harmonic and harmonic analyser is the fixed value of 10240 Hz, which is 200 times of fundamental wave (about 50 Hz) in order to avoid aliasing, while ensuring high harmonic detection accuracy.

In addition, the analyser can upload the collected original signal to a computer to facilitate the comparison with a variety of other algorithms and calculation results. In this experiment the original signal is compared with the FFT and second-level WIFFTA methods. The results are in Tables 1-3.

154.5	0.05	154.65	0.15	0.04	0.01

7 Conclusions

Judging from the analysis, traditional FFT method is affected by spectral leakage, and accurate parameters of harmonics and inter-harmonics cannot be obtained; though the secondary WIFFTA method is with higher accuracy in the measurement, it cannot effectively suppress mutual interference

between Inter-harmonics and harmonics. Therefore, the accuracy of measurement will be affected, in case of serious mutual interference. In the three times measuring results for harmonics and 154.5 Hz inter-harmonics, both frequency and amplitude errors are relatively large. Yet, the present method, which provides better stability and accuracy, even in the case of serious mutual interference, and in which the accuracy of sub-harmonic measurement is able to meet the requirements, is significantly superior to the other two methods.

Abstract

A method for automatically selecting the asymptotical optimal parameters is presented for signal de-noising in discrete wavelet transform. The parameters of wavelet de-noising were first encoded. A generalized cross-validation algorithm was then used to select these parameters automatically. The parameters that obtained the smallest generalized cross-validation were asymptotically optimal. Simulation signals with different features and range signal-to-noise ratios were used to demonstrate the optimality of the proposed method. In addition, the Raman spectrum of edible oil and nuclear magnetic resonance spectrum of quinine and Boc-protected proline were employed as real-world data to validate the proposed method. The proposed method achieved superior performances in both real-world data and in artificial simulation.

Keywords: signal de-noising, wavelet transform, generalized cross-validation, parameter optimization

1 Introduction

Obtaining accurate characteristics of instrumental signal is important, however, the required signal is often polluted by noise. To extract reliable information from instrumental signals such as infrared spectra (IR), Raman spectral, unwanted noise should be removed [1, 2]. The effects of noise in spectra can be reduced in several ways. One of the most recent methods is based on wavelet transform (WT). Because of the advantages of the localization of time-frequency characteristics and the sparse representation of signal in the wavelet domain, discrete wavelet transform (DWT) is becoming an increasingly important tool in and compression [3-7]. The most popular tool in wavelet de-noising is the wavelet coefficient shrinkage method known as wavelet threshold de-noising [8-10]. The quality of wavelet threshold de-noising is strongly affected by several essential parameters, including wavelet function, decomposition levels, threshold estimate, and thresholding policy [2]. How to obtain these optimal parameters is an important issue for wavelet de-noising. To overcome this problem, cross-validation (CV) and generalized cross-validation (GCV) have been proposed to optimize the threshold estimate [2, 11-16]. Pasti et al. proposed a method to optimize individually the parameters, including the optimal decomposition level, wavelet function, and threshold estimate [2], Cai et al. employed minimum description length (MDL) algorithm to select the threshold and wavelet functions [17]. However, individual optimal parameters do not guarantee a global optimal when all parameters are considered simultaneously. To the best of our knowledge, no single method can optimize these parameters automatically and simultaneously in DWT threshold de-noising.

The present study obtains the optimal parameters by maximizing DWT threshold de-noising. The DWT threshold de-noising parameters are first encoded using Arabic numerals. The GCV algorithm, which was originally developed to optimize the soft threshold value, is then applied to determine automatically the optimal parameter combinations so that the optimal performance of DWT threshold de-noising can be reached.

2 Theory

2.1 DISCRETE WAVELET TRANSFORM (DWT)

Discrete wavelet transform is a linear transform, and the wavelet transform of a discrete signal f can be described as the follows:

$$w = Wf \,, \tag{1}$$

where W is an orthonormal matrix represented as wavelet basis or wavelet filter coefficients, and w I is the wavelet transform coefficients. f is decomposed by the filterbank with a lowpass filter and highpass filter of W into set of wavelet coefficients w:

$$w = [cD_1, cD_2, ..., cD_J, cA_J] \,, \tag{2}$$

where J is decomposition level, and $cD_1, cD_2, ..., cD_J$ represent the detail information of signal f and cA_J represents the approximation information. This transform localizes the most important spatial and frequent characteristics of f in a limited number of wavelet coefficients since the wavelet basis can be derived from a common function called

* ***Corresponding author*** e-mail: yep@wzu.edu.cn

mother wavelet, which has two operations: translation and dilation.

Signal reconstruction can be processed by the same highpass filter and lowpass filter in the W can be described by the simple equation:

$$f = W^t w, \tag{3}$$

where W^t is inverse wavelet transform. In practice, a fast algorithm developed by Mallat [18] is commonly used for performing the transformation.

2.2 DWT THRESHOLD DENOISING

An input instrumental signal can be represented as the sum of two components:

$$y = f + \varepsilon, \tag{4}$$

where f represents the ideal signal and ε represents the noise. A DWT yields the same situation in terms of wavelet coefficients:

$$w = v + \omega. \tag{5}$$

The vector $v = Wf$ contains the wavelet coefficients of the original instrumental signal. Here, $\omega = W\varepsilon$ is the noise coefficient and $w = Wy$ is the noisy signal coefficient. To obtain the ideal signal f, v and ω are separated from one another using a comparison of their wavelet coefficients. The simplified procedure for DWT threshold de-noising can be described as follows:

1) A wavelet transform is applied to signal y to obtain the wavelet coefficient w.

2) The wavelet coefficient ω is removed to obtain the estimated wavelet coefficient f_d.

3) The inverse discrete wavelet transform is applied to f_d to obtain the de-noised signal y_d.

One of the key issues of DWT threshold de-noising is how to estimate ω (i.e., how to distinguish ω from v). Many possible approaches can be used to estimate the noise level, a systematic analysis of the performance of these approaches can be found in [1, 19]. The universal threshold has the following format:

$$\mathrm{TUV} = \sigma\sqrt{2\ln N}, \tag{6}$$

where N is the length of signal y, σ is the standard deviation of the noise, and estimated from the median of the detail coefficients at the first level of signal decomposition.

$$\sigma = \mathrm{median}\left|(\mathrm{de\,tai1})\right| / 0.674. \tag{7}$$

Once the threshold value has been calculated, the key question is how to obtain f_d. In general, DWT threshold de-noising methods use two different policies: hard and soft thresholding. The hard thresholding policy simply sets all the wavelet coefficients below a certain threshold th to zero:

$$\begin{cases} w_{ij}^t = w_{ij} & if\ \left|w_{ij}\right| > th \\ w_{ij}^t = 0 & if\ \left|w_{ij}\right| < th \end{cases}. \tag{8}$$

In soft thresholding, the values of the wavelet coefficients are shrunk by a certain threshold if they are above a certain threshold th:

$$\begin{cases} w_{ij}^t = \mathrm{sgn}(w_{ij})(\left|w_{ij}\right| - th) & if\ \left|w_{ij}\right| \geq th \\ w_{ij}^t = 0 & if\ \left|w_{ij}\right| < th \end{cases}, \tag{9}$$

where sgn is the sign function that returns the sign of the wavelet coefficient w_{ij}.

2.3 GENERALIZED CROSS-VALIDATION (GVC)

The goal of signal de-noising is to minimize the difference between the de-noised and the ideal (i.e., noiseless) signal, thereby minimizing the mean square error (MSE), as shown below:

$$\mathrm{MSE} = \frac{1}{N}\left\| f_d - f \right\| = \frac{1}{N}\sum_{i=1}^{N}\left(f_d(i) - f(i) \right)^2, \tag{10}$$

where f_d is the de-noised signal, f is the ideal signal. However, normally, the ideal signal is not known. Thus, MSE cannot be obtained.

The GVC theory was developed to estimate the best threshold value to optimize DWT threshold de-noising using the soft thresholding policy. GVC defines the risk estimate function as follows:

$$GCV(\xi) = N\left\| w - w_\xi \right\|^2 / N_0^2, \tag{11}$$

where N_0 is the number of the coefficients replaced by zero, N is the total number of the wavelet coefficients, w_ξ is the modified wavelet coefficient after applying a threshold ξ, and w is the wavelet coefficient of the original noisy signal. [12] proved that the threshold ξ that results in the smallest GCV is asymptotically optimal under certain conditions. Moreover, [20] improved the GCV algorithm for the hard thresholding policy. The detailed description of the GVC theory can be found in the document [20]. In general, when GCV is smallest, MSE is asymptotically at minimum, which means searched parameter for de-noise might be optimal, and might also rank among the top 10%, and implies that the de-noising result is asymptotically optimal. Moreover, GVC only depends on input and output data, which are of vital importance in practice. Therefore, GCV is able to measure MSE when the shape of the signal is unknown or the noise energy is difficult to estimate.

3 Experimental and calculations

3.1 ENCODING OF DWT THRESHOLD DENIOSING PARAMERERS

Many types of wavelet functions exist, and some wavelet families contain wavelets of different orders. The Db, Bior, Sym, and Rbio wavelets which are the different filters have been proven effective in signal processing [21]; however, the present study is limited only to the daubechies, symmlet, bior, and rbio families of filters. A total of forty-eight filters were investigated in the present study. To obtain the minimum GCV, these wavelet functions need to be encoded as variables denoted as Arabic numerals. For example, "1" denotes the wavelet function "sym1," "11" denotes the wavelet function "db1," and "48" denotes the wavelet function "dmey." At the same time, other parameters, such as decomposition levels, threshold policy, and threshold estimation, are also encoded as Arabic numerals. The definitions and the encoding of these parameters are shown in Table 1.

TABLE 1 Definition and Encoding of wavelet de-noising parameters

Parameters description	Definition domain	Remark
Wavelet function	[1, $N_{wavelet\ name}$][1]	$N_{wavelet\ name}$ is the number of wavelet function in definition domain. Here, $N_{wavelet\ name}$ is 48.
Decomposition scales	[1, N_{max}]	N_{max} is the maximum of decomposition scales. Here, N_{max} is 10.
Threshold estimation	[5Tuv, 8Tuv]	Tuv is universal threshold.
Thresholding policy	[1, 2]	Hard or soft thresholding.

[1] Wavelet filters from 1 to 48: sym1, sym2, sym3, sym4, sym5, sym6, sym7, sym8, sym9, sym10, db1, db2, db3, db4, db5, db6, db7, db8, db9, db10, db12, db15, db18, db20, db30, bior1.1, bior1.3, bior2.2, bior2.4, bior3.1, bior3.3, bior3.5, bior3.7, bior3.9, bior4.4, bior5.5, bior6.8, rbio1.1, rbio1.5, rbio2.2, rbio3.3, rbio3.5, rbio3.7, rbio3.9, rbio4.4, rbio5.5, rbio6.8, Dmey;

3.2 SIMULATION SIGNALS AND CALCULATIONS

Different simulation signals were considered in order to evaluate the performance of the proposed method. The simulation signals of Blocks, Bumps, Heavysine and Doppler signal in the wavelet tool are employed in present study. The four signals contain abundant frequency components, many peak information and lots of catastrophe parts, so they are always used as the typical signals for comparing the quality of de-noising algorithms. The four original signals and noisy signals are showed in Figure 1.

In this study, the Wavelet Toolbox 3.0 (The Math Works, Natick, USA) was used, and the Pieflab Toolbox for GCV algorithm can be obtained from http://homepages.ulb.ac.be/~majansen/software/ thresh -lab.html, and all the calculations were performed on the platform of MATLAB 7.6 (The Math Works, Natick, USA).

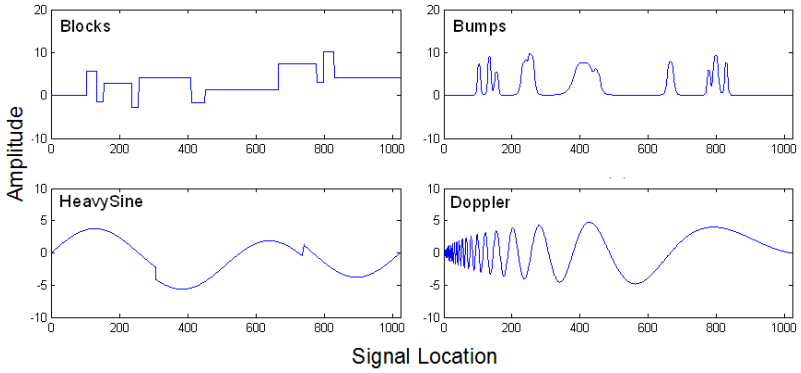

FIGURE 1 Four simulation signals

4 Results and discussions

4.1 SIMULATION DATA

In this study, the definition domain of the threshold was from 5Tuv to 8Tuv with the interval of 1 unit. As a result a total of 40 definition points are available.

As mentioned above, when the minimum GCV value is achieved, MSE is also near to the optimal value under certain conditions. This means that the parameter combinations of DWT threshold de-noising corresponding to the minimum GCV are also near to optimal. For real-world signals, MSE cannot be estimated, hence, rather than MSE, the proposed GCV approach was adopted to optimize the parameter combinations.

Random noise was added 100 times to each type of simulation signal with the signal-to-noise ratio (SNR) ranging from 16.34 to 21.18 (Level 1) to validate whether the parameter combinations corresponding to the minimum GCV (or optimal GCV) are optimal. Each type of simulation signal can obtain 100 noisy signals. Here, only Doppler noisy signals are listed in Figure 2a (Level1). The MSE value corresponding to the minimum GCV (GCV-MSE) can be obtained from 38,400 (48 * 10 * 40 * 2 parameter combinations) different MSE values. Observing the arrangement locations of GCV-MSE in all 38,400 MSE

values is a simple way to determine whether GCV-MSE is minimum. When GCV-MSE is minimum (or ranks first), and imply the obtained parameter combination is optimal. Similarly, if GCV-MSE is near to minimum (or ranks in the top ten or top one hundred), the searched parameter combination is asymptotical optimal. The GCV-MSE concrete arrangement distribution of 100 noisy signals of each type of simulation signals is shown in Figure 3a. In Figure 3a, the abscissa values for Blocks, Bumps, Heavysine, and Doppler signals are 1–100, 100–200, 201–300, and 301–400, respectively. The small circles in Figure 3a represent the arrangement position of each noisy signal. Each discrete point is connected with solid lines for easy comparison of several different signals.

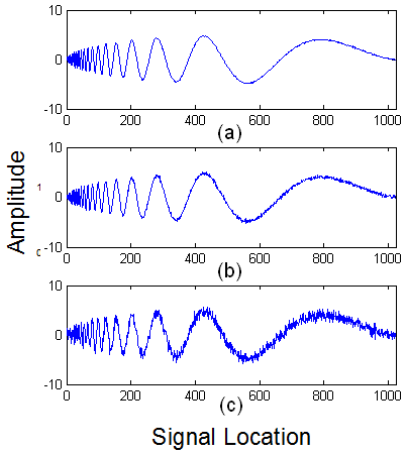

FIGURE 2 Noisy Doppler signals with different SNR level: (a) Level 1 (b) Level 2 (c) Level 3

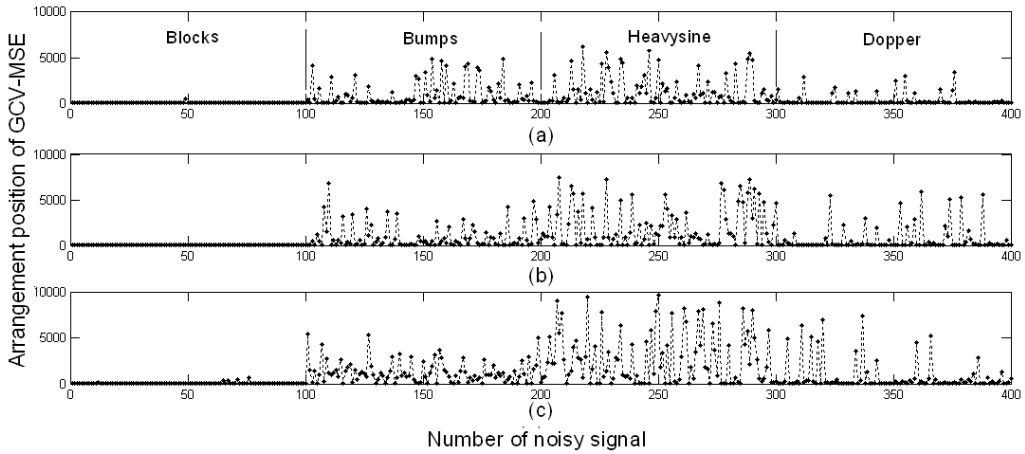

FIGURE 3 GCV-MSE Arrangement locations of four simulation signals with different SNR, 1-100 is the arrangement locations of GCV-MSE for the Blocks signals, 100-200 are for Bumps signals, 201-300 are for Heavysine signals, 301-400 are for Dopper signals: (a) level 1 SNR (b) level 2 SNR (c) level 3 SNR

As seen in Figure 3a, the arrangement locations of GCV-MSE is relatively small for signals with the SNR level 1, and most of them are lower than 5,000, which indicates that the identified parameter combination is working well. A comparison of the optimization results of four signals shows the results of the Block signal sequence 1–100, as shown in the Figure 3a to be the best. This result can be explained by the GCV algorithm principle. Because the GCV algorithm is more suitable for regular signals, it is more appropriately applied in signals with less frequency information. The mean and standard deviation of GCV-MSE arrangement positions listed in Table 2 further validate the optimization effect of the proposed method. As shown in Table 2, the mean of the arrangement locations of the GCV-MSEs is top-ranked (corresponding to 38,400 combinations), indicating that optimization results are very satisfactory. Compared with these results, the mean of Heavysine is the largest, which indicates that the optimization result is the worst among the four simulation signals. Moreover, the standard deviations of the Blocks signals are smaller than that of the other three signals, which indicate that the proposed method is relatively stable for Blocks signals.

TABLE 2 Mean and standard deviations of GCV-MSE arrangement locations of four simulation signals

Level 2	17	16	847	1297	1947	2215	580	1339
Level 3	38	92	1239	1176	2729	2840	690	1586

TABLE 3 Mean and standard deviations of MDL-MSE arrangement locations of four simulation signals

Signals SNR level	Blocks		Bumps		Heavysine		Doppler	
	Mean	*Sd*	*Mean*	*Sd*	*Mean*	*Sd*	*Mean*	*Sd*
Level 1	71	74	2007	981	3897	1895	1131	692

The MDL algorithm is free from any parameter setting or any subjective judgment when used for data compression and de-noising [17]. In the present study, the MDL algorithm can also be used in the parameter optimization of the DWT algorithm, with the coding and setting of the parameters the same as before. The optimization result shown in Table 3 also shows a comparison of the results of GCV algorithm of the noise level 1. Based on the Table 3, the MDL algorithm is inferior to the GCV algorithm, which is consistent with the result proposed by the document [2]. Moreover, MDL can only be used for optimization of hard threshold values. Hence, the following studies are all based on GCV algorithm.

To investigate the influence of adding signals with different noise levels on the proposed method, 100 noisy signals with SNRs ranging from 11.17 to 16.22 (Level 2) and from 8.82 to 11.37 (Level 3) are employed. The noisy signals with different SNRs are shown in Figure 2b and 2c, along with a list of the Doppler noisy signals. Similarly, the GCV-MSE specific arrangement distributions of the SNR levels 2 and 3 are shown in Figures 3b and 3c. Clearly, the performance of the proposed method is influenced by different levels of noises. Based on Figure 3, the Heavysine and Doppler signals are influenced the most, followed by the Bumps signal, whereas little influence is generated on the Blocks signal. These results indicate that the proposed method is suitable for several regular signals, further verifying that the GCV algorithm is more suitable for regular signals. In Figure 3b, most of the GCV-MSE arrangement locations are within 5,000, and only a few Bumps and Heavysine signals exceed 5,000, and the GCV-MSE arrangement locations greater than 5,000 are slightly increased for the SNR level 3, especially for Heavysine signal, as seen from Figure 3c. However, compared with the 38,400 MSE values, the arrangement locations are still placed at the front location. The mean and standard deviations of the arrangement positions of 100 GCV-MSE of the four types of signal with SNRs at Levels 2 and 3 are listed.

As seen from Table 2, the means of all the arrangement locations are small, which indicates that the parameter optimization results are satisfactory. The Heavysine and Doppler signal are greatly affected by noise on the aspect of standard deviation values, whereas noise has little influence on Blocks signals.

At the same time, the specific numbers of different arrangement scopes have been summarized out, as shown in the Table 4. The optimization results of the parameters of three types of noises which is shown in the Table 4 indicate that the numbers of those whose arrangement locations are below 384 are 292, 269 and 227 respectively, which means that there are probability values of 73.00%, 67.25 and 56.75% to select the optimal combinations of top 1% correspondingly. Meanwhile, this also means that there are probability values of 94.50%, 91.75% and 89.25% for the optimal combinations of top 10% to be selected respectively. This result is very satisfactory for such a huge combination of 38400.

In order to investigate the relation between the GCV value and the corresponding MSE values, each GCV value of the 38,400 different parameters and the corresponding MSE values should be listed. However, illustrating such massive data would be impossible because of page limitations. Hence, only 200 data were selected randomly from Block and Heavysine signals, their GCV values and the corresponding MSE values are reported in Figure 4. As one can see from Figure 4a, small GCV is not always corresponds to the small MSE, however, in the region of GCV smaller than 0.5, the trends of GCV and MSE are similar, based on Figure 4b, it was found that the smaller GCV and MSE correspond to same data point (parameter combination). Similar situation is also happened in the Heavysine signal; the detailed results are showed in Figures 4c and 4d.

4.2 REAL-WORLD DATA

The real-world data used in the present study is the Raman spectrum of edible oil (mainly composed of protein and fat). The T64000 Raman spectrometer used was produced by the French HORIBA Jobin Yvon Company. All Raman tests were conducted at room temperature. The excitation light source used was an argon ion laser with a wavelength of 514.5 nm, laser power of 120 mw, and scanning wavenumber range of 500–3,500 cm^{-1}. The experimental light path was backscattered. Laser-formed light spots were shown to have a diameter of approximately 1 um on the sample surface after being focused 100 times by the object lens. The original Raman spectrum in Figure 5a shows four peaks with different widths; the figure also shows the height and the area of the spectra peaks. In general, the shapes of the peaks, including width, height, and area should be maintained in the de-noising process to avoid influence on the analysis results. This makes signal de-noising very challenging.

Using the proposed GCV methodology, the optimal parameter combinations were obtained as 8, 5, 4, and 1. Correspondingly, wavelet function of sym8, decomposition level of 5, a 4/5 Tuv threshold and hard threshold were employed. De-noising result in Figure 5b shows that the shapes of several peak values to be well kept, whereas most of the noises were eliminated. The attributes of the peak, including position, height, width, and area, are the main indices that define the components in the Raman spectrum analysis. The changes of the attributes of the peak before and after de-noising are shown in Table 5. The position, width, height, and area of the peak showed no prominent changes after the noise of the original spectrum was eliminated.

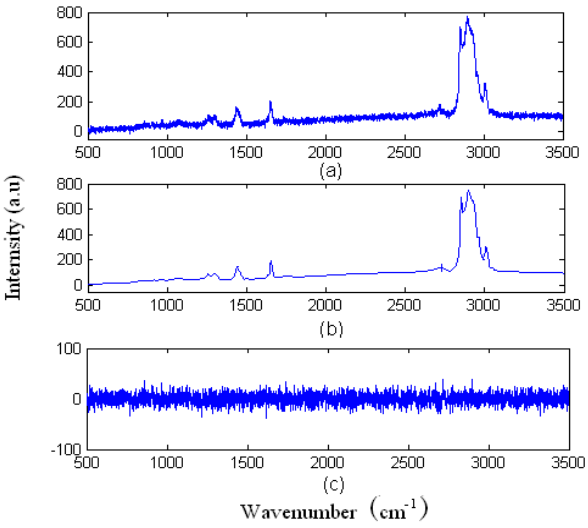

FIGURE 5 Raman spectrum of edible oil: (a) noisy spectrum (b) denoised spectrum (c) noisy signals

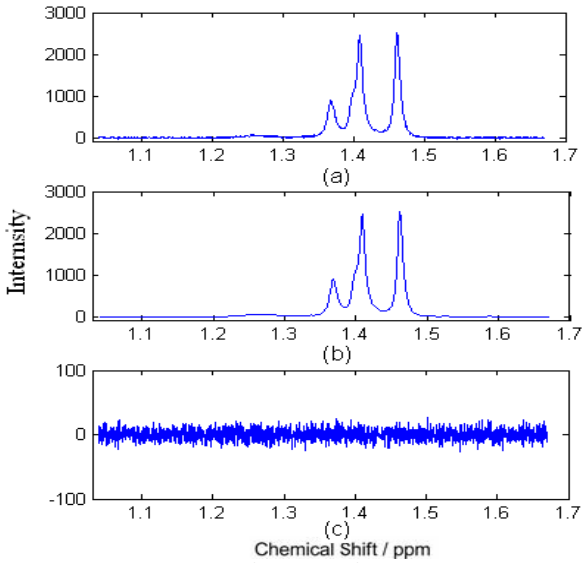

FIGURE 6 NMR spectrum of mixtures of quinine and Boc-protected proline: (a) noisy spectrum (b) denoised spectrum (c) noisy signals

Another real-world data is nuclear magnetic resonance (NMR) spectrum in Figure 6a, which was obtained 16:84 mol ratio mixtures of quinine and Boc-protected proline with enantiomeric excess of 10% in CDCl3. The NMR spectra were recorded after several minutes of thermal equilibration time. NMR spectrum was recorded on a Bruker Avance 500 MHz spectrometer. Spectrum was recorded using 16 scans at 298K. A full spectrum of sample was recorded referenced to TMS. An exponential window function with a line-broadening factor of 1Hz was applied to the FID before Fourier transformation. The 1H-NMR spectrum was phased and baseline-corrected using Topspin 2.1(Bruker) and was automatically reduced by using the AMIX (Bruker GmbH, Germany) software package to continuous integral segments of equal width of 0.004ppm corresponding to the chemical shift range 1H, δ 6.9–8.8 after removing the solvent resonance region (δ 7.2-7.3). Similar to the situation of Raman spectrum, to de-noise NMR spectrum is a very challenging thing because it requires that the shape of the peak should remain unchanged as much as possible. Since several peaks of this NMR spectrum are connected together, there is impossible to calculate the area and width of each peak. Therefore, we give the height of the peak and total area and width of three peaks prior to de-noising here. Using the proposed GCV methodology, the obtained optimal parameter combination is 4, 5, 4 and 1, correspondingly, parameters of wavelet function is sym8, decomposition level is 5, and 4/ 5Tuv threshold and hard threshold are employed. De-noising results are shown in the Figure 6b. The changes of the attributes of the peak before and after de-noising are shown in Table 6, as one can see from the Table 6, the spectral profile after de-noising, the height of the peak changes relatively less, and the shape of peaks almost remain unchanged, indicating that the de-noising effect is relatively satisfactory. Hence, it can be concluded that the parameter combination thus generated is relatively ideal.

5 Conclusions

The present paper proposed an algorithm that automatically selects DWT threshold de-noising parameters based on the GCV algorithm. Parameter optimization includes wavelet function, decomposition level, threshold estimation, and threshold policy. Four simulation datasets and real-world data of Raman spectral and NMR signals were used for validating the proposed algorithm. The results show that the identified minimum GCV value produces a better MSE value. Therefore, DWT threshold de-noising can be optimized automatically through reasonable parameter encoding based on GCV value. At the same time, the optimization ability of the proposed method slightly degrades with the increase of the magnitude of added noise.

Abstract

The experiments of dry turning hardened steel with ceramic tool (CC6050) were carried out. The cutting forces of ceramic tool with different cutting parameters were measured by Kistler cutting force acquisition system, the prediction model of the surface roughness was built by Particle Swarm Optimization (PSO), the wear morphology of the tool and chip characteristics were observed by scanning electron microscope (SEM), analyzed the wear zone of the tool by the EDAXPV990(EDS). Results indicated that the cutting depth was the dominant factor affecting the cutting force, next was feed speed, the minimum was cutting speed. The feed speed was the dominant factor affecting the surface roughness, next was cutting depth, the minimum was cutting speed. The crater wear was shown on the rake face and the evenly distributed strip shaped wear was shown on the flank of the CC6050 tool, the main wear mechanism was abrasive wear, diffusion wear, adhesive wear and oxidation wear. The shape of chip was saw-tooth, the rough slice layers with periodic flow were shown on the upside of the chip and the streaks were evenly distributed on the underside of the chip. The cutting speed and feed speed were larger, the serrated level of the chip was higher and the angle of shear was larger.

Keywords: Ceramic Tool, Dry Turning, Hardened Steel, Machinability

1 Introduction

Hardened steel has been used in manufacturing all kinds of mechanical parts with high hardness and high wear resistance attribute to its excellent mechanical properties. Grinding was the most traditional processing technology on finishing hardened steel, however, it would cause lower production efficiency, high cost and heavy environmental pollution [1-3]. With the development of the super-hard tool materials, dry turning instead of grinding on finishing hardened steel is expected to become the new technology. However, hardened steel has high hardness and poor machinability, in order to achieve the technology by using dry turning instead of grinding, the tool material should have good resistance of thermic wear, tool edge and tool nose should have enough strength and low breakage rate of wear, all of above can ensure that the machining error is within the scope of the working accuracy.

Ceramic tool has high micro hardness and heat stability. It has good resistance of thermic wear when turning the hardened steel and the materials of ceramic tool are abundant, its price is not half of the CBN tool. The strength and fracture toughness would be increased greatly by advanced milling, sintering process and toughening technology. It has good comprehensive mechinablity and high cost performance [4]. So it is the ideal tool in dry turning hardened steel.

Xiaobin cui etc researched the evolution of the tool failure in intermittent turning hardened steel with ceramic tool, built the formulas of the tool life in the different failure stage of evolution under the condition of intermittent turning [5]. Professor Gabriel C. Benga in Romania did the research on the influence of tool life and surface roughness by cutting depth when turning 100Cr6 bearing steel with ceramic and PCBN cutting tools [6]. Xiaoguang Wang etc did the experiments on dry turning hardened steel by ceramic tool, researched the endurance, wear morphology and wear mechanism of the ceramic tool [7]. Xuhong Guo etc researched the wear morphology, wear properties and wear mechanism when turning GCr15 hardened steel with ceramic tool and PCBN tool [8]. Many scholars did the studies of dry turning hardened steel by ceramic tool, but most studies focused on the tool endurance and tool wear, it was lacked for intensive study on cutting force, surface quality, tool wear and chip characteristics in dry turning hardened steel, reports on these aspects at home and abroad were few.

The experiments of dry turning hardened steel by ceramic tool (CC6050) were carried out in this paper. Measured the values of cutting force in different cutting parameters, built the prediction model between cutting parameters and surface roughness by PSO, researched the impact of cutting parameters on the cutting force and surface roughness, micro analyzed the wear morphology of the CC6050 and the chip characteristics, researched their affects on dry turning hardened steel. We hope we can provide some experimental basis for popularization of the high hardened tool material.

2 Materials and Methods

The work material was GCr15 bearing steel，its chemical composition was shown in Table 1. It was provided by Suzhou Jingji Mech & Elec CO., LTD, which was φ40×300mm cylindrical specimen. The hardness of the

* ***Corresponding author*** e-mail: tucj@siit.edu.cn

workpiece quenched by machine oil at 840℃was 60HRC (58HRC~61HRC).

TABLE 1 Nominal chemical composition of GCr15 bearing steel (wt%)

C	Si	Mn	Cr	Mo	P	S
0.95~ 1.05	0.15~ 0.35	0.25~ 0.45	1.40~ 1.65	≤0.1	＜0.027	＜ 0.020

Dry turning experiments were carried out on the CA6140A lathe. The lathe was the product of Shenyang No.1 Machine Tool Plant. The ceramic cutting tool was the product of SANDVIK Company in Sweden. The type was SNGA120408S01525 6050. After clamping, the geometric parameters of the tool were shown in Table 2.

TABLE 2 Geometric parameters of the tool after clamping

γ_o	α_o	λ_s	κ_r	r_ε	b_{rn}	γ_n
-6°	0°	-6°	75°	0.8 mm	0.15 mm	25°

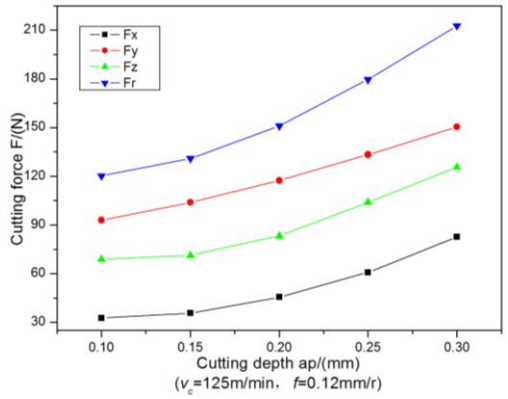
The values of the cutting force in different cutting parameters were measured by the cutting force data acquisition system, which was made up of Kistler9257B piezoelectric crystal sensor dynamometer, Kistler 507A10100 charge amplifier, Kistler9403 steel tool rack and computer. The surface roughness experiment based on $L_9(3^3)$ orthogonal, the factors of experiment were cutting speed, feed speed and cutting depth. The values of the surface roughness in different cutting parameters were measured by 2025 surface roughness tester. Enlarged photomicrograph of the wear morphology on the rake face and flank of CC6050 and chip characteristics were acquired by S-4700 scanning electron microscope (SEM), analysed the wear zone of CC6050 by EDAXPV9900 (EDS).

3 Results and Discussion

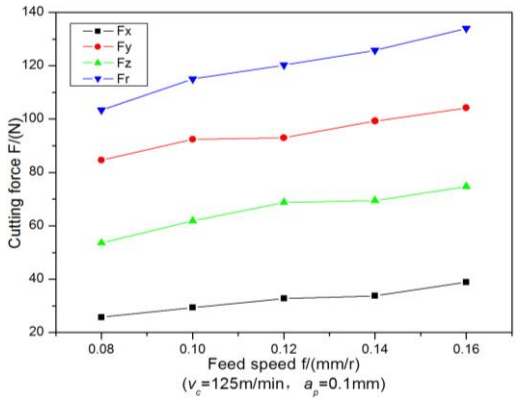
3.1 IMPACT OF CUTTING PARAMETERS ON CUTTING FORCE

The influence curves of cutting force in different cutting depth were shown in Figure 1(a) when cutting speed was 125m/min and feed speed was 0.12mm/r. The influence curves of cutting force in different feed speed were shown in Figure 1(b) when cutting speed was 125m/min and cutting depth was 0.1mm. The influence curves of cutting force in different cutting speed were shown in Figure 1(c) when feed speed was 0.12mm/r and cutting depth was 0.1mm. F_x was axial cutting force, F_y was radial cutting force, F_z was main cutting force and F_r was resultant tool force in three directions.

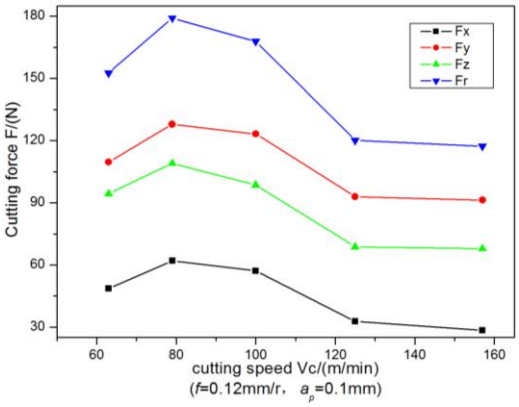
Figure 1(a) showed that the cutting forces in three directions of CC6050 increased gradually with cutting depth increasing when feed speed and cutting speed were certain and the relation was approximately linearity. When the cutting depth was less than 0.15mm, the trend of cutting force increasing was slow, when the cutting depth was larger than 0.15mm, the trend of cutting force increasing was fast. Figure 1(b) showed that the cutting forces in three directions of CC6050 also increased with feed speed increasing when cutting speed and cutting depth were certain, but the trend of cutting force increasing was not obviously, especially the cutting force in three directions keep basically stable when feed speed was within the scope of 0.12mm/r and 0.14mm/r. Figure1(c) showed that the cutting forces in three directions increased with cutting speed increasing when cutting speed was less than 80m/min and decreased when the cutting speed was larger than 80m/min. Especially the trend of cutting force decreasing was obviously when cutting speed was within the scope of 80m/min and 125m/min, the trend was slow when the cutting speed was larger than 125m/min. Compared with Figure 1(a), (b) and (c), the radial force was maximum, next was the main cutting force, the minimum was axial force when dry turning hardened steel by CC6050.



(a) Impact of cutting depth



(b) Impact of feed speed



(c) Impact of cutting speed

FIGURE 1 Influence curves of cutting force in different cutting parameters

The reason was: cutting width a_w increased in direct proportion to cutting depth ($a_w=a_p/\sin K_r$), it caused cutting layer area, the deformation resistance and friction force increased, so cutting force increased. Cutting force increased with cutting power increasing when feed speed increased and cutting thickness a_c increased in direct proportion to feed speed ($a_c=f\sin K_r$), the deform coefficient ξ and friction coefficient μ decreased, so cutting force decreased. Therefore the trend of cutting force increasing was not obviously when feed speed increasing.

When the cutting temperature raised with cutting speed increasing, the metal softening effect was produced in the workpiece [9, 10], the friction coefficient μ decreased with cutting speed increasing, the angle of shear φ increased, it caused the deform coefficient ξ decreased, so the cutting force decreased.

3.2 IMPACT OF CUTTING PARAMETERS ON SURFACE ROUGHNESS

The values of the surface roughness after dry turning hardened steel by ceramic tool were shown in Table 3 based on L_9 (3^3) orthogonal experiment.

The theoretical prediction model of surface roughness was shown in Eq.1. The objective function built by Particle Swarm Optimization (PSO) was shown in Eq.2. Optimized the objective function with 1stOpt mathematical analysis software, the constraint expression was $x_{min} \leqslant x_i \leqslant x_{max}$ (x_{min} was the lower limit value of the variable and the x_{max} was the upper limit value of the variable) [11].

The each parameter in Particle Swarm Optimization was as follows: the populations size was 100, adjacent population was 2, the value of weighting factor was 0.1, learning factor was 2.05, the max speed was 2, the iterations was 5000. The model simulated with experiment results was shown in Eq.3.

TABLE 3 The measure results of surface roughness experiment

NO.	v_c(m/min)	f (mm/r)	a_p (mm)	R_a (um)
1	100	0.08	0.1	0.51
2	100	0.12	0.2	0.67
3	100	0.16	0.3	1.01
4	125	0.08	0.2	0.48
5	125	0.12	0.3	0.76
6	125	0.16	0.1	0.78
7	157	0.08	0.3	0.49
8	157	0.12	0.1	0.57
9	157	0.16	0.2	0.93

$$R_a = ka_p^x f^y v_c^z = e^{x_1} a_p^{x_2} f^{x_3} v_c^{x_4}, \quad (1)$$

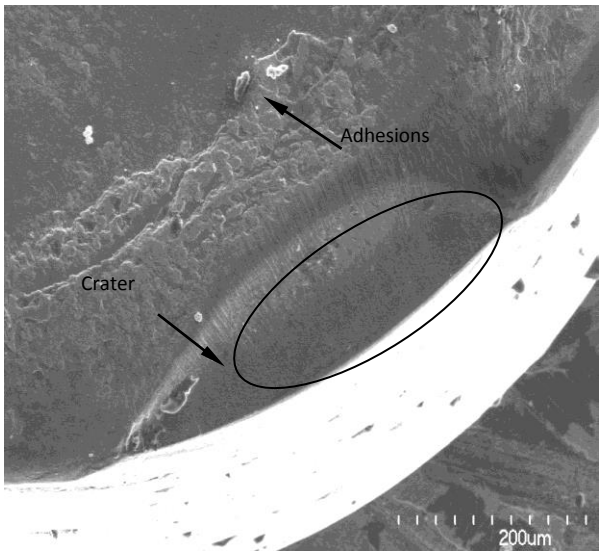
$$\min(f(x_1,x_2,x_3,x_4)) = \sum_{i=1}^{9} \left| e^{x_1} v_{ci}^{x_2} f_i^{x_3} a_{pi}^{x_4} - R_{ai} \right|, \quad (2)$$

$$R_a = e^{2.1599} v^{-0.0189} f^{0.9739} a_p^{0.2314}. \quad (3)$$

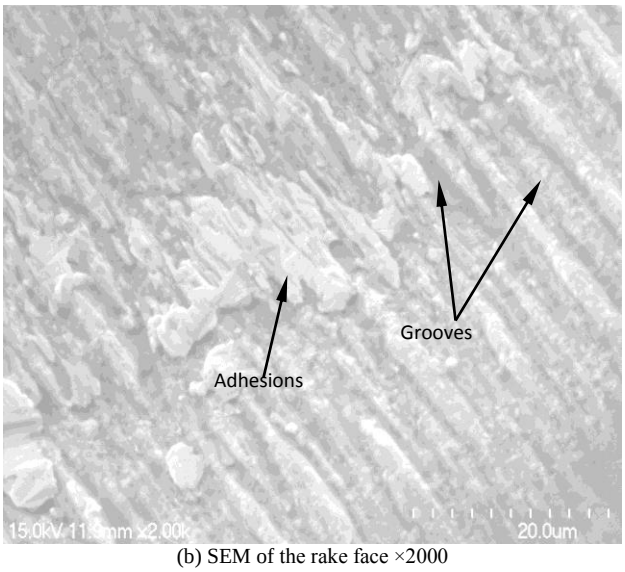
Eq.3 showed that the index of feed speed and cutting depth were positive value, so the surface roughness increased when feed speed and cutting depth uninterrupted increasing, the index of cutting speed was negative value, the surface roughness decreased when cutting speed uninterrupted increasing. It was apparent from the value of every index that the dominant influence factor of cutting parameters was feed speed, next was cutting depth, the minimum was cutting speed.

3.3 WEAR MORPHOLOGY ANALYSIS

The wear morphology of the rake face and flank were shown in Figure 2 and Figure 3 when dry turning hardened steel by ceramic tool (CC6050). The cutting parameters were v_c=125m/min, a_p=0.2mm, f=0.12mm/r, cutting time was 25min.



(a)SEM of the rake face ×200

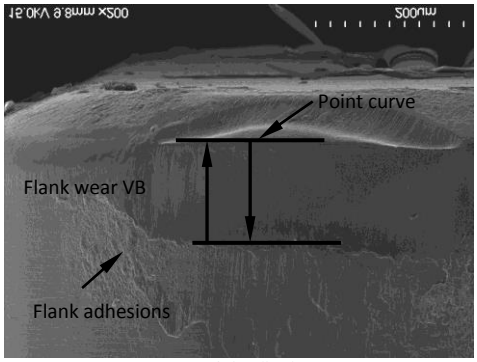


(b) SEM of the rake face ×2000

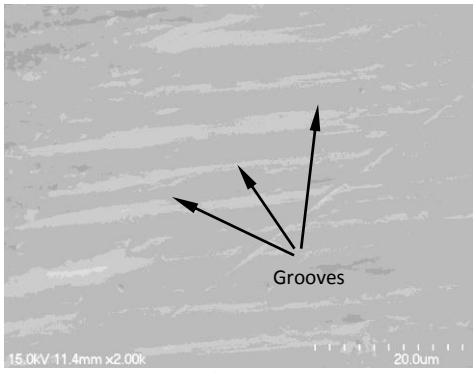
FIGURE 2 The Wear morphology of the rake face of CC6050 in later period of wear

Figure 2(a) showed that there was obviously crater wear on rake face of CC6050, wear zone was basically parallel to the rake face, it was wide at center and narrow at both sides. The wear area grouped mainly on the negative chamfering of the tool nose, it was directly connected with the tool edge,

the depth of the crater was steady. Figure 2(b) showed that the groove like plowed covered on the wear area of the rake face, accompanied with more adhesions. The features of abrasive wear and adhesive wear were obviously showed in Figure 2.



(a)SEM of the flank ×200



(b) SEM of the flank ×2000

Figure 3 The wear morphology of the flank of CC6050 in later period of wear

Figure 3(a) showed that there was strip shaped wear on the flank of CC6050 and its width was steady, the abrasion was relatively large on the arc chamfering of tool nose, accompanied with more adhesions near by the flank wear area, the wear marks was not obviously on the border of wear area, large slough was not exist. Figure 3(b) showed that the groove like plowed on the wear area of flank was steady. The steady feature of abrasive wear was showed in Figure 3.

The main reason to produce the wear morphology of the above was: in the cutting progress, the acutely friction was produced by high stress contact between the rake face of tool and chips, the average temperature measured in these cutting areas was higher than 1000℃ according to work-tool thermocouple principle, adhesive, diffusion and oxidation wear were intensified, the high temperature zone of the tool was close to the tool edge and the cutting force was also focused on the near to the tool edge, the softened tool edge with heat deformed and collapsed [12]. Elastic and plastic deformation were produced because the contact force between the flank and surface of the workpiece was very large, the contact area between flank and workpiece was small, the strength of tool nose was lower and the cooling condition was poor, so the wear was serious.

3.4 WEAR MECHANISM

The EDS spectra of the tool face on CC6050 before and after dry turning were shown in Figure 4.

Compared with Figure 4(a), (b) and (c), the mass fraction of oxygen in the rake face and frank of CC6050 was improved from 13.43% to 25.38% (in the rake face) and 39.04% (in the flank), it proved that the oxidation wear was produced. The mass fraction of Ti was decreased from 37.58% to 8.28% (in the rake face) and 11.92% (in the flank), it proved that Ti in the tool had been diffused to the material and chip, the diffusing phenomenon in the rake face was more obviously. The mass fraction of Si and Al had little change, it proved the chemical affinity between Si, Al and material was small, it was hard to adhere in turning. Otherwise, the Fe, C and Cr was added in the flank of the tool, the mass fraction was 7.96%, 5.37% and 3.63% respectively, the three elements of the material were separated out because of the high temperature in turning and diffused to the flank of the tool. There had no Cr element in the rake face, but the content of the Fe and C in the rake face was higher than flank, its mass fraction was 25.85% and 17.75% respectively, the chemical affinity between the tool and material was improved with the content of the Fe and C improved, it caused the adhesive wear of the tool was produced [13].

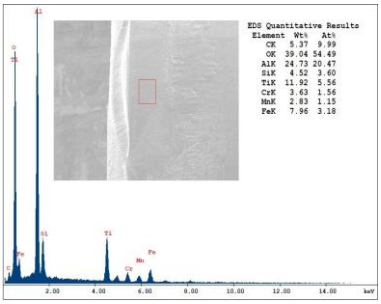
(b) The EDS spectra of the rake face after dry turning



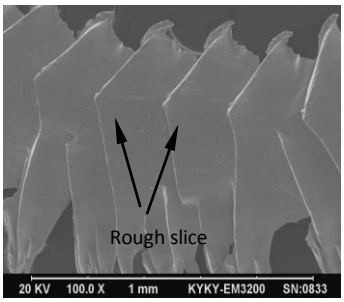
(c) The EDS spectra of the flank after dry turning

FIGURE 4 The EDS spectra of CC6050 before and after dry turning

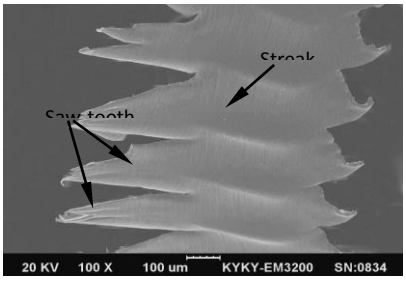
3.5 CHIP CHARACTERISTICS ANALYSIS

The shape of chips was shown in Figure 5 when dry tuning hardened steel by CC6050. Figure 5(a), (b), (c) showed the shape of chips when the cutting parameters were v_c=157m/min, f=0.2mm/r, a_p=0.3mm. The values of three cutting forces measured in these cutting parameters by Kistler cutting force acquisition system were F_z=262.95N, F_x=142.44N, F_y=371.04N. Figure 5(d),(e),(f) showed the shape of chips when the cutting parameters were v_c=125m/min, f=0.12mm/r, a_p=0.4mm. The values of three cutting forces were F_z=213.06N, F_x=145.67N, F_y=259.61N.

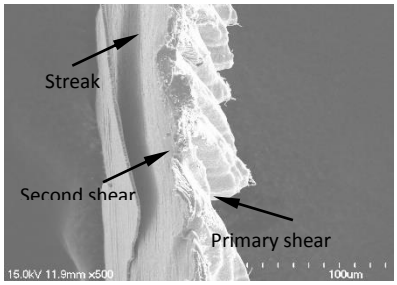
Figure 5 showed that the chip characteristic was obviously saw-tooth when dry turning hardened steel by CC6050. The extrusion plasticity shear of the chip was produced in the primary and second shear zone [14]. The severe plastic deformation was produced under extreme stress in the primary shear zone, so the rough slice layers with periodic flow was shown on the upside of the chip and the underside of the chip was smooth, the streak was evident as a result of the extrusion and friction of the chip against the rake face of tool.



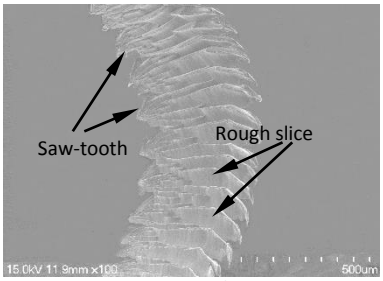
(a)Upside SEM of chip×100
(vc=157m/min, f=0.20mm/r, ap=0.3mm)



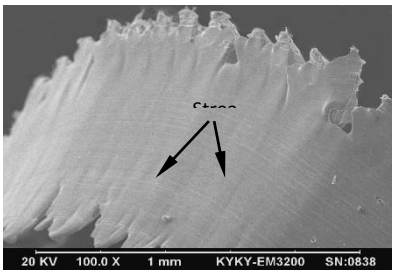
(b) Underside SEM of chip×100
(v_c=157m/min, f=0.20mm/r, a_p=0.3mm)



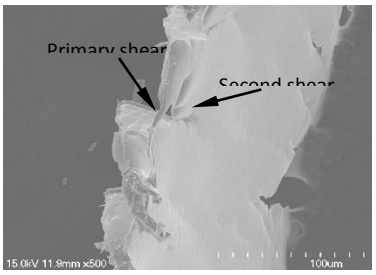
(c)SEM of the chip in profile×500
(v_c=157m/min, f=0.20mm/r, a_p=0.3mm)



(d)Upside SEM of chip×100
(v_c=125m/min, f=0.12mm/r, a_p=0.4mm)



(e) Underside SEM of chip×100
(v_c=125m/min, f=0.12mm/r, a_p=0.4mm)



(f)SEM of the chip in profile×500
(v_c=125m/min, f=0.12mm/r, a_p=0.4mm)

FIGURE 5 The shape of chip

Compared with the Figure 5(a),(b),(c) and (d),(e),(f), when the values of the cutting speed and feed speed were larger, the serrate level was higher, the spacing of rough slice layers was wider and the angle of shear was larger[15]. The reason was: the strain rate was increased when the cutting speed increased, moreover the metal removal in unit time was increased when the feed speed increased, the power consumption and the cutting heat was increased, the deformation time of the chip was shorten, it caused that the cutting heat was produced more fast and diffused more harder. These changes all of the above caused the adiabatic shear was aggravated, improved the deformational degree of the chip [16]. The saw-tooth chip caused the cutting force fluctuated and then influenced the machining precision, surface roughness and the tool wear [17].

4 Conclusion

1. The dominant factor affecting the cutting force is cutting depth, next is feed speed and the minimum is cutting speed when dry turning hardened steel by CC6050, the radial cutting force is maximum, next is main cutting force and the minimum is the axial cutting force.

2. The dominant factor affecting surface roughness is feed speed, next is cutting depth and the minimum is cutting speed.

3. There is obviously crater wear on the rake face and steady strip shaped wear on the flank of CC6050. The mainly wear mechanism is abrasive, diffusion, adhesive and oxidation wear.

4. The chip characteristics is saw-tooth when dry turning hardened steel with ceramic tool, the cutting speed and feed speed are larger, the serrated level of the chip is higher, the spacing of the rough slice layers on the upside of the chip is wider and the angle of shear is larger.

Design of reflective optical fiber displacement sensor using double optical paths

Wenlong Du*

Computer and Communication Engineering, Huaian College of Information Technology, China

Received 1 March 2014, www.cmnt.lv

Abstract

A reflective optical fiber displacement sensor using double optical paths is designed based on the principle of reflective optical fiber displacement sensor. The sensor has double optical paths composed of random fiber and semicircle fiber. The output signal of double optical paths is disposed by using the preamplifier, intermediate amplifier, band-pass filter and AC to RMS circuit. The ratio and the displacement of the output signals of the two optical paths have linear relationship, effectively enlarging the measuring range on basis of the accuracy of measurement.

Keywords: Displacement Measurement, Reflection, Optical Fiber

1 Introduction

Optical fiber displacement sensor makes up of LIOFDS (Laser Interferometric Optical Fiber Displacement Sensor) based on phase modulation and ROFDS (Reflective Optical Fiber Displacement Sensor) based on intensity modulation. The former is used for detection by interference principle of coherent light, so it has a good performance in accuracy, but it requires the optical source stable and has a high price [1]. However, the later has lots of advantages – simple structure, stable performance, low price, flexible design and working in harsh environments, thus being widely used and occupying a very important position in optical fiber sensors. The output characteristics of ROFDS present a parabolic approximation, so the linearity is low within the measurable range. Only the front slope with a high linearity is used for measurement in actual application, thus limiting the measuring range and application [2]. Because the semicircle type fiber displacement sensor and the random type fiber displacement sensor have different peak positions, the ratios are calculated as the outputs of the former divided by those of the latter. So the obtained ratios and the displacements have a good linear relation. The function is realized by circuit design, making good compensation and enlarging the range of fiber displacement sensor.

2 Principles for temperature measurement with fluorescent lifetime

Figure 1 shows the principle diagram of ROFDS. The fiber, divided into two parts – the transmitting fiber and the receiving fiber, is used for signal transmission. The surface of the reflector corresponding to the fiber probe is a reflecting surface. The optical emitted by the optical source goes through the transmitting fiber and irradiates displacement reflection. Then the reflected optical goes through the receiving fiber and is received by the photo sensor. The output intensity is determined by the distance between the reflector and the fiber probe, that is, if the displacement changes, the output intensity will change as well. The displacement is got by the detection of the output intensity.

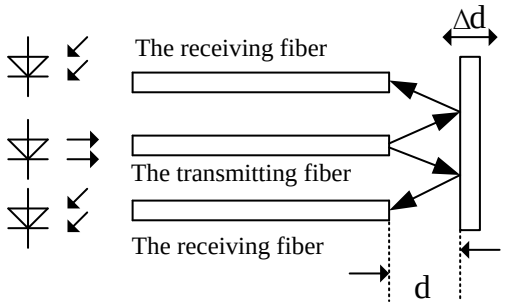

FIGURE 1 Principle diagram of reflective displacement fiber sensor

Figure 2 shows the method of equivalent coordinates analysis. Firstly, the mirror of the receiving fiber about the reflection is drawn; secondly, the optical intensity received from the optical field of the transmitting fiber end; at last, the equivalent results of the system is calculated as the optical intensity multiplied by the reflectivity of the reflection.

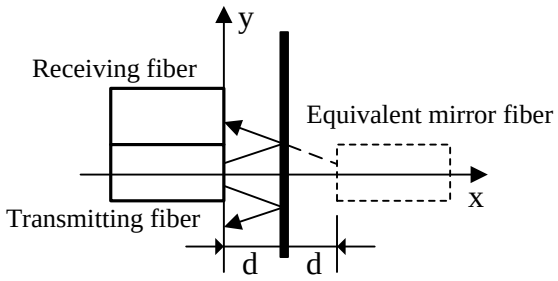

FIGURE 2 Equivalent coordinates analysis

For the multimode fiber, the output optical field flux distribution function of the fiber end is calculated as:

**Corresponding author* e-mail: duwenlongha@163.com

$$\Phi(d,r) = \frac{k_0 I_0}{\pi(a_0 + K\tan\theta_c d^{3/2})^2}\exp(-\frac{r}{a_0 + K\tan\theta_c d^{3/2}}), \quad (1)$$

where I_0 is the optical intensity of the transmitting fiber coupled with the optical source, $\Phi(d,r)$ is the optical flux density in the position (d,r) of output optical field, k_0 is the optical power loss coefficient of the transmitting fiber, a_0 is the fiber radius, K is the coupling parameter, θ_c is the fiber maximum incidence. If the fibers of the same kind are put in the output optical field as the detection receivers, the received optical intensity can be expressed as:

$$I(d,r) = \iint_s \frac{kk_0 I_0}{\pi R^2(d)}\cdot\exp(-\sum_i \eta_i r_i)\cdot\exp(-\frac{r^2}{R^2(d)})ds . \quad (2)$$

In equation (2) $R(d) = (a_0 + K\tan\theta_c d^{3/2})$, where k is the optical power loss coefficient of the receiving fiber, $\exp(-\sum_i \eta_i r_i)$ stands for the added loss because of the winding of the receiving fiber, S is the core area. For convenience, in the output optical field, the optical intensity in the center point of the receiving fiber end can be as the average optical intensity of the whole core surface. Approximately, the detected optical intensity of the receiving fiber end can be calculated by:

$$I(d,r) = \frac{Skk_0 I_0}{\pi R^2(d)}\cdot\exp(-\sum_i \eta_i r_i)\cdot\exp(-\frac{r^2}{R^2(d)}) . \quad (3)$$

Figure 2 shows that the optical intensity received by the fiber in the reflected optical field is equivalent to the receiving optical intensity of the mirror fiber multiplied by the reflection coefficient R of the reflector. The coordinate of the equivalent receiving fiber center (shown as the dashed line) is $(2d,r)$, where r is the distance between the center of the transmitting fiber and that of the receiving fiber. The coordinate is substituted in equation (3):

$$I(2d,r) = \frac{S_1 k_0 k_1 I_0}{\pi R^2(2d)}\cdot R\cdot\exp(-\sum_i \eta_i r_i)\cdot\exp(-\frac{r^2}{R^2(2d)}) . \quad (4)$$

Equation (4) shows that when the reflector, that is the detected object, is determined and the incident optical source remain stable, the modulation function of the fiber probe will be related to the displacement d. Namely the change of optical intensity reflects that of the displacement. So, the measurement of the displacement is transferred into that of the optical intensity [3].

3 Design of reflective fiber using double optical paths

At the end of the fiber probe, the transmitting fiber and the receiving fiber have four kinds of distribution: the random distribution, the semicircle distribution, the coaxial internal emission distribution and the coaxial external emission distribution. In the work, the random type and the semicircle type fiber are used. The transmitting and receiving fiber at the end of the random type are randomly distributed; the transmitting and receiving fiber at the end of the semicircle type occupy the semicircle region. Figure 3, the output curve of random type fiber and the semicircle type fiber, shows that the ROFDS has a poor linearity within the measuring range. Both the semicircle type and the random type have a peak value in the output curve, and the displacement related to the peak value of the random type is smaller than that of the semicircle type. Meanwhile, the curves have a bad linearity in the top region. In the actual measurement, only the front slope with a good linearity is applied, limiting the range of measurement and application. According to reference [4], the ratio of the output signals of the semicircle type and the random type probe (B/A) has a good linear relation with the displacement. Figure 4 shows that if the B/A output characteristic curve is fitted by the least square method, the nonlinear error will be less than 2.5%. So the double optical paths are used in the design. Figure 1 shows that one receiving fiber uses the random type, the other uses the semicircle type. The nonlinear error of the sensor is decreased by the method and the using range of the fiber displacement sensor is enlarged to about 4 mm.

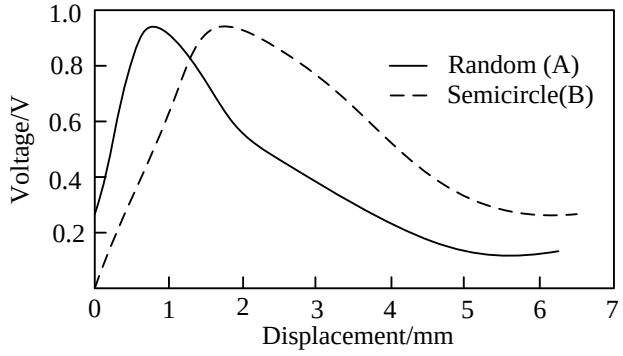

FIGURE 3 The output curve of random type fiber and semicircle type fiber

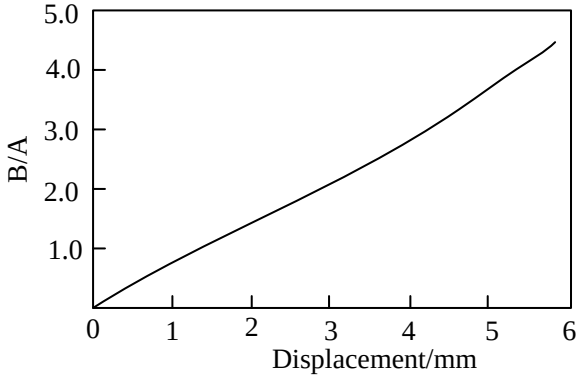

FIGURE 4 B/A output characteristic curve

Figure 5 shows the reflective fiber displacement measurement system using double optical paths. It is made up of the light source driver, the photoelectric detector, the preamplifier, the filter and the AC to RMS conversion circuit. The

working process is as follows: firstly, The LED, driven by the square wave generator made up of 555, emits the optical pulse waves with a wavelength of 940 nm suitable to the low loss window of the quartz fiber. The optical pulse waves are focused by the lens, poured into the transmitting fiber, received by the semicircle and random type fiber after being reflected and transformed to the electric signals through the photoelectric devices. The electric signals are transformed to the DC signals through the preamplifiers, the filters and AC to RMS conversion. The DC signals are sent to the divider to get the ratio of the optical intensities of the two receiving fibers in the form of DC. After A/D module transformation of the SCM MSP430F449, the ratio-displacement function is obtained by linearization of the measuring data, using polynomial interpolation. In actual measurement, the detected displacement can be obtained by substituting the ratio of a position back into the function.

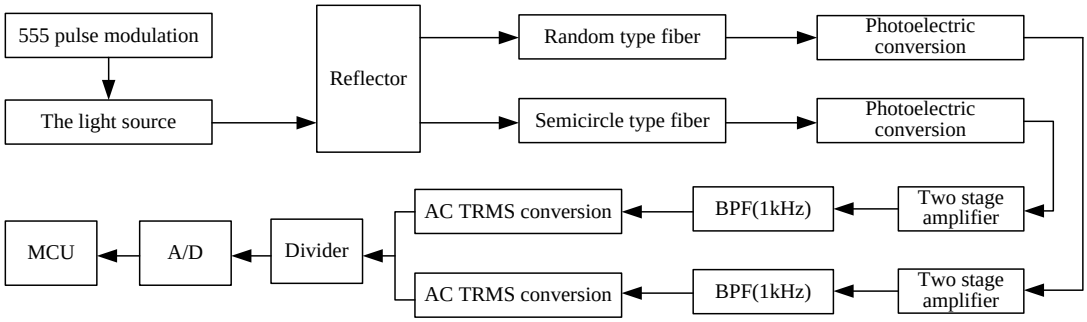

FIGURE 5 Diagram of the displacement measuring system

4 Design of light source driving and signal processing circuit

4.1 LIGHT SOURCE DRIVING CIRCUIT

The colorless and transparent LED L51R4 is selected as the light source in the circuit. It is considered that the error signals caused by external disturbing light are usually slowly changing DC or random signals, and those caused by the dark current of the photoelectric detector and the drifting of the amplifier circuit are also DC error signals. In order to eliminate these error signals, the LED is driven by the square wave driving circuit. The pulse is generated from the 1 KHz square wave generator, made up of the timer 555 and the peripheral resistance capacitance element. By using this method, the LED is in the intermittent working state with low power consumption, making the fiber sensor system work steadily for a long time. When the displacement changed, the amplitude of the pulse light will be modulated by the detected displacement signals. So, the signals arriving at the photoelectric detector are the wave signal after amplitude modulation with a message of displacement.

4.2 PREAMPLIFIER AND THE INTERMEDIATE AMPLIFIER

To get stable outputs of the preamplifier, the integral type light I/V conversion circuit is used in the system. The integrated circuit LF351 with low power consumption and noise is used for the preamplifier. Figure 6 shows the practical preamplifier circuit with low noise, where C_1 is the anti-hunt capacity used to make the performance of the preamplifier more stable. C_1, usually valuing from 30 to 100 pF, is 68 pF here. And the output voltage of the preamplifier is expressed as:

$$U_o(t) = -I_{ph}R_f \,, \tag{1}$$

where I_{ph} is the output light current of the detector; R_f is the feedback resistance. In order to make the preamplifier have enough linear dynamic range and provide enough output voltage signals for the lower amplifier; R_f values 2.2 $M\Omega$. The dynamic range of the output signals is about 0.7 V, being in the linear part of the preamplifier [5].

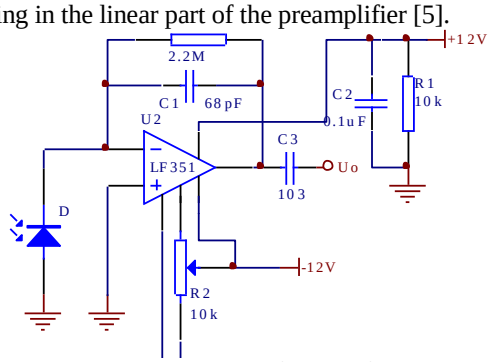

FIGURE.6 Circuit of preamplifier

In order to make the preamplifier have stable performance and good linearity within the dynamic range of the signals, the I/V conversion coefficient should not be too large. Meanwhile, considering the working performance of the narrow band filter, an intermediate amplifier is set between the preamplifier and the filter circuit. The circuit LF353A, integrated by double operation amplifiers with low power consumption and noise, is used to make up of intermediate amplifier with double paths, and the gain G, determined based on the whole condition of the system, values 5 more or less.

4.3 BAND-PASS FILTER

In this system, the static displacement is measured. If the light source is driven by using the pulse driving mode, then

only the 1 KHz pulse optical intensity modulation signals will be related to the displacement variable. Besides, all the high and low frequency signals caused by the stray light and the electromagnetic field, except the above signals, are disturbing signals. The voltage controlled voltage source filter circuit is used to filter the noises and unnecessary frequency components added in the detected signals. The 1 KHz signals can pass through the filter, and the signals with different frequencies decay fast, increasing the signal-to-noise ratio of the system. Figure 7 shows the circuit and Fig. 8 shows the filter amplitude-frequency characteristics. The band-pass width is a narrow frequency range making the modulation frequency as the center frequency.

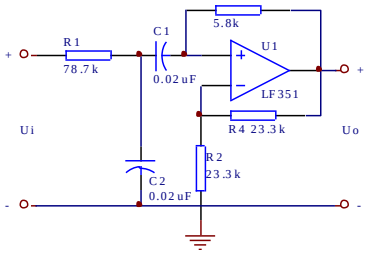

FIGURE 7 Circuit of BPF at 1.0 kHz

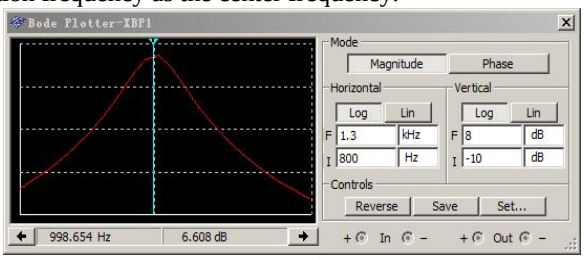

FIGURE 8 Filter amplitude-frequency characteristics

4.4 AC TO RMS CIRCUIT AND DIVIDER

Compared with the average conversion circuit, the RMS to DC integrated chip has many advantages, e.g. high integrated level, perfect function, less peripheral component, simple circuit connection and good performance in electric. So, the chip AD536 is selected to measure the RMS of all kinds of voltage wave form accurately and in real time. The high precision conversion within the measuring range can be achieved by only a capacitance, without considering the wave form parameter and distortion. AD536, supplied by double sources voltage or single source voltage ranging from +5V to +36V, compute the RMS of the input signals of AC or AC plus DC and output a equivalent DC signal. The maximum error within the wider dynamic range is 0.5%.

The divider is used to eliminate the wave of the light source, the difference of the reflectivity and the influence of the fiber loss [6]. The preset adjustment single chip multiplier or divider AD532 can control the maximum multiplication error within ±1.0% and the range of the output voltage within ±10V. The output data are converted to digital signals after entering the A/D converter. Then the digital signals are entered to the MCU and the results are achieved and shown on the MCU.

5 Data analysis and results

The high precision dial gauge calibrator with a resolution of 0.5 μm and a range of 0.5 μm is used as the calibration device to make a calibration to the system within effective measuring range. The reflector is controlled to move along the radial of the fiber, making the received light quantity decrease, and the output voltage is measured at certain intervals of displacement. Then the linearization revise is performed to the measuring results by using the least square method. The MCU system reads all the A/D conversion results, calibrates them, computes the gradient k and the intercept b of the fitting lines and stores them in ROM. In actual measurement, the fitting coefficients are called to compute the displacement according the measuring results. Table 1 shows the results of the experiment.

TABLE. 1 Experiment data of the displacement sensor

Displacement (μm)	Actual Output	Fitting Value	Displacement (μm)	Actual Output	Fitting Value	Displacement (μm)	Actual Output	Fitting Value
0	3.573	3.7690	400	2.749	2.6954	750	1.776	1.7560

The fitting linear equation of the working curve by using the least square method can be calculated as:

$$y = -0.002684 * x + 3.769$$

The degree of linearity of the sensor is 2.3%, the resolution of the sensor reaches 0.5 μm within the range of 0~1.2 mm and the repeatability error is 0.6%. Fig. 9 shows the experimental results and the fitting line. In application, the reflector cannot be replaced because the surface roughness of the reflector has influence on the change of the reflective optical.

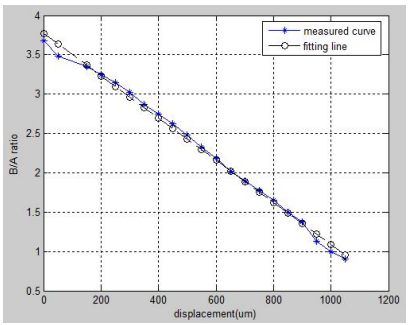

FIGURE 9 Measured result of displacement sensor

6 Conclusions

The output characteristic curve of ROFDS has a good degree of linearity in the fore slope. The traditional fiber displacement sensor only uses the fore slope, ensuring good degree of linearity, but greatly reducing the measuring range of the fiber sensor. In the work, ROFDS is designed to do division to the output signals of double optical paths using the different output characteristics of different types of fiber probes to get the ratio that has good linear relationship with the displacement, thus ensuring the degree of the linearity and enlarging the measuring range. In addition, the fiber is sensitive to temperature and vibration, and easily affected by environment. These problems are to be improved in the process of application for fiber sensors.

Abstract

As a new network technology, wireless sensor network (WSN) have been applied to military, intelligent transportation, environmental monitoring and other fields. Localization is one of the important support technologies of Wireless Sensor Networks. Location information is important to network monitoring. It is meaningless, if there is no location information. We need to adopt a certain mechanism and algorithm to implement the localization of Wireless Sensor Networks. Based on the analysis of the features of Wireless Sensor Networks on range-free positioning algorithm and DV-Hop positioning algorithm error sources, this paper focuses on the improvement research on DV-Hop positioning algorithm. Inspired by biological immune system and mechanism, this paper introduces the immune information processing mechanisms in the immune system to the particle swarm optimization algorithm and thus gets an immune particle swarm optimization (IPSO) algorithm. By applying into the running of DV-Hop positioning algorithm, the paper proposes a DV-Hop improved algorithm, which is, the WSN positioning algorithm based on IPSO algorithm. Simulation experiments show that the improved algorithm can significantly reduce positioning errors to improve positioning accuracy.

Keywords: wireless sensor networks, immune particle swarm optimization, DV-Hop positioning algorithm

1 Introduction

Wireless Sensor Networks positioning control is a basic problem in WSN applications. It is a study on how to maximize the network coverage to provide reliable monitoring and tracking services in the guaranteed quality of service conditions. Effective strategies of the coverage control and algorithms can be used to optimize the allocation of resources of WSN, increase the efficiency of the energy usage of network nodes, and improve the perceived quality of service and the overall survival time. How to combine different environmental demands and design a practical strategy for positioning is a significant research field.

Particle Swarm Optimization (PSO) have the advantages of natural paralleled, strong robustness, and global optimization, and have obvious advantages in dealing with the complex problems. Therefore, the PSO will be very suitable to solve the nodes positioning problem in the WSN. This paper makes the investigations on the PSO in solving the nodes positioning problem in the WSN, and proposes coverage mechanism based on an immune particle swarm optimization algorithm to optimize the problem. The paper gives a review on the WSN and its nodes optimal coverage problem. Moreover, the implementation details for the IPSO solving the nodes optimal positioning are described, including the particle code representation, and the complete algorithm flowchart. Simulations have been conducted and the results are compared with the ones obtained by other algorithms. The experimental results and comparisons demonstrate the effectiveness and efficiency of our proposed algorithm.

At last, based on simulation platform, the paper makes a simulation experiment on the existing DV-Hop improve algorithms and the new DV-Hop positioning algorithm based on IPSO algorithm. Through the simulation experiment results, this paper analyses the merits of the IPSO algorithm. This paper is highlighted with the contributions to the theoretical researches and practical applications of the PSO and the WSN as follows: Firstly, the IPSO is successfully applied to provide a new solution to the nodes optimal positioning in the WSN. Secondly, the proposed algorithm is simpler than the traditional algorithms, and with a higher computational effectiveness. Thirdly, the proposed algorithm has a better performance that can obtain higher positioning accuracy.

2 Basic particle swarm optimization

The basic PSO could be described as follow: supposing in a n-dimension research space, the population is $X=\{x_1,...,x_i,...,x_m\}$, among which the position of I particle is $X_i=\{x_{i1},x_{i2},\cdots,x_{in}\}^T$, the speed is $v_i=\{v_{i1},v_{i2},\cdots,v_{in}\}^T$, the individual extremum is $p_i=\{p_{i1},p_{i2},\cdots,p_{in}\}^T$, the global extremum is $p_g=\{p_{g1},p_{g2},\cdots,p_{gn}\}^T$. Based on the principle of following the optimized particle, the particle X_i will change

* ***Corresponding author's*** e-mail: 2954043892@qq.com.

the speed and position in accordance with the following Equation, as is shown in the Figure 1:

$$v_{id}^{(k+1)} = v_{id}^{(k)} + c_1 r_1 (p_{id}^{(k)} - x_{id}^{(k)}) + c_2 r_2 (p_{gd}^{(k)} - x_{id}^{(k)}) . \quad (1)$$

$$x_{id}^{(k+1)} = x_{id}^{(k)} + v_{id}^{(k+1)} . \quad (2)$$

In the Figure 1, m is the sum of the particles in the population. d=1,2,…,n, n is the dimensions of particle search space. $v_{id}^{(k)}$ is the iterative particle i's Flight velocity vector's d dimension component at the K time, which is between $-v_{d\max}$ and $v_{d\max}$. $v_{d\max}$ could be set according to different controlling variables by the users. $x_{id}^{(k)}$ is the iterative particle i's d dimension component at the K time. $p_{id}^{(k)}$ is the iterative particle i's best position at the K time p_{best} 's d dimension component. $p_{gd}^{(k)}$ is the iterative group's best position at the K time g_{best} 's d dimension component. c_1, c_2 is the learning factor or speeding up factor. r_1, r_2 is the random figure among [0,1] produced by random function [1, 2].

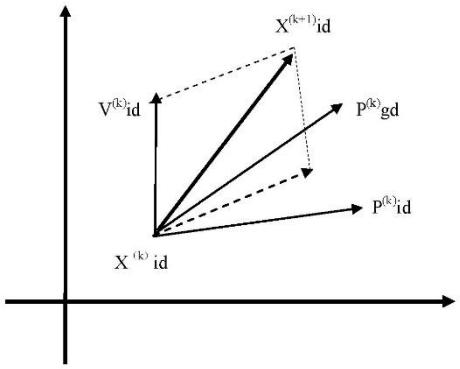

FIGURE 1 The d dimension variable diagram of basic particle

In Equation (1), a constant inertia weighting factor ω could be added before $v_{id}^{(k)}$. Normally, the ω's Figure 1 and Figure 2 is the formula of basic particle swarm algorithm formula.

In Equation (1), three are three parts to calculate the new speed of particle i: the first part is the $\omega v_{id}^{(k)}$, the speed at the former time, indicating the status of the particle at that moment. The second part is the $c_1 r_1 (p_{id}^{(k)} - x_{id}^{(k)})$, the distance of the current position and the best position of particle i, which is the part for self-recognition, indicating the thoughts for itself. The third part is the $c_2 r_2 (p_{gd}^{(k)} - x_{id}^{(k)})$, distance of the current position of particle i and the best position of the group, which the social part and the best vector from current point to the group, indicating the cooperation and knowledge share between particles.

All the three parts determine the spatial search capabilities of the particles. The first part has played a role in the balance of global and local search capability; the second part of the particles has a sufficiently strong global search capability; third part reflects the sharing of information between the particles. Under the combined effect of these three parts, the particles thus could effectively reach the best position. Particle i calculates the coordinates of the new location by the Equation (2), and determines the position and velocity of movement next by Equations (1) and (2).

There are few parameters need to be adjusted in PS algorithm. But the setting on the parameters makes a great impact on the performance of the algorithm. The parameters as well as experience setting are listed below: inertia weight ω has a better performance in [0.9, 1.2], and performs better from 1.4 to 0 than the fixed. The largest speed $v_{d\max}$ also influences the ω, generally speaking, when the $v_{d\max}$ is small, ω is about 1 and when $v_{d\max}$ is big, the ω is about 0.8 with the better performance of PSO algorithm.

Learning factor c_1 and c_2 are used to control the particle's own memory and the memory of companions. Selecting the appropriate algorithm can improve the speed and avoid local minima. Experiments showed that $c_1 = c_2 = 2$ or $c_1 = c_2 = 0.5$ is a good choice, but $c_1 + c_2 \le 4$ is better.

When the particles constantly adjust their positions according to the speed, they are restricted by the maximum speed $v_{\max}$. When $v_{id}^{(k)}$ exceeds $v_{d\max}$, the particles would be defined as $v_{d\max}$. Maximum speed $v_{d\max}$ determines the maximum travel distance of the particles in a loop, which typically should not exceed the width of the particles. If $v_{d\max}$ is too large, the position of the particle may fly optimal solution; If $v_{d\max}$ is too small, it may reduce the global search ability of particles [3].

Particles flying speed cannot exceed the maximum speed $v_{d\max}$ of the algorithm set. In general, in

$$v_{\max} = (v_{1\max}, ..., v_{d\max}, ..., v_{n\max})^T =$$
$$a * (v_{1\max} - v_{1\min}, ..., v_{d\max} - v_{d\min}, ...v_{n\max} - v_{n\min})^{T_1}$$

$x_{d\max}$ and $x_{d\min}$ represent the upper and lower limit values of the particles of the d-dimensional variables. a is a control factor, 0<a<1. Setting a large $v_{\max}$ could promote the global search capability of particle populations, while when $v_{\max}$ is small, the local search capability could be strengthened. The numbers of particles (population size or population size) generally could use 20~60. For general optimization problems, 10 particles are enough. For some special problems, the number of particles can take up to 100~200. Particle dimension is determined by the dimension of the optimization problem (solution space dimension) [4].

3 Immune particle swarm optimization process

The design flow chart of IPS algorithm used in this paper is as shown in Figure 2:

1) Initialization parameters. The algorithm is given an initial value of the inertia factor $\omega(0)$, the acceleration factor c_1, the number of immune population of particles N, the maximum number of iterations (the number of generations) K_{max} and other parameters.

2) Initial antibody (population) yields. N immune particles are randomly generated and the "flying" speed is V_i, so that to form the initial immune particle population P_0. Set the value of each individual particle initial immunization optimal solution P_{best} and the global optimal solution G_{best}.

3) Antibodies fitness evaluation. In the current population, to calculate all antibodies (immune particle) fitness. In the immune particle swarm algorithm, the fitness function usually takes the transformation of some function's objective function which needs to be optimized [5]. In the design of the main fitness function, it should satisfy the following conditions:

a) Reasonable and conformed requirements. The fitness should reflect the degree of solution of the pros and cons of the corresponding value solution; small;

b) small task of calculation. The amount of the fitness function should be designed as simple as possible;

c) strong versatility. The fitness for certain specific issues should be commonly used as possible as it can.

d) Calculation of antigen and antibody binding strength and concentration of antibody. Corresponding antigen immune system optimization objective function corresponding antibody solution optimization problems. To decide antigen and antibody binding force based on the value of the objective function; to decide the binding force of the antibody based on the degree of similarity solution and use the combination of these two forces to make solution evaluation and selection.

The binding force between antibody and antigen is defined as A_v, and could be changed by the target function into:

$$A_v = \mu[f(v)]. \tag{3}$$

In Equation (3): $f(v)$ is the target function, $\mu(x)$ is the monotone function of x, which reflects the evaluation to the target function [6].

This article taken sorting selection method, the size of the binding force A_v between the antibody and antigen has no absolute meaning. A_v value does not need to guarantee positive, so the reactive power optimization problem studied in this paper can be the binding force A_v between the antibody and antigen and directly take reactive power optimization objective function model:

$$A_v = f(v). \tag{4}$$

Process of solving the objective function is as follows: the control variable is calculated based on the decision of the antibody, and then derived value of the state variables into the objective function optimization problems. Then put the objective function into the Equation (4), which can obtain antigen and antibody binding force. Since the target function of this paper is to get the minimum value of the solution function, the smaller the antigen and antibody binding force, the closer the optimal solution antibody to the optimization.

The binding force between the antibodies reflects the degree of similarity. When two antibodies are similar, the binding force is larger, on the contrary, the smaller, as is shown in the following equation:

$$B_{v,w} = \frac{1}{1+H_{v,w}}. \tag{5}$$

$H_{v,w}$ is the vector from the definition of the two antibodies type. In this paper, Euclidean space 2-norm can be used to define the sense of distance:

$$H_{v,w} = \left\{\sum[(V_{Giv}-V_{Giw})^2+(D_{civ}-D_{ciw})^2+(T_{iv}-T_{iw})^2]\right\}^{\frac{1}{2}}. \tag{6}$$

Thus the calculation of antibody density c_v could use the following Equation:

$$c_v = \frac{\sum_{w=1}^{N} B_{v,w}}{N}. \tag{7}$$

N is the number of antibody populations. The larger the concentration of the antibody is, the greater the similarity of such antibodies and other antibodies is.

5) Memory structure and unit prohibition. The largest concentration of antibody population antibody showed that it accounted for in the antibody group in an absolute advantage, namely to achieve a relatively optimal solution, which reflects the evolution of the results of this generation of population. The largest concentration of antibody should be retained by the principle to retain it which is the role of memory structure. The high concentration of antibodies and other antibodies showed large similarities between large groups, in order to maintain the diversity of the antibody, it needs higher concentrations of antibody suppression. Setting the antibody according to the size of its concentration, the author sort through the set-out rate (This article set it as 10%), finding that the higher concentrations of antibodies were eliminated and new randomly generated antibodies and antibody replaced the eliminated. Inhibiting the high concentrations of antibodies can well prevent the development of antibodies from being a single group so as to maintain the antibody population diversity and avoid local optimal solution. That is the role of inhibition of cell.

Fitness value of antibody v showed its performance. The fitness value calculation function could be formed by the binding force A_v and the concentration c_v:

$$p = \alpha A_v + (1-\alpha)c_v. \tag{8}$$

α is a scaling factor ($0<\alpha<1$) antibody V's adaptation has the following characteristics: the smaller the antibody and the antigen binding capacity A_v, the smaller

the value of the corresponding adaptation; the smaller the antibody concentration, the smaller the value of the corresponding adaptation; the smaller the adaptation value, the closer the near-optimal solution. Setting the size of α could adjust the weight between antibody-antigen binding force and concentration, which can also retain the antigen binding force small (i.e., the objective function value is small) antibodies, but to ensure the diversity of individuals through inter-antibody concentration based on mutual promotion and inhibition mechanisms, so that the optimal solution for improving the convergence of favorable vicinity [7].

6) Group updating and the generation of new immune particle. To update particle speed and produce new immune particle *N* in accordance with the following equation:

$$v_{idid}^{(k+1)} = \omega^{(k)} v_{id}^{(k)} + c_1 r_1 (p_{id}^{(k)} - x_{id}^{(k)}) + c_2 r_2 (p_{gd}^{(k)} - x_{id}^{(k)}) \quad (9)$$

$$x_{id}^{(k+1)} = x_{id}^{(k)} + v_{id}^{(k+1)} \quad (10)$$

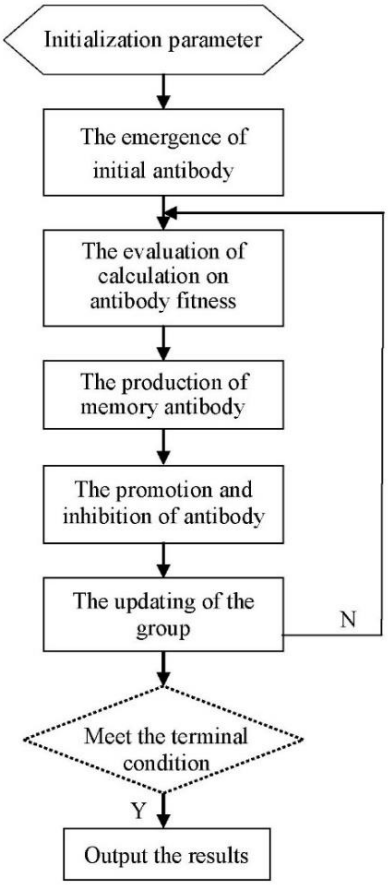

FIGURE 2 The flow chart of immune particle swarm optimization algorithm

PSO in the early age has a fast convergence but has a not high accuracy in the late convergence stage, which is easy to fall into local optimum. Therefore, the author designed the inertia factor ω, which will have a great impact to optimize the performance of the algorithm. The large ω values could help to improve the convergence speed while the small ω could help to improve the convergence of the algorithm accuracy. According to this feature, this paper used the Equation (11) to improve ω, so that it can adaptively adjust to achieve the purpose of decreasing ω with the increasing of the value of the iterations

$$\omega^{(k)} = (2/(1+e^{\sigma k / K\max}))\omega(0) . \quad (11)$$

σ is the positive coefficient; K_{max} is the set maximum number of iterations (the number of generations); $\omega(0)$ is the initial value; k is the current iteration [8].

7) To judge if it meets the termination condition. If being satisfied, to stop the running and put out the results, otherwise, go to step 3.

4 Simulation of improved algorithm

In order to evaluate the performance of immune particle swarm optimization algorithm, this paper makes a comparison on the DV-Hop algorithm based on IPSO and several other DV-Hop algorithms through simulation experiment. In the simulation, all the sensor nodes are arranged in the 100M, 100M square area. According to the relevant literature, anchor nodes arranged in a border area is relatively good accuracy. For this case, the paper put 100 unknown nodes and anchor nodes evenly on the boundary of the square area. The total proportion of the anchor node of the node changes as the experimental conditions.

While maintaining the other parameters constant, the author changed the proportion of anchor nodes in the total nodes, the communication range of the unknown nods and the three parameters respectively to make simulation experiments. Meanwhile, in order to make the results more convincing, this paper made a simulation experiment on the DV-Hop positioning algorithm based on IPSO and the improved several DV-Hop algorithms under the same experimental conditions and then made an analysis on the positioning results. By making a plurality of simulations on the same algorithm, the author took the average value of the final simulation results in order to reduce the error caused by the experiment itself and make the results more accurate. In the immune particle swarm optimization algorithm, the number of particles is 30, the largest and the smallest particle fitness values were max, min.

4.1 THE RELATIONSHIP DIAGRAM OF THE ANCHOR NODE PROPORTION AND THE AVERAGE POSITIONING ERROR OF THE NODE

Figure 3 shows the relationship diagram of the anchor node proportion and the average positioning error of the node. From this, it can be seen as follows:

(a) The positioning error ratio of several positioning algorithms decreased with of increasing of the anchor nodes. That is because if the anchor node ratio increases, it will provide more information and the corresponding positioning accuracy would be promoted. There is an extreme case, when all nodes are anchor nodes, the node can position itself, which is also conformed with the achievement situations.

(b) When the proportion of the anchor nodes is the same, the improved DV-Hop algorithm has a smaller positioning error compared to the original location DV-Hop algorithm, among which the DV-Hop algorithm based on immune particle swarm optimization has the minimal positioning error, which also shows a good performance of IPSO.

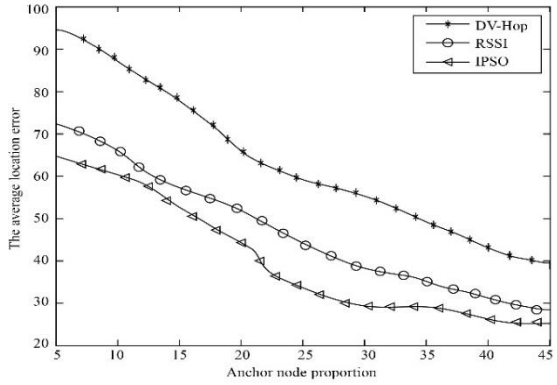

FIGURE 3 The relationship diagram of the anchor node proportion and the average positioning error of the node

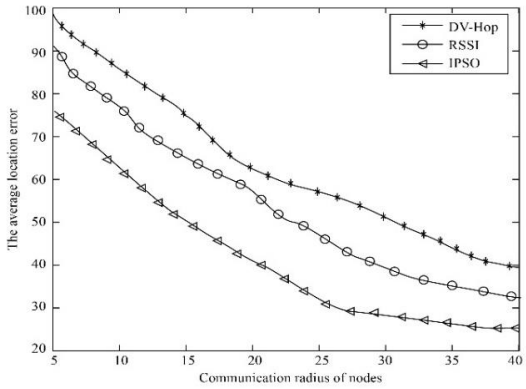

FIGURE 4 The relationship diagram of the communication radius and the average location error of the node

4.2 THE RELATIONSHIP DIAGRAM OF THE COMMUNICATION RADIUS AND THE AVERAGE POSITIONING ERROR OF THE NODE

Figure 4 shows the relationship diagram of the communication radius and the average positioning error of the node. From this, it can be seen as follows:

(a) The positioning errors of the shown positioning algorithm declines with the expansion of the unknown node communication radius for the expansion of the unknown node communication radius strengthens the corresponding connectivity of the unknown node with other nodes, thus the node can get a larger range of information exchange and to improve the positioning accuracy of the algorithm.

(b) Although the positioning errors of several positioning algorithms were decreased, it is relatively small, because even though the communication range of the node were increased to some extent, the exchange information of the number of the anchor node exchanged with the unknown node may be increased. And not every anchor node can provide useful information for locating the unknown nodes.

4.3 EFFECT OF TOTAL NODES ON AVERAGE POSITIONING ERROR OF THE NODE

Figure 5 shows the relationship diagram of total number of nodes and average positioning error. From this, it can be seen as follows:

(a) When the total number of nodes increases from 5 to 30, the positioning of several errors in the positioning algorithm has a certain impact. The average error of nodes declines with the increasing of the total number of nodes.

(b) With the change of the total number of nodes, the magnitude of change in average bit error localization algorithm is relatively large, which also reflects the scalability of the algorithm needs to be further improved.

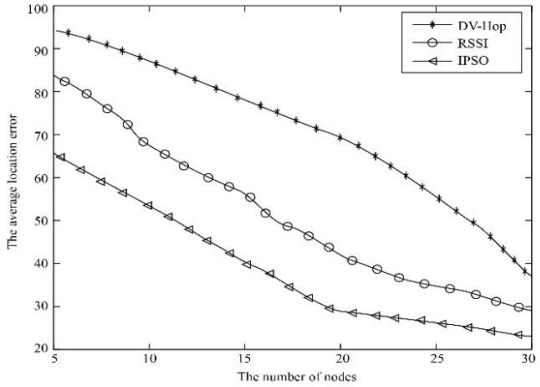

FIGURE 5 The relationship diagram of total number of nodes and average location error

5 Conclusion

This paper introduced the research background and research status at home and abroad for the WSN, and then introduced the Wireless Sensor Networks characteristics, as well as its structure and key technologies. While making a classification on positioning algorithms, this paper illustrated the basic principles of the typical positioning algorithm. On the basis of the analysis of the basic ideas of immune particle swarm optimization, this paper analysed the positioning error sources of DV-Hop positioning algorithm. By combining with the characteristics of immune particle swarm optimization algorithm, this paper proposed a new DV-Hop algorithm based on immune particle swarm optimization algorithm. Finally, the simulation experiments showed that the improved algorithm can significantly reduce positioning errors to improve coverage accuracy.

Jing Zeng An image threshold segmentation method based on multi-behaviour global artificial fish swarm algorithm

*Computer Modelling & New Technologies 2014 **18**(11) 38-42*

Firstly, this paper describes how the histogram analysis method pre-processes the images to be segmented. Then is makes a detailed analysis of the working principles and behaviour pattern of basic artificial fish swarm algorithm (AFSA); dissects the defects of AFSA in principle and proposes an improved AFSA with global convergence. Finally, it presents the main steps of image threshold segmentation method based on AFSA; compares the performances of AFSA with those of other intelligent algorithms and proves that this improved AFSA makes all-around improvements on image segmentation.

Ganzhou Wu, Haiyan Liang A modified BFGS method and its convergence

*Computer Modelling & New Technologies 2014 **18**(11) 43-47*

In this paper, a new modified BFGS method for unconstrained optimization problems is presented. The algorithm preserves the convergence properties of the famous BFGS algorithm. The relation between the new algorithm and a self-scaling quasi-Newton algorithm is revealed. If we assume the objective function is twice continuously differentiable and uniformly convex, we prove the iteration converge globally to the solution. And under some additional conditions, the superlinear convergence is given. Finally, the experimental results show that the proposed algorithm performs very well, which indicate that the numerical performance of the new algorithm is somewhat like the self-scaling quasi-Newton algorithm.

Qian Chen, Junhao Liu, Chaowei Fu, Haitao Wang Performance analysis and side lobe suppression in radon-Fourier transform based on random pulse repetition interval

*Computer Modelling & New Technologies 2014 **18**(11) 48-54*

In order to solve the Blind Speed Side Lobe (BSSL) appeared in Radon-Fourier Transform (RFT) method used for dim target detection, a novel method of BSSL suppression is proposed in this paper. It is based on Random Pulse Repetition Interval (RPRI). The process of RPRI-RFT and the BSSL properties are described, the performance of coherent integration and the modulation noise of RFT algorithm based on RPRI are analysed in detail. Both the theoretical analysis and the numerical experimental results show that RPRI-RFT can be used to improve signal-to-noise ratio (SNR) and suppress BSSL effectively, and the influence of modulation noise of RPRI can be suppressed by the long-time integration characteristic, thus significantly improve the ability of low pulse repetition frequency radar to detect and measure long-range weak high-speed multi-targets.

*Computer Modelling & New Technologies 2014 **18**(11) 55-59*

Ant colony algorithm (ACA) is a bionic intelligent optimization algorithm with positive feedback, distributed computing and heuristic search. As an important branch of computational intelligence and swarm intelligence, ACA has been successfully applied in solving many combinatorial optimization problems. Artificial neural network is a large-scale distributed parallel processing system with the characteristics of self-organization, self-study, self-adaptation and non-linear dynamic processing and it has a broad prospect in settling the complicated non-linear problems. This paper has proposed an algorithm used to solve multi-objective optimization problems and the applications of ACA.

Chang Liu, Zhenyu Na, Xin Zhang An improved algorithm for multi-factor fuzzy correlation

*Computer Modelling & New Technologies 2014 **18**(11) 60-65*

As a means for Vessel Traffic Service (VTS) to oversee the vessels, the traditional radar and the new navigation method of Automatic Identification System (AIS) are the two sources of getting the vessels' information. Tracks Fusion of the data received from these two sensors becomes the fundamental problem to be resolved in VTS. The tracks correlation is the premise and basis of the tracks fusion. This paper proposed an improved algorithm of multi-factor integrated fuzzy correlation based on the least square-time interpolation. We make generous correlation

decision of distance and achieve the targets set in a fixed range, and then after time correction based on the least square-time interpolation we get the correlated tracks set and make fuzzy correlation used the membership function of normal distribution. The simulation experiment shows the proposed fuzzy correlation algorithm is more precise and the data are more close to the actual data of the vessel. The result of this effort can become an efficient method that impacts greatly on the vessel traffic management.

Chang Zinan, Shao Fei Epidemic spreading in weighted homogeneous networks with community structure

Computer Modelling & New Technologies 2014 ***18****(11) 81-85*

Community structure has been proven to have great impact on epidemic spread in weighted networks. To understand the epidemic propagation in weighted homogeneous networks with community structure, a model of pseudo-random network is presented with adjustable community structure. By changing the number of edges connecting to the nodes in the same community and the weight of edges connecting to the nodes in the same community, we investigate the epidemic spreading in weighted homogeneous networks with different community structure. Simulations show that both the number of within-community edge and the weight of within-community edge have great impact on epidemic spreading behaviour.

Keywords: epidemic spread, weighted network, homogeneous network, community structure

Shengneng Hu, Xiaoming Lu, Juan Han Design and realization of road geometry alignment simulation

Computer Modelling & New Technologies 2014 ***18****(11) 86-91*

Embarking from road's characteristic and road design's demand to the simulation system, road simulation system's characteristics have been discussed, and then road simulation system frame based on multi-agent has been constructed. The simulation agents have been divided into response agent, corporation agent and interface agent, and their structures have been analysed too. The car dynamics model, road ground view model and driver model have been built, the simulation results are validated by basic experiments. The simulation system is an efficient tool for road design evaluation.

Keywords: road simulation, road engineering, multi-agent, simulation model

Hao Yan, Xiaoyong Yan, Rulin Dou A multivariate analysis-based for range-free localization algorithm

Computer Modelling & New Technologies 2014 ***18****(11) 92-98*

Proposed an improved DV-Hop localization algorithm (PLS-DVHop) based on partial least squares, which uses the partial least squares to model of hop-count and the Euclidean distances, along with the maximum covariance of input matrix and output matrix to estimate the location of unknown nodes. PLS-DVHop has strong adaptability for different deployment network, and overcomes the shortage of only suitable for isotropic networks in the original

algorithm. Simulation results show that PLS-DVHop algorithm has high estimate precision and stable performance, can adapt to different network topologies, and is very suitable for large scale deployment network.

Keywords: range-free localization, wireless sensor network, partial least squares

Hualong Xie, Xiaopeng Mei, Yongxian Liu The dynamic characteristic analysis of spindle based on ANSYS
Computer Modelling & New Technologies 2014 ***18****(11) 99-107*

The basic concept of dynamic characteristics of spindle is introduced. The first ten order vibration mode and natural frequency of shaft are obtained by modal analysis and harmonic response analysis using software ANSYS. The deformation trend of spindle under resonance state is analysed and the contrast between theory and simulation critical speed is done. The frequency response curve of spindle is given. The first order, second order dynamic stiffness and dynamic stiffness under general conditions are calculated. The influence of bearing damping to spindle dynamics characteristics is discussed. In the end, the measures of improving spindle performance are summarized.

Keywords: Shaft, Dynamic characteristic, ANSYS, modal analysis, harmonic response analysis

Ran Ding, Caoyuan Ma, Yongyi Zhao, Yanfang Luo, Jianhua Liu Anti-synchronization of a class of fractional-order chaotic system with uncertain parameters
Computer Modelling & New Technologies 2014 ***18****(11) 108-112*

In order to pull the fractional-order theory to better application, the detailed of computer numerical simulation of the Adams-Bashforth-Moulton Algorithm is proposed in this paper. Anti-synchronization of a class of fractional-order chaotic system with uncertain parameters is realized on this basis and the stability theorem of the system is presented at the same time. And thus it indicates that this method can be adapted to chaotic system with certain parameters and a class of chaotic system with not equal fractional-order. And corresponding implementation conditions is given as well. Besides, it is pointed out that the method, which unites the synchronization and anti-synchronization is also suitable for synchronization issues of the system. Finally, take classic Lorenz system for instance, track time domain and error map about drive system and response system of anti-synchronization are given. The results prove the effectiveness of the control method in the realization of anti-synchronization of a class of fractional-order chaotic system with uncertain parameters and the feasibility of fractional order computer numerical simulation

Keywords: fractional-order, chaotic system, anti-synchronization, chaos control

Liang Zhao, Zhanping Yang Validation assessment with uncertain model inputs
Computer Modelling & New Technologies 2014 ***18****(11) 113-118*

This paper presents a validation assessment method to measure the discrepancies between the model predictions and experimental observations under both aleatory and epistemic uncertainty. The model inputs considered in the paper are sparse point data or interval data, which leads to uncertain parameters for the distribution of the model inputs. A likelihood based method is used to represent the stochastic model inputs and it yields a single probability distribution which integrates the aleatory and epistemic uncertainty of model inputs. This representation of model inputs provides an advantage in computation efficiency for the conventional double loop sampling requirement in uncertainty propagation is collapsed into a single loop sampling. An area based validation metric is extended to compare the probabilistic model predictions obtained from uncertainty propagation with the empirical distribution function of the experimental observations, it reflects an objective quantification of the entire discrepancies between predictions and observations. The confidence interval for the validation metric, which just depends on the amount of experimental observations and confidence level is also developed. A numerical example is used to illustrate the proposed method.

Keywords: validation assessment; likelihood based method; validation metric; confidence interval

Yun Peng Fuzzy set and rough set based evaluation algorithm of web customers
Computer Modelling & New Technologies 2014 ***18****(11) 119-122*

A fuzzy algorithm of web customers evaluation based on rough set is presented. Key attributes can be gotten through rough set. The evaluation from the data objects based on key attributes can reduce the data size and algorithm complexity. After Clustering analysis of customers, then the evaluation analysis will process to the clustering data. There are a lot of uncertain data in customer clusters, so the traditional method of classification and evaluation to the incomplete data is very difficult. Superposition evaluation algorithm based on fuzzy set can improve the reliability and accuracy of web customer evaluation. Evaluation of the web customer also can improve efficiency, service quality and profitability of web businesses.

Keywords: Rough Set, Membership Function, Cluster Analysis, Fuzzy Set

Cunchang Gu, Xiaoyan Xu Coordinated scheduling on single serial batching machine with transportation considerations

Computer Modelling & New Technologies 2014 ***18****(11) 123-128*

The coordination of production scheduling and transportation has recently received a lot of attention in logistics and supply chain management. We study a coordinated scheduling problem, in which each job is transported to a single serial batching machine for further processing, each batch to be processed occurs a processing cost, and the objective is minimizing the sum of the makespan and the total processing cost. Under the condition of the jobs' processing times are equal, if the job assignment to the vehicles is predetermined, we provide a polynomial time dynamic programming algorithm, for the general problem, we prove it is NP-hard. When the returning time of vehicle is zero, we present the approximation algorithm and prove that the worst case ratio of the algorithm is not greater than $2-\frac{1}{m}$, and the bound is tight.

Keywords: supply chain scheduling, dynamic programming algorithm, complexity, worst case analysis

Yaolin Huang, Shuangli Wang, Chengjun Xie, Zhuo Jiang, Jinyan Zhao Chaos control of unified chaotic system base on tridiagonal matrix stability theory and adaptive hybrid synchronization

Computer Modelling & New Technologies 2014 ***18****(11) 129-133*

This paper presents a new chaos control method to control the unified chaotic system to zero. In order to control a unified chaotic system to zero, the first step is to design a stable system, which stable to zero base on tridiagonal matrix stability theory, the stable system as the master system. The second step is to make the unified chaotic system with controlled as slave system, the third step to make the master system and the slave system synchronization. Different system state apply different adaptive synchronize method to realize synchronization. The adaptive control law and parameter update law are obtained base on Lyapunov stability theory. Numerical simulations are presented to demonstrate the effectiveness of theoretical analysis.

Keywords: chaos control, adaptive hybrid synchronization, tridiagonal structure matrix stability theory

Lirong Qiu The impact on collaborate level of cluster

Computer Modelling & New Technologies 2014 ***18****(11) 134-138*

Due to the impact of the characters of nodes in complex network on collaboration level, we put forward a new iterated game model based on conformist mechanism. In this model, nodes can update tactic not only according to their payoffs but also to their species, which they belong to. The new model can assure that nodes in the same species adopt the same tactic. Simulation results show that the collaboration level of the networks that adopt conformist mechanism is higher than the networks that adopt normal mechanism. In the other words, the collaboration level is in inverse proportion to the species number. On the other hand, we find that the average payoffs increased with the penalty gene instead of increasing alternately. So the new model can promote the collaboration level and the average payoffs of the nodes in network at the same time.

Keywords: Conformist Mechanism, Iterated Game, Collaborate Level, Complex Network

Tengda Shi, Kaifeng Su, Linqian He, Lei Yan A gait recognition system based on BP neural network and plantar pressure

Computer Modelling & New Technologies 2014 ***18****(11) 139-142*

In order to get a faster, more effective and stable control over lower extremity exoskeleton of power assist robot, precise examination on gait information is necessary, thus it is so important to design and establish a gait recognition system with accurate detection. In this paper, a wireless in-shoe wearable plantar pressure acquisition system based on ATmega16 and 8 FSR sensors will be applied to data acquisition for the gaits which consist of standing, walking, jumping and going upstairs. And four volunteers (2 males and 2 females) will be invited in this research to collect the pressure information. The NNT of MATLAB will be applied to establish an 8-12-4 BP neural net model. The input factors come from the eight sensors of plantar pressure system, the output is gait category. Proved by a great deal of experiments, the gait recognition method proposed in this research is quite feasible.

Keywords: gait recognition, BP neural networks, plantar pressure, lower extremity exoskeleton of power assist robot

Jinjiang Liu, Jingjing Liang Automatic verification of embedded system based on EFSM

Computer Modelling & New Technologies 2014 ***18****(11) 143-147*

To ensure the correctness of embedded system, automation of test case generation is necessary in industrial. This

paper present a technique for specifying coverage criteria and a method for generating test suites for embedded systems whose behaviours is depend on its interactive environment. The embedded system under test can be described as extended finite state machines (EFSM) and the coverage criteria can be specified as monitor automata with parameters, which monitor and accept traces that cover a given test criterion of an EFSM. The flexibility of the technique is demonstrated by specifying a number of well-known coverage criteria based on control- and data-flow information using observer automata with parameters. We also develop a method for generating test cases from coverage criteria specified as observers. It is based on transforming a given observer automata into a bitvector analysis problem that can be efficiently implemented as an extension to an existing state-space exploration such as, e.g. SPIN or Uppaal.

Keywords: EFSM (Extended Finite State Machine), embedded system, test case generation, model-based testing

Baowen Hu, Changhong Li Damage characteristic of rock sample with circular defect based on the distinct element and moment tensor methods
Computer Modelling & New Technologies 2014 ***18****(11) 148-153*

Based on the distinct element and moment tensor theory, the damage process and mechanism of rock sample with circular hole were researched. The crack evolution patterns corresponding to the laboratory test showed that there were mainly four stages. Firstly, the microcracks were randomly distributed in the rock sample. Secondly, the larger primary cracks are formed around top of circular hole with the increasing of microcracks. Then, more microcracks were localized near the boundary of circular hole, which formed the competition of several possible sets of fractures. Finally, the rupture zone was formed along one of crack zones. The size effect of circular hole showed that there would take on different rupture forms with increasing of diameter. Meanwhile, for better probing into damage mechanism, the acoustic emission (AE) algorithm based on moment tensor theory was implanted into the whole loading process. The AE magnitudes of all parts of rock sample were shown in AE contour maps, and these contour maps showed that the formations of rupture zone were contributed by different stress or energy levels.

*Keywords: c*ircular hole, damage mechanism, acoustic emission, distinct element, moment tensor

Hongwei Ye, Lianjiao Zhang, Xiaozhang Liu Network intrusion clustering based on fuzzy C-Means and modified Kohonen neural network
Computer Modelling & New Technologies 2014 ***18****(11) 154-158*

Kohonen neural network recognizes and clarifies substantive network data, but with a long running time and a slow convergence process. To solve this problem, a network intrusion clustering method is presented in this paper. Specifically, the training data is pretreated using Fuzzy C-Means (FCM). Then some selected data will be trained with using Kohonen neural network. Meanwhile, to speed up the convergence process of Kohonen neural network and to form a better optimized network topology, a neighbourhood function is established for the competing neuron. Each neuron has neighbourhood topology collections. The data simulation results demonstrate the efficiency and effectiveness of the proposed algorithm.

Keywords: Kohonen neural network; neuron, FCM, network intrusion clustering

Jiansheng Xia, Shasha Dou Numerical analysis of sheet metal U-Bending process
Computer Modelling & New Technologies 2014 ***18****(11) 159-165*

The sheet metal U-bending forming is a complex process, based on the assumption of Prandtl-Reuss flow rule and Von Mises yield criterion, the incremental elastoplastic large deformation finite element model was established based on the Updated Lagrangian Formulation (ULF). The elastoplastic conversions of boundary and deformation are reduced with rmin rule. The friction phenomenon of slippage and viscosity at the boundary interface is revised with increment of revision Coulomb rule. The increment rules are led into the whole stiffness matrix, and derived out the stiffness equation. The studies show that the influence on U-Bending deformation of sheet metal is influenced by die structure and parameter. The results show there is a good consistency between the finite element simulation and experimental result.

Keywords: elastoplastic, FEM simulation, sheet metal, U-Bending, warpage

Ming Tao Frequency analysis of the area error in the triangular partition of a discrete global grid
Computer Modelling & New Technologies 2014 ***18****(11) 166-173*

The discrete global grid is a method of hierarchical space expression with global scale, multi-resolution, and multi-scale transform features. It is a basic theory related to global geographic information systems and spatial grid computation. The main challenge in the practical application of discrete global grids is the generation of errors. Thus,

four typical kinds of global discrete grid models were investigated in this study of partition errors. Area was considered an indicator of partition errors. Furthermore, this study computed the area errors in levels 3 to 10 partitions of each kind of global discrete grid model. The frequency of each indicator was also analysed. Analysis results show that the Synder models have the smallest area deformation.

Keywords: discrete global grid, triangular partition, frequency analysis

Chen Ye Research on the application of clustering algorithm based on minimum spanning tree
Computer Modelling & New Technologies 2014 ***18****(11) 174-177*

Cluster analysis is one of the most important technologies in data mining. Minimum spanning tree (MST) is an advanced algorithm in cluster analysis. Studying MST has important practical significances. Firstly, this paper analysed partitioning, hierarchical, density and grid clustering algorithms based on MST thoroughly. Secondly, implementation principles and shortcomings of these four algorithms were discussed. Finally, practical applications of clustering algorithm based on MST were introduced, aiming to solve some practical problems.

Keywords: data mining, clustering algorithm, MST model

Jing Yang Routing method of quantum genetic algorithm
Computer Modelling & New Technologies 2014 ***18****(11) 178-181*

Quantum genetic algorithm was applied in the work to solve multiple-QoS routing problems of bandwidth-delay constraint, thus meeting current requirements for multimedia messaging. Mathematical model and constraint condition of QoS routing were established, analysing algorithms principles and steps that how quantum genetic algorithm optimized QoS routing. By comparing average fitness and maximum polymerization fitness under different running times, quantum genetic algorithm can effectively find optimal solutions to multiple-QoS routing problem.

Keywords: genetic algorithm, quantum genetic algorithm, mathematical model, route choice, fitness

Jinguo Zhao A novel method for K-Means clustering algorithm
Computer Modelling & New Technologies 2014 ***18****(11) 182-188*

This paper investigated K-means algorithm, a well-known clustering algorithm. K-means clustering algorithms have some shortfalls and defects, and one defect is reviewed in this study. One of the disadvantages of K-means clustering algorithms is that they can produce clusters that do not always include all the correct components. It is due to the presence of the error rate during the clustering process. The purpose of this research was to decrease error rates in the K-means clustering algorithm and to reduce iteration of running this algorithm. A novel method is proposed to calculate the distance between cluster members and cluster centre. To evaluate the algorithm proposed in this study, seven well-known data sets consisting of Balance, Blood, Breast, Glass, Iris, Pima and Wine data sets were used. This investigation revealed that the performance of K-means algorithms was increased and resulted in valid clusters and that it reduced error rates, run time and iteration.

Keywords: K-means, clustering algorithm, error rate, iteration, reduction, stable

Hong Wang, Tao Zhang Research on transition priorities in group based on CPN
Computer Modelling & New Technologies 2014 ***18****(11) 189-196*

Transition priorities might be a useful mechanism when modelling using Petri nets. Accordingly, the newest CPN Tools, widely used for modelling and simulating the Coloured Petri net, implements transition priorities. Whereas, the algorithms compute enabling for all transitions in a highest-priority-first order. In the real system, it is usually that there are priorities relationships not for all transitions but only some ones. Based on the above analysis, this paper put all the transitions, having priority relations, into one group and advances relative theoretical definitions of transition priorities in group, such as absolute preset of transition, key place set, key colour set, etc. Furthermore, it proposes new algorithms when the systems have different key place set and key colour set, and construct the model of the interrupt priorities to solve the problem of software model checking for interrupt system.

Keywords: Petri net, CPN, transitions, transition priorities in group, counter place

Yuejun Liu, Aiping Tang, Ketong Liu, Jiewen Tu Mechanical characteristics and form-finding analysis of iced transmission lines
Computer Modelling & New Technologies 2014 ***18****(11) 197-203*

Form-finding is the important problem to be solved in the cable structure analysis, to the different forms of loads, the direct iterative method is used to determine the initial configuration of the cable structures. Horizontal tension or

cable tension is used as iterative convergence condition, the form-finding of the cable is researched under its own gravity, uniform ice and non-uniform ice load. As for the multi-span transmission lines, two conditions of uniform ice and non-uniform ice loads on the whole span were analysed. The results of initial configuration are consistent with the analytical method, which verified the correctness of the direct iterative method, under the condition of non-uniform ice load, the stress of conductor is larger than the maximum stress, which is very dangerous in the actual operation.

Keywords: mechanical characteristics, form-finding, uniform ice, non-uniform ice, finite element method

Ying Sun, Meikui Deng, Shenghua Ye Mobile ECG QRS detection algorithm and implementation
Computer Modelling & New Technologies 2014 ***18****(11) 204-211*

The ECG signal contains a lot of interference in the mobile ECG monitoring system. Reasonable selection of signal filtering and QRS wave detection method are the key to ECG signal analysis. According to the characteristics of ECG signals, the design of low-pass filtering and the improved median filter that can filter the interference has been conducted in the paper. Meanwhile, addressing to the limitation generated by selecting and fixing the median threshold using the traditional differential slope method, the paper has proposed the adaptive dynamic threshold and used quadratic difference algorithm to process signal in order to obtain R wave, and then locate Q and S wave based on R wave location. In addition, combining the characteristics of the QRS wave group, judgments on the missing and over detection are conducted, so that the algorithm is robust and has good fault-tolerant ability. The experimental results show that, this algorithm can not only satisfies the need of the real-time QRS wave detection, but is also more suitable for the transmission and processing of ECG signals in mobile ECG monitoring.

Keywords: mobile ECG signal, QRS detection, algorithm

Xie Wu, Ouyang Shan, Hailin Xiao Concurrent quantum key distribution using quantum teleportation and time division multiplexing
Computer Modelling & New Technologies 2014 ***18****(11) 212-218*

In view of the problem that it is difficult to use only one typical channel to deal with many quantum channels during multi-channel QKD (Quantum Key Distribution), the method of TDM (Time Division Multiplexing) in typical channel is introduced to construct a new CQKD (concurrent QKD) system. Using multi-channel quantum teleportation, every concurrent quantum channel is mapped to a time slot of TDM. The results of case study with EPR (Einstein-Podolsky-Rosen) pairs show that this problem can be solved with the CQKD methods. Moreover, this CQKD scheme also has the advantage of unconditional security, while the QKD bit rates can be improved. It opens a new way to develop large-capacity long-distance quantum secure communications.

Keywords: quantum information security, concurrent quantum key distribution, quantum teleportation, time division multiplexing

Kaishi Sun, Fasheng Liu A few expanding integrable models of WKI hierarchy and their Hamiltonian structures
Computer Modelling & New Technologies 2014 ***18****(11) 219-226*

The integrable coupling of the WKI hierarchy is obtained by the perturbation approach. With the help of a higher dimensional loop algebra, the coupling integrable couplings of the WKI hierarchy are obtained, respectively. Their Hamiltonian structures are worked out by employing the component-trace identities and variational identity.

Keywords: coupling integrable couplings, component-trace identities, perturbation equation

Lijuan Hong, Ju Qian, Jifeng Cui Automated unit-level testing of java memory leaks
Computer Modelling & New Technologies 2014 ***18****(11) 227-233*

Java programs may suffer from serious memory leak bugs. To resolve these bugs, various leak diagnosing and even fixing techniques have been proposed. However, in literature, there is very few work, which focuses on memory leak testing. Without revealing leak phenomenon by testing in advance, even excellent leak diagnosing and fixing techniques can be hard to work. In software testing, unit testing is a technique to avoid faults at early stage of software development. This paper proposes an automated unit-level memory leak testing approach to find potential leak bugs in Java methods. It firstly identifies the methods with high leaking risks. Then, strengthened unit tests are generated accordingly to check whether those risky modules can really cause leaks. Cases studies show that our method could be valuable for real programs.

Keywords: Java, memory leak, unit testing, test generation

Minsheng Tan, Huan Zhou, Yangwei Li, Jianxue Liu Improved PSO clustering routing algorithm for WSN
*Computer Modelling & New Technologies 2014 **18**(11) 234-241*

For cluster head selection randomness of clustering algorithm, and PSOC algorithm were not considered the distance from cluster head to base station, an improved particle swarm optimization (I-PSOC) routing algorithm was brought out. The improved algorithm particle swarm fitness function was improved by considering the node residual energy, nodes' distance and the distance between nodes and base station. At the same time, the optimal nodes were selected as the cluster head and the cluster head has transmitted the data to base station in a single or more jumps through searching right path in the improved algorithm. The simulation results show that the nodes energy consumption of network was reduced significantly and the network life cycle was extended

Keywords: PSO, Clustering Routing Algorithm, cluster head, Wireless Sensor Network

Wei Zhong, Ming Lei, Zhou Tian Theoretical analyses and numerical simulation of the interaction time and the separation time of two elastic bars after the loading of a triangular wave
*Computer Modelling & New Technologies 2014 **18**(11) 242-248*

With theoretical analyses, the stress-wave propagation and reflection between two elastic bars, whose left side achieved a triangular wave load, is mainly studied. Considering the effects of pulse width of the load, length and wave impedance of the bars and the relationship between the length of the load wave and the two bars, the regularities of the stress-wave propagation and reflection between the two bars is analysed, and the formulas for calculating the interaction time and the separation time of the two bars are derived, in three different conditions. The same problems in three different conditions are simulated by using AUTODYN, and curves of displacements of points at contact surface of the two bars varying the time are given. According these curves, the simulating results of the separation time can be obtained. By the comparison of the simulating results and the theoretical calculated results using formulas derived in this paper, the correctness of the theoretical analyses and formulas here is demonstrated.

Keywords: triangular wave load, elastic bar, separation time, theoretical analyses, AUTODYN

Zhiyan Li, Baoxia Jin Research of numerical solutions of differential equations model based on the finite element method
*Computer Modelling & New Technologies 2014 **18**(11) 249-252*

Using the finite element method solving a class of second order ordinary differential equations, analyses the two-point boundary value problem of a class of second order ordinary differential equations, through numerical examples to validate its effectiveness.

Keywords: ordinary differential equations, finite element method, two-point boundary value problem

Jing Cao, Xuefeng Xing, Shan Liu Design and application of iterative Monte Carlo localization for mobile wireless sensor networks based on MCL
*Computer Modelling & New Technologies 2014 **18**(11) 253-258*

In recent years, wireless sensor network had been more and more widely used in our daily life, and with the propose of Monte Carlo localization (MCL) algorithm, node localization of the mobile wireless sensor network had been solved effectively. But it needed to have a large number of samples if it used the Monte Carlo localization algorithm to obtain a high positioning accuracy. This paper proposed a new improved algorithm (iterative Monte Carlo localization algorithm) based on the Monte Carlo localization algorithm. In iterative Monte Carlo localization (IMCL) algorithm, each anchor node location information was forwarded by its neighbour nodes only once and preserved by the receiving node in each period. Then the next period, merge it and the sent/forwarding information into a packet and forward. Make sure that points have more observations for estimating previous location sets. IMCL, meanwhile, also can make full use of observation to filter out some samples that were far from the real position of node, so as to improve the accuracy of node localization. We finally confirmed by experiment: IMCL algorithm had higher positioning accuracy compared with other algorithm.

Keywords: IMCL, immune genetic algorithm, wireless sensor network, improve the accuracy of localization

Jian-Wei Li, Xiao-Wen Li Algorithm design and the application for cluster validity based on geometric probability
*Computer Modelling & New Technologies 2014 **18**(11) 259-263*

Determining optimum cluster number is a key research topic included in cluster validity, a fundamental problem unsolved in cluster analysis. In order to determine the optimum cluster number, this article proposes a new cluster

validity function for two-dimension datasets theoretically based on geometric probability. The function makes use of the corresponding relationship between a two-dimension dataset and the related two-dimension discrete point set to measure the cluster structure of the dataset according to the distributive feature of the point set in the characteristic space. It is designed from the perspective of intuition and thus easily understood. Through TM remote sensing image classification examples, compare with the supervision and unsupervised classification in ERDAS and the cluster analysis method based on geometric probability in two-dimensional square, which is proposed in literature 2. Results show that the proposed method can significantly improve the classification accuracy.

Keywords: Cluster validity, Geometric probability, optimum cluster number

Information and Computer Technologies

Si Tian, Shui Wang, Yang Liu, Le Wang An algorithm for mining frequent itemsets on uncertain dataset
Computer Modelling & New Technologies 2014 ***18****(11) 264-272*

Mining frequent itemsets from uncertain transaction dataset is a research topic in data mining. Some algorithms are based on FP-Growth, but they construct the tree structure in a manner that cannot be as compact as the original FP-Tree, so the tree is easily developed to huge size and this hinders their performance. In this paper, we propose a new tree structure called IT-Tree (Itemset Tail-node Tree) to efficiently maintain probability information of itemsets in tail-nodes; we also propose a corresponding algorithm IT-Mine to mine frequent itemsets from IT-Tree without additional dataset scans. We evaluate our approach on real sparse and dense datasets with different minimum support numbers that can produce non-null frequent k-itemsets ($k \geq 2$); the results show that IT-Mine outperforms other algorithms in terms of execution time, especially for large dataset or small minimum expected support number.

Keywords: frequent itemset, frequent pattern, uncertain transaction dataset, data mining

Changsu Liao, Xiaojing Niu, Meili Wang, Dongjian He Simplification of 3D point cloud data based on ray theory
Computer Modelling & New Technologies 2014 ***18****(11) 273-277*

To effectively reduce the amount of 3D point cloud data, whose shape is symmetrical or spherical, this paper proposes an efficient simplification algorithm based on ray theory. Meanwhile, a boundary retention method based on the distribution uniformity of neighbouring data points is used to keep the model complete. Avoiding time-consuming recursion and curvature estimation, the proposed method is much efficient and achieves good simplification results.

Keywords: 3D Point Cloud, Data Simplification, Ray Generation, Boundary Retention

Lei Zheng Virtual machine resource allocation algorithm in cloud environment
Computer Modelling & New Technologies 2014 ***18****(11) 279-284*

To resolve the problem that virtual machine deployment reservation scheme waste a lot of resources and single-objective deployment algorithm is not comprehensive, a virtual machine resource allocation algorithm based on virtual machines group multi-objective genetic algorithm is proposed. The algorithm is divided into group coding and resources coding. Resources coding integrated coding according to the history resource need of virtual machines to physical machine and integrate number of physical machine and resource need of physical machine occupied by virtual machine through improved crossover and mutation operations. The experimental results show that the algorithm is effective to reduce the number of physical machine and resource utilization of physical machine, saving energy as much as possible.

Keywords: Cloud computing, Resource allocation, Virtualization, Energy-saving, Genetic algorithms

Hudai Fu, Jingang Gao Multi circle detection by using evidence accumulation
Computer Modelling & New Technologies 2014 ***18****(11) 285-289*

The traditional circle detection algorithm has complex computation, large memory space occupation and other deficiencies. It has low detecting efficiency and not suitable for the multi circle detection. So it proposes a multi circle detection method based on global search and evidence accumulation in the paper. The evidence accumulation and the weighted average are combined in the algorithm. The pseudo centre processed during the evidence accumulation are classified and analysed. Three kinds of pseudo centres are eliminated by class. Finally, the other circle parameters are calculated. It is proved that the algorithm has high precision, high efficiency, and low sensitivity to the defect of local information. Also the detecting time will not increase with the number of circles. The

multi circle detection effect is obviously superior to the traditional randomized circle detection algorithm.

Keywords: Multi Circle Detection, Global Search, Evidence Accumulation

Ye Chen, Xiaoqun Qin Applications of dynamic adaptive bee colony algorithm in multi-threshold image segmentation

Computer Modelling & New Technologies 2014 ***18****(11) 290-295*

Artificial bee colony (ABC) is an evolutionary computation method, which is inspired from the specific collaborative social group behaviour among the individual bees in the colony and which is a heuristic optimization algorithm based on population search strategy. This paper has proposed a quick dynamic adaptive bee colony algorithm, which analyses the performances of the artificial bee colony algorithm and it designs a multi-threshold image segmentation method realizing a dynamic adaptive artificial bee colony (DAABC) with multi-threshold OTSU as the fitness function. The main characteristics of this method include: reducing the noise interferences in the multi-threshold image segmentation; effectively narrowing down the search range of the threshold; guaranteeing the quickness of the segmentation speed; determining the search range of the reconnaissance ants with adaptive dynamic control and accelerating the convergence speed of bee colony algorithm. The experimental results demonstrate that the method in this paper is better than the image segmentation method based on particle swarm optimization (PSO) and artificial fish swarm algorithm (AFSA).

Keywords: Artificial Bee Colony Algorithm, Multi-Threshold, Image Segmentation, OTSU

Yu Liu, Lei Chen, Shihong Chen Alignment-based approximate SPARQL querying on linked open data

Computer Modelling & New Technologies 2014 ***18****(11) 296-303*

With the growth of Linked Open Data, more and more applications are developed to take full advantage of its massive data. However, all these applications face an inevitable problem - how to retrieve information from these datasets with different schemas, which results in that a query for a dataset may get none answer from other datasets. To solve this problem, ontology alignment has been adopted in some Linked Open Data querying systems. In this paper, we follow this idea and make further efforts to find more approximate answers by employing relations and probability values in the result of ontology alignment. The fundamental of our method is the similarity between entities, which is used to evaluate the similarity of rewritten query relative to original query. In order to facilitate user to query other dataset with original query, an algorithm for alignment-based approximate querying is proposed. In experiments, the SPARQL queries for DBpedia are rewritten on the basis of alignment result between DBpedia and YAGO. The results of experiments show that alignment-based approximate querying can not only retrieve approximate results, but also overcome the problem caused by imprecise result of ontology alignment, which is very common for most of alignment techniques.

Keywords: Linked Open Data, Approximate Querying, Ontology Alignment, SPARQL

Hui Guo, Jie He A fractal de-noising algorithm based on least absolute deviation method

Computer Modelling & New Technologies 2014 ***18****(11) 304-310*

Against the shortcoming that the traditional method of fractal image compression coding has inferior decoding quality on the original image subject to salt-and-pepper noise interference, this paper raises a least absolute deviation (LAD) method to be applied in fractal image compression, which can replace the method of least square error in computing contrast and brightness adjustment value and solve the L1-norm recursive problem using weighted median. The experimental result indicates that the LAD method has a very good anti-noise effect on the outliers introduced by salt-and-pepper noise.

Keywords: Fractal Image Compression, Least Square Error Method, Least Absolute Deviation Method, Salt-and-Pepper Noise

Ye Chen, Xiaoqun Qin, Xinmin Zhou Single threshold segmentation for noisy image based on fuzzy ant colony algorithm

Computer Modelling & New Technologies 2014 ***18****(11) 311-316*

Firstly, this paper pre-processes the image to be segmented through grey-scale morphological method. Then, based on the in-depth analysis of basic ant colony algorithm, it explains the shortcomings of this algorithm; proposes the improved strategy of ant colony algorithm, namely fuzzy ant colony algorithm, which designs the fitness function of artificial ant colony algorithm with minimum cross entropy and applies the improved fuzzy ant colony algorithm in the spatial-domain noisy image single segmentation. Finally, starting from the segmentation results and convergence, it compares the performances of the improved ant colony algorithm and the basic ant colony algorithm, GA

algorithm and AFS algorithm.

Keywords: Noisy Image, Ant Colony Algorithm, Histogram Feature, Threshold Segmentation, Cross Entropy

Jiali Tang, Chenrong Huang, Yijun Liu, Honghui Fan, Jianmin Zuo Face super-resolution algorithm based on SVM-improved learning

Computer Modelling & New Technologies 2014 ***18****(11) 317-322*

As many other inverse problems, human face image super-resolution is an ill-posed problem. The problem has been approached in the context of example-based superresolution learning. However, these methods need to run though all the sample set, which results in high calculation load and image degradation because of mis-matching. In this paper, we propose a new face image superresolution algorithm based on Support Vector Regression (SVR) pre-classified learning. A Principal Component Analysis (PCA) based pre-process is used to select a subset of samples. Then the best-matching sample images are trained to ensure the content relevance between the sample patch and the input low-resolution image. Further improvement involves a combination of classification and SVR-based techniques. Therefore, experiment results show that the proposed algorithm gets better reconstruction performance and faster program running speed.

Keywords: Face Super-resolution, Support Vector Machine (SVM), Principal Component Analysis (PCA), Example-based Algorithm

Jingang Gao, Shuang Zhang, Hua Wang Application of halcon in the image analysis of dry cutting gear meshing region

Computer Modelling & New Technologies 2014 ***18****(11) 323-327*

The master-slave bevel gear pair of some automobile rear axle is used to be as the research object, to obtain the image of the gear meshing contact region. Firstly, get the grey image of HSV space from RGB image to HSV space by the pre-processing algorithm; secondly, segment features of image accurately by the adaptive threshold segmentation algorithm; thirdly, fill the holes in the image of meshing region perfectly by proposed holes repair algorithm; fourthly, mark all connected domains of image with 4 -adjacent points domain labelling algorithm; finally, the Marking image area, width and the ratio of width and height features are selected to extract the image of the gear meshing region to obtain the geometry information of the gear meshing region. Research results show: contact centre E/L should be in 45% ~ 50%, and the length of the contact region B/L should be in 45% ~ 55%.

Keywords: HALCON, dry cutting gear, contact region, Image processing

Wenju Wang, Liujie Sun, Zhang Xuan Editing method of virtual human motion path based on motion cycle step-length

Computer Modelling & New Technologies 2014 ***18****(11) 328-336*

An editing method of virtual human motion path based on movement cycle step-length is presented: it uses the Cardinal spline interpolation to extract the original path and equably sets the path editing control points; alters the positions of path editing control points to generate a new path and adjusts the position and orientation of the original motion sequence frame's root joint nodes on the new path; automatically judges any path curve segment that generates the problems of footstep disharmony after editing; for every incorrect curve segment, deletes the frames of general motion cycle step-length between the two path editing control points that contain incorrect curve segment based on the definition of motion cycle step-length and adjusts the spacing and moving direction of root nodes in every frame on the paths between the two control points; finally does constraint re-establish to all floor frames in the new path. The experimental results show that: the motion path editing method is simple and easy to operate. The generated virtual human motion is natural and smooth. It can effectively eliminate the footstep sliding phenomenon to improve the reusability of motion capture data.

Keywords: Motion path editing, Cardinal spline interpolation, Motion cycle step, Constraint reestablishment, Footskate cleanup

Yumei Ning, Zhenguo Ding, Ping Zeng Early fault warning mechanism based-on association rules in server clusters management system

Computer Modelling & New Technologies 2014 ***18****(11) 337-343*

With the rapid development of Internet and business internal information technology, the problem of server cluster fault early warning becomes important in server clusters management. To solve the problem, a server cluster fault early warning system (SCFEWS) based on event association rules is presented. This system is mainly based on the fault event association tree. First obtain event relationship and association rules. Construct early warning events

associated tree with system logs and association rules, and store it in binary tree linked list. Then by using the warning event filtering algorithm, redundancy fault early warning events are filtered out and only source event for early-warning notification are kept. Experiment shows the proposed algorithm can effectively improve the accuracy of fault location for server clusters management.

Keywords: Server Cluster, Early Warning, Fault Association Tree, Warning Event Filtering Algorithm

Wensheng Wang, Huifeng Xue, Feng Zhang A new dynamic regulation UIPO model of groundwater based on cloud computing and hydroinformatics
Computer Modelling & New Technologies 2014 ***18****(11) 344-351*

In order to solve the problem of excessive mining of the coal resources in Yulin mine area caused enormous damage to groundwater and in turn threatening the regional sustainable development, proposed a new dynamic regulation UIPO model of groundwater, which combined hydroinformatics, cloud computing and multi-source data fusion algorithm, and the mine hydrogeological spatial database, the visualization of 3D geological model and groundwater dynamic evolution model are created. Simulation results show that the UIPO complete with these models and with groundwater - ecological environment - economy system model all connected data analysis for decision support system and with complete hydrogeological and spatial process method by means of big data, can simulate the temporal and spatial variations of groundwater resources, forecast future impact on Yulin mine area groundwater for sake of large-scale exploitation.

Keywords: hydroinformatics, cloud computing, groundwater, dynamic regulation, big data

Zuowen Wang Composition of web applications in clouds environment
Computer Modelling & New Technologies 2014 ***18****(11) 352-357*

In recent years, for the advances of Cloud Computing technologies, cloud applications have been popularity for their rich set of features. The advantages of cloud applications include that users can utilize them in a low cost, threshold, and risk way; these applications can be quickly deployed on the clouds without duplication of work such that developers can focus on enhancing their QoS to improve core competitiveness. Therefore, their practical use on business with promising values can be expected. As such, cloud applications are recognized as a trend for the next generation of business applications, and hence how to migrate these on-premise applications to the clouds becomes a desired field in the literature. For this need, we present an ontology-based method for the composition process that specifically addresses the cloud features and the composition of on-premise applications into the clouds. In particular, for enabling the selection of desired clouds, the method imposes semantic ontologies on the specifications of the candidate clouds from which the desired ones can be effectively selected. For illustration, the method is applied to the composition of a CSS application to its cloud version.

Keywords: cloud computing, cloud application, semantic ontology, service composition

Chunyan Han OSTU image segmentation algorithm of fruit fly optimization algorithm
Computer Modelling & New Technologies 2104 ***18****(11) 358-363*

Traditional OSTU algorithm has the disadvantages of a large amount of calculation and low calculating speed. Based on the combination of Fruit Fly Optimization Algorithm and OSTU algorithm, an image segmentation algorithm is created from Fruit Fly Optimization Algorithm to improve OSTU, stressing the basic principles and calculation procedures of this revised algorithm. In order to verify the validity of this algorithm, the work compared the quality of image segmentation, segmentation speed and algorithm stability of 4 sets of standard test images. The simulation results show that the segmentation speed of revised OSTU algorithm is much faster than that of traditional OSTU algorithm when Fruit Fly Optimization Algorithm is applied to improve OSTU algorithm. Meanwhile, the quality of image segmentation is also more stable under the same condition of time limit.

Keywords: OSTU algorithm, image segmentation, Fruit Fly Optimization Algorithm, grey value, stability

Lili Jing, Yang Nie, Lifang Zhao Colour recognition system based on TCS3200D
Computer Modelling & New Technologies 2014 ***18****(11) 364-368*

The colours of objects can be converted into pulses with different frequencies by TCS3200D. Colour recognition system was designed through the combination of Single Chip Microcomputer (SCM) and PC on the basis of the colour vision principle of TCS3200D. Fully utilizing TCS3200D, the system integrates the advantages of photodiodes and converter of light intensity to frequency to simplify circuit. The effects of factors, such as illuminant, orientation and the surfaces of objects, on the measurement were eliminated by the white balance adjustment. Additionally, colour vision errors were effectively reduced by the correction of the measured data with

ANFIS and subtractive clustering.

Keywords: TCS3200D, colour recognition, ANFIS

Chun Zhang Distributed ontology based information retrieval using semantic web
Computer Modelling & New Technologies 2014 ***18****(11) 369-374*

In recent years, user demand for integrated searches over several independently operating semantic web systems have been increasing rapidly. Integrated semantic searches enable more meaningful results to be generated because information with similar meanings in diverse areas and domains is likely to be used for inference. However, it is not easy to integrate physically independent, distributed, and heterogeneous database systems to provide a single, integrated semantic web system to end-users. In this paper, we propose a novel system that integrates heterogeneous semantic web systems based on schema mapping. The user can generate only one SPARQL query using the integrated schema without the necessity of checking the schemas of individual systems each time thereby reducing additional costs to generate queries for individual systems. Furthermore, the user is not required to collect individual query results manually after performing a query and additional costs for establishing systems can be reduced because no change in existing system structures is required. If currently established systems are expanded by adding the schema structures of other ontology systems, the cost to establish another integrated retrieval system can be saved. To evaluate the effectiveness of our approach, we have implemented a prototype that integrates two national information retrieval systems.

Keywords: integrated information retrieval, ontology, schema mapping, semantic web

Yuwen Huang Research on cost-sensitive ensemble classification for mining imbalanced massive data streams
Computer Modelling & New Technologies 2014 ***18****(11) 375-382*

The existing classifiers for massive data streams do not consider the imbalance distribution and cost factors, so this paper proposes the approach of the cost-sensitive ensemble classification for imbalanced massive data streams (CECIDS). Firstly, this paper gives the construction method for cost-sensitive ensemble SVM Classification, which is integrated by the classifiers with oversampling, sub-sampling and reconstituted sample space. Secondly, we propose a classifier method BL_KNNModelб which is based on KNNModel algorithm for imbalanced massive data streams. BL_KNNModel can detect the concept drift streams by using the variable windows size, which has lower time complexity. At last, the cost-sensitive ensemble classifier for imbalanced massive data streams is given, which has the virtue of high classification and lower time complexity. In addition, the cost-sensitive ensemble SVM algorithm is used to handle the confused instances. The experiments using both synthetic and real datasets show that compared to the other classification algorithms for imbalanced data streams, CECIDS has higher evaluating indicator and more excellence integrated learning curve.

Keywords: Imbalanced data streams, Ensemble classification, Cost-sensitive SVM

Xiaoming Dong Accurate self-localization of mobile robots based on vision sensors
Computer Modelling & New Technologies 2014 ***18****(11) 383-387*

Robot localization is a challenging problem in indoor environment since no GPS information is available. In this paper, an algorithm was proposed for accurate localization, which designed a delicate way to extract the feature points at first, then the position of the robot was determined using the relation of the features in different images, finally, the Kalman filer was designed to decrease the error caused by robot's moving. Experiments showed the accuracy and robustness of this algorithm.

Keywords: mobile robot, multi-cues fusion, vision sensor, Kalman filer, localization

Zhihui Zhu, Ting Liu, Lirong Xiong, Meihu Ma Identification of the hatching egg before the incubation based on hyperspectral imaging and GA-BP network
Computer Modelling & New Technologies 2014 ***18****(11) 388-393*

The removal of the unfertilized egg from the hatching egg before the incubation could improve the efficiency of incubation. The identification of the unfertilized and fertilized eggs by hyperspectral imaging technology combined with GA-BP algorithm was proposed. The comparative analysis for the unfertilized and fertilized eggs was implemented by different pretreatment and principal component. In order to improve the performance of BP neural network, GA algorithm was used to optimize the network parameters. The application of GA-BP network was established the qualitative detection model. The results of the study showed that the MSC + SD pretreatment method was the most suitable for the model. The determination coefficient was 0.95, which indicated the optimized network

model had a good generalization ability and high prediction precision with unfertilized eggs accuracy being 93%, fertilized eggs accuracy being 94%, the overall accuracy being 93.5%. The results indicated that the method of non-destructive identification for fertilized and unfertilized eggs based on hyperspectral imaging technology combined with GA-BP algorithm was feasible.

Keywords: hyperspectral imaging technology, before incubation, hatching eggs, identification, GA-BP

Haiyan Zhuang, Gang Wang Mining multiple level association rules under weighted concise support framework

Computer Modelling & New Technologies 2014 ***18****(11) 394-400*

Association rules tell us interesting relationships between different items in transaction database. Traditional association rule has two disadvantages. Firstly, it assumes every two items have same significance in database, which is unreasonable in many real applications and usually leads to incorrect results. Secondly, traditional association rule representation contains too much redundancy which makes it difficult to be mined and used. This paper addresses the problem of mining weighted concise association rules based on closed itemsets under weighted support-significant framework, in which each item with different significance is assigned different weight. Through exploiting specific technique, the proposed algorithm can mine all weighted concise association rules while duplicate weighted itemset search space is pruned. As illustrated in experiments, the proposed method leads to better results and achieves better performance.

Keywords: weighted concise association rule, transaction database, closed itemset, support-significance

Hui Bu, Ran Liu Data oriented workflow using semantic technologies

Computer Modelling & New Technologies 2014 ***18****(11) 401-407*

Scientific workflows are a topic of great interest in the Grid community that sees in the workflow model an attractive paradigm for programming distributed wide area Grid infrastructures. Scientific workflows have recently emerged as a new paradigm for scientists to formalize and structure complex and distributed scientific processes to enable and accelerate many scientific discoveries. In contrast to business workflows, which are typically control flow oriented, scientific workflows tend to be dataflow oriented, introducing a new set of requirements for system. In this paper, we consider a general workflow setting in which input data sets are processed by a graph of transformations to produce output results. Our goal is to perform efficient selective refresh of elements in the output data, i.e., compute the latest values of specific out-put elements when the input data may have changed. The data provenance is investigated to be used to enable efficient refresh. The proposed approach is based on capturing one level data provenance at each transformation when the workflow is run initially. Then at refresh time provenance is used to determine (transitively) which input elements are responsible for given output elements, and the workflow is rerun only on that portion of the data needed for refresh. The reported preliminary experimental results are developed on the overhead of provenance capture, and on the crossover point be-tween selective refresh and full workflow computation development.

Keywords: scientific workflows, scientific workflow management system, semantic technologies

Shan Feng A boundary knowledge field based data mining method

Computer Modelling & New Technologies 2014 ***18****(11) 408-414*

Data mining (the analysis step of the "Knowledge Discovery in Databases" process, or KDD), an interdisciplinary subfield of computer science, is the computational process of discovering patterns in large data sets involving methods at the intersection of artificial intelligence, machine learning, statistics, and database systems. Knowledge is the source of getting and keeping the strength of competence, knowledge becomes an important strategic resource at the age of knowledge economy. The way to facilitate knowledge transfer smoothly plays a critical role in determining the competence of an organization or organizational system. To explore the mechanism of knowledge transfer, the characteristics of sticky transfer (flow) is compared with the flow characteristics of viscous fluid, and the knowledge on the theories of field in physics, viscous fluid mechanics and boundary layer is employed and analysed in this paper. Firstly, the concept of boundary layer in the knowledge field is proposed to analyse the difference of knowledge stickiness in the knowledge field and describe the contradictory relationship between knowledge stickiness and liquidity. Secondly, based on the analysis of the knowledge transfer in the boundary layer, the dynamic mechanisms of sticky knowledge transfer are analysed from the three aspects of the knowledge potential difference force, the viscous force and the extern driving force. The rotation mechanism of knowledge in the knowledge field is discussed, and the dynamic model of the boundary layer of knowledge field is built. Finally, the phenomenon of knowledge flowing into and flowing out of boundary layer is discussed, and the knowledge transfer conservation equation in the boundary layer is constructed to describe the updating and appreciation of knowledge in the boundary

layer of knowledge field.

Keywords: data mining, knowledge transfer, knowledge field, boundary layer

Lijuan Liao Design of real-time clock based on ARM embedded system
Computer Modelling & New Technologies 2014 ***18****(11) 415-418*

Real-time clock of ARM processor has disadvantages such as dependence on the processor, low interrupt level and unadjustable accuracy. Linux embedded system based on ARM processor is provided with independent real-time clock using X1227 real-time clock chip. In addition, the work presents transplant of uCLinux system in S3C2440A, procedure of system boot loader and frame of Linux character device driver, thus achieving design of RTC driver based on I2C protocol of uCLinux system.

Keywords: S3C2440A, RTC, X1227

Xiaolei Li Spatial and temporal mining method using GPS data
Computer Modelling & New Technologies 2014 ***18****(11) 419-425*

Geographic information has spawned many novel Web applications where global positioning system (GPS) plays important roles in bridging the applications and end users. Learning knowledge from users' raw GPS data can provide rich context information for both geographic and mobile applications. However, so far, raw GPS data are still used directly without much understanding. Spatial-temporal data analysis plays an important role in many applications, including transportation infrastructure, border security and inland security. To analyse the moving patterns of vehicles on a road network, a measure for determining the similarity of vehicle trajectories with respect to space and time has to be defined. Although previous research has addressed the trajectory similarity problem, most of the studies focus on Euclidian distance instead of network distance. This paper deals with the variations in applying a spatial-temporal similarity measure with given Points of Interest (POI) and Time of Interest (TOI), treating spatial similarity as a combination of structural and sequence similarities that is evaluated using the techniques of dynamic programming. The similarity set thus formed will be used by the remote database to broadcast trigger-based messages to participating vehicles in a neighbourhood for future route- and information-sharing activities. The performance of the scheme is evaluated using experiments on standard real-life data.

Keywords: K-means, clustering algorithm, error rate, iteration, reduction, stable

Wenhong Wu, Hengmao Niu An improved watershed algorithm for image segmentation
Computer Modelling & New Technologies 2014 ***18****(11) 426-431*

Watershed transform is a key operator in image segmentation algorithms. However, the computation load of watershed transform is too large for real-time applications. Previously published watershed segmentation algorithms required at least three global synchronization points: minima detection, labelling and flooding. This paper presented an algorithm of watershed transformation based on opening-closing operation and distance transform. It improved the classical watershed segmentation algorithm based on distance transform, overcoming over segmentation. The experiment result demonstrated that this method for segmentation inherits the advantage of watershed algorithm based on distance transform that it successfully segment out each dowel in the image bringing convenience to computer vision and auto-counting of dowels. It also overcame over-segmentation existed in traditional watershed segmentation preserving the original edges of each dowel in the image completely. This algorithm can be combined with any image segmentation algorithm to give more precise segmentation results. An example is also shown by combining a background registration and change-detection-based segmentation algorithm with Watershed. This new video segmentation algorithm can give accurate object masks with acceptable computation complexity.

Keywords: watershed transform, image segmentation, automatic segmentation method

Ying Fang, Heyan Huang A hybrid multi-class text categorization based on SVM-DT
Computer Modelling & New Technologies 2014 ***18****(11) 432-438*

How to improve the text categorization efficiency as well as keeping high speed is a research problem. Several factors are effected the processing of the decision tree construction, such as, the degree, the balancing degree, the constructing way, the group number and the division degree between groups etc. Considered the various roles between the above factors, a comprehensive algorithm to construct the SVM-DT (Support Vector Machine - Decision Tree) is proposed. In this method, three conditions are considered respectively. The text categorization experiments on massive corpus demonstrate that the algorithm can improve the efficiency in some degree and decrease the training and testing time largely at the same time. The algorithm to construct the SVM-DT is feasible

and adaptable.

Keywords: Text Categorization; Support Vector Machine; Decision Tree; Multi-class category; Corpus; Positive Sequence Tree

Xuewen Yu Design of data acquisition node based on CAN bus
Computer Modelling & New Technologies 2014 ***18****(11) 439-443*

Taking single chip microcomputer (SCM) STC90C58AD as control core, a universal CAN bus data acquisition node was designed using CAN bus controller SJA1000 and CAN bus transceiver PAC82C251. Also, the hardware circuit and software design of CAN bus communication were given. Before data collection, current signal has been I-V transformed, and voltage signal has been filtering processed and amplified. Such program is suitable for multi-sensor field data collection in industry.

Keywords: CAN bus, SJA1000, data acquisition

Jiong Cai Reducer optimization design based on chaotic particle swarm optimization (CPSO)
Computer Modelling & New Technologies 2014 ***18****(11) 444-446*

For the optimization design of two-stage gear reducer, an optimization mathematical model is built in this work to determine the objective functions and constraints. And chaotic particle swarm optimization (CPSO) is utilized to optimize these functions and constraints. Algorithm simulation is carried out based on CSPO algorithm steps, and the results are compared with particle swarm optimization (PSO). Simulation indicates that CSPO can optimize the results of PSO and achieve faster convergence rate.

Keywords: chaos particle swarm algorithm, optimization design, mathematical model, reducer

Lifang Yang, Lin Liu TV image enhancement technology based on particle swarm optimization
Computer Modelling & New Technologies 2014 ***18****(11) 447-453*

Television images can be blurred and indistinct by noises in the acquisition and transmission process. Traditionally, control parameters of fuzzy enhancement algorithm are manually controlled, which leads to poor enhancement effect and efficiency. In this work, particle swarm optimization (PSO), due to its fewer parameters and global optimization capability, is combined with fuzzy enhancement algorithm for the optimization of fuzzy enhancement parameters. Simulation results show that PSO can make television images clearer and highlight in certain features, thus improving the visual effect of television images.

Keywords: particle swarm optimization, fuzzy enhancement, image processing, fitness function

Daode Zhang, Yanli Li The automatic cutting algorithm of the plastic film based on image processing
Computer Modelling & New Technologies 2014 ***18****(11) 454-458*

This paper proposes an algorithm based on image processing to solve the dislocation problem when cutting the edge**,** which is in the light of the uneven edge and the wrong side phenomenon. First of all, the images of the plastic bag edge captured by the camera are pre-treated**;** then the image is enhanced by fuzzy contrast enhancement algorithm**,** which is aim to extract the creases contour; finally the edge of the image is detected used by the Canny operator to get the crease on the edge of plastic bag, the cutter position can be obtained by offset some distance from the creases. The research results show that this algorithm is very effective to solve the dislocation problem when cutting the plastic bag edge automatically.

Keywords: fuzzy contrast enhancement, the Canny operator, edge detection, plastic film cutting

Rui Li, Qingshan Feng, Maolin Cai, Haijun Li, Chenghai Liu, Xiaoming Zhao The method of measurement for buried pipeline centerline based on data fusion
Computer Modelling & New Technologies 2014 ***18****(11) 459-464*

For the problem of long-distance oil and gas pipeline centerline measurement, a method of multi-sensor data fusion using the pipe centerline calculation is presented. The error model is set up by the system of navigation and nonlinear dynamic systems. Using the data of IMU and odometer to calculate the information of pig navigation. All of the errors were calculated by Kalman filter for estimation and compensation. It is concluded that the error for horizontal is 0.35m, the error for vertical is 0.74m for comparison of same pipeline centerline in different inspection time. One feature point is dug to verify the accuracy of the inspection which error is less than 1m. This method is effective for the buried pipeline to perform safely.

Keywords: in-line inspection of long distance pipeline, sensor fusion, inertia navigation, extended Kalman filter, error correction

Weiqing Li, Zehui Lu, Shihong Shen A hand gesture interaction system based on Kinect
*Computer Modelling & New Technologies 2014 **18**(11) 465-469*

We introduce a hand gesture interaction system using Kinect, which takes advantage of real-time dynamic motion capture, image recognition and so on, so that people can interact with computer by natural hand gestures. Five kinds of gesture are defined and can be recognized by the system. Kinect-based hand movements and gesture recognition algorithm is studied. A method for hand area image segmentation from the depth map is proposed, using the information of hand joints in skeleton map. We realized a hand gesture recognition algorithm with SVM and tested its stability and robustness. Finally, experimental results verified the feasibility of the algorithm, and a hand gesture interactive demonstration is implemented.

Keywords: hand gesture recognition, Kinect, SVM, interaction

Yujia Li, Jingbing Li Robust volume data watermarking based on perceptual hashing
*Computer Modelling & New Technologies 2014 **18**(11) 470-476*

This paper proposed a perceptual hashing algorithm of robust blind watermarking method for volume data. Which address the problems of authentication and protection of personal information. The scheme obtains the feature vectors of volume data and quantizes them to generate the hash value of the volume data. By combining the concept of zero-watermarking, the algorithm for watermarking of volume data that is robust to geometric attacks. The experimental results demonstrate that the proposed algorithm has good invisibility and robustness

Keywords: watermarking, perceptual hashing, volume data, DFT

Fan Wu, Jingbing Li The text image watermarking using arnold scrambling and DFT
*Computer Modelling & New Technologies 2014 **18**(11) 477-481*

With the popularization of Internet and the development at full speed of the multi-media technology, the copyright protection of digital works has already become the hot issue at present. Generally speaking, image, audio and video watermarking is comparatively similar in algorithm realization, with their redundancy, in which we can embed watermark. But other than the aforementioned, there is no redundancy to transfer secret info in text document. Nowadays, to embed watermark in text documents are limited to methods such as shifting the line and word, amending the characters' traits and disposing in the level of semantics. All these algorithms are not robust or lack of concealment, generally not serving the turn of Chinese text documents riffles. Based on the studies of the document digital watermarking methods and techniques, this dissertation presents that the problems of existed documents watermarking algorithms can be solved by Arnold Scrambling and DFT technique. The experimental results show that the scheme has strong robustness against common attacks and geometric attacks.

Keywords: Arnold scrambling, digital watermarking, DFT, zero-watermarking, text image

Xue-Chen Wang, Xiao-Guang Yue, Mostafa Ranjbar, Sanjay Kumar Boddhu, Maia Viera Cañiv Opposite degree algorithm and its application in engineering data processing
*Computer Modelling & New Technologies 2014 **18**(11) 482-485*

In order to analysis and predict data, a new intelligent algorithm (opposite degree algorithm) is used for actual engineering example. The algorithm is based on concept of prior numerical, posterior values and opposite degree in the nature. The human's languages have positive words and negative words. The matrix method can calculate the opposite degree and predict data by considering data's relationship and opposite degree. At the same time, relevant results are obtained through the opposite degree calculation by using the data of coal and gas outburst. After the comparison of the actual results, the accuracy of prediction is 100%. The preliminary validation of opposite degree algorithm shows that the algorithm is basically feasible and effective. If this algorithm can be improved, it is expected to be applied in practical fields more widely.

Keywords: opposite degree, algorithm, engineering data processing, coal and gas outburst, prior value, posterior value, prediction method

Hui Wang, Tao Zheng, Weiwei Zhang A strategy of attribute reduction based on partition
*Computer Modelling & New Technologies 2014 **18**(11) 486-491*

The attribute reduction is an important pre-processing step for data mining. In order to avoid striking equivalence classes repeatedly for positive region or information entropy reduction it is proposed to calculate attribute reduction by constructing partition directly. At the same time the judgments of the absolute reduction and the relative reduction based on the equivalent division are proved. And the data description quality for the relative reduction has been

defined. It is shown that striking minimum relative reduction of decision table is in the cost of the relative decline of description quality for classification.

Keywords: attribute reduction, partition, rough sets, data mining

Chao Chen, Jian Tang, Zuguang Jin A path planning algorithm research for seeing eyes robot based on visibility graph algorithm

Computer Modelling & New Technologies 2014 ***18****(11) 492-497*

This paper presents a new indoor path planning algorithm for seeing eyes robot using the RFID system. Through combination of UHF radio frequency identification system and low radio frequency identification system to realize accurate positioning for robot. New algorithm combines the idea of visibility graph algorithm with A^* search algorithm, which not only improves the efficiency of searching but also guarantees the feasibility of path planning at the same time. The simulation verify the effectiveness and feasibility of the method.

Keywords: path planning, seeing eyes robot, visibility graph algorithm

Meng Xu, Qingzhong Li, Lizhen Cui A framework to support flexible application collaboration in cloud computing

Computer Modelling & New Technologies 2014 ***18****(11) 498-504*

With the development of Internet, software has more and more collaborative trends. Collaboration application is becoming a new hotspot. Development of collaborative application process is complicated and need many technologies to realize it. It is difficult for an ISV (Independent Software Vendor) or a business department to provide all application modules of a whole collaboration application. Moreover it is difficult to integrate heterogeneous application module developed by different organizations (ISV or business department). According to the problems mentioned above, this paper proposes a PaaS platform framework to build collaboration application dynamically and flexibly. Such PaaS platform can provide the ability of application delivery deployment for organizations and provide the ability of collaboration application customization for end users.

Keywords: cloud computing, PaaS, collaboration application, process

Shaohua Tao, Meilian Li, Zhili Zhang Synchronization optimization under symmetry network

Computer Modelling & New Technologies 2014 ***18****(11) 505-509*

Rich symmetries have been found in many real networks, which is an extensive structural of networks. We study the relationships between synchronization and symmetry of network. One of fascinating problems related to symmetry network is how to optimization phase synchronization by employing symmetric structure. For this purpose, we optimize the network structure by symmetry properties of network, which is statistics the orbits of network. Nodes in the same orbit have similar properties, and then we reduce the network size by nodes in same orbit. We simulate the BA and SW model. The simulations result show that symmetry structure can optimize the network topology and can enhance phase synchronization of network.

Keywords: synchronization, symmetry network, orbit

Xinyuan Cao, Mingsheng Chen, Bingbing Chen, Liangliang Cheng, Qi Qi Solution of compressed sensing for wide angle EM scattering analysis based on MFIE

Computer Modelling & New Technologies 2014 ***18****(11) 510-515*

Fast analysis of electromagnetic scattering problems over a wide incident angle is always a difficult problem in computational electromagnetics. Up to the present, almost all of the traditional numerical methods need to solve one discrete angle after another to finish calculating this kind of problem. In this paper, we propose a new method, which can fix it effectively by applying compressed sensing into method of moments for magnetic field integral equation. The theory and calculation process of the solution are described in detail in the paper, and by numerical experiments of different three dimensional objects, the accuracy and the efficiency of the algorithm are also discussed.

Keywords: compressed sensing, method of moments, magnetic field integral equation

Zili He, Tingchun Shi, Biaobiao Gao The influence and improvement of scanning speed to the line width in fused deposition manufacturing

Computer Modelling & New Technologies 2014 ***18****(11) 516-520*

During the process of fused deposition manufacturing, the extruding speed and the scanning speed of nozzle don't match in some path of large change in direction may lead the extrusion of material more or less than demand too

much which causes accumulation of material or the lack of line width. The method of controlling FDM's forming accuracy which is under the restrictions of the mechanical structure of the work platform is studied. By adjusting the extruding speed and measuring the line width on the work platform the width of forming line in process can be controlled in allowed range. The experiment results indicate that through controlling the speed of extruding motor the extrusion of material is controlled efficiently and the accuracy of molding is improved.

Keywords: movement theory of nozzle, scanning speed, extruding motor controlling, measure of line-width

Haifei Zhang Query semantic data from relational database: an on-demand mapping approach
Computer Modelling & New Technologies 2014 ***18****(11) 521-524*

One of the tasks for semantic web is to integrate large amounts of current information in relational database, which behind Web into machine-understandable RDF data model to form a "web of data". So relational database semantic query namely RDF access to relational database is an important issue in semantic web research. To realize the query is to build mapping relation between relational database schema and ontology. However, there is natural isomerism between them. The traditional method to eliminate the isomerism is to convert relational database schema into a similar ontology form and then to build all concepts and attributes mappings between conversion ontology and input ontology. This paper realized an on-demanding mapping method when users request query, avoided building all concepts and attributes mappings between conversion ontology and input ontology and improved mapping efficiency.

Keywords: relational database, semantic data, conversion ontology, input ontology, on-demanding mapping

Xu Bing, Yizhi Zhang The study and design on the campus network surveillance
Computer Modelling & New Technologies 2014 ***18****(11) 525-528*

In order of improving the efficiency of network administration, one of the most useful methods is to inspect and measure of the network traffic. By introducing technology relevant to network flow monitor and analysing monitor system of campus network flow, this paper brings forth collection of Campus network flow and statistic of network flow, adopting Visual C++ 6.0 technology to design structure of this plan. This paper also points the key technology and means to realize monitor system of campus network flow and monitor system of campus network flow. It is reliable and extensible to for realization of system to improve administrative function. It is easy to realize the function of collection of campus network flow and flow statistic.

Keywords: network monitor, network flow, collection of flow, data statistic, VC++ 6.0

Fen Guo, Huaqing Min, Ming Yin A self-aware strategy for virtual machines placement on clouds
Computer Modelling & New Technologies 2014 ***18****(11) 529-535*

Cloud computing is a new computing service mode, and virtualization is a key technology of it. A self-aware strategy (SAST) for Virtual machines (VMs) management on clouds is proposed which is multi-attributed weighted on the resources. It manages the virtual resource basing on the requests of users and the real-time state of the system dynamically. It consists of three phases: (1) monitoring the cloud performance including VMs and Physical Machines (PMs), with the data standardized; (2) measuring the cloud load balance value with the attribute weighted measurement model; (3) using the placement algorithm to choose the best appropriate PM to place the VM requested. The main contribution of the paper is that a cloud load balance measurement model is introduced and a VM scheduling strategy is proposed which includes the VMs placement optimization algorithm and the VMs dynamic migration algorithm. The SAST is tested on the simulation platform comparing with other traditional ones. As a result, we concluded that it guaranteed the SLA and achieved better load balance of cloud. And at the same time, it minimized the number of the started PMs on clouds to reduce energy consumption.

Keywords: cloud computing, virtualization, placement, scheduling

Xiaorong Cheng, Sizu Hou Searching security policy with acyclic directed graphs
Computer Modelling & New Technologies 2014 ***18****(11) 536-539*

To improve the efficiency of policy searching, a method based on the use of a weighted directed graph is studied. Regarding security states as vertices and trigger conditions as edges, the security policy knowledge base can be described as an acyclic weighted directed graph. Firstly, the graph is divided into some areas with just has an initial state node and a termination state node. Secondly, weights for each edge are set according to trigger condition frequencies, and then the optimal path from the initial state node to the termination state node is found using the A* algorithm. Finally, all state nodes are reordered on the basis of their optimal path to build an adjacency matrix and conduct depth-first traversal to search policies. Experiments showed that this method improved policy search

efficiency.

Keywords: security policy search, acyclic directed graph, A* algorithm, adjacency matrix

Sizu Hou, Xiaorong Cheng Design and implementation of an event correlation model in a network security linkage system

Computer Modelling & New Technologies 2014 ***18****(11) 540-544*

Based on the shortcomings of poor compatibility, weak practicality, and low accuracy in current linkage systems, this paper designed a gradation of event correlation model with real-time response mechanism. It will be analyzing technology in data mining association rules is introduced to analyse the processing of security incidents. Then the system through the analysis of a large number of real-time data collecting all kinds of security devices found hidden in the data and related information to improve detection precision and safety accident treatment work. At last, apply this model into the system, to demonstrate the effectiveness of the model and priority.

Keywords: linkage system, event correlation model, correlation rule, security event

Yueqiu Jiang, Yujun Wang, Hongwei Gao, Shuang Ma Research on key technologies of medicine grain defect detection system based on machine vision

Computer Modelling & New Technologies 2014 ***18****(11) 545-551*

In the process of medicine grain production may generate many kinds of defects. If these unqualified medicine granules are not timely detected, it will not only affect the company's reputation but also the health of the patient. This paper mainly studied how to detect the unqualified medicine grain base on machine vision. It mainly consists of three kinds of common defects segmentation and defect area calculation. Firstly, preprocess the medicine grain image for the following procedures. Secondly, obtain the defect region by improved segmentation algorithm, in order to deal with three different drugs grain defects this paper improved three segmentation algorithms, for the damaged tablets propose a local edge detection algorithm that based on grey level difference, for the irregular-shaped tablets adopts the ellipse detection algorithm, which based on Hough transform technology, for the Capsule has air uses the multi-scale Canny edge detection operator. Finally, adopt Chain code contour tracking algorithm and Three-point method calculate the area of the damaged tablets, determine whether the tablets meet the requirements. Experiments show that the system can detect unqualified medicine granule quickly and accurately, it is of great practical value.

Keywords: image processing, median filtering, defect detection, region segmentation, area calculation

Jiangbo Zheng Research on a regional innovation system: viewed from the degree distribution of complex networks theory

Computer Modelling & New Technologies 2014 ***18****(11) 552-557*

A Regional Innovation Systems is viewed as a special type of complex network in this paper, and the complex features of the entities in the system as well as the interactions between the entities are discussed in detail. Based on the Degree Distribution of Complex Networks theory, firstly this paper proves the feasible degree distributions in practical networks through mathematical reasoning and analysing. Then, an empirical case of degree distribution characteristics for the Regional Innovation System is tested by mean of calculating the Correlation Coefficient with the statistical data of Guangdong Province. Coupling Complex Networks Theory with these data and the practical conditions of Guangdong province, this paper sheds light on the insight of the calculating results. Such research shows that the methodologies and conclusions of this paper are proper.

Keywords: regional innovation system, degree distribution, complex networks, data calculation, Pearson correlation coefficient

Weiqing Li, Ranran Xu, Mengyu Yuan A GPU-based simulation system for infrared images of deep space targets

Computer Modelling & New Technologies 2014 ***18****(11) 558-564*

In study of deep space targets recognition, infrared images of deep space targets are needed for repeat testing and evaluating. Since the limitation of deep space flight experiments, it is difficult to obtain sufficient infrared images under different conditions. Infrared image simulation technology is brought up to solve this problem efficiently. The principle of deep space targets infrared imaging was studied. Based on the infrared sensor's optical properties, a hierarchical imaging model was built. The infrared camera and all the effects were simulated respectively, including motion trail of target and space objects, blurring, dispersion, blind elements, and noise. A mixed noise model was introduced by combining the random noise and Perling noise model. In the image simulating process, Graphic Processing Unit was used to produce noise image in real time. According to the reference photo of infrared sensors,

infrared simulated images were evaluated using histogram distribution, the trend of intensity, and Signal to Noise Ratio, and the results show these images satisfied targets recognition algorithm.

Keywords: deep space targets, infrared optical properties, infrared imaging, graphic processing unit, Perling noise

Nan Yao, Kaisheng Wang, Jin Yu Analysis based on computer graphic design and visual communication design

Computer Modelling & New Technologies 2014 ***18****(11) 565-568*

The development and application of computer graphic design and visual communication design greatly changes people's life. Designers can use design tools, which are highly-advanced and professional to create a broader scope of design and design theme works. In our daily life, computer graphics technology is widely applied into various fields, such as the military, medical, communication, art etc. Computer graphics and image technology has been emphasized in the visual field, which improves the overall effect and the level of visual communication design to a large extent. This article mentioned the definition of the technology of computer graphics and the visual communication, then described the significance of realizing the visual communication design elements, and hoped the results will be helpful to relative fields.

Keywords: computer graphics, visual communication, the overall effect, the significance

Xiehua Yu Content of smart wireless sensor network security and its network security policy

Computer Modelling & New Technologies 2014 ***18****(11) 569-573*

Wireless sensor network is generally composed by plenty of micro-sensors that arranged on designated area. The supervision of these sensor nodes is used to finish the collecting, disposing and uploading of vast information. However, the security of wireless sensor network has many problems, since the sensor node itself exists plenty of limitation. Aiming at the problems of smart wireless sensor network security as well as the analysis of wireless sensor network node easy been attacked, wiretapped and forged without safeguard, this paper put forward a security policy of smart wireless sensor network. Simple and useful intrusion detection policy was realized from a series of improvement of LEACH protocol of low-energy self-adaptation cluster routing protocol.

Keywords: smart wireless sensor network security, secure routing, key management, intrusion detection

Hong Yang Duality for multi-objective semi-infinite programming with $K-(F_b,\rho)-$ convexity

Computer Modelling & New Technologies 2014 ***18****(11) 574-577*

In this paper, some nonsmooth generalized convex functions called uniform $K-(F_b,\rho)-$ convex function, uniform $K-(F_b,\rho)-$ pseudoconvex function, uniform $K-(F_b,\rho)-$ quasiconvex function are defined using $K-$directional derivative and $K-$subdifferential. Nonsmooth multi-objective semi-infinite programming involving these generalized convex functions is researched, some Mond-Weir type duality results are obtained.

Keywords: Nonsmooth, Multi-objective Semi-infinite Programming, Mond-Weir type duality, Uniform $K-(F_b,\rho)-$ Convex Function

Yihe Liu, Shuang Zhang, Yuping Qin A role-based security information flow model in grid environment

Computer Modelling & New Technologies 2014 ***18****(11) 578-583*

Security is an important component of a grid, and it directly affects the development of the grid and the practical application of the grid system software. According to the practical application problem (namely realization of the role-based management) in the role management occurring in the information application system of my school, a role-based security information flow model is proposed from the point of view of guaranteeing the information security. In this paper, the object concept in the general network environment is expended, and the organization security classification of an object and relation between the security classification and the role set are used to classify the security and define the strategy for information flow, finally a security information flow model based on the grid environment is presented. The safe classify of the object is divided by the related information of role set, the organization security classifications, and classifications etc. At the same time, the information flow role is described. A new secure information flow model based on rules and grid environment is described using these methods. It is proven from strict mathematical justification that the new model satisfies properties of the finite lattice and least upper bound operator, and it is reasonable and safe. Furthermore, it is an extension of the BLP model and the role-based information flow model as well as extension of the security information flow model in the general network environment. Therefore, it is significant to the study of grid security.

Keywords: Grid Security, BLP model, Rule, Information flow model

Operation research and decision making

Xiaohong Kon, Lixia Chan, Junpeng Xu Fashion colour forecasting based on BP neural network
Computer Modelling & New Technologies 2014 ***18****(11) 584-591*

Fashion colour forecasting is a hot issue in fashion industry and also a hard problem because of much uncertain information. Utilizing strong mapping capability of BP Neural Network (BPNN) for nonlinear function, this paper investigated the forecasting model of fashion colour. Based on colour data of recent several years, the forecasting model for future colour trend is discussed and built. The historical data are input to train the Neural Network weights and the different parameters of BPNN were investigated to find how to affect the forecasting performance. The results demonstrate the algorithm is very efficient in colour forecasting and can approximate nonlinear relationship of fashion colour very close.

Keywords: Fashion colour, BP neural network, Trend forecasting, Network parameters

Jinghai Yin, Zhendong Mu Gender impact on the identification based on EEG
Computer Modelling & New Technologies 2014 ***18****(11) 592-599*

To study the genders impact on identification, this paper analysis the electroencephalograph (EEG) of eight male subjects and seven female subjects. In order to reduce the noise signal interference, the high pass and low pass were used to cut extra frequencies, and in order to prominent the feature signal, the power spectrum method was used to convent the time domain signal to frequency domain, and then fisher distance was used to extraction the feature. All EEG signal was acquired by neurescan, and the EEG signal was evoked by VEP method used subjects photo. The experiment was divided into three models: all subjects were the same sex, added some opposite sex, added some stranger. The analysis results show, to model 1, the correct recognition rate for male subjects, average is 88.50, and this for female, average is 92.51%; the false recognition rate for male subjects, average is 30.84%, and this for female, average is 27.67%,this result indicates VEP can be used as identification tool, the results of model 2 and model 3 show weather opposite sex or stranger should affect the correct recognition rate, but to male subject, the opposite sex effect is greater than stranger, to female, the result were reversed. The results also show noise photo affected female lower than male.

Keywords: Genders Impact, EEG, gender, Fisher Distance

Zhengmei Lin, Jiwei Yao Sport service evaluation of urban community based on fuzzy comprehensive evaluation
Computer Modelling & New Technologies 2014 ***18****(11) 600-604*

Fuzzy comprehensive evaluation refers to a comprehensive assessment method based on fuzzy mathematics through quantifying the factors difficult to quantify with obscure boundaries and using the principle of fuzzy relation synthetic. Fuzzy comprehensive evaluation can comprehensively evaluate the object system involving fuzzy factors and is widely applied in the fields of economy and society. This paper takes new public service theory as the research perspective; designs evaluation index system which can comprehensively reflect sport development level of urban community applies fuzzy comprehensive evaluation to evaluate sport development level of urban community in Hunan province and provides the evaluation process. The evaluation results show leadership organization and team construction of the urban community fail to develop to certain level and that the health index of community residents is slightly low. This paper presents suggestions to improve this situation.

Keywords: Fuzzy Mathematics, Fuzzy Comprehensive Evaluation, Evaluation Index System, Urban Community, Sport Service

Feng Jiang, Min Gao, Hui Xia, Qingyu Xiong, Junhao Wen An evaluation approach based on word-of-mouth for trust models in recommendation systems
Computer Modelling & New Technologies 2014 ***18****(11) 605-609*

Recommendation systems have been recognized as an effective approach to heavy information load. In recommendation systems, trust/reputation has attracted increasing attention because it helps to improve the precision of recommendation and the robustness of systems to shilling attacks. Recommendation system oriented trust models, mostly rating-based, used to build the reputation and trustiness among users. They are often evaluated in terms of how accurately they help to predict user ratings and how robustly they resist shilling attacks. However, those evaluation techniques disregard the trust values themselves: how accurately they calculate the trust values themselves is not measured. To solve the problem, in this work, we propose an approach to measure the trust values based on

electronic word-of-mouth (eWoM) theory. The eWoM believes a user is reliability if he is of good public praise. In our approach, firstly, according to eWoM, the reliability value of a user can be judged by other users' votes - whether the user's ratings or feedbacks are positive or negative. Secondly, the trust values of users can be calculated by a trust model. Finally, we compare trust values and reliability values. As a case study, we propose a simple rating-based trust model and then evaluate the trust model based on the proposed evaluation approach and Amazon dataset.

Keywords: Recommendation Systems, Evaluation Approach, Trust Model

Huajie Chen, Mingchang Liu Application of principal component analysis in fire risk prediction of stadium
Computer Modelling & New Technologies 2014 ***18****(11) 610-615*

The security of stadium is one of the problems increasingly concerned by people. Among various security problems, the fire risk of stadium is the most important. By using principal component analysis (PCA) and combining the influencing factors of risk prediction of stadium, several influencing factors of the fire risk of stadium are evaluated and analysed, then the uppermost principal component factors are selected, the inconspicuous components are eliminated, the influence of relevant factors on the fire risk prediction of stadium is analysed, and the correlation of various indicators with fire risks of stadium is understood to find the potential best security management prediction system, for the purpose of taking pertinent prediction measures of fire accident risks to overcome the unfavourable factors in the security management, and ensure the safe and normal operation of stadium as well as the personal and property security of sporters.

Keywords: Principal Component Analysis, Stadium, Fire Risk, Prediction

Ronghui Hu Application of factor analysis in risk evaluation of basketball arena project construction
Computer Modelling & New Technologies 2014 ***18****(11) 616-620*

In basketball arena project construction, the project safety is an important topic. Aimed at the current situation of basketball arena project construction, the risk factors in the project construction are evaluated from the aspect of factor analysis method and the data in the process are processed according to relevant theory of factor analysis method and by virtue of SAPP software, so as to verify the scientific reasonableness of the method. In addition, in the process of evaluation, the subjectivity is linked with the objectivity in combination with the reality to provide main basis for the safety risk problems in the basketball arena project construction, which is beneficial for the safety management in the project construction. The application of factor analysis method in the basketball arena project construction can provide some new thoughts for other analysis methods, so as to enhance the theoretical research basis for the factor analysis method.

Keywords: Factor analysis method, Basketball arena, Project construction risk, Evaluation

Hao Zhang Short-term traffic flow forecast of highway network based on chaos time series method
Computer Modelling & New Technologies 2014 ***18****(11) 621-625*

With the construction of the highway network and the growing traffic flows, demand for real-time control and guiding service have become increasingly prominent. As for short-term forecast of highway network, it is not only the basis and foundation of the real-time control and guiding service for traffic flows, and the precise forecast result will have a magnificent impact on improving the traffic capacity and service levels. This paper builds a short-term traffic flows forecast model for highway network based on chaotic time series analysis and prediction theory. The forecast of the traffic flows in given areas can be calculated. Results show that this model is feasible and has a high accuracy.

Keywords: highway network, traffic flow, chaos theory, time series, prediction

Sujiao Liu Optimization of industrial structure configuration based on fruit fly optimization algorithm
Computer Modelling & New Technologies 2014 ***18****(11) 626-630*

Establishing the mathematical optimization model of Shangqiu's agricultural structure from three aspects - economy, ecology and society, the agricultural industry structure in Shangqiu is regarded as the research object, utilizing fruit fly optimization algorithm to solve the mathematical model. Simulation results show that fruit fly optimization algorithm can solve the optimal solution for Shangqiu's agricultural industry structure to achieve the maximum benefits, thus providing the decision-making basis for adjustment and development of Shangqiu's agricultural structure.

Keywords: fruit fly optimization algorithm, industrial structure, optimization model, population size, iterations

Shuwen Ma Investigation of the strategic alignment in public sector organisations using knowledge based

strategy
*Computer Modelling & New Technologies 2014 **18**(11) 631-636*

Ageing workforce is one of the critical challenges a public sector organisation is facing and will face more terribly. The cost of knowledge loss can have huge impact on the bottom line of business. A major issue facing Public Sector Organisations (PSOs) in recent times has been the increasing pressure to demonstrate value from investments in Information Technology (IT). One omnipresent but often overlooked solution is Strategic Alignment (SA) between corporate business objectives and IT initiatives as achieving SA remains one of the more enduring challenges for organisations. Moreover, deriving value from IT investments through SA requires both IT and business executives to foster synergies between their respective areas, which contributes to increased organisational performance. Conversely, business-IT misalignment may eventually lead to failure in achieving business goals. Shared Domain Knowledge (SDK) is a key factor within the social dimension of SA and is concerned with the level of knowledge business and IT have of each other's to each other's missions, objectives, and plans. This paper presents findings from a study which investigated the influence of SDK on SA within organisations in the Australian public sector. The developed research model examined SDK between business and IT professionals as a factor that would potentially influence SA. The findings suggest that increased levels of SDK between professionals from the business and IT domains leads to more efficient SA in PSOs.

Keywords: shared domain knowledge, strategic alignment, public sector, organisational performance

Gang Lu Evaluation of e-commerce website based on fruit fly algorithm optimization RBF algorithm
*Computer Modelling & New Technologies 2014 **18**(11) 637-644*

The feature and various index properties of E-commerce website are considered as a whole by applying the expert grading method, with the construction of the multi-index hierarchical structure of an E-commerce website competitiveness index evaluation and the establishment of an E-commerce website competiveness index evaluation index system. The competiveness level of the website is quantified after calculating the competiveness index of the E-commerce website. On this basis, this work adopted Radial Basis Function (RBF) neural network algorithm to perform evaluation research on the competiveness index of E-commerce website. Aiming at the problems exist in the evaluation research, this work tried to use Fruit Fly Optimization Algorithm (FOA) to perform improvement on the RBF neural network algorithm. Through the simulation and comparison of practical examples, FOA-RBF algorithm is obviously better than RBF neural network algorithm when the E-commerce website competiveness index is calculated and evaluated, thus the validity and reliability of calculating method presented in this work are verified.

Keywords: e-commerce, neural network, radial basis function, fruit fly optimization algorithm, expert grading method

Zihui Yang Web search engine based trend analysis of electronic commerce market
*Computer Modelling & New Technologies 2014 **18**(11) 645-650*

Google Trends offer weekly free information about internet searches. Users can see and download search volume patterns for the search term and the information is available by the category and by the location of those making the search. Also, Google provides "Hot searches" and "Top charts" including top and rising searches that include the search term. All these information is up to date as it provides weekly figures for a period up to and including the current week. In here, the proposed methods present a predictive model for Electronic Commerce market using the searched data in Google search engine (Google Trend data). Through the predictive model for the market and analysis of the Google Trend data, the proposed methods can get an efficient and meaningful result for the Electronic Commerce market, also we can enforce the marketing on highly ranked countries and cities. Those are very useful information for the Electronic Commerce manufacturers.

Keywords: electronic commerce, search engine, trend analysis

Hong-Liang Qiu Impacts of tourist destination image on place attachment and tourist loyalty
*Computer Modelling & New Technologies 2014 **18**(11) 651-656*

Although the importance of tourist destination image as a tool to enhance tourist loyalty is commonly acknowledged, prior research on the relationship between tourist destination image and tourist loyalty is not in-depth. Drawing on place attachment theory, a model depicting the relationship among tourist destination image, place attachment and tourist loyalty is constructed. Using the sample of 337 inbound tourists from Japanese and Korean and the structural equation modeling method, the empirical results reveal that: 1) Landscape image, merchandise image and facility image have positive effects on affective image. Landscape image and merchandise image significantly and directly affect place attachment while partially mediating the effect of affective image. Service image has a direct effect on place attachment. Facility image has an indirect effect on place attachment. Facility image significantly and directly

affects tourist loyalty while partially mediating the effect of place attachment. 2) Affective image has a direct effect on place attachment and it is an antecedent of tourist loyalty while completely mediating the effect of place attachment.

Keywords: tourist destination image, cognitive image, affective image, place attachment, tourist loyalty

Lei Hong Deployment algorithm based on dynamic multi-populations particle swarm optimization for wireless sensor networks

Computer Modelling & New Technologies 2014 ***18****(11) 657-662*

Aiming at improving coverage rate and reducing coverage holes of wireless sensor networks, this paper proposes a deployment algorithm based on dynamic multi-populations particle swarm optimization. K-Means clustering algorithm is employed to divide the network into several sub-populations dynamically, which could weaken particles on the pursuit of local optima, realize the improvement of basic PSO (Particle Swarm Optimization) algorithm, and solve the "premature" problem of basic PSO algorithm effectively. In addition, it also accelerates the convergence of the algorithm. Simulation results show that this deployment algorithm can improve the network coverage rate effectively. Comparing with the conventional particle swarm optimization algorithm, its coverage rate is increased by 3.66%.

Keywords: deployment, particle swarm optimization, *k*-means, wireless sensor networks

Bao Wu Financial contagion dynamics and fragility assessment of industrial complex network

Computer Modelling & New Technologies 2014 ***18****(11) 663-668*

The paper proposed a mathematical modelling of financial contagion dynamics that is tightly linked to systematic risk of industrial complex network. And the paper provides a practical method to assess fragility of industrial complex network in the context of financial contagion. To examine its function, an experimental analysis based on real data set of a Chinese textile industrial network is conducted. The experimental analysis shows that the method proposed in the paper is effective ad reliable, and is capable to assess fragility of industrial complex network in the context of financial contagion.

Keywords: financial contagion, fragility, industrial complex network, assessment method

Han Jingwei, Owen Liefung Yue Study of collaborative relations through "Daily Maersk" service in China

Computer Modelling & New Technologies 2014 ***18****(11) 669-674*

Maersk Line has recently introduced a daily service in Asia-Europe route. This new service will bring in a revolutionary impact on the current fixed schedule shipping service in China. There are different views from China market on such daily service since the daily Asia-Europe service route calls mainly China's ports. Through the study of the 'daily Maersk' from 5 perspectives, namely shipping market demand, the required basic port infrastructure, relevant Government policies and regulations, operational aspects and low carbon emission, it is possible to reveal a kind of 'collaborative relations' in the China fixed schedule shipping market. The analysis adopts a qualitative approach via a questionnaire survey of selected experts. With the support of a theoretical mathematical model, it is possible to quantify the collaborative relations in different development phases in China. The study concludes that there are 3 broad phases of the development of collaborative relations and the current daily service emerges in the 'new development era' phase. It is because there are sufficient freight and adequate port infrastructure. The daily service outperforms the general industry practice under the "Rotterdam Rules" on carrier's responsibility and liability and injects contemporary logistics management concepts in the industry. Moreover, it is in the same pace of current China's requirements on energy saving and carbon emission reduction targets.

Keywords: 'Maersk', collaboration, collaborative relations, Asia-Europe

Zhuo Yang, Hong-liang Qiu Empirical analysis on influencing factors of capital structure of China's real estate listed company: evidence from Chinese listed company

Computer Modelling & New Technologies 2014 ***18****(11) 675-681*

Capital, the guarantee for normal operation of an enterprise, is crucial to production. Therefore, optimizing the capital structure has been an important task in the development of enterprises. Combining with VAR model, this paper selects 7 factors, which are profitability, operation ability, the current debt servicing ability, development ability, tax, strategic position and the assets structure, so as to make an exploratory study on the capital structure of Chinese real estate industry, based on the data from June 2002 to December 2012. The study shows that the Liquid ratio and the gross profit are of great effects on the capital structure of a listed company.

Keywords: capital structure, listed company, the real estate, impulse responses

Liming Yang, Yanwen Wang, Xiuju Gao Research on the performance measurement model of knowledge management based on Grey relational analysis
Computer Modelling & New Technologies 2014 ***18****(11) 682-688*

Performance measurement of knowledge management is a decision-making analysis project that involves multiple complex factors, levels and fuzzy uncertain information. On the basis of analysis of influence factors of knowledge management performance measurement, the study established an evaluation index system of enterprise knowledge management performance. Meanwhile, by combining grey relational analysis method and Euclidean distance measurement, a performance measurement model of knowledge measurement was established. Via standardization of different types of evaluation indexes of knowledge management performance, Euclidean distances of standardized evaluation indexes of knowledge management performance and the grey relational coefficients based on Euclidean distances were established respectively. Then the weighted grey correlations of evaluation indexes of knowledge management performance were obtained. In this way, evaluation analysis of enterprise knowledge management performance was realized. Finally, the model and algorithm was tested with a case study. The result proves that the method of combining grey relational analysis and Euclidean distance is efficient and has its application value in performance evaluation of knowledge management.

Keywords: knowledge management, performance measurement, Grey relational analysis, euclidean distance, model

Yaqin Lu, Cunzhi Tian, Yi Wu Corporate growth, liquidity assets value and financing decision
Computer Modelling & New Technologies 2014 ***18****(11) 689-694*

Based on the external financing analysis framework under asymmetric information, this paper analyzes the influence of corporate growth on liquid assets value and financing decision. Both of the theory and numerical calculations show that liquid assets value would increase with the increasing in corporate growth. For the reinvestment decision in the case of higher reinvestment demand, if the price of liquidity assets is higher than value, it is optimal not to reinvest; if the price is lower than value, it is optimal to reinvest; if the price is equal to value, there is no difference found in reinvesting or not.

Keywords: liquidity shocks, liquid assets value, corporate growth, financing decision

Xiaoyuan Geng, Yongde Wang Identification and application of investors' risk appetite-based on the analysis of risk allocation of China multi-layer capital market system
Computer Modelling & New Technologies ***18****(11) 695-705*

In order to measure investors' risk appetite more accurately, from the focus on the investors' demand for the capital market, this article deduces the utility level of investors in the capital market by the inverse of the investor demand (only when the demand function satisfies integrablility, then it will be deduced the utility function inversely), and thus measure and identify the investors' risk appetite. While based on this theory approach, the paper empirically analyses the risk allocation of China multi-layer capital market, and the results show that: risk allocation of China multi-layer capital market system is non Pareto efficient, the risk allocation of each market does not meet the structure of multi-layer capital market established, but these problems can be improved by adjusting the market trading mechanisms.

Keywords: Stochastic demand; Integrability problem; Risk appetite; Risk allocation

Yan Li, Fuyu Wang The Decision of Scrap Reverse Logistics Operation Mode for Steel Enterprises Base on Evolutionary Game Theory
Computer Modelling & New Technologies 2014 ***18****(11) 706-712*

This paper discusses how steel enterprises choose the appropriate scrap reverse logistics operation mode from self-operation mode and the third party mode. To solve the problem, evolutionary game theory is used to research the game relation of cooperation between steel enterprises and the third -party enterprises. Firstly, the replication dynamic equations of both players are build based on payoff matrix .Secondly, the evolutionary stable strategies are acquired by stability analysis on evolution dynamic process of the game two players. Finally, combined with numerical simulation, some factors that impact stable strategy choice are analyzed such as initial state of system, extra income and risk cost of cooperation, invested initial cost and loss for cooperation. The conclusion provides theoretical reference for steel enterprises selecting scrap reverse logistics mode.

Keywords: scrap reverse logistics mode;evolutionary game theory;replication dynamic equation;steel enterprises

Biao Song A Scientific and Research Performance Evaluation model of Institutes of Higher Learning Based on Multilevel Fuzzy Comprehensive Decision Analysis
*Computer Modelling & New Technologies **18**(11) 713-717*

Scientific and research performance is an important part of the evaluation on the overall strength and the ability to achieve sustainable development of institutes of higher learning. With the purpose to deal with the multi-attribute, multilevel and fuzziness, this paper constructs a scientific and research performance evaluation system for institutes of higher learning and proposes an evaluation model based on multilevel fuzzy comprehensive decision analysis. After indicators are standardized, we can get the fuzzy nearness by fuzzy comprehensive decision analysis and Analytical Hierarchy Process for evaluating various schemes. It provides support for the analysis of teaching ability, research ability and the sustainable development of institutes of higher learning.

Keywords: Higher school; scientific and research; fuzzy decision analysis; performance evaluation; model

Liao Yiqin, Chen Xun Social welfare, climate change and strategy selections for developing countries
*Computer Modelling & New Technologies **18**(11) 717-723*

This paper introduces external effect of carbon emission in social welfare function, constructs two-stage trade game among three countries, analyzes partially equilibrium output of the three countries and then discusses the influences of different carbon tax policies on social welfare in each country. The study shows it is more effective for developing countries to adopt strategies about founding free trade area and domestic carbon tax collection, up to a higher social total welfare lever, when they face carbon border tax adjustments(BTAs) from developed countries under Nash game conditions. By further studying, the efficiency of domestic carbon tax policy depends on the carbon intensity relation of each country; a higher relative intensity of carbon abroad decreases the negative external effect value caused by the carbon emissions.

Keywords: border tax adjustments, social welfare function, game theory

Guishen Yu An evaluation model of sustainable development of sports tourism industry based on matter-element theory
*Computer Modelling & New Technologies 2014 **18**(11) 724-731*

The sustainable development of sports tourism industry is concerned with many factors. Its evaluation is a complex system engineering. This paper studies the complexity and diversity of factors that influence the sustainable development of sports tourism industry and proposes an evaluation model of sustainable development based on matter-element theory. An indicator system is put in place. Evaluation indicators of classical field matter-elements model, section domain matter-element model and evaluation objects matter-element model are constructed based on matter-element theory. Different methods of calculating extension degree are adopted according to characteristics of the evaluation objects matter-element model to calculate the comprehensive extension degree between evaluation objects matter-element model and classical field matter-elements model. This extension degree refers to the layer of sustainable development capability of evaluation objects. It will provide strategic support for the development of sports tourism industry. Case study has proved that the model and the algorithm are effective.

Keywords: sports tourism industry; sustainable development; matter-element theory; extension degree; evaluation model

Xiqin Wen, Kaibo Wu, Anhua Peng A method of relative Grey relation degree combined with combination weights for materials selection
*Computer Modelling & New Technologies 2014 **18**(11) 732-738*

The quality and cost of a product rely heavily on suitable material selection, and therefore the ability to select the most appropriate material for a given application is the fundamental challenges faced by the design engineer. The general grey relational analysis (GRA) has three weaknesses, (i) the weight determination depends only on expert judgments, (ii) the qualitative indexes are simply quantified with exact numbers, and (iii) the general GRA only takes into account the relationship between the imaginarily best material and the candidate materials. Weights were determined by combining subjective and objective weights based on maximum deviation, the qualitative indexes were fuzzily quantified through trapezoidal fuzzy numbers (TFNs), and then ranked alternatives according to relative grey relation grade. The illustrative example showed that the results matched well with that using WAA and TOPSIS, proved the proposed method reasonable and trustworthy. And therefore the proposed method possesses important application values.

Keywords: material selection, combination weights (CW), relative Grey relation analysis (RGRA), fuzzy numbers, maximum deviation

Jian Zhang, Zhongwei Shen, Hao Shen An analysis of landscape characteristics of urban rivers – with the case of Chengdu
*Computer Modelling & New Technologies 2014 **18**(11) 739-749*

Urban river landscape is a key ecological regulating system in cities, attracting increasing attention from people. Our research conducted a systematic and comprehensive research of landscape characteristics of main rivers in Chengdu from some new perspectives, including the city in the large, city location and Single River. This research is intended to better understand the landscape structure along main rivers in Chengdu, to facilitate the evaluation of macro-regional ecological environment, and to provide references for the study of regional ecological environment.

Keywords: urban rivers, landscape characteristic, city location, tree crown sizes, canopy contribution rate, landscape area

Zhenhua Liu Analysis of flood disasters from 206 BC to 1949 in China
*Computer Modelling & New Technologies 2014 **18**(11) 750-757*

Flood disasters produces not only direct economic losses but also serious environmental problems, the government attaches great importance to flood disasters prevention from ancient times to the present. A variety of analytic methods are adopted, for example mathematical model analysis, chart analysis, qualitative and quantitative analysis. Some mathematical models are constructed by means of statistical analysis of historical data for flood disasters, such as mathematical model for flood cycle each dynasty. There are the following results. First, there are 1037 times flood disasters from 206 BC to 1936, once every 2.07 years. According to analysis of mathematical model for flood cycle each dynasty from 206 BC to 1936, the flood cycle is the declining concave curve, except for the Five Dynasties. Second, in modern history, the most number of catastrophic floods is the Yellow River reaching 8 times, the Yangtze River 5 times. Finally, water pollution caused by floods can not be ignored. In 2012 92 percent of untreated rural sewage was discharged dispersedly.The vast majority of pollution load on the ground runs into directly riverway through stormwater runoff. Water wells are easily contaminated for germs and parasite. We should pay attention to water pollution caused by floods and combine organically flood control with water environment protection.The government coordinates closely ideas, rule of law, technology and investment with rural residents for governing rural sewage to reduce the risk of water pollution caused by floods.

Keywords: flood disasters, flood cycle model, qualitative and quantitative analysis, rural sewage, water pollution

Mei Sun, Hui Feng, Siyuan Tang, Ziqiang Luo Application of fuzzy mathematics models in hospital management evaluation
*Computer Modelling & New Technologies 2014 **18**(11) 758-763*

To formulate a hospital management evaluation system and conduct empirical research, Delphi, analytic hierarchy process, and fuzzy comprehensive evaluation are used to build a hospital management evaluation system and conduct hospital management empirical research. And then a hospital management evaluation system is built. This system contains five first-level indices, namely, administrative management, human resource management, medical management, financial management and logistical support, and 23 second-level indices. Empirical research shows that the comprehensive evaluation of hospital management is above average and that service quality and infrastructure construction have the highest and lowest evaluation scores, respectively. This evaluation system is an effective tool for studying hospital management. Chinese hospital management requires further improvement, especially in terms of infrastructure construction.

Keywords: fuzzy mathematics, hospital management, evaluation system, analytic hierarchy process

Jian Zhang, Zhongwei Shen, Hao Shen Chengdu River status and cause analysis
*Computer Modelling & New Technologies 2014 **18**(11) 764-770*

Focusing on the basic model of the riverside landscape of Chengdu's five major rivers, this paper conducts contrastive analysis on the model characteristics of urban riverside landscape, location of the city where it locates and the urban construction status and explains in detail about the relation between the formation reasons of urban riverside landscape and the level of urbanization development. It discusses the effect of urban development and residents demand on urban riverside landscape design so as to perfect the design thought about it.

Keywords: cause analysis, landscape model, correlation analysis, land property, river status

Wu Xiao, Guanghua Yang, Yaoqi Yang Coal mining subsidence data extraction and verification in a high groundwater area based on Landsat-8 imagery and subsidence prediction
*Computer Modelling & New Technologies 2014 **18**(11) 771-775*

Coal is the main energy resource in China, with its extraction and utilization playing an important role in national economic development. However, coal mining may be causative with respect to critical land subsidence and damage to land. The eastern plain coal mining region of China represents an example of overlapping crop cultivation and coal extraction, and is considered a coal mining area characterized by a high water table. Accordingly, declining ground elevation and seasonal water logging of land due to mining subsidence have become major concerns within the region. Based upon the existing procedure for land reclamation planning, both land damage boundaries and land damage magnitude were determined for the region via subsidence prediction and vertical displacement, respectively. In the current study, a coal mine in Shandong province was employed as a case study area with the following work phases implemented: 1) subsidence prediction was implemented, with land damage magnitude demarcated via the proposed standard; 2) mining induced water area and wetland was extracted via use of remote sensing; 3) comparative analyses of the aforementioned methodologies were undertaken, with a revised methodology proposed for effective provision of improved land damage demarcation. Results indicate that land subsidence at Dongtan coal mines during May 2013 was 1616.70 hm^2, of which categorically mild, moderate, and severe lands were 22.54 hm^2, 257.67 hm^2, and 436.49 hm^2, respectively.

Keywords: Landsat-8, high groundwater, mining subsidence, land damage information, subsidence prediction, damage assessment

Wei Wang, Xiaodan Huang Computational model of implicit interaction for entertainment

Computer Modelling & New Technologies 2014 ***18****(11) 776-784*

Implicit interaction between human and computer is worthy of being researched, especially in the entertainment application. The reason is that in order to be more natural, computers need to interact and collaborate with persons actively. For this purpose, a computational model of implicit interaction is proposed and applied to a computer for entertainment. Firstly, emotional Hidden Markov Model (eHMM) as a part of the computational model of implicit interaction is researched. Then, three parts of ACT-R cognitive architecture are integrated into it to apply for entertainment. Finally, some experiments are carried out with styles of game process recording. Results indicate that the proposed model is helpful to make computers more active and adaptive to persons by adjustting entertainment process, which illustrates a good prospect of application.

Keywords: implicit interaction, ACT-R, affective computing, entertainment

Jingtao Liu Construction and effect evaluation of the college English multimedia teaching system based on the Blended-learning model

Computer Modelling & New Technologies 2014 ***18****(11) 785-790*

As network technology develops, an increasing number of new technologies and concepts have entered the traditional college teaching system. To improve the education quality and level of domestic college English, as well as to meet the demand for the reform of domestic college English education, the Blended-learning model is introduced to construct a new multimedia teaching system based on the traditional multimedia teaching model of college English. Moreover, a questionnaire analysis is conducted among all staff members that participate in the new multimedia teaching system. Questionnaire analysis indicated that the construction of the Blended-learning model-based traditional multimedia teaching system of college English proposed in this study is practically operable. The effect of this model is significantly better than that of the traditional English teaching model.

Keywords: Blended-learning model, college English, multimedia teaching, system construction

Jianbing Liu, Fang Guo Construction quality risk management of projects on the basis of rough set and neural network

Computer Modelling & New Technologies 2014 ***18****(11) 791-797*

Construction quality associated with the life of construction enterprises. Risk assessment of construction quality referred to a comprehensive evaluation of the degree of risk confronting construction units during the construction process. Construction units provide a decision-making basis for employers and supervisors, who considered the evaluations of construction quality and accidents in their decisions. The risk factors of construction project quality were classified into personal risk and material risk and machinery and equipment risk and method risk and environment risk. On the basis of these factors, we constructed an index system of project construction quality risk. The risk evaluation model of project construction quality was constructed on the basis of rough sets and neural networks. Finally, a case study residential building projects in the Ganzhou Development Zone and research tools of Rosetta based on rough sets and MATLAB7.0 based on neural networks were used to test model accuracy and reason ability. Empirical results showed that the model has great practical significance.

Keywords: construction quality risk assessment, projects, rough set, neural networks

Lingyun Zhou, Youheng Huang Dynamic modelling of container transport modes between inland terminals and seaports

Computer Modelling & New Technologies 2014 ***18****(11) 798-801*

Container transport has played an important role in international trade. This paper mainly focuses on the container transport modes selection between inland terminals and seaports through a comprehensive comparison of multiple decision factors. According to the multi-object fuzzy mathematics decision-making theory and the container transport processes, the main factors influencing the container transportation mode decision are analyzed. Moreover, a fuzzy decision model of container transport modes between inland terminals and seaports is built by introducing varied weight factors. Thereafter, the proposed model for the final selection of container transport modes between Changsha city and Shanghai harbor is demonstrated through an illustrative example. The results of this example indicate that the model can reflect dynamically importance degrees of related decision factors and different demands of decision makers, and this approach provides a more accurate, effective, and systematic decision support tool for the optimized intermodal mode selection between inland terminals and seaports.

*Keywords: c*ontainer transport, transport mode, route optimization, fuzzy decision making

Xiaohua Ma Location of competitive basketball athletes based on RSR comprehensive evaluation method

Computer Modelling & New Technologies 2014 ***18****(11) 802-806*

Rank sum ratio (RSR) positions each research index to superior or inferior index, conducts rank allocation of these indices in all evaluation objects according to rank principles, sorts them, and carries out grading according to the RSR value. In this way, the superior and inferior indices can be clearly determined. For complex open sports, good sport decisions can make each member give play to their strong points to achieve good results. However, most existing research methods belong to non-quantitative research methods. Research on the location of competitive basketball athletes is rare. This study adopts RSR comprehensive analysis method to assess examination indices for 15 members in a basketball team of a college to select the members that are most suitable for five locations in basketball competitions and corresponding benches and candidates. A general method is provided to decide the location of commercial basketball athletes.

Keywords: sport decision-making RSR comprehensive evaluation method, commercial basketball athlete

Wenxin Xu, Jiwei Yao Management information system for college track and field games on the basis of infrared radio-frequency technique

Computer Modelling & New Technologies 2014 ***18****(11) 807-813*

College track and field sports involve numerous participants and events. Moreover, recording and announcement jobs are complex. The requirements for accuracy and precision are high. The traditional manual management mode cannot adapt to development needs. Based on the advantages of Radio Frequency Identification (RFID) such as no-barrier read, remote penetration, speed scanning, large memory space, anti-pollution capacity, durability, diversified shapes, reusability, and good security, an RFID-based infrared radiofrequency technique is designed to achieve automatic identity verification for athletes and to construct a complete score management information system. An automatic check mode is used to identify athletes by combining an ID card, a card reader, and a computer. This mode can rapidly identify the personal information of athletes and prevent cheating. This system has important significance for improving management level and reducing manpower.

Keywords: RFID, track and field games, management information system, card reader

Guo-yi Chen Models for measuring and predicting value creation during merger and acquisitions: a study of bank industry

Computer Modelling & New Technologies 2014 ***18****(11) 814-819*

This paper employs event study methodology with a 36-day event window to assess the value effects of the US bank mergers occurring between 1994 and 2003. A 38-transaction sample is chosen from the top fifty US bank mergers (according to the assets of targets) occurred during the period from 1994 to 2003. Through analysis, result indicates that the average cumulative abnormal return of the bidders in the chosen sample is negative (-0.99%), while the targets and combined firms are both positive (15.07% and 2.57% respectively). Significance testing also verified that the negative bidder return is confirmed to be insignificant, whilst the positive return of the target and combined firm are both significant. Combined together, It indicates that the 3,517 US bank mergers occurred between 1994 and 2003 create insignificantly negative value for bidders, whilst benefit the target and the integrated banks with significant positive

gains.

Keywords: mergers, acquisitions, event study, value effects, measurement model

Fumeng Gao Structural equation model of college foreign language writing and classroom teaching quality from perspective of teacher evaluation

Computer Modelling & New Technologies 2014 ***18****(11) 820-823*

Existing teaching quality evaluation systems have insufficient comprehensive indices reflecting teaching quality: index repetition, complication, quantification difficulty, and difficulty in judging the relationship. To make classroom teaching quality evaluation consistent with teaching effect, element weight is confirmed based on a structural equation model. The present paper takes a college foreign language writing class as the object of study and sets up a structural equation model for classroom teaching quality evaluation. Effect coefficients of each variable are calculated, and the weight of each element of classroom teaching quality evaluation is then obtained. Such method avoids artificially scoring elements during the confirmation of element weight, reduces evaluation subjectivity, and makes the evaluation results more accurate, rational, and credible.

Keywords: structural equation model, teacher evaluation, classroom teaching, teaching quality

Chen Yan, Lan Nan, Liu Yunlang, Huang Rong The empirical analysis on mode of developing the rural areas with the aid of the urban areas

Computer Modelling & New Technologies 2014 ***18****(11) 824-831*

Developing the rural areas with the aid of the urban areas, which was summarized through the long practice in China, is a new mode of promoting the coordinated development of urban-rural areas. The evaluation of the impact of this mode on promoting the coordinated development of urban-rural areas has great significance for reference for the urbanization development in other countries around the world. This paper takes Chenggong New District in Yunnan, China as an example, calculates the coordination degree of its urban and rural development in 1999, 2004 and 2009 with the use of urban and rural development coordination degree model, then makes clustering analysis of the urban and rural development coordination degree in various districts in Chenggong New District in 2009 with the use of Ward's method. Results indicate that a) the urban and rural development coordination degree of Chenggong New District is 0.359 in 1999, 0.545 in 2004, and 0.504 in 2009. The increase in the coordination degree year by year shows the mode of developing the rural areas with the aid of the urban areas has obvious effects on the coordinated development of urban-rural areas; b)the mode of developing the rural areas with the aid of the urban areas has obvious coordination impact on the aspects of infrastructure construction and basic livelihood guarantee, but has not enough coordination impact on the aspects of environmental governance, medical treatment and education; c) when the mode of developing the rural areas with the aid of the urban areas is applied, the coordinated development of industries and especially the agricultural industrialization development should be paid attention to.

Keywords: the mode of developing the rural areas with the aid of the urban areas, the coordinated development of urban-rural areas, Chenggong New District, China

Qi Yue, Yuhua Li Two-sided matching considering the preferences of agents and intermediary

Computer Modelling & New Technologies 2014 ***18****(11) 832-835*

This paper proposes a novel method for solving the two-sided matching problem, in which the preferences provided by agents are ordinal numbers, and the preferences provided by intermediary is the expense standard on ordinal numbers. In this paper, the description of the considered two-sided matching problem is given. Then the concepts of satisfaction degrees and expense are introduced. Furthermore, a multi-objective optimization model can be set up consider satisfaction degrees of agents and expense of intermediary. The method of weighted sums based on membership function is used to convert the multi-objective optimization model into a single-objective model. The matching result is obtained by solving the model.

Keywords: two-sided matching, ordinal number, satisfaction degree, expense

Zhaoxia Si, Ningli Chen VAR dynamic analysis of the impact of population structure on urban residential land price: the case of Zhengzhou

Computer Modelling & New Technologies 2014 ***18****(11) 836-842*

Based on the vector autoregression model, this paper focuses on Zhengzhou and uses the 1994–2013 population structural variables and relevant data on commercial and residential land price to analyze the dynamic relationship between population structure and residential land price through impulse response function and variance decomposition. Results show a co-integration between Zhengzhou residential land price and three variables, namely,

urbanization rate, per capita disposable income, and household size. The short-term variation in land price is mainly caused by the residential land price itself, and the three population substructural variables show long-term effects on the land price with a certain time lag. Among these variables, per capita disposable income has the shortest positive effect on residential land price, whereas urbanization rate has the longest and most remarkable positive effect.

Keywords: population, land price, VAR model, Zhengzhou

Xue Wu Research on the application of ARMA model in China's trade economic development
Computer Modelling & New Technologies 2014 ***18****(11) 841-847*

The slowing down development of China's foreign trade brings significant impact to its regional economy, which makes many middle and small-sized export enterprises facing with business crisis and even bankruptcy. In this paper, a deep analysis on the development status of China's trade economy was conducted with ARMA model. The short-term development trend and causes of China's trade economy were predicted and analyzed. Results demonstrated that China's imports will decrease while export will keep increasing. The balance of trade in China will decrease and the total volume of foreign trade will decline. This indicates the depression of China's trade economy, which is against China's economic development. To improve the export structure and facilitate the rapid development of trade economy, China is suggested to adopt various measures, such as optimizing fiscal policy, promoting technology upgrading, enhancing export management and perfect import-export infrastructures. Meanwhile, China shall expand domestic demand vigorously to offset impact of trade economic slowdown on regional economy.

Keywords: ARMA model, trade economy, application research, decision reference

Yanpeng Feng, Hongyan Zheng, Bo Wu Transmission power control strategy based on partially observable Markov processes for IEEE802.11 WLAN
Computer Modelling & New Technologies 2014 ***18****(11) 848-854*

With the limitation of independent channels in IEEE802.11 WLAN, co-channel AP interferes with each other in repeat coverage area. As traditional AP launched a fixed power in sending data packages, which ignores the differences and mobility of STA. According to the mobility of STA and the partially observable feature of AP-STA link, this paper analyses the internal relations among the link state, transmission power and channel interference of co-channel AP, and proposes a single-link transmission power control (TPC) algorithm based on the Partially Observable Markov Decision Processes (POMDP). Firstly, the single AP-STA link POMDP-TPC model is constructed, and the neural network learning model is established to describe the observation function of POMDP-TPC. Secondly, the algorithm constructs reachable belief searching trees to obtain the approximate optimization, which implements the dynamic creating and on-line updating of the power consumption policy. Finally, under the experiment environment in OPNET and IEEE802.11b, the results demonstrate the algorithm can reduce the AP power consumption efficiently and improve the network throughput greatly.

Keywords: wireless local area networks, access point, POMDP, transmission power control, anti-interference

Tan Li, Weiwei Wu An analysis framework for building commodity futures market simulation model based on heterogeneous traders
Computer Modelling & New Technologies 2014 ***18****(11) 855-860*

Futures price volatility is always the hot topic for academic researchers and traders in futures market. For exploring the rules of futures price fluctuation, we try to develop a new analysing framework from the angle of the heterogeneous traders. We describe heterogeneous traders as four respects: trading motive, predict styles, risk-return preference, reaction speed, which can accurately describe the heterogeneous traders in futures market. According to the categories of heterogeneous traders, we construct traders' internal model, which is used in a commodity futures market simulation model to verify the framework, and the results show the framework is useful.

Keywords: bounded rationality, commodity futures markets, simulation model, heterogeneous traders

Jingxian Tang, Yan Yu, Haitao Zhou GEM-based evaluation of competitiveness of enterprise cluster
Computer Modelling & New Technologies 2014 ***18****(11) 861-864*

Enterprise cluster development can improve development capacity of enterprises and industrial competitiveness by lowering cost, stimulating innovations, increasing efficiency and intensifying competition. It is one key industrial development trend in the future and an important consideration of enterprises in choosing regions. Recently, industrial cluster in China has achieved primary development. Provinces and cities are putting great efforts to creating industrial parks of Industrial Cluster. This plays an important role in promoting regional economic development and regional industrial competitiveness. In this paper, a competitiveness evaluation model of enterprise

cluster was established using the GEM model. It was applied to the furniture enterprise cluster in Guangdong Province. Accuracy, time effectiveness, advantages and disadvantages of the model was analyzed through the case study. Advantages and disadvantages of regional enterprise cluster can be identified from competitiveness analysis of the model. Countermeasures to these disadvantages were suggested.

Keywords: GEM model cluster competitiveness

Yuejun Liu, Fang Fang, Yali Zhang Research on contract management evaluation of construction company based on fuzzy comprehensive evaluation model
Computer Modelling & New Technologies 2014 ***18****(11) 865-873*

Contract management is the core of project management of construction companies. Establishing a perfect contract management evaluation system of construction companies is of important significance to enhance their contract signing and performance as well as competitiveness in international market. Based on the overall contract management of construction companies, this paper discussed how to establish an evaluation system. Combined with fuzzy comprehensive evaluation, the established evaluation system was verified by an empirical analysis.

Keywords: contract management capability, evaluation model, fuzzy comprehensive evaluation, empirical analysis

Hailei Zhao, Dehuan Jin Research on the risks of financial derivatives and risk control from the perspective of the financial crisis
Computer Modelling & New Technologies 2014 ***18****(11) 874-879*

After the economic crisis in Wall Street in 2008, the risks of financial derivatives and risk control have received great attention from countries in the world. The research on the risks of financial derivatives and risk control can effectively prevent the financial crisis. Through the extraction of the characteristics of risks of financial derivatives, the paper expounds the application of sensitivity analysis and in the risk measurement financial derivatives. The result shows that despite certain achievements of China's financial derivatives in the development process, there is still much room for improvement. Based on the result and with reference to the practice of the UK, US and Japan in the risk prevention and control of financial derivatives, the paper proposes some suggestions.

Keywords: financial derivatives, risk prevention and control, VAR model, financial crisis

Xueying Zheng A study on the relationship between the developments of China's trading economy and environmental factors
Computer Modelling & New Technologies 2014 ***18****(11) 880-884*

Trade environment refers to the social and economic environment facing trading economy, and it can directly affect the pace of trade development and trade structure. Establishing a good trade development environment can optimize trade structure, and promote the sustained and healthy economic development. This paper firstly analyzes the current environment of China's trade development with relevant theories, then analyzes the relationship between environmental factors and the development of trading economy based on indexes, builds error correction model, and uses the model to make in-depth analysis on the impacts of environment on the development of trading economy. According to the study results, the ratio of trade dependency over trade surplus exerts side effects on the development of trading economy, while trade openness exerts positive effects on the development of trading economy. In terms of import, the development of China's trading economy shows excessive dependence on foreign energy and other resource-based products, this seriously affects the stable development of economy. In terms of export, some Chinese companies that have overcapacity show over-reliance on international markets, thus reducing the competitiveness of export products, and leading to the situation where China's trading economy is vulnerable to fluctuations of international markets. Based on this, a method is proposed in the paper to improve China's trade environment.

Keywords: error correction model, trading economy, environment; impact

Pingping Qiao Empirical analysis of Chinese cultural products trade based on the gravity model
Computer Modelling & New Technologies 2014 ***18****(11) 885-889*

Based on date of bilateral cultural trades between China and 26 other countries (regions), the paper uses a gravity model to perform an empirical test on the influencing factors and export potential of cultural products. The research shows that Chinese economic size, importing country's economic scale, GDP per capital, trade openness and preferential trade arrangements have a positive effect on the export of Chinese cultural products. Spatial distance and cultural distance from China have a negative effect on exports of Chinese cultural products. The effect of cultural

distance is bigger than that of spatial distance. It is very important for promoting the exports of Chinese cultural products to strengthen communication and overcome "cultural discount". In the 26 samples, the trades of cultural products between China and 7 countries (regions) are sufficient, and the trades of cultural products between China and other 19 countries (regions) are insufficient. China has a great potential for cultural products trades, but China should develop it targeted.

Keywords: gravity model, cultural products trade, influencing factors, export potential

Xuewen Jin Research on the influential factors of China's logistics demand based on the econometric model

Computer Modelling & New Technologies 2014 ***18****(11) 890-894*

Logistics demand reflects the pace of economic development, and the pace of economic development also affects the change of logistics demand in turn. In fact, logistics demand is affected by many factors. Through the theoretical analysis, the paper points out that the influential factors on logistics demand mainly include four aspects, namely, economic development level, regional industrial structure, macro-economic policy and economic system, and consumption level and concept. Then, the econometric model is established with the data in different periods of time based on those four aspects to make an in-depth analysis of the application of the model. At the same time, in order to promote the development of the logistics industry, improve logistics demand and meet the development demand of the regional economy, it puts forward reasonable suggestions.

Keywords: logistics demand, econometric model, influential factors

Hong Wang The review and research on agile oriented method n the pilot industry system

Computer Modelling & New Technologies 2014 ***18****(11) 895-901*

Agile methodology has getting wide recognition within the software industry due to its flexibility and ability to cope with rapid changes in the software development environments. It is however comes with a number of demands that must be complied with. This paper presents a pilot systematic literature review (SLR) study on the limitations of Agile methods in the industry based on primary research. In this study, conference and journal papers in the IEEE, published between 2007 and 2012 were investigated. 29 papers were found as the most relevant. While the SLR findings have brought to both limitations in the implementation and in the Agile methods, the former becomes the most addressed issues. The result revealed that high dependency on people/personnel, organizational dependency, as well as high impact on organizational structure and culture as the three most repeatedly addressed factors. While these three factors are mutually related, people factor especially upper level management strong involvement and support can be regarded as a primary necessity in the Agile implementation. In spite of apparent emphasis on people critical function stated in the Agile principles, plus the excellent rules in the gist of the principles, the problem still arose when it comes to the implementation part. This indicates the need for future work on proper guidelines for management, given that existing guidelines for Agile adoptions and implementations are general and less focus given to upper level managers.

Keywords: Agile, limitation, human factor, pilot management, systematic review

Jianda Zhu Study on GIS based intelligence transportation

Computer Modelling & New Technologies 2014 ***18****(11) 902-907*

Recently a vast amount of geographic information system (GIS) data make road networks around the world as polylines with attributes. In this form, the data are insufficient for applications such as simulation and 3D visualization—tools which will grow in power and demand as sensor data become more pervasive and as governments try to optimize their existing physical infrastructure. With the increased dissemination and computing power of mobile devices, it is now possible to execute distributed artificial intelligence applications for various situations: intelligent routing using algorithms, planning, is tribute optimization of traffic lights. This paper reports on our development of a GIS-based traffic network analysis system, named GIS-based Transport Decision Support System, which provides a graphical analysis platform to transportation planners and researchers for transportation network analysis. The system has the functions of designing traffic networks on digital maps and doing traffic equilibrium analysis, as well as a novel function to integrate local detailed structures of intersections into global networks. The latter is particularly useful for the analysis of large traffic network where the detailed local network structures of some intersections have to be taken into account. The system links great volumes of traffic data and geography information data accumulated for visualization traffic analysis. We added information data on the following: road structure data, zone geography information data and node geography information data. The system also enabled us to extract traffic data by road section and by specific condition.

Keywords: K-means, clustering algorithm, error rate, iteration, reduction, stable

Ting Hao, Xi Zhao Financial management based decision making in the big data era
Computer Modelling & New Technologies 2014 ***18****(11) 908-913*

Financial management are derived for the profitability analyses of demand-side management (DSM) alternatives. The present value of cost and equivalent uniform annual cost models are selected to determine the least-cost solution, while the net present value, pay back year and benefit/cost ratio models are proposed for the execution of cost–benefit analyses. In a market economy, Market orientation is the only correct choice for economic development strategy, so it is also significant for financial management innovation. While most studies in the past decade focused on the consequences of fund in financial management, few have investigated antecedents to market orientation concept. This paper derives two fuzzy financial profitability models, namely, a least cost solution model and a cost-benefit analysis model, to evaluate the fuzzy financial profitability of load management alternatives. A straightforward vertex parameters' fuzzy mathematics operation using the function principle is de-rived as an alternative to the traditional extension principle and is applied to evaluate a number of different financial decision indexes. The developed models represent readily implemented possibility analysis tools for use in the arena of uncertain financial decision-making.

Shixiong Wang, Yi Jiang Extending opinion dynamics model for collective online behaviours analysis
Computer Modelling & New Technologies 2014 ***18****(11) 914-920*

In online social networks, opinion dynamics generally lead to different types of collective online behaviour such as consensus, polarization and fragment. Then an open problem arises: how are different typical collective online behaviours emerged from the behavioural decisions of individual and interactions among individuals during the process of opinion dynamics? This work examines the process of opinion dynamic in online social networks and different types of interactions among individuals on this process. An opinion-driven dynamics model, which combines a social network-based opinion dynamics model with generative individual behaviour, is proposed by adding antagonistic responses to the DW model. The proposed model integrates three types of interactions and setting up two thresholds to characterize individual behaviour. The behavioural component utilizes an initiation threshold such that if an individual's opinion exceeds this threshold, the individual will initiate the behaviour. In order to verify the effectiveness of the model, simulations are presented to examine how different typical collective behaviours emerge. As a result, we find that opinion dynamics with different threshold lead to different types of collective online behaviours. The openness of individuals to a differing opinion is the key factors to consensus or fragment.

Keywords: opinion dynamics, consensus, antagonism, fragment, online social network

Aiyun Guo A student profile model based online English learning
Computer Modelling & New Technologies 2014 ***18****(11) 921-926*

Many Chinese universities have begun reforms to enhance educational competitiveness in our globalizing economy. This study aims to ascertain the status of English education and English-medium instruction at a Chinese engineering school and to offer workable suggestions for English communication training for Chinese graduate engineering students. Colleges and universities across China are adopting bilingual education to meet the need for well-rounded personnel with sound knowledge in specialized areas and competency in foreign languages. The development and difficulties of current bilingual education in China are discussed. First, the short-term English word context is generated to identify related concepts of the word. Second, the user context is generated based on the click through data of users. Finally, a forgetting factor is introduced to merge the independent user context in a user session, which maintains the evolution of user preferences. It is significant to the reform from teacher-centered to student-centered teaching mode. It is helpful to the cultivation of the students' collaborative ability and spirit, and has important theoretical significance and practical value.

Keywords: English education, online learning, student profile

Jianxun Wang, Qingyun Zhou Industrial design based on computer aided simulation
Computer Modelling & New Technologies 2014 ***18****(11) 927-933*

Recently, new technologies have emerged in industrial automation platforms. A rapid modelling and simulation environment is required to integrate these new technologies with existing devices and platforms to reduce the design effort and time to market. System-level modelling is a popular design technique that provides early simulation,

verification, and architectural exploration. However, integration of real devices with system models is quite challenging due to synchronization and hard real-time constraints in industrial automation. Simulations are software tools approximating and predicting the behaviour of real industrial plants. Unlike real plants, the utilization of simulations cannot cause dam-ages and it saves time and costs during series of experiments. A shortcoming of current simulation models is the complicated runtime integration into legacy industrial systems and platforms, as well as ad-hoc design phase, introducing manual and error-prone work. This paper contributes to improve the efficiency of simulation model design and integration. It utilizes a semantic knowledge base, implemented by ontologies and their mappings. The integration uses the Automation Service Bus and the paper explains how to configure the runtime integration level semantically.

Keywords: assembly systems, estimation, part feeding, pose statistics, simulation

Jie Guo Intelligent human resources systems in the information technology era
Computer Modelling & New Technologies 2014 ***18****(11) 934-939*

Effective human resource management facilitates the success of an organization and the progress of a society. We describe an evolutionary computer model that simulates different modes of interaction between people and their environment. A two-level genotype-phenotype structure is used to represent the characteristics of an individual. The environment is modelled as a two-dimensional array of regions in which each region is characterized by a set of regional features and organizational culture (e.g., leadership strategies). Human resource decisions are subject to limitations, because they always depend on human knowledge, judgment and preference. Decision support applications can be used to provide fair and consistent decisions, besides to improve the effectiveness of decision making processes. This study consists of three parts; the first part is to understand the IDSS concepts, applications and related research in human resources decision making application known as HR DSS. The second part is to identify the potential intelligent techniques that can be used in HR DSS application, and the third part is to suggest the HR DSS framework that is related to human resource decisions. Finally, the paper proposed the HR DSS framework and the potential intelligent techniques that can be used to develop the IDSS application in any phases of decision making processes.

Keywords: human resource decision support, human resource management systems, human resource strategy

Ting Hong PCA-based analysis on factors of English translation ability
Computer Modelling & New Technologies 2014 ***18****(11) 940-944*

This work studied the relationship between English proficiency and translation ability as well as that between English and translation teaching among English majors. PCA is utilized to quantify and analyze the relationship between translation ability and English skills such as listening, reading, error correction and writing. Then we obtain the quantitative relation between translation ability and its factors, providing decision basis for the improvement of English translation skills and teaching.

Keywords: PCA analysis, translation ability, English teaching, quantitative analysis

Jiale Tian Collaborative mechanism of project management based on complex system theory
Computer Modelling & New Technologies 2014 ***18****(11) 945-950*

Although it is arguable that humans have been studying complex systems for thousands of years, the modern scientific study of complex systems is relatively young in comparison to conventional fields of science with simple system assumptions, such as physics and chemistry. The history of the scientific study of these systems follows several different research trends. The project management community is actively demonstrating substantial interest in the development of viable methods to assess and improve project management maturity. There is little empirical evidence on the benefits of deploying a project management office (PMO) and/or conducting project reviews. The increasing complexity of exploratory activities in pharmaceutical innovation makes less likely that a project can stand alone. Project managers not only resort to in-house innovation but also external sources to propel a central project. This paper introduces the notion of a quality function for individual tasks and uses the functional form of the bivariate normal, to model quality at the task level. Using real data from two case studies, a translation agency and a software development company, the quality function is specified and incorporated into a mathematical programming model that allows quality to be explicitly considered in project planning and scheduling. An alternative model formulation leads to the creation of quality level curves that enable managers to evaluate the nonlinear tradeoffs between quality, time, and cost for each of the example projects. The results of these analyses lead to specific decisions about the planned values for these three fundamental dimensions at the task level and provide insights for project planning and scheduling that can be gained through improved understanding of the choices and tradeoffs.

Keywords: project management, project planning, project scheduling, quality management

Wentao Xiao, Gongfa Li, Honghai Liu, Guozhang Jiang, Ze Liu, Disi Chen, Weiliang Ding, Wei Miao, Zhe Li Soft sensor system of coke oven flue temperature based on CBR and PCA-RBFNN
Computer Modelling & New Technologies 2014 ***18****(11) 951-958*

The key process indicator - coke oven flue temperature – is difficult to detect online with instruments in the coke oven heating process, thus an intelligent forecasting model is developed which is composed of four parts: the data gathering and handling unit, the optional forecasting unit, the online amendment unit and the effect evaluation unit. The optional intelligent forecasting model and its corresponding algorithm are established for different categories of practice operating conditions. In normal operating condition, the nearest neighbor clustering algorithm based on the principal component analysis and neural network with the radial basis function is selected. In unconventional operating condition, the case-based reasoning technology is selected. The models of different conditions are validated and applied according to the actual data in a steel enterprise coke production, the results show that the established forecasting model can reflect different practice conditions and meet the real-time control requirements.

Keywords: intelligent prediction, neural network, principal component analysis, neighbor clustering algorithm

Hongli Xiao Intelligent transportation systems based on computer aided simulation method
Computer Modelling & New Technologies 2014 ***18****(11) 959-964*

Road transportation is one of the main sources of greenhouse gas emissions, which lead to global warming and climate change. Promoting the decarbonisation of this sector through more efficient and greener mobility is a challenging task that can be achieved by intelligent transportation systems (ITS) enabled by vehicular communications. Intelligent Transportation Systems (ITS) have been developed for more than ten years in China. Furthermore, a new generation Intelligent Transportation Systems should be launched to meet the requirement of rapid development of transportation in China. For the last two decades, intelligent transportation systems (ITS) have emerged as an efficient way of improving the performance of transportation systems, enhancing travel security, and providing more choices to travellers. A significant change in ITS in recent years is that much more data are collected from a variety of sources and can be processed into various forms for different stakeholders. This paper presents an overview of the background, concepts, basic methods, major issues, and current applications of Parallel transportation Management Systems (PtMS). In essence, parallel control and management is a data-driven approach for modelling, analysis, and decision-making that considers both the engineering and social complexity in its processes. The developments and applications described here clearly indicate that PtMS is effective for use in networked complex traffic systems and is closely related to emerging technologies in cloud computing, social computing, and cyber physical social systems.

Keywords: agents, intelligent transportation systems (ITS), mobile agent systems, multiagent systems

Xing Xu, Yun Zhao, Jia Hu, Xinli Wu Research on the robustness of supply chain network with uncertainty
Computer Modelling & New Technologies 2014 ***18****(11) 965-970*

A new method is proposed to enhance robustness of complex supply chain network structure in uncertain conditions of market, costs and others. The researcher constructs the topology of a supply chain network firstly, and then explains the concept of central nodes of network and robust supply chain network based on scale-free network model from the perspective of quality control and places research emphasis on the method of enhancing the robustness of complex supply chain network structure. Finally, the supply chain network of auto parts enterprises in Zhejiang Province is cited as an example to verify the validity of the method.

Keywords: supply chain network, network quality control, scale-free network, robustness

Benxue Wang Housing price forecast based on rough-set extreme learning machine
Computer Modelling & New Technologies 2014 ***18****(11) 971-975*

The work, based on various factors affecting housing price in 31 provinces cities as research object, firstly adopted rough set theory to reduce those factors. Then, the main reduced influence factors were used as the input of extreme learning machine. On such basis, the housing price forecast model based on rough-set extreme learning machine was ultimately established. According to the simulation results, the algorithm in this work has good prediction effect, and its prediction precision is higher than that of BP neural network and RBF neural network. Therefore, this algorithm, with a certain practical and theoretical value, can be promoted to other areas for predication and classification.

Keywords: rough set theory, neural network, extreme learning machine, real estate, forecast error

Xiaoyan Li, Min Zhang Prediction of employment figures in the three main industries based on extreme learning machine
*Computer Modelling & New Technologies 2014 **18**(11) 976-980*

Extreme learning machine, with a fast speed of training, achieves globally optimal solutions and excellent generalization ability. This work is based on the production value and employment figure of the three main industries in China during 1996-2012 as research objects. An ELM employment figure prediction model was constructed with production value and the employment figure of the three main industries respectively as the input and output of extreme learning machine. Simulation test results proved a good effect and high accuracy of ELM employment figure prediction model. Besides, the comparison of ELM, BP and RBF algorithms further proved the effectiveness and precision of ELM, which has certain practical application value.

Keywords: three main industries, extreme learning machine, production value, neural network, training samples, test samples

Lihua Yu, Qingsheng Xie Research on quality information integrated management for complex precision parts in multi-varieties and small batch manufacturing mode
*Computer Modelling & New Technologies 2014 **18**(11) 981-985*

There were many problems such as quality information interaction low, real-time monitoring and tracing of production quality difficulty in workshops for multi-varieties and small-batch complicated precision parts. These problems restricted seriously the improvement of product quality. Therefore, a quality information integrated operation mode was built, combining with advanced management thoughts of lean management and integration. The main characteristics of quality information integrated management process were analysed. At last, the mode was applied in a manufacturing enterprise in CASTC 061 base for testing its effects. Results show that it is successful and satisfactory in practical application effect.

Keywords: workshop, integration, multi-varieties and small-batch, quality control

Yanli Yang, Xianyu Wang Incentive analysis of labour dispatch under asymmetric information theory
*Computer Modelling & New Technologies 2014 **18**(11) 986-990*

Under the circumstances of the fierce market competition, great importance is attached to labour dispatch as an innovative employment way since it saves more labour costs for enterprises. However, there exists obvious asymmetric information among the dispatched employees, employers and accepting entities. This paper makes an analysis of the incentive offered by accepting entities to the dispatched employees and employers under the circumstances of asymmetric information and symmetric information. It verifies through models that in the case of symmetric information accepting entities can offer incentive to the dispatched employees and employers so as to achieve Pareto optimality by means of linear contracts. In case of asymmetric information, the expected revenue of accepting entities will be influenced by the abilities, degree of risk aversion and effort costs of the dispatched employees and employers, which is of great reference value to the enterprise practice.

Keywords: Labour Dispatch, Symmetric Information, Asymmetric Information, Risk Aversion, Effort Costs

Qiang Li Establishment of comprehensive index model based on raster data and its application in the study of regional differentiation
*Computer Modelling & New Technologies 2014 **18**(11) 991-997*

The small grid calculation model was used as the theoretical basis; A variety of meteorological data in 1971-2007 of Chinese Loess Plateau, remote sensing image (TM), DEM and other maps in 2000 were used; factor analysis, raster calculator, variance analysis and other methods in ArcGIS were used; the mathematical model of the latitude and longitude related to the main meteorological elements of the loess plateau and comprehensive index model for regionalization were obtained; the north and south boundaries of the Loess Plateau were determined.

Keywords: factor analysis, analysis of variance, raster data, comprehensive index model, boundaries, loess plateau

Yinglan Fang, Bing Han, Binghui Chen Data mining applications research based on ISBN management
*Computer Modelling & New Technologies 2014 **18**(11) 998-1003*

ISBN management systems existed irregularities publishing. How to summarizes the current book publishing rule according to publish information, it can better grasp the overall book market trends based on existing books. This paper introduced data mining ideas to the book publishing field through the study of real-name system to apply business processes. There were two data mining models. One was association rule analysis model based on subject field to book type distribution. It analyzed book type using classic Apriori association rule analysis algorithms to

identify book publishing hot and the overall trend of publishing business. It can effectively regulate press book publishing behaviour and has great significant to the China's publishing industry healthy and orderly development.

Keywords: data mining, association rule analysis, ISBN

Zhihang Tang, Zhonghua Wen Recommendation system based on collaborative filtering in RapidMiner
Computer Modelling & New Technologies ***18****(11) 1004-1008*

Recommender systems facilitate decision-making processes through informed assistance and enhanced user experience. To aid in the decision-making process, recommender systems use the available data on the items themselves. Personalized recommender systems subsequently use this input data, and convert it to an output in the form of ordered lists or scores of items in which a user might be interested. These lists or scores are the final result the user will be presented with, and their goal is to assist the user in the decision-making process. The application of recommender systems outlined was just a small introduction to the possibilities of the extension. Recommender systems became essential in an information- and decision-overloaded world. They changed the way users make decisions, and helped their creators to increase revenue at the same time. Bringing recommender systems to a broader audience is essential in order to popularize them beyond the limits of scientific research and high technology entrepreneurship. The recommender systems will assist you in reaching quality, informed decisions.

Keywords: recommender systems, collaborative-based systems, nearest neighbour

Yu Wang A study of region division based on spatial units fusion of clustering algorithm
Computer Modelling & New Technologies 2014 ***18****(11) 1009-1013*

Region division is the foundation of regional socio-economic development planning. Traditional regional division is only built upon the information of attributes in each spatial unit. However, the spatial relationships and their spatial interaction between units are ignored. In the study, based on the spatial linkage theory, the principle and steps of spatial units fusion of clustering algorithm is proposed. According the spatial range of Chinese railway as a case, determine the spatial units and the linkage model was built based on the proximity and attribute characters, the experiments of regional division for Chinese railway are achieved. The experiment shows the results are highly accordant with the real situations and have proved the feasibility of the algorithm.

Keywords: spatial linkage theory, region division, spatial units fusion of clustering algorithm, Chinese railway

Tao Meng A FAHP-based comprehensive evaluation on rural supermarket service quality: a case study of Jiangsu province
Computer Modelling & New Technologies 2014 ***18****(11) 1014-1019*

With the changes of market supply and demand, as well as increasing business competition, service quality has become a key factor constraining rural supermarket survival and development. This article targets at the rural supermarkets in Jiangsu Province. In the context of constructing an indicator system of rural supermarket service quality evaluation, it acquires data by questionnaires, uses AHP to establish the weights, and applies the multi-level fuzzy AHP to assess rural supermarket service quality. It concludes that there are some spaces for further improvement of rural supermarket service quality and proposes relevant solutions.

Keywords: FAHP, rural supermarkets, service quality

Jun Li Face recognition algorithms for embedded entrance guard system
Computer Modelling & New Technologies 2014 ***18****(11) 1020-1025*

Biometric identification technology is used to identify individuals based on their unique physiologica1 characteristics under sampling and measurement. The hardware platform of our entrance guard system is based on SAMSUNG S3C6410 embedded development board with ARM11 processor, and we adopt ordinary camera as facial image capture device, 7-inch touch-screen LCD display as an input, electronic door locks as executing components by the onboard port control. The software platform is based on Linux operating system to design and optimize face recognition algorithm, which is combined with local binary pattern (LBP) algorithm, principal component analysis (PCA) algorithm, and ridge regression algorithm. Also, the face recognition system is divided into two parts, namely, a face database training part and a face recognition part. Precisely, the face database training part acquires face information through the processes of face detection, feature extraction and stores the face information to serve as the detection basis of the face recognition part; then the face recognition part is connected with the entrance guard system and sends out an instruction for executing related action to the entrance guard system according to the face recognition result. Specially, the embedded face recognition entrance guard system is contactless and easy to collect

the facial database, less in power consumption, low in cost, and has easy installation and stable performance.

Keywords: face recognition, local binary patterns, principal components analysis, embedded system

Xin Ma, Fuxiaoxuan Liang, Wenbin Wang Control particle swarm optimization for unit commitment problem under emissions reduction

Computer Modelling & New Technologies 2014 ***18****(11) 1026-1033*

The control particle swarm optimization (CPSO) algorithm is introduced to solve the unit commitment problem under the background of emissions reduction. Because the standard particle swarm optimization algorithm is easy to fall into local optimal solution. The closed loop control concept and feedback mechanism of classical control theory are posited, each particle is considered as controlled object to meet the changing needs in searching process, while dynamically adjust the inertia weight by proportion-Integra-derivative (PID) controllers according to the adaptation value of each step. These strategies greatly ensure the diversity of particles and improve the global search ability of the algorithm. The simulation results show that CPSO algorithm can reduce the dimension of the problem and ensure the feasibility of the particle in the optimization process, while it also has good convergence characteristics and global search ability.

Keywords: power system, emissions reduction, unit commitment, control particle swarm optimization

Tao Yi, Shanshan Cui, Yi Zhang Research on the cost estimation of transmission line project with case-based reasoning

Computer Modelling & New Technologies 2014 ***18****(11) 1034-1041*

Investment estimation phase of power transmission line project is an important stage of project cost control, the traditional unit investment forecasting methods, however, cannot meet the need of engineering rapid estimation. The research objective of this paper is to forecast the unit investment of the Transmission Line Project applying the case-based reasoning system. Based on the factor analysis tools of multivariate statistical software SPSS, the correlation coefficient matrix of characteristics factors are identified, and weight coefficient of characteristics factors is calculated. Based on the formula of European weighted distance, the similarity is calculated and case similarity is retrieved. Finally, the model is constructed to predict the unit investment of Transmission Line project, and the correctness and usefulness of the model is verified. It is shown that this case-based reasoning system of unit investment can achieve real-time updating of cost index database. The primary contribution of this research is the combination of the cost forecast and Case-based reasoning system of artificial intelligence. It is expected that this work will provide a reference and guidance for transmission line project investment decision in estimating phase.

Keywords: case-based reasoning, transmission line projects, forecasting

Qingbin Han Comparison on turnovers of agricultural products futures based on wavelet packet transform method

Computer Modelling & New Technologies 2014 ***18****(11) 1042-1047*

In order to distinguish the different patterns and evolving trends on turnovers of agricultural products futures between Zhengzhou Commodity Exchange and Dalian Commodity Exchange. A time-frequency analysis approach, i.e. wavelet packet energy spectrum, is investigated in this paper. Firstly, wavelet packet energy spectrum is briefly introduced. Secondly, two different non-stationary signals of turnover of agricultural products futures from 2009 to 2013 coming from Zhengzhou Commodity Exchange and Dalian Commodity Exchange are described in wavelet packet energy spectrum. First, reconstructed coefficients of main analysis wavelets packet of signals of turnover of agricultural products futures of Zhengzhou commodity exchange and Dalian Commodity Exchange are calculated. The obtained frequency band power ratios are used to show the different characteristics and evolving trends on turnovers of agricultural products futures between Zhengzhou Commodity Exchange and Dalian Commodity Exchange. With these results, the two signals are distinctly different from each other. It is proved that the technique of wavelet packet energy spectrum is effective for the purpose of distinction of turnover of agricultural products futures in commodity exchanges.

Keywords: turnover amounts, time-frequency analysis, non-stationary signals, wavelet packet energy spectrum, frequency band power ratios

Yuan Qin Research on Cooper ethical decision model based on Chinese opera

Computer Modelling & New Technologies 2014 ***18****(11) 1048-1051*

The effectiveness of Chinese opera decision directly affects the quality of traditional opera. In the era of rapid

development of internet technology today, the transmission mode of opera has changed. Its spreading range is wider, and its propagation speed is faster. For not considering the ethical factors, traditional opera decision is easy to have decision deviation. With reference to the theory of Cooper ethical decision model, the basic framework of Chinese opera ethical decision is constructed, including its definition, criterion, flow block diagram, etc.

Keywords: Chinese opera decision, ethical decision, Cooper's ethical decision model

Dongling Sun A construction of an autonomous vocabulary self-study system aided by the web pages
Computer Modelling & New Technologies 2014 ***18****(11) 1052-1055*

The thesis conducted a survey to confirm the hypothesis that vocabulary is the stepping stone in English Study to have an innovative application of modern educational technology to enrich the ways, methods and devices of enlarging the students' vocabulary. From the survey, it is easy to see that the hypothesis is true and the most students of the researcher felt vocabulary affected their motivation and interest in English study. So it is necessary to enlarge the vocabulary of the students in order to promote their application ability of foreign language. Vocabulary study is a process of self-study, and based on the theory of English study, the researcher has designed an autonomous vocabulary self-study system aided by the web to give flexible help for the students. The research is at its designing period and needs further assessments with a case study.

Keywords: construction, vocabulary, autonomous, system, web

Bin Ge, Kai Wang, Yue Han A design for simulation model and algorithm of rail transport of molten iron in steel enterprise
Computer Modelling & New Technologies 2014 ***18****(11) 1056-1061*

An emulation method can be chosen according to the characteristics in rail transport of molten iron in steel companies and a simulation model can be established based on the basic conditions for model, distributed tank mode and path selection, etc. By studying the automatic collision avoidance algorithm, a method of shortest path optimization for rail transport scheduling of molten iron was proposed based on ant colony algorithm. Simulation results show the validity and the feasibility of the algorithm. Programs and strategies of implementing visual simulation platform are proposed laying the theoretical foundation of further research and application for rail transport scheduling model of molten iron and intelligent optimization algorithm.

Keywords: dynamic routing, selection model, ant colony optimization algorithm, collision avoidance algorithm, mode of allocated tank, rail transport of molten iron

Hairui Wang, Ya Li The design and implement of alarm processing system for large-scale railway maintenance equipment diesel engine combustion control based on multi-agent
Computer Modelling & New Technologies 2014 ***18****(11) 1062-1067*

The Alarm Processing System reference model for large-scale railway maintenance equipment diesel engine combustion control, which is based on multi-agent, is an important system for high speed and automation. Alarm Processing System are vital aspects in M large-scale railway maintenance equipment diesel engine combustion control, in this sense, alarm processing system should support decision-making tools as known as decision support system(DSS), new maintenance approaches and techniques, the enterprise thinking and flexibility. In this paper a Multi-agents based alarm processing System reference model for large-scale railway maintenance equipment diesel engine combustion control is presented which combines the existing models and multi-agents. This model is based on a generic framework using multi-agent systems for the diesel engine combustion control the diesel engine combustion control on-line monitoring system. In this sense, the alarm processing system is viewed like a feedback control process and the actions are related to the decision-making in the scheduling of the preventive maintenance task and the running of preventive and corrective specific maintenance tasks. The result of an evaluation of the Multi-agents based alarm processing system reference model for the diesel engine combustion control are presented. This new model is compared to some important existing models and applied to a real investigation.

Keywords: diesel engine combustion control, alarm processing systems, multi-agent system, automation

Ming Pu, Hairui Wang Fault diagnosis expert system for large-scale railway maintenance equipment based on BP neural network
Computer Modelling & New Technologies 2014 ***18****(11) 1068-1072*

According to the characteristics of the neural network and expert system, a fault diagnosis method for large-scale railway maintenance equipment based on Back Propagation (BP) neural network and expert system is proposed. Fault diagnosis for large-scale railway maintenance equipment on BP neural network and expert system model are

constructed. A weak of collection and expression of knowledge on traditional expert system is overcome. Availability of the method based on BP neural network system and expert system is verified by experimental results of large-scale railway maintenance equipment fault.

Keywords: BP neural network; neural network-knowledge base; expert system; fault diagnosis

Jiahua Zhou Innovation model for college ideological and political education in network environment
Computer Modelling & New Technologies 2014 ***18****(11) 1073-1077*

Ideological and political education is impacted by the rapid development of network technology, computer technology and high-speed communication technology, in aspects of concept, content, ways and means, and can not meet requirements of current network age development. Therefore, the ideological and political education is placed in network technology to form new pattern. This paper, first, made brief overview of the concept and characteristics of ideological and political education in network environment, then summarize college ideological and political education at home and abroad. Afterwards, it analyzed the challenges and opportunities after combined network technology and college ideological and political education, then proposed relative solutions in the perspectives of concept, content, means and position. At last, it put forward the construction of shared community pattern for ideological and political education in network environment, consisting of the organization structure and operation mechanism of shared community.

Keywords: network platform, college ideological and political education, teaching model research, innovation

Juan Zhang, Guanghui Chen, Boqin Liu Management on the recombination of manufacturing whole process logistics operation based on MES
Computer Modelling & New Technologies 2014 ***18****(11) 1078-1081*

With the constant intensification of market competition, manufacturing enterprises are racking their minds to lower the cost so as to obtain more profit. As the enterprise's third profit source, logistics has attached more and more enterprises' attention. According to the relevant data statistics, in the current production system, trucking expense accounts for 30% to 75% of total expense. However, after optimal management of logistics, it can save 15% to 30% of expense for enterprises. This paper discussed the current situation and research results of the workshop logistics of machine manufacturing, and analyzed the loopholes existed in the whole process of traditional logistics management of manufacturing. It also established a kind of manufacturing whole process logistics lean management operation model based on MES, which provided a kind of feasible management mode for machinery industry to lower the logistics cost of the whole manufacturing process.

Keywords: MES, manufacturing whole process, logistics lean management, operation model

Jingdong Hao Design and construction of college English teaching model based on multi-dimensional integrated technology
Computer Modelling & New Technologies 2014 ***18****(11) 1082-1084*

How to enhance language teaching efficiency, especially college English is always the focus of people. People pay more and more attention to the progress of the CAT with the development of linguistics and improvement of computer and network technology, at the same time, the combination of language teaching and computer science is also a major breakthrough in the history of the development of language teaching. This paper used the C3I-CAT integrated technology into college English curriculum design and research and development of independent study system, and developed more college English courseware and application methods that is matching to the need of teaching practice, thus to improve the learning efficiency of college English course.

Keywords: college English course, information technology, integration, design of model

Ying Bai Comprehensive evaluation of education mode of university English model and swot analysis
Computer Modelling & New Technologies 2014 ***18****(11) 1085-1088*

College English is a compulsory course for non-English majors, which is an important public class. The pros and cons of university English education are directly related to the improvement of comprehensive quality of college students. What the specific requirements of implementing quality education for college English education and how to further strengthen and improve the university English education are hot topics and have been widely concerned. This paper analyzes the traditional mode of university English education quality, and set up a comprehensive evaluation mode of education model, so as to provide some help for the university English reform.

Keywords: university English education, character building education, analysis of advantages and disadvantages, comprehensive evaluation

Yan Zhang Research of golden week's tourism flow based on tourism system model visual
*Computer Modelling & New Technologies 2014 **18**(11) 1089-1093*

Travel system is a set of various travel issues; some negative effect of tourism factors in the overall tourism system will affect the tourists' decision. Since the "golden week" holiday, the growing numbers of residents traveller, form a tourist flow for a period of time, while promote domestic economic growth, accompanied by some negative effects, such as poor quality of "golden week" travel, poor tourist satisfaction, cause certain environmental pollution and so on, all aspects of the social concern is caused. This article make Huangshan scenic spot and the ancient villages in southern Anhui province as an example, based on tourism system vision, on the basis of the tourism golden week to explore, set up and analyze the "golden week" tourism flow system model. Classified tourism flow mobility factors by using the model, analyzing influence factor of golden week tourism, according to affect the positive and negative effects of tourism flows, come up with some suggestions and improvement measures, in order to improve the management and planning of tourism, meet the needs of the national holiday.

Keywords: travel system, golden week, tourist flow, Huangshan, villages in southern Anhui province

Pingping Xiao Establishment and implementation of network congestion control algorithm based on real-time streaming transmission
*Computer Modelling & New Technologies 2014 **18**(11) 1094-1098*

In order to improve the network performance of computer and avoid the occurrence of network congestion better, this paper analyzed the problems faced by the integration of real-time streaming transport and network and their solutions in the perspective of the characteristics of real-time streaming transport. As to the congestion control of streaming media, TFRC algorithm was analyzed emphatically. Based on TFRC, network congestion was improved, monitored and predicted with parameter of real-time cache length; sending rate was corrected based on cache length when the network was saturate, in order to avoid congestion in time and improve fairness; at last, the test comparison proceeded by network simulation platform NS2. The result indicated that, the improved TFRC was fairer; meanwhile, it showed more friendliness to TCP.

Keywords: real-time streaming transport, congestion control, TFRC, cache length

Jindong Chen Analysis evaluation and quantitative research on economic law behaviour cost and market efficiency
*Computer Modelling & New Technologies 2014 **18**(11) 1099-1103*

Fiscal expenditure, as the material support of economic law behaviour, plays a critical function in regulating resource distribution, promoting economic development and guaranteeing social far equity. Analysis evaluation of fiscal expenditure is obtained through connotation of fiscal expenditure and investigation evaluation. This paper thought that, analysis evaluation of economic law behaviour cost referred to make comprehensive evaluation in aspects of economy, efficiency and benefits on fiscal expenditure process and result according to specific principles and using scientific and normative evaluation method and technology, with fiscal expenditure as management objectives. The results it obtained will be mostly reflected on market effect. Through the quantitative research on fiscal expenditure and economic benefits evaluation in our country, this paper made digitalization and objectification analysis on the comparison of economic law behaviour cost and market benefit, studied the relationship between fiscal expenditure scale and market economic, further estimated the optimal fiscal expenditure scale in our county, in order to provide basis and rule for the formulation of economic law behaviour cost based on quantitative analysis.

Keywords: economic law behaviour, fiscal expenditure, market benefits, quantitative analysis

Yanli Yang, Xianyu Wang Incentive system of skill-oriented dispatched employees based double moral hazard
*Computer Modelling & New Technologies 2014 **18**(11) 1104-1108*

As market competition gets increasingly fierce, the elastic way of employment arouses great concern among more and more enterprises, which results in rapid development of labour dispatch. Labour dispatch is different from the traditional way of employment and it involves the three parties of the employer, the accepting entity and the dispatched employee with the striking feature of asymmetric information. From the perspective of the employer, this paper analyses the incentives of the three parties in labour dispatch while taking the employer as the first principal and the accepting entity as the second principal in consideration of the factors that the intermediary agent's training will influence the quality of the employee. It verifies through models the sharing ratio paid by the accepting entity to the employer, the sharing ratio paid by the employer to the dispatched employee and the fixed wage paid by the accepting entity to the dispatched

employee in expectation of offering concrete suggestions to the practice of enterprises.

Keywords: Labour Dispatch, Agent's Effort, Double Programming, Sharing Ratio

Zhihang Tang, Zhonghua Wen Comparative study of personalizing recommender systems based on shopping system

*Computer Modelling & New Technologies **18**(11) 1109-1114*

Making choices is an integral part of everyday life; Recommender systems facilitate decision-making processes through informed assistance and enhanced user experience. To aid in the decision-making process, recommender systems use the available data on the items themselves, Personalized recommender systems subsequently use this input data, and convert it to an output in the form of ordered lists or scores of items in which a user might be interested. These lists or scores are the final result the user will be presented with, and their goal is to assist the user in the decision-making process. Recommender systems facilitate making choices, improve user experience, and increase revenue, therefore should be easily accessible for deployment to interested parties. The implementation of recommender systems in RapidMiner has been additionally simplified through the Recommender Extension.

Keywords: shopping system, personalized recommender systems, RapidMiner, decision-making

Caihong Zhang Analysis on Ideological and Political Teaching Curriculum Design and Information Transfer Based on Complex Adaptive System Theory

*Computer Modelling & New Technologies 2014 **18**(11) 1115-1118*

In the field of technology, based on scholar's research results of instructional system design complexity, this paper discussed the development of instructional system design thought. It also analyzed the basic framework of ideological and political teaching curriculum design based on complex adaptive system.

Keywords: system, complexity, instructional design

Liming Xiao, Rui Jing The Attractiveness and Motivation of China's International Investment Based on Positive Investment Inertia

*Computer Modelling & New Technologies 2014 **18**(11) 1119-1122*

Nowadays, economic globalization is the main trend of world economic development. Each country takes the participation in international investment as a strategy. This paper analyzes China's international investment from the view of investment inertia. Though the attractiveness and motivation of China's investment keeps increasing, the integral development level is low which stays in the stage of zero inertia. The total amount of China's investment is increasing. But the invitation of investment is unreasonable; the short-term investment in foreign country prevails. We seek the strategic asset of developed country eagerly, and prefer to seek the market and resource of developing country.

Keywords: international investment; inertia; attractiveness; motivation

Yue Zhang Operation Path and Strategy of Logistics Enterprise Supply Chain Logistics Management under Horizontal Integration

*Computer Modelling & New Technologies 2014 **18**(11) 1119-1122*

This paper put forward the significance of horizontal integration service provided for society by logistics enterprise, and discussed in detail about how to realize horizontal integration service and what kind of operation model can be adopted by relevant sub-service. Researches on these contents not only have certain effect on correlated theoretical research, but also can provide certain guidance for logistics enterprise. This research aimed to promote the compound integrated service ability and international competiveness through horizontal integration management mode.

Keywords: Logistics, horizontal integration, operation and management mode

Weidong Wang An entropy method-based index system for the competiveness of industrial cluster – a case study on the typical clusters in Zhejiang province in China

*Computer Modelling & New Technologies 2014 **18**(11) 1128-1131*

Basing on the previous research results, this study constructed an index system for the competiveness of the industrial cluster using analytic network process (ANP) method. Moreover, it employed the entropy method in objective assignment method to assign weights to the indexes and conducted empirical analysis by exampling the typical clusters in Zhejiang province. The results showed that the industrial concentration degree, specialization degree (location quotient), and Herfindahl-Hirschman index (HHI) took relatively high proportions in the indexes

concerning the competitiveness of industrial clusters. This study also drawn an important conclusion, namely, high industrial concentration degree was conducive to improve cluster competitiveness and reduce cluster risk, while lower industrial concentration degree facilitated the formation of high overall cluster competitiveness.

Keywords: ANP, entropy method, Industrial cluster competitiveness

NATURE PHENOMENA AND INNOVATIVE ENGINEERING

Wei Huang Wireless vehicle detection node based on tunnelling magneto resistance sensor

Computer Modelling & New Technologies 2014 ***18****(11) 1128-1133*

A wireless node based on tunnelling magneto resistance sensor was designed for large scale vehicle detection in Intelligent Transport System. With regard to the sensor's characteristic of high resistance, rapid response and high linearity, the signal acquisition and regulation circuits were designed to meet the requirement of geomagnetic measure for three dimension axis of the sensor. A vehicle noise pre-detection unit was implemented to wake up the microcontroller from sleep state before vehicle enter the detection area. Low power chips were considered and the all sensor units were power supplied by MCU, cooperated with the improved power-efficient ATA algorithm, the power consumption was minimized. Experimental results showed that the designed node was capable of capturing the magnetic feature of different vehicle types and on line vehicle flow detecting for long time.

Keywords: tunnelling magneto resistance, geomagnetic induce, vehicle detection, ATA, WSN

Wan Ning Mechanical characteristics of multi-span concrete continuous girder oblique bridge based on ANSYS

Computer Modelling & New Technologies 2014 ***18****(11) 1134-1138*

In order to adapt to environment and reduce the damage of construction for environment, the principle that environment adapts to construction is updated for bridge design, therefore lots special-shape bridges including oblique bridge emerge. However, there is no accurate and developed theory for computing the mechanical characteristics of oblique bridge. Generally, equivalent straight bridge is applied for computing. By performing finite element modelling, the internal force and displacement of oblique bridge and equivalent straight bridge with load were compared. The results showed that due to the special structure of oblique bridge, torque is generated under load, accompanying with coupling effect of bend-twist. Therefore, the mechanical characteristics analysis of straight bridge can not accurately explain that of oblique bridge.

Keywords: ANSYS, oblique bridge, computer simulations, finite element modelling

Xiangyue Yuan, Zhongjia Chen Design of new type biomass pellet forming machine with plunger roller and ring-die at room temperature

Computer Modelling & New Technologies 2014 ***18****(11) 1139-1145*

Bio-energy has become the fourth major energy resource after oil, coal, natural gas energy on account of the properties of green, clean, and renewable. And biomass densification is an important technology which makes the biomass resource be low cost and high value. But for current biomass forming equipment, there exist common shortcomings of high energy consumption, low efficiency, serious wear of forming parts, and etc. In this paper, a forming mechanism of a new type biomass pellet machine with plunger roller and ring-die was proposed, which using the mesh extrusion pressure between plungers and forming cavities (or called holes) to make the loose biomass material densification. It could avoid direct contact and intense friction of forming parts and biomass materials out of the holes. So the energy consumption of the materials in ineffective forming process was reduced and the wear of forming parts was effective alleviated. Then the new type biomass pellet forming machine was designed according to the requirements by Solidworks after force analysis and theoretical calculation, and a prototype was built with the whole power 22 kW and production capacity 450 kg/h. Compression experiments were done finally on the prototype. It was shown that the forming quality of solid pellet fuel tended to be stable after 30 minutes' running and the pellet density could reach more than 0.8 g/cm^3. So it represented that the designed pellet machine had a good practical operation and met the design demands.

Keywords: forming technology of biomass densification, pellet forming mechanism with plunger roller and ring-die, pellet fuel

Yong Zhang, Lixia Li Reaction mechanism of carboxymethyl starch-based wood adhesive

Computer Modelling & New Technologies 2014 ***18****(11) 1146-1151*

The technology involved in manufacturing carboxymethyl starch-based adhesive was studied with the aim of enhancing its water-resistance. The optimum formula was based on previous research using a quadratic orthogonal

rotation combination design to synthesise the carboxymethyl starch-based wood adhesive. Compared with the original starch, carboxymethyl starch improves the performance of starch adhesive due to its advantageous properties such as hydrophilicity and stability during freezing and thawing etc. Infrared spectroscopy and scanning electron microscopy were used to analyse the synthesis of the carboxymethyl starch-based adhesive. Many functional groups could be identified by their characteristic Fourier transformation infrared vibration frequency and this was used to explain the structural changes. At the same time, the microstructure of the adhesive was analysed by scanning electron microscopy (SEM), and porous, round or elliptical granules in the carboxymethyl starch were observed. An SEM of the main starch agent revealed a network structure; the granules did not aggregate together to form large groups due to the polyvinyl alcohol that prevented granule agglomeration. However, the SEM of the starch adhesive showed a smoother and more compact network structure, due to the large number of strong chemical bonds that were formed by the association of isocyanate with the main starch agent.

Keywords: carboxymethyl starch, wood adhesive, optimisation, mechanism

Cai Lipeng Experimental study on heat-preservation wall materials made from waste foam
Computer Modelling & New Technologies 2014 ***18****(11) 1152-1155*

In this paper, a new energy-saving-and-environmental-protection heat-preservation wall material is studied. This material is mainly made by waste foam, cement and sand in the structure of "sandwich" - cement foamed plastic is in the middle of cement mortar. Experimental study reveals that the heat-preservation block of this material has lighter self-weight and higher compressive strength and better performance in heat preservation, sound insulation and frost resistance, that is to say, its overall property is obviously superior to that of others such as aerated concrete block. This block consumes a large amount of waste foam that is difficult to dispose, which conducive to environmental protection and energy is saving. It can bring favourable social, economic and environmental benefit. Besides, less energy is consumed in the production of this material and it is easy to realize volume production, so this material is a new wall material of energy saving and environment protection.

Keywords: waste foam, heat preservation, wall material, new technologies

Wang H F, Fan Y H, Yang L The analysis of vibrations induced by variation section vortex in tension leg platform for a floating wind turbine
Computer Modelling & New Technologies 2014 ***18****(11) 1156-1162*

During the previous decade, several offshore wind-farms were constructed for offshore wind energy generation showed promise as a source of green energy. However, there are several challenges to be met in the design and construction of the foundations for offshore wind turbines. The fatigue load plays an important and crucial role in the design of the supporting structures. In this paper, the vortex-induced vibrations of the tension leg platform were studied. Two types of structures namely; cylindrical Tension Leg Platform (TLP) and variable cross-section TLP were designed and studies on them were conducted to compare the advantages and drawbacks resulting from vortex-induced vibrations. Both uniform and shear flow were considered to simulate water flow through the structures. The variable cross-section TLP, which possesses outstanding mechanical properties, gave lower vortex shedding frequency compared to the cylindrical TLP for the same velocity. This is the objective desired in vortex-induced vibration.

Keywords: vortex-induced, tension leg platform, variation section

Yang Zhongguo Study on the device of multipath household heat metering
Computer Modelling & New Technologies 2014 ***18****(11) 1163-1166*

One of the most important contents of reforming heating system is that more attention will be paid to residential energy conservation and improvement of heating facilities in order to charge heating fee by heat consumption. But the out-dated technology prohibits the widespread use of multipath household heat metering. Since the heating system in China is still confronted by the substantial energy waste, the jumble of pipelines and difficult management of the system etc, a company in Liao Ning has developed a new kind of water supply system on multipath household heat metering. The new system blazes new trails on household heat metering, solving the problem of traditional pipelines. The paper uses the computational method of hydrodynamics and provides the experimental platform of pipe resistance measurement and its theoretical parameter for the system. The study shows that resistance coefficient of the experimental pipeline corresponds with the theory, and multipath household heat metering has favourable prospects.

Keywords: converter multipath, household heat metering, pipe resistance measurement

Lv Jingxia, Gao Lin, Wen Jian Research on the relationship between moisture content and the dielectric constant of the tree trunk by the radar wave

Computer Modelling & New Technologies 2014 ***18****(11) 1167-1171*

Radar wave technology offers a noninvasive, quick determination technique and has potential for the applications of the non-destructive detection (NDT) for the trees trunk and wood based materials. The precision of NDT determination by radar wave is influenced the wood dielectric constant which is closely related to the moisture content of the trees trunk. For our investigations we used TRU trees radar wave to detect the trees trunk. Four typical trees trunks were selected: polar, willow, pine, eucalyptus. Different trees trunks moisture content and dielectric constant were tested under the radar wave frequency respectively. Models of the relationship between moisture content and dielectric constant of the trees trunks were established for improving the accurate of radar wave NDT.

Keywords: radar wave, dielectric constant, moisture content, tree trunk, non-destructive detection

Wang Zijian, Wu Liming Physical parameter identification and wave force inversion research of bridge pier structure

Computer Modelling & New Technologies 2014 ***18****(11) 1172-1180*

According to total compensation composite inversion algorithm, physical parameter identification and inversion of wave time interval are done under the condition of input information of isolated pier in wave force part being unknown. Based on the characteristics of large-diameter piers in shallow water which are affected by wave force and combining with “statistical average method” in probability theory, structural physical parameter identification and wave inversion calculation are done under the condition of unknown wave force. Analysis of numerical values shows that results of structural physical parameter identification cater for accuracy requirements which is feasible for inversion method of parameter identification of large-diameter piers in shallow water with unknown input information thus providing a new method for structural physical parameter identification research of river-spanning and sea-crossing piers affected by wave force and providing references for engineering application.

Keywords: bridge pier structure, parameter identification, unknown input, load inversion, time domain correlation

Kang Yiting, Feng Yali, Lin Jinggao, Zhang Wenming Load spectrum for creep-fatigue life prediction of viewport used in human occupied vehicle

Computer Modelling & New Technologies 2014 ***18****(11) 1181-1186*

Acrylic plastic, polymethylmethacrylate (PMMA), are widely employed as the material for the viewports of human occupied vehicle (HOV) which usually dives into deep sea. The service life of viewport is critical to the reliability and safety of HOV. In order to predict life of viewport in design stage, mathematical statistics method is applied to establish the load spectrum for viewport. It is found that ALVIN (America) HOV’s dive-depth data is in a skewed distribution, and a piecewise function combined Gumbel and Weibull distributions is proposed for data fitting. HOV undertakes long-term and cyclic load in service, which will cause damage on viewport, so a creep-fatigue load spectrum is established and applied for JIAOLONG (China) HOV’s viewport, which integrates both the dive-frequency of each depth range and the duration that maximum stress acts. The proposed method for determination of creep-fatigue load spectrum could thus be considered to be employed for failure analysis and life prediction of modern HOV’s viewport.

Keywords: viewport, human occupied vehicle, distribution function, creep and fatigue failure, load spectrum

Cheng Xinmin, Li Jing, Jiang Yunliang, Gao Ge Application of GMM-UBM with an embedded AANN in the acoustic emission signal recognition

*Computer Modelling & New Technologies 2014 **18**(11) 1187-1191*

In this paper, we propose to recognize the Acoustic Emission (AE) signal, by using a Gaussian Mixture Model-Universal Background Model (GMM-UBW) with an embedded AANN. The AANN based GMM-UBW combines the learning ability of neural network and strong distribution capabilities of GMM. And, it trains the model parameters alternatively in order to approach the maximum likelihood. For illustrating the effectiveness of the proposed recognition method for the AE signal, an experiment is conducted. In the experiment, three cases of AE signal are considered, namely with no rub impact, slight rub impact and serious rub impact. The experimental results reveal that the AANN based GMM-UBW outperforms the GMM, with respect to the recognition rate, for any case of AE signal. For the case of slight rub impact, the GMM-UBW and that with embedded AANN both have the worst recognition performance, among the three cases. And, the proposed method has the biggest improvement for this case.

Keywords: acoustic emission; Auto-Associative Neural Network; Gaussian Mixture-Universal Background Model

Wang Xiaorong, Liu Chenpeng, Liu Bo, Tang Wenxian, Zhang Jian Research on method to promote performance of multiple injections diesel engine

*Computer Modelling & New Technologies 2014 **18**(11) 1192-1199*

Based on certain type of two-stroke, low-speed diesel engine for marine propulsion, we, in our research project, developed a 3-D model of in-cylinder combustion processes in a diesel engine. Thus, we were able to compare simulated in-cylinder pressure against the experimental pressure under single injection with a maximum error tolerance of 0.36%, the results of which imply that the two are basically consistent. Subsequently, based on the same injection timing, a comparison was made between the performance of a diesel engine using single injection and one using dual injection. The results indicate that the additional injection can lower NOx by58.9% and soot by 30.1%. Moreover, the piston's workload is reduced by 10.1%. Through calibrating injection quality centre, adjusting injection timing of secondary injection reasonably, we gained the method improving performance of combustion and secondary injection diesel engine. By verifying, the method can promote working ability of secondary injection diesel engine effectively. After adjusting injection timing, working ability of secondary injection is as well as it of single injection, but emissions reduce sharply, thereinto, NOx reduced 12.7%, soot reduced 41.1%.

Keywords: Marine low-speed two-stroke diesel engine; injection timing; double injection; diesel performance

Wang Jun, Wang Guoqing, Li Ming, Yu Wenhui, Tian Hao An improved hand vein image acquisition method based on the proposed image quality evaluation system

*Computer Modelling & New Technologies 2014 **18**(11) 1200-1204*

In the part of hand vein image acquisition of vein recognition, we basically cannot get the images that are suitable for later process due to both the subjective factors and the objective factors. After a deep analysis on the main reasons including the different thickness of hands and mass of things on the hand, we propose the design of hand vein acquisition device based on the adaptive modulation control. The key part of the design is the proposed double-processing image quality assessment system: the first part of which involves the process of quality assessment based on the effective information of multidimensional histogram and the normalized information entropy; the second part involves adding the grey image variance and quantities of cross points with the proper weights, then two process will be made according to the final score: if the score is lower than the set threshold then image will be discarded, and on the other hand the brightness degree of the LED groups of the device will be adaptively adjusted according to the D-value of the score and the threshold so that we can get the high-quality hand vein image for later feature extraction and matching and get a higher recognition rate.

Keywords: hand vein recognition; adaptive control; two-set quality evaluation system; D-value

Yang Jingfeng, Li Yong, Zhang Nanfeng, He Jiarong, Xue Yueju Pure electric buses status information compression and transmission methods basis on optimized Huffman coding algorithms

*Computer Modelling & New Technologies 2014 **18**(11) 1205-1212*

To strengthen safety supervision, satellite positioning information is needed to be uploaded as well as battery status information of pure electric buses. For the unbalanced coverage of mobile communication base station, data loss and incomplete data are prone to emergence when a large amounts of real-time data transmission through 3G/GPRS network in the poor communication environment of subregion, which is difficult to achieve large-scale farmland information collection and transmission simultaneously. Therefore, optimized Huffman coding compression algorithm for text-oriented information is promoted in this paper. The whole process test results of data exchange and decompression show that, the data compression algorithms can realize data compression effectively. The data sampling period is relatively smaller and its adjacent data is closer, the higher compression rate can be obtained by

corresponding compression algorithms, and it can the basically ensure the decompression data without distortion. This will improve the efficiency of information transmission of transportation, as well as to ensure the integrity of information, which is of great significance to realization of transportation energy conservation.

Keywords: vehicle information, data compression, pure electric buses, battery status information

Du Huiqiu, Wang Jingbo, Lin Zhong-hai, Wang Pingjian, Yan Long Allowed capacity calculation of wind farm based on probabilistic constraint

Computer Modelling & New Technologies 2014 ***18****(11) 1213-1218*

This paper presents a method for penetration capacity calculation of wind farm based on probabilistic constraint. According to the stochastic programming theory, under a confidence interval, a mathematical model that considers the randomness of wind speed is established based on the static safety and power quality constrains. The solving method is proposed according to particle swarm optimization algorithm and stochastic simulation technique too. According to a real power system in Yunnan, the penetration capacity of wind power is calculated under different confidence interval, and the feasibility and effectiveness of this method are verified too. The related factors of affecting the penetration capacity of wind power are analysed, which provide the reference for the planning and design of wind farm.

Keywords: penetration capacity of wind power, chance constraint, stochastic simulation, confidence interval, particle swarm optimization

Zhu Lida, Chen Hongyu, Tian Zhongzi, Wang Hai Parametric design and simulation analysis of turbine blade

Computer Modelling & New Technologies 2014 ***18****(11) 1219-1224*

To improve design quality and efficiency of turbine blade, the geometric model of blade is parameterized by using the quintic polynomial method in this paper. The geometric shape and performance of blade mainly depend on blade profile and cascade with parametric model. First of all, the blade profile lines are designed and generated in different parameters based on the theory of quintic polynomial. The effect of relative parameters on the blade profile is analysed conveniently and rapidly. Then, the geometric shape of blade is generated in the arranged blade profiles according to blade cascade position and consistency. The 3D model of blade is created by the parametric blade profile and cascade. It is shown that parametric model of blade will provide the reference and foundation for application research.

Keywords: turbine blade, quintic polynomial, parametric design, 3D model

Xia Shulan, Wang Jilin A speech emotion enhancement method for hearing aid

Computer Modelling & New Technologies 2014 ***18****(11) 1225-1228*

In this paper, emotional perception of the hearing-impaired patients for hearing aid is investigated, and a speech enhancement algorithm is proposed, which is text-independent and requires less and non-parallel training data. In addition, the conversion of prosodic and spectral parameters is also studied. The Eigenvoice Gaussian mixture model (EV-GMM) is used to transform the F0s and spectral parameters, which is built using multiple pre-stored sources emotional and target neutral speech sentences. In the training and testing stages, the duration modification is utilized to improve the performance of EV-GMM training and converted output quality and an adaptive median filter is proposed to smooth the trajectory of the converted speech. Perceptual and objective experiments are presented, simulation results corroborate the effectiveness of the proposed algorithms.

Keywords: hearing aid, emotional speech enhancement, EV-GMM, duration modification

Sun Yan, Lang Maoxiang, Wang Danzhu Optimization and integration method for railway freight stations based on a hybrid neural network model

Computer Modelling & New Technologies 2014 ***18****(11) 1229-1237*

Given to the current problems existing in the operation of railway freight stations and the entire railway freight transport network, in order to integrate the railway freight stations and optimize the traditional railway freight transport mode, we first propose a strategy on the optimization and integration for railway freight stations, then design a hybrid neural network model to recognize the operating performance of each railway freight station by classifying them into four ranks based on the proposed strategy. The characteristic of the proposed model is its combination of the respective advantages of unsupervised learning algorithm based neural network and supervised learning algorithm based neural network. Finally, an empirical study from Hohhot Railway Administration is given to verify the feasibility of the proposed model. The simulation results of the empirical study indicate that (1) the accurate recognition of training samples has significant influence on the classification result; (2) the proposed model can recognize the operating performance of the railway freight stations under relatively high accuracy.

Keywords: Railway Freight Station, Optimization and Integration, Hybrid Neural Network Model, SOM Neural Network, Probabilistic Neural Network

Yu Song, Hua Liu *PH* sensor design based on potentiometric analysis method
Computer Modelling & New Technologies 2014 ***18****(11) 1242-1246*

In order to accurately, continuously detect solution *pH* on line, regarding C8051F020 as the control centre, the output voltage of glass electrode is amplified through high input impedance circuit utilizing potentiometric method to obtain related voltage signal of *pH* value. Standard solution and temperature sensor ADT7301 are utilized for system calibration and moving average filter of the detected *pH* values, thereby achieving real-time online detection of *pH* value. Detection results are accurate and reliable; low power consumption and miniaturation also facilitate rapid collection and analysis of data under different environments.

Keywords: pH detection, C8051F020, glass electrode

Chen Weihua Digital controller for electric vehicle synchronous motor rotor
Computer Modelling & New Technologies 2014 ***18****(11) 1247-1251*

At present, the number of electric vehicle is increasing, and, in case of big vehicle speed change, the vehicle motor cannot be used efficiently. In order to resolve this problem, it is necessary to improve the topological structure and control strategy, and design a new converter. In this paper, we apply a two-channel synchronous Buck converter. The main circuit is to achieve the maximum power output by the stage regulation, while the improved converter topology realizes the overall system function. The experimental results show that the new converter has superior performance in big vehicle speed change, and has the high quality energy output. This research has an important practical significance to improve the utilization of renewable energy.

Keywords: power system, electric vehicle, digital controller, inverter, converter

Peng Zhangming, Cai Huihua, Sun Qingchen, Chen Guojin, Su Shaohui Effect factor research on monitoring wear of piston ring based on magnetoresistive sensor
Computer Modelling & New Technologies 2014 ***18****(11) 1252-1255*

Piston ring is one of the important parts in diesel engine, and its excessive wear reduces the sealing performance of the combustion chamber, the method on monitoring wear of piston rings with the magneto-resistive sensor is researched from the simulation viewpoint, the research shows that the amplitudes reduce with the increase of the piston ring wear. The theoretical basis for monitoring piston ring wear with a MR sensor is provided.

Keywords: piston ring wear, magneto-resistive sensor, diesel engine

Liao Xuechao Steel sheet location tracking and automatic sorting self-adaption control model
Computer Modelling & New Technologies 2014 ***18****(11) 1256-1260*

The sorting control system is the critical procedure in the final product line of cold rolling mill. Taking the tinning steel sheet sorting control system of shearing production line of WISCO's cold rolling plant as an example, the process of steel sorting control system is introduced. The running principle and control concept of steel sheet position tracking and sorting are particularly presented. The practical application proves that the system can position the tinning steel sheet which is moving in high speed, which is of high controllability and reliability.

Keywords: sorting control, position tracking, magnet system, self-adapt regulating, dropping posture control

Dong Lei, Li Weimin, Zhao Weiguo, Chen Yunfei Probabilistic neural Network with statistical feature for fault diagnosis of permanent magnet motor
Computer Modelling & New Technologies 2014 ***18****(11) 1261-1265*

Permanent magnet motors are very important components in commercially available equipments and industrial applications due to high reliability and robust performance, and it is important to take an appropriate and effective approach to diagnose fault for them. The implementation of probabilistic neural network (PNN) with the statistical features for permanent magnet motor is developed in this paper, and the statistical features are determined according to the stator current characteristics of motor to effectively reduce dimensionality of sample space. The experimental results demonstrate that, compared with RBF network, the proposed method is more effective in identifying various types of faults.

Keywords: Permanent Magnet Motor, Probabilistic Neural Network, Statistical Feature

Tan Xiaoling, Tan Zefu, Qu Juan, Xi Guangwen SVM -Based evaluation model for college laboratory learning

*Computer Modelling & New Technologies 2014 **18**(11) 1266-1270*

Evaluation for laboratory learning is based on different factors, while each factor is varied by individuals. Hence it is difficult to express the quantitative nonlinear functional relationship among the evaluation indexes. With limited sample, Support Vector Machine (SVM) could be generalized by compromising between model's complexity and learning ability. That is its advantage on the evaluation of small sample, nonlinear and multi-indexes. It is a good try to apply Support Vector Machine (SVM) to laboratory learning evaluation. With Support Vector Machine (SVM), the relationship between the learning quality and evaluation indexes could be revealed. Experiments show that Support Vector Machine (SVM) model is with high prediction accuracy, faster speed and simple algorithm. It is suitable and more reasonable for laboratory learning evaluation.

Keywords: Support Vector Machine (SVM), evaluation model, laboratory learning quality

Zhang Yalong, Ogura Hisakazu, Ma Xuan Usefulness of lethal chromosomes in genetic algorithms solving the constrained optimization problems

*Computer Modelling & New Technologies 2014 **18**(11) 1271-1274*

The infeasible solutions are often generated in population as evolutionary computation solving the combinatorial optimization problems. The number of infeasible solutions impacts the performance of the evolutionary computation searching the optimal solution, in the worst case the algorithm ceases to run. In genetic algorithms, encoding of infeasible solutions is referred to as lethal chromosomes. In this study, we discover a property of lethal chromosomes that: although lethal chromosomes carry out the infeasible solutions in genetic algorithms, their statistical property implies an underlying similarity with the exact solution of the optimization problems. Hereby we propose an operation using statistical property of lethal chromosomes to handle with the lethal chromosomes themselves. Simulation experiments on a large number of test cases demonstrated that it can improves obviously the performance of genetic algorithms to use the statistical property of lethal chromosomes.

Keywords: Genetic Algorithm, Infeasible Solution, Lethal Chromosome, Evolutionary Computation

Zhang Min, Fan Qiang, Zhang Fucang, Li Xia, Xue Xuzhang, Wang Guodong Crop canopy temperature model of ditch-cultivated based on artificial neural network

*Computer Modelling & New Technologies 2014 **18**(11) 1275-1280*

Aiming at the mechanism model are influenced by multiple random factors, this paper establishes canopy temperature models based on BP network and RBF network respectively. The models take the temperature, humidity, illumination, soil temperature and ditch depth in the closed greenhouse as input neurons and takes canopy temperature as the output neuron. The results show that both models can well predict ditch-cultivated crop canopy temperature. The mean error between the simulation value and measured value of BP network model is 0.8408℃, and root-mean-square error of 0.5789℃. Actual output and expected output of RBF network model differ little, mean error of 0.2236℃ and root-mean-square error of 0.3496℃. In contrast, RBF network model can more accurately predict crop canopy temperature of ditch-cultivated than BP network model.

Keywords: Ditch-cultivated, Canopy Temperature Model, Artificial Neural Network

Wang Liying, You Lisha Analysis on vibration of small-scale hydroelectric generating unit

*Computer Modelling & New Technologies 2014 **18**(11) 1281-1285*

An analytical model for the vibrations of operating conditions of small-scale hydroelectric generating unit is developed based on frequency domain and time domain. Firstly the vibration of unit 2 in Xida hydropower station is tested by using intelligent data logger, where the DASP10 software is used to collect the data and analyse them; and then the data are analysed by the time domain analysis, shaft centreline orbit analysis and auto-spectrum analysis respectively. Finally some instructive conclusions on the exceedance of shaft degrees and the overweight phenomena are drawn, which may assist an overhaul to raise the operating efficiency and the power output.

Keywords: Hydroelectric Generating Unit, Vibration, Time Domain Analysis, Shaft Centreline Orbit, Auto-spectrum Analysis

Zhu Shisong, Zhang Haiyan, Zhang Cuiyun, Li Changqing The application of fusion structure in the coal mine safety state evaluation

*Computer Modelling & New Technologies 2014 **18**(11) 1286-1290*

Coal mine safety is a very important link in the current coal mine production. Currently, there are a lot of kinds of

methods for the evaluation of coal mine safety environment in order to solve the evaluation of the coal mine safety status. However, the complexity and diversity of coal mine environment cause that there is no method can evaluate coal mine safety status. So a new method is proposed, which called two-stage fusion structure according to China's natural environment of the underground coal mine, is used to evaluate the condition of coal mine safety. Firstly, it gets various parameters for affecting the safety of underground using the first level evaluation method; secondly, the second level fusion method is used to realize the coal mine security situation assessment. The experimental results show that this method has better performance more than other methods in evaluating coal mine safety.

Keywords: the first level fusion algorithm, fusion decision, mine safety, better performance

Liu Shuchong, Chen Xun Seismic signals wavelet packet de-noising method based on improved threshold function and adaptive threshold

Computer Modelling & New Technologies 2014 ***18****(11) 1291-1296*

Wavelet analysis is one of the effective method to improve the signal to noise ratio and resolution of seismic data, a wavelet packet seismic signal denoising method based on a new threshold function and adaptive threshold was put forward according to the distortion problem of traditional threshold function denoising method, which make up the defects of traditional thresholding method. Wavelet packet decomposition techniques was used for seismic wave signal denoising processing, and the synthetic seismic signals and actual seismic data was done wavelet packet decomposition processing through MATLAB, better removing high frequency random noise to retain the useful signals. Experimental results showed that the method can effectively remove noise and improve seismic resolution, with better denoising effect.

Keywords: seismic signal, adaptive threshold, denoising, resolution

Xia Jiening, Chen Zhigao Study on automatic identification method of X-ray fluorescence spectrum

Computer Modelling & New Technologies 2014 ***18****(11) 1297-1305*

The way to improve the accuracy and reliability of automatic unscrambling and identification technology on X-ray fluorescence spectrometer spectrum is studied in this essay. Accordingly, two different automatic identification methods based on Fast Fourier Transform and Wavelet Transform are presented. By the tool LabVIEW, such two methods are applied to the qualitative analysis on X-ray fluorescence spectrums, and the features of such two methods are compared. Based on the experiments and analysis on amount of samples, it can be concluded that the automatic identification method based on the Wavelet transform theory is better than the other method for the former has a better local resolution. Therefore, the characteristic values of the singular points are more clearly recognized by the method based on the Wavelet transform. Through the study in this essay, theories on automatic identification are enriched, which set a foundation for further studied in future.

Keywords: X-ray fluorescence spectrometer, spectrum identification, LabVIEW, fast Fourier transform, wavelet transform

Cui Fan, Wu Zhiyuan, Chen Jia, Wang Lei Fine detection of mine collapse column by anti-explosive ground penetrating radar

Computer Modelling & New Technologies 2014 ***18****(11) 1306-1311*

This work discussed the technique for fine detection of mine collapse column by anti-explosive ground penetrating radar (GPR) and its feasibility. In stage of theoretical research, numerical forward modelling was used to study the response characteristics of collapse column on radar profile. In actual exploration, the spatial distribution pattern of collapse column was accurately stored by installing complex environment observing system in the pit. In processing and explanation, the disturbance types of mine were comprehensively analysed, and various measures were taken in the suppression of interference signals to obtain better exploration effects. The study showed that fine detection of collapse column can be realized by anti-explosive ground penetrating radar under the complex conditions in the pit.

Keywords: Anti-explosive ground penetrating radar (GPR), collapse column, fine detection

Chen Disi, Li Gongfa, Liu Honghai, Jiang Guozhang, Liu Jia, Liu Ze, Ding Weiliang, Miao Wei, Li Zh Analysis of thermal-mechanical coupling and structural optimization of continuous casting roller bearing e

Computer Modelling & New Technologies 2014 ***18****(11) 1312-1315*

The continuous casting roller bearing was one of the important parts of continuous caster [1], its working temperature was relativity high, the working load was also very large and the working condition was complex. Since the external heat of casting roller bearings was much higher than internal, the continuous casting roller bearing was different from the general high-speed rolling bearing with heavy load. If the external heat that the bearing suffered could not dissipate in time, the extreme high working temperature might accelerate the failure of the bearing and severely reduce the

productivity of the caster. To optimize the thermal structure of the continuous casting roller bearing, the thermal coupling analysis of the bearing should be conducted. Firstly, the stress field of the working continuous casting roller bearing should be analysed by ANSYS and the three-dimensional geometric CAD model and the CAE model of it should be established. Then find out the location where the bearing suffered the largest force by stress analysis, in the case of bearing block with cooling water, load the working temperatures to the bearing, after analysing, the result showed that the external temperature was the main contributor of internal stress, and the rolling element was the part inside of the bearing which suffered the largest stress. To optimize the structure of the continuous casting roller bearing, the rolling element was turned into axial hollow structure, which could reduce the extreme stress of the rolling element bearing. By analysing all the maximum thermal stress of rolling element in different feasible hollowness, and finally the most suitable hollowness could be found out. The analysis results above showed that the optimization of the rolling element structure of the bearing could effectively reduce the internal stress and improve reliability of bearings in high working temperature. The conclusion of this study was significant in bearing optimizing or designing.

Keywords: thermal stress, coupling, structural optimization, continuous casting roller

Cheng Fuwei, Li Gongfa, Liu Honghai, Jiang Guozhang, Liu Ze, Chen Disi,Miao Wei, Li Zhe, Ding Weiliang Temperature data acquisition and remote monitoring of ladle based on LabVIEW

Computer Modelling & New Technologies 2014 ***18****(11) 1320-1325*

Ladle is an important container parts, plays a vital role to storage and operation of steel smelting. The length of the ladle service life directly affects the efficiency of steel production and the cost of production. The service life of the ladle is mainly affected by thermal mechanical stress of ladle lining, thermal mechanical stress is mainly caused by the severe changes of temperature, in order to fully understand the working state of ladle to ensure the safety of the ladle, the ladle temperature monitoring is particularly important. Ladle design of remote monitoring system uses the structured and modular design thought, on the basis of using the LabVIEW virtual instrument platform; realize the collection of ladle temperature data and remote monitoring. Establish ladle remote client monitoring system by TCP communication protocol, realize the ladle monitoring networked. This system uses the real-time waveform display and friendly human-computer interaction interface, greatly enhanced the real-time and visibility of the ladle remote detection system.

Keywords: the ladle, LabVIEW, remote monitoring list

Zhao Liang, Yu Tao A new decoupled sliding mode control approach for the linear motion of a spherical rolling robot

Computer Modelling & New Technologies 2014 ***18****(11) 1326-1329*

This paper investigates the dynamics and control aspects of the linear motion of a pendulum-driven spherical rolling robot. The dynamic model is deduced for the linear motion of a spherical robot by using the Euler-Lagrange formulation. By appropriate definitions the equations of motion for the robotic system are transformed into the state space form. A novel decoupled sliding mode control approach is proposed to achieve set-point regulation of the linear motion. This approach consists of the construction of a cascade sliding mode controller and the design of a nonlinear reaching law by using a switching component that dynamically adapts to the variations of the controlled system. The asymptotic stability of the robotic system is verified through Lyapunov analysis, and the validity of the proposed approach is illustrated through numerical simulations.

Keywords: spherical robot, linear motion, dynamic model, decoupled sliding mode control, exponential reaching law

Bian Xiangjuan, Gong Youping, Zhen Liyun MEMS model order reduction method based on SPRIM

Computer Modelling & New Technologies 2014 ***18****(11) 1330-1334*

According to large scale MEMS united constraints equations, the paper investigates model order reduction (MOR) techniques based on Structure Preserving Reduced-order Interconnect Macro modelling (SPRIM) method, which can be used to generate computationally efficient solutions for multiphasic MEMS simulation. To united constrained model, the high dimensionality of the original system state space is mapped to a suitable low-dimensional subspace, obtained a low-dimensional state sub-space model. A improved algorithms(SPRIM) from Arnoldi algorithms are implemented to extract low dimensional Krylov subspaces from Unified state subspace models for model order reduction, reduced order electro thermal–mechanical models are generated for a MEMS micro beam using the developed programs. Developed programs automatically generate compact structure preserving models and can be used to significantly improve the computational efficiency without much loss in accuracy and model stability for coupled-field MEMS simulation.

Keywords: MEMS (Micro-Electrical Mechanical System), model order reduction, sub-space model, model reflection

Chen Jianjun Wireless monitoring system for temperature and humidity based on ZigBee
*Computer Modelling & New Technologies 2014 **18**(11) 1335-1339*

Traditional methods of environmental monitoring have the shortages including difficult network layout and low intelligent of node. A monitoring system for temperature and humidity was designed based on ZigBee (wireless network), with SHT11 (temperature and humidity integrated sensor) and CC2430 (wireless radio frequency module integrated with MCU). Data of temperature and humidity, collected at some acquisition terminals in SHT11 and CC2430, were displayed on monitoring host via centre node. By using solution of single chip ZigBee, the system was optimized with high precision, low power dissipation and simple equipment.

Keywords: CC2430 wireless network; monitoring temperature and humidity

Zou Jiazhu, Yuan Fengwei, Deng Qian Analyses on flow and heat transfer performance and of heat exchanger with continuous helical baffles
*Computer Modelling & New Technologies 2014 **18**(11) 1340-1345*

A numerical simulation for heat exchanger with continuous helical baffles was carried out. The study focuses on the effects of helix angle on flow and heat transfer characteristics, and heat exchanger performance is evaluated by entropy generation number based on the analysis of the second law of thermodynamics. The results show that both the shell-side heat transfer coefficient and pressure drop decrease with the increase of the helix angle at certain mass flow rate. The latter decreases more quickly than the former. The tangential velocity distribution on shell-side cross section is more uniform with continuous helical baffles than with segmental baffles. The axial velocity at certain radial position decreases as the helix angle increases in the inner region near the central dummy tube, whereas it increases as the helix angle increases in the outer region near the shell. The heat exchange quantity distribution in tubes at different radial positions is more uniform at larger helix angel.

Keywords: continuous helical baffles, heat exchanger, helix angle, entropy generation, numerical simulation

Zhang Jifei Exploratory development of ancient village based on the low carbon travel development model
*Computer Modelling & New Technologies 2014 **18**(11) 1346-1349*

This paper summarized basic theory of low carbon travel and the functional mechanism of the low carbon economy to improve the village tourism development by analysing its conception, and development status and existing problem of the ancient village tourism in the low-carbon tourism development mode of our country nowadays is put forwarded. Combining with actual situation, this paper aims to propose the emission reduction countermeasures in allusion to these problems above, in order to provide certain reference to the development of ancient villages low carbon tourism.

Keywords: Low carbon concept; Low carbon travel; Ancient village travel; Emission reduction countermeasure

Nan Bo, Wu Yue Numerical simulation on winding CFRP pipe axial compression stability
*Computer Modelling & New Technologies 2014 **18**(11) 1350-1355*

Because of the requirements of strict weight, airship structures are usually built by high strength and light-weight CFRP composite truss, CFRP composite tube is the basic unit of it. Winding CFRP tube ultimate bearing capacity has been further improved by combinations of various fiber directions, while stable bearing capacity is an important indicator that could influence the bearing characteristics. It concludes the destruction and deformation characteristics, as well as the relationship between stability factor Φ and slenderness λ, through analysing different CFRP tubes of slenderness ratio with The arc-length method, and drawing the Load-displacement curve, which provided a theoretical basis to better the truss design, and discussed the laws of how component defects affect its stability capacity via a large number of parameters.

Keywords: carbon fiber-reinforced plastic (CFRP), the arc-length method, stability coefficient, slenderness ratio

Luo Xin, Liu Xuezheng, Tao Ran, Shi Youqun Content-based retrieval of music using mel frequency cepstral coefficient (MFCC)
*Computer Modelling & New Technologies 2014 **18**(11) 1356-1361*

In the last few years, with the growing of multimedia in Internet, MP3 music become one of the most popular types. Some of the MP3 music collections available are approaching the scale of million tracks and this has posed a major challenge for searching, retrieving, and organizing music content. In this paper, we proposed a method to retrieve the MP3 lossy compression format music by using MFCC features. The Kullback-Leibler Divergence and Earth Mover's Distance (EMD) are used to compute music similarity. Experiments show that the retrieving probability of our design can achieve high recall values of 95% out of a total of 1951 tracks in the database.

Keywords: content-based music retrieval, MP3, MFCC, kullback-leibler divergence, EMD

Guo Yali, Han Yan, Liu Linmao Inversion strategy research of travel time tomography with sparse rays
*Computer Modelling & New Technologies **18**(11) 1362-1367*

The incomplete data travel time tomography with sparse rays can result in the ill-posed inverse problem in practical engineering, so the inversion strategy is very important in order to obtain reasonable inversion result. In this paper, the generalized inverse theory is taken and the influences are discussed which the system layout, initial model and prior information will impose on the inversion. The indexes of system optimal layout, the selection principle of initial model and regularization methods are presented in this paper. A velocity model of explosion is imitated and the inversion results are compared. A conclusion can be gained that system optimal layout, initial model rational selection and regularization methods utilization can help to improve inversion precision farthest in practical project.

Keywords: sparse rays, inversion strategy, regularization methods

Qiao Wei, Sun Jie, Du Qingfu Diffusion limited aggregation of magnetic particles with exponential decreasing interactions in three-dimensional space
*Computer Modelling & New Technologies 2014 **18**(11) 1368-1373*

Using the Monte Carlo simulation, we investigate the three-dimensional fractal growth of a magnetic diffusion-limited aggregation (MDLA), which consists of magnetic particles interacting with an exponential potential βCe-αr. The cluster morphology, fractal dimension and magnetic susceptibility of this MDLA are analysed with respect to the range facto rα and the coupling energy βC. In the case of long-range ferromagnetic interaction, our results show that the cluster morphology grows to be a hexagonal symmetry as the coupling energy increases, which is different from the two-dimensional simulation. For a proper coupling energy, the fractal dimension takes the maximal value and the cluster morphology becomes more compact. In the case of short-range interaction, the critical value of the cluster specific magnetic moment is much larger than the simulation result in the MDLA with the interacting potential of power law.

Keywords: diffusion limited aggregation, magnetic particle, exponential decreasing potential

Zhang Yuekan, Liu Peikun, Xiao Linjing, Yang Xinghua, Yang Junru Numerical simulation of multiphase flow inside hydrocyclone based on CFD
*Computer Modelling & New Technologies 2014 **18**(11) 1374-1379*

This paper applied computational fluid dynamics (CFD) method to investigate the internal multiphase flow filed in a 75 mm hydrocyclone. The Reynolds stress model (RSM) and VOF model were employed in the numerical simulation. This study discussed the velocity and pressure distribution in the hydrocyclone, and analysed the formation and development mechanism of air core. The numerical simulation results showed that the flow field was very unstable in the region of the air core. The axial velocity gradient reached its maxima, and the turbulent fluctuation was strongest in the simulation region. This study provided theoretical basis on further research of the air core effect on separation efficiency and pressure drop.

Keywords: numerical simulation, multiphase flow, hydrocyclone, CFD

Lin Yisong, Zhuang Mingjie The complexity analysis and performance comparison of MIMO systems based on antenna selection techniques
*Computer Modelling & New Technologies 2014 **18**(11) 1380-1386*

MIMO systems, also known as multiple-input multiple-output, can effectively improve the capacity and reliability of wireless communication. Antenna selection (AS) is a low-cost low-complexity attractive approach in MIMO systems that capture many advantages of these systems. In this paper, we comprehensively review and describe various kinds of AS schemes in MIMO systems. First, we discuss the techniques of antenna selection from the perspective of different channel environments. Analysis results show that exploiting the AS technique can avoid sending redundant information and improve the channel capacity in the low rank and correlated channel conditions. Then the applications of AS systems in spatial diversity and spatial multiplexing are considered. In order to reduce the complexity of AS algorithm, we propose a novel joint transmit and receive AS scheme in MIMO systems. The results of simulations demonstrate that the proposed AS method of performance outperforms other methods, and the proposed algorithm can significantly reduce computational complexity compared to the optimum algorithm. Finally, we summarize some conclusions about the antenna selection.

Keywords: MIMO, antenna selection, spatial diversity, spatial multiplexing

Zhang HongTao, Zhao Wei Design and realization of atmospheric pressure altitude measuring system with

temperature compensation based on FPGA
*Computer Modelling & New Technologies 2014 **18**(11) 1387-1392*

Starting from the analysis of the measuring principle of atmospheric pressure altitude and the necessity of the pressure sensor temperature compensation, this paper presents the design and realization of an atmospheric pressure altitude measuring system with high performance which use FPGA as the data processor and with the pressure sensor temperature compensation design. Article discusses in detail the hardware circuit design of the measuring system, and the internal structure of FPGA software design. At last, the results of system test verify the feasibility and effectiveness of the atmospheric pressure altitude measuring system. Because of the FPGA's characteristics of high reliability, strong data processing ability, high speed and so on, and the effective combination of temperature compensation design, the atmospheric pressure altitude measuring system has the advantages of high measuring precision, high reliability, good real-time and low power consumption.

Keywords: atmospheric pressure altitude, FPGA, temperature compensation algorithm, measuring system

Chen Xiaojie, Qiu Chengjun, Liu Hongmei, Qu Wei, Liu Yibo Design and implementation of a vibration cantilever energy harvester with suspended piezoelectric beam
*Computer Modelling & New Technologies 2014 **18**(11) 1393-1398*

The frequency response and energy conversion efficiency are the critical issue for vibration energy harvester. In this paper, a vibration energy harvester with suspended piezoelectric beam is proposed. This harvester structure is composed of a discrete support beam in the bottom and a suspended piezoelectric beam on top. This suspended beam structure is beneficial to the higher response frequency and the energy conversion efficiency by applying the tension on the shear mode piezoelectric layer. An analytical bending model of suspended piezoelectric beam is developed, based on the actual deformation: rotational and translational movement modes. The characteristic of suspended piezoelectric beam is also analyzed by Finite element method. Finally, a 1000:1 prototype is fabricated and measured. The optimums acquired experiment results show that it is matching well with the model. The maximum of output voltage is 6.5 V.

Keywords: energy harvester, vibration, suspended piezoelectric beam, piezoelectric layer

Ye Pengchao, Guan Xiaochun, Chen Xiaojing Prediction of capacitance of electrolytic capacitor with ripples
*Computer Modelling & New Technologies 2014 **18**(11) 1399-1405*

The electrolytic capacitor is one of the most critical components in the switching power supply, in actual use of the power supply, the ripple is an important factor that leads to failure of the electrolytic capacitor. The research on the ripple's effect on the service life of the electrolytic capacitor is significant to the stability of the switching power supply. This paper designed a controllable circuit generating ripples of different phases, tested the electrolytic capacitors' changes in capacitance with ripples of different phases, analysed the reason of the changes in the capacitance, selected the fastest change, and used three prediction models of support vector regression, radial basis function and kernel-based partial least-squares algorithm to predict the change trends of capacitance of electrolytic capacitor with ripples of this phase. The results showed that compared with radial basis function and support vector regression model kernel-based partial least-squares algorithm can more accurately predict the service life of the electrolytic capacitor.

Keywords: electrolytic capacitor, ripples, different phases, prediction of capacitance, capacitor life

Chen Yang, Zhou Bin, Yin Jingwei Quadratic polynomial fitting of total energy of null subcarriers in underwater acoustic OFDM communication
*Computer Modelling & New Technologies 2014 **18**(11) 1406-1409*

Doppler scale estimation is one key module in underwater acoustic (UWA) orthogonal frequency division multiplexing (OFDM) communication. In this paper, null subcarrier based blind Doppler scale estimation is considered, which is an extremal problem. The cost function is constructed of the total energy of null subcarriers through DFT. The frequencies of null subcarriers are calculated according to non-uniform Doppler shifts at each tentative scaling factor. Then it is proofed that the cost function can be fitted as a quadratic polynomial near the global minimum. So the accurate location of the global minimum can be achieved through polynomial interpolation. This theory is a basement of developing new methods of Doppler scaling estimation and is verified through an experiment conducted in shallow water.

Keywords: orthogonal frequency division multiplexing (OFDM), underwater acoustic (UWA) communication, polynomial interpolation, Doppler scale estimation

Liu Haohua, Wan Zhou, Li Yiyang, Chen Zhunen Research of the vibrating infrasonic sensor based on Fiber Bragg Grating

*Computer Modelling & New Technologies 2014 **18**(11) 1410-1415*

Current research on infrasound more extensive and in-depth, the sensor is essential prerequisite for infrasonic detection, in order to overcome some lack of current infrasound sensor for detecting the infrasound, paper innovative design a vibrating wire sensor structure, and make it capable of receiving a full rang infrasound, range adjustable, easy installation, etc. and use fiber Bragg grating which has obvious advantages in terms of low-frequency detection as the sensing element. Test the performance of the sensor and the results show that the average of the sensor is 6.11%, within 1 Hz-20 Hz range, the sensor has good linearity and small error, has practical value.

Keywords: Fiber Bragg grating; vibration wire; infrasonic sensor

Gao Ang, Hu Yansu, Duan Weijun The error analysis of TDOA based ultrasonic position

*Computer Modelling & New Technologies 2014 **18**(11) 1416-1420*

How to enhance the accuracy and range is a typical issue in the ultrasonic position technology. The position accuracy depends on the hardware architecture and the detecting methods. This paper designs a hardware platform called Hexagon-Buck with six transceivers around. For the inherent property of TDOA (Time of Difference of Arrival) ranging, the RF synchronous time and embedded software processing time are two inevitable factors that leads to the distance error. At the same time, the ultrasonic velocity is sensitive to the environment temperature. The paper considers both the temperature compensation and Least Squares Linear Regression to enhance the ranging accuracy. By taking the physical test data to identify the linear regression model, we can estimate the real distance. The validity of the method has been proved by the final experiment.

Keywords: ultrasonic ranging, TDOA, least squares linear regression, hexagon-buck

Fan Zheng, Zheng Xianfeng The study and design of inter-harmonic detection device based on quasi-synchronous technique in power system

*Computer Modelling & New Technologies 2014 **18**(11) 1421-1424*

On the basis of analyzing the characteristics of harmonic signals, the inter-harmonic detection algorithm of quasi-synchronous sampling is introduced in this paper. This algorithm pre-processes the original sampled signal and separates all the harmonics and inter-harmonics of the reconstructed signal with designed comb FIR filters, to restrain the mutual interference between them, and finally achieve accurate measurement of harmonic and inter-harmonic in power system. At last, the validity of this algorithm is verified with harmonic and inter-harmonic signal generated from standard signal source.

Keywords: quality of electric energy, inter-harmonics, quasi-synchronization, comb FIR filter

Chen Xiaojing, Liu Ke, Ye Peng An optimization method of signal de-noising in discrete wavelet transform based on generalized cross-validation

*Computer Modelling & New Technologies 2014 **18**(11) 1425-1431*

A method for automatically selecting the asymptotical optimal parameters is presented for signal de-noising in discrete wavelet transform. The parameters of wavelet de-noising were first encoded. A generalized cross-validation algorithm was then used to select these parameters automatically. The parameters that obtained the smallest generalized cross-validation were asymptotically optimal. Simulation signals with different features and range signal-to-noise ratios were used to demonstrate the optimality of the proposed method. In addition, the Raman spectrum of edible oil and nuclear magnetic resonance spectrum of quinine and Boc-protected proline were employed as real-world data to validate the proposed method. The proposed method achieved superior performances in both real-world data and in artificial simulation.

Keywords: signal de-noising, wavelet transform, generalized cross-validation, parameter optimization

Tu Chunjuan, Guo Xuhong Research on the machinability when dry turning hardened steel with ceramic tool

*Computer Modelling & New Technologies 2014 **18**(11) 1432-1437*

The experiments of dry turning hardened steel with ceramic tool (CC6050) were carried out. The cutting forces of ceramic tool with different cutting parameters were measured by Kistler cutting force acquisition system, the prediction model of the surface roughness was built by Particle Swarm Optimization (PSO), the wear morphology of the tool and chip characteristics were observed by scanning electron microscope (SEM), analyzed the wear zone of the tool by the EDAXPV990(EDS). Results indicated that the cutting depth was the dominant factor affecting the cutting force, next was feed speed, the minimum was cutting speed. The feed speed was the dominant factor affecting

the surface roughness, next was cutting depth, the minimum was cutting speed. The crater wear was shown on the rake face and the evenly distributed strip shaped wear was shown on the flank of the CC6050 tool, the main wear mechanism was abrasive wear, diffusion wear, adhesive wear and oxidation wear. The shape of chip was saw-tooth, the rough slice layers with periodic flow were shown on the upside of the chip and the streaks were evenly distributed on the underside of the chip. The cutting speed and feed speed were larger, the serrated level of the chip was higher and the angle of shear was larger.

Keywords: Ceramic Tool, Dry Turning, Hardened Steel, Machinability

Wenlong Du Design of reflective optical fiber displacement sensor using double optical paths
Computer Modelling & New Technologies ***18****(11) 1438-1442*

A finite element three-dimension space model is built by ANSYS based on the first multi-tower self-anchored suspension bridge in China. After that, the work aims at developing finite element analysis using backward and forward methods, discussing internal force of main bridge components in different construction stages. Then, linear change law of the main cable in different load conditions is analysed, and mechanism behaviour of this new structure in the whole construction is acquainted. Therefore, the work provides key force analysis for multi-tower self-anchored suspension bridge, making a good example for design and construction of similar bridges.

Keywords: Multi-tower Self-anchored Suspension Bridge, Mechanism Behaviour, Backward Analysis, Forward Analysis, Finite Element

Jiang Fei Optimization of immune particle swarm algorithm and application on wireless sensor networks
Computer Modelling & New Technologies 2014 ***18****(11) 1443-1448*

As a new network technology, wireless sensor network (WSN) have been applied to military, intelligent transportation, environmental monitoring and other fields. Localization is one of the important support technologies of Wireless Sensor Networks. Location information is important to network monitoring. It is meaningless, if there is no location information. We need to adopt a certain mechanism and algorithm to implement the localization of Wireless Sensor Networks. Based on the analysis of the features of Wireless Sensor Networks on range-free positioning algorithm and DV-Hop positioning algorithm error sources, this paper focuses on the improvement research on DV-Hop positioning algorithm. Inspired by biological immune system and mechanism, this paper introduces the immune information processing mechanisms in the immune system to the particle swarm optimization algorithm and thus gets an immune particle swarm optimization (IPSO) algorithm. By applying into the running of DV-Hop positioning algorithm, the paper proposes a DV-Hop improved algorithm, which is, the WSN positioning algorithm based on IPSO algorithm. Simulation experiments show that the improved algorithm can significantly reduce positioning errors to improve positioning accuracy.

Keywords: wireless sensor networks, immune particle swarm optimization, DV-Hop positioning algorithm
