Abstract

The attribute reduction is an important pre-processing step for data mining. In order to avoid striking equivalence classes repeatedly for positive region or information entropy reduction it is proposed to calculate attribute reduction by constructing partition directly. At the same time the judgments of the absolute reduction and the relative reduction based on the equivalent division are proved. And the data description quality for the relative reduction has been defined. It is shown that striking minimum relative reduction of decision table is in the cost of the relative decline of description quality for classification.

Keywords: attribute reduction, partition, rough sets, data mining

1 Introduction

The attribute reduction is an important pre-treating step in the process of data mining [1]. It can reduce the data scale for the following mining effectively [2, 3]. But finding a minimum attribute set is a NP-hard problem due to the combinatorial explosion of properties [4]. It has been the main problem of various reduction algorithms to get results quickly and accurately.

There are three classical methods for attribute reduction, such as distinguish matrix [5], positive region [6] and information entropy [7]. However, the reduction algorithm based on distinguish matrix is only suitable for processing small decision tables relatively because of the matrix calculation increasing the space overhead. So the reduction for large data tables is on the basis of the positive region or information entropy mainly [8]. But calculating equivalence classes is a basic and essential step whether it is positive attribute reduction or information entropy. To avoid duplication of obtaining equivalence classes, it is proposed to reduce directly in the process of equivalence classes obtained. This can decrease computational overhead for the positive region and information entropy reduction.

2 The concept of attribute reduction

The target of attribute reduction is to delete irrelevant or unimportant attributes. There is same basic category between the original set and the set having removed some attributes. Those attributes removed do not change the overall description of the domain. Any object of the information system is on behalf of a class with the same regularity properties after reduction. So the number and composition of the object have been simplified for the information system. This will reduce the time and space overhead for the subsequent data processing. The knowledge used in rough set and equivalence relation is shown as follows:

Definition 1 [9] The information system can be represented as a quadruplet $S = (\tilde{X}, R, V, f)$, where, $\tilde{X}$ represents a non-empty finite set of objects named domain. $\tilde{X} = \{X_1, X_2, \cdots, X_N\}$. X_i is an object. R is attribute set. V represents the set of the property value. V_a is range of the attribute $a \in R$. f is an information function $\tilde{X} \times R \to V$, $a \in R$, $X \in \tilde{X}$, $f_a(X) \in V_a$.

Definition 2 [9] Let A is an attribute set of the information table. a is on behalf of a particular attribute value. The objects X_i, X_j are named equivalence relation with respect to the property A. If X_i, X_j satisfies the relation as follows:

The equation $f_a(X_i) = f_a(X_j)$ founded for $\forall a \in A$, $A \subset R$, $X_i \in \tilde{X}$, $X_j \in \tilde{X}$. This relation is also known as indistinguishable relationship expressed as:

$$IND(A) = \{< X_i, X_j > \mid < X_i, X_j > \in \tilde{X} \times \tilde{X}, \forall a \in A, f_a(X_i) = f_a(X_j)\}. \quad (1)$$

Definition 3 [9] Let object $X \in \tilde{X}$. The set posed by the elements having the same values with X of $\tilde{X}$ on the attribute collection B will be named equivalence class of relation $IND(B)$ as $[X]_B$.

$$[X]_B = \{X_i \mid < X, X_i > \in IND(B)\}, \quad (2)$$

$[X]_B$ is also known as the basic concept or category of the attribute set B.

[*]***Corresponding author*** e-mail: wanghui_wwh@163.com

Definition 4 [9] The partition related to attribute set B on the basis of domain $\tilde{X}$ is expressed as:

$$\pi_B = \tilde{X} / B = \{E_i \,|\, E_i = [X_i]_B, i = 1,2,\cdots\}, \quad (3)$$

the partition has the properties as $E_i \neq \varnothing$. If $i \neq j$ then $E_i \cap E_j = \varnothing$ and $\tilde{X} = \bigcup E_i$.

Definition 5 [10] The entropy $H(P)$ of knowledge P defined as:

$$H(P) = -\sum_{i=1}^{n} p(X_i) \log_2(p(X_i)), \quad (4)$$

where, P is an attribute set of domain $\tilde{X}$.

Definition 6 [10] The partitions of the indistinguishable relationship about attribute set P and Q expressed as $\tilde{X} / IND(P) = \{X_1, X_2, \cdots, X_n\}$ and $\tilde{X} / IND(Q) = \{Y_1, Y_2, \cdots, Y_m\}$. The conditional entropy $H(Q|P)$ about Q related to P defined as:

$$H(Q|P) = -\sum_{i=1}^{n} p(X_i) \sum_{j=1}^{m} p(Y_j|X_i) \log_2(p(Y_j|X_i)), \quad (5)$$

where, $p(Y_j|X_i) = |Y_j \cap X_i| / |X_i|$. $i = 1,2,\cdots,n$. $j = 1,2,\cdots,m$.

Definition 7 [10] Let P and Q are equivalence relation clusters on the basis of domain $\tilde{X}$. The P positive domain of Q defined as $POS_P(Q)$.

$$POS_P(Q) = \bigcup_{X \in \tilde{X}/IND(Q)} P_-(X), \quad (6)$$

where, $P_-(X) = \bigcup \{Y \,|\, Y \in \tilde{X}/IND(P) \wedge Y \subseteq X\}$.

Definition 8 [10] $\tilde{X}$ is a domain. P and Q are attribute sets on the basis of $\tilde{X}$. $r \in P$. If $POS_P(Q) = POS_{(P-\{r\})}(Q)$ then relation r of P is absolutely unnecessary property related to Q. Or r of P is absolutely necessary property. If any $r \in P$ is necessary absolutely that the attribute set P is independent according to Q.

Lemma 1 [10] $\tilde{X}$ is a domain. P is conditional attribute set of $\tilde{X}$. The necessary and sufficient condition that r in P is necessary absolutely is $H(\{r\}|P - \{r\}) = 0$.

Lemma 2 [10] $\tilde{X}$ is a domain. P is conditional attribute set of $\tilde{X}$. d is decision attribute and domain $\tilde{X}$ is consistency with respect to $\{d\}$ on P. Then the necessary and sufficient condition that r with respect to $\{d\}$ is necessary absolutely is $H(\{d\}|P) = H(\{d\}|P - \{r\})$.

Lemma 3 [10] $\tilde{X}$ is a domain. P is conditional attribute set of $\tilde{X}$. d is decision attribute and domain $\tilde{X}$ is consistency with respect to $\{d\}$ on P. Then the necessary and sufficient condition that p with respect to $\{d\}$ is independent is $H(\{d\}|P) \neq H(\{d\}|P - \{r\})$ for any attribute $r \in P$.

Lemma 4 [10] $\tilde{X}$ is a domain. P is conditional attribute set of $\tilde{X}$. d is decision attribute and domain $\tilde{X}$ is consistency with respect to $\{d\}$ on P. Then the necessary and sufficient conditions that $Q \subseteq P$ with respect to $\{d\}$ is a reduction are two things as following:

1) $H(\{d\}|Q) = H(\{d\}|P)$.

2) Q with respect to $\{d\}$ is independent.

3 Reduction description based on partition

The relationship with equal value is an equivalence relation in an attribute information table. Any of equivalence relations will form a partition on the object belonged to the domain. This partition means a kind of classification model corresponding to the domain. The reduction result for attribute information table contains the minimum number of attributes. All of attributes in the reduction set are necessary absolutely. These attributes have same classification compared to all attributes on the domain objects. Generally there are two reduction forms as the absolute reduction and the relative reduction. The absolute reduction process applies to general information processing system. In this system all the properties aren't distinguish, and the reduction contains only part of properties. The relative reduction is suitable for handling special information table as the decision table. The properties are divided into condition attribute and decision attribute in this table. There are multiple properties but only one decision attribute in the table usually. For multi-attribute decision table, the process is needed to convert it into a single decision table at first. The condition attributes and the decision attributes formed a classification model for domain respectively. The reduction means to strike a condition attribute set containing the minimum attributes for the decision table. The result with respect to the decision classification is consistent with all the condition properties and expresses as a subset of condition attribute set. If the relativity of the decision attributes isn't considered the absolute reduction is the relative reduction also. Either the absolute reduction or the relative reduction has similarities to strike a minimum reduction. And the results of the reduction may be multiple normally.

Definition 9 $\tilde{X}$ is a domain. P and Q are attribute sets on the basis of $\tilde{X}$. And $Q \subseteq P$. If $\pi_{IND(Q)} = \pi_{IND(P)}$ and for either attribute $r \in Q$ the formula

$\pi_{IND(Q)} \neq \pi_{IND(Q-\{r\})}$ is founded. Then Q is an absolute reduction with respect to P.

Definition 10 $\tilde{X}$ is a domain. P and Q are attribute sets on the basis of $\tilde{X}$. And $Q \subseteq P$. d is decision attribute. If $POS_P(\{d\}) = POS_Q(\{d\})$ the Q is a relative reduction with respect to P.

In short, the main problem of attribute reduction is committed to strike less conditions meeting the consistent classification. The absolute reduction is suitable for general information table. The information table reduced can be used for finding association rules, clustering and other data mining process. The relative reduction is applicable to special information table like decision table. The classification rules can be generated with respect to the decision attributes through reduction. But the absolute reduction does not mean the relative reduction. The absolute reduction has strong constraint.

3.1 ABSOLUTE REDUCTION BASED ON PARTITION

The indistinguishable relation of the absolute reduction set will generate classification with objects on the domain. If a property a has r value that it will form a partition $\tilde{X}/\{a\}$ involving r equivalence classes for all objects of the domain. $\tilde{X}/\{a\} = \{X_1, X_2, ..., X_r\}$. When the rest of properties add to the equivalence classes as a part of the division the classes will be split likely. So the classification will be refinement further. When adding an attribute does not change the equivalence classes of division this property having no contribution to the classification is unnecessary. If the division generated by the distinguished relationship on the attribute set is smallest that the remaining properties can be reduced as unnecessary attributes.

Definition 11 The information system is a quadruplet $S = (\tilde{X}, R = C \cup D, V, f)$, where $IND(P)$ and $IND(Q)$ are indistinguishable relationships on C and $\tilde{X}/IND(P) = \{X_1, X_2, ..., X_m\}$, $\tilde{X}/IND(Q) = \{Y_1, Y_2, ..., Y_n\}$. For any $X_i \in \tilde{X}/IND(P)$ there is a $Y_j \in \tilde{X}/IND(Q)$ making $X_i \subseteq Y_j$ established. And there are $X_k \in \tilde{X}/IND(P)$ and $Y_r \in \tilde{X}/IND(Q)$ making $X_i \subseteq Y_j$ established at least. So the partition $\tilde{X}/IND(P)$ is more refined than $\tilde{X}/IND(Q)$. Or $\tilde{X}/IND(P)$ is a subdivision of $\tilde{X}/IND(Q)$.

Theorem 1 The information system $S = (\tilde{X}, C, V, f)$. $C' \subseteq C$ .The necessary and sufficient condition that the property $r \in C - C'$ is unnecessary absolutely is $\pi_{C'} = \pi_{C' \cup \{r\}}$.

Proof (Sufficiency) Let $\pi_{\{r\}} = \{B_1, B_2, \cdots B_k\}$ and $\pi_D = \{C_1, C_2, \cdots C_m\}$. According to the system S, if $\pi_{C'} = \pi_{C' \cup \{r\}}$ then $IND(C') = IND(C' \bigcup \{r\})$. Let $\pi_{C'} = \pi_{C' \cup \{r\}} = \{A_1, A_2, \cdots A_n\}$. And the partition $\pi_{C'}$ is more refined than $\pi_{\{r\}}$. From the definition 4 of equivalence division, either $A_i \subseteq B_j$ or $A_i \bigcap B_j = \varnothing$ has been established for any A_i or B_j. So $p(B_j|A_i) = 1$ or $p(B_j|A_i) = 0$. From the Equation (5) it is known that $H(\{r\}|C') = -\sum_{i=1}^{n} p(A_i) \sum_{j=1}^{m} p(B_j|A_i) \log(p(B_j|A_i)) = 0$.

According to Lemma 1 that attribute r is absolutely unnecessary relative to C'.

(Requirement) If the attribute r is absolutely unnecessary relative to C' then $IND(C') = IND(C' \bigcup \{r\})$. From one to one relationship between the equivalence relation and the division the equation $\pi_{C'} = \pi_{C' \cup \{r\}}$ is founded.

Theorem 1 illustrates that both equivalent division reduction and information entropy reduction are similar to for determining the absolute necessary properties. The process for seeking absolute reduction based on equivalent partition is shown according to the data in Table 1.

TABLE 1 Information table of sample (1)

$\tilde{X}$	a_1	a_2	a_3
x_1	1	1	1
x_2	0	0	0
x_3	2	1	3
x_4	1	0	3
x_5	1	1	1
x_6	3	2	2
x_7	3	0	0
x_8	0	0	0

From Table 1, $R = \{a_1, a_2, a_3\}$. Beginning from the attribute a_1 for division construction, the division formed by increasing properties a_2 and a_3 sequentially is shown as:

$$\tilde{X}/\{a_1\} = \{\{x_1, x_4, x_5\}, \{x_2, x_8\}, \{x_3\}, \{x_6, x_7\}\},$$

$$\tilde{X}/\{a_2\} = \{\{x_1, x_3, x_5\}, \{x_6\}, \{x_2, x_4, x_7, x_8\}\},$$

$$\tilde{X}/\{a_1, a_2\} = \{\{x_1, x_5\}, \{x_4\}, \{x_2, x_8\}, \{x_3\}, \{x_6\}, \{x_7\}\},$$

$$\tilde{X}/\{a_1, a_2, a_3\} = \{\{x_1, x_5\}, \{x_4\}, \{x_2, x_8\}, \{x_3\}, \{x_6\}, \{x_7\}\}.$$

From the result of division, it is seen that the distribution of equivalence classes division has not changed by adding a_3. So the attribute a_3 is unnecessary absolutely. $\{a_1, a_2\}$ is independent because of

$\tilde{X}/\{a_1,a_2\} \neq \tilde{X}/\{a_1\}$ by removing a_2. As same time, $\tilde{X}/\{a_1,a_2\} \neq \tilde{X}/\{a_2\}$ by removing a_1. An absolute reduction of R in Table 1 is $\{a_1,a_2\}$. By similar method $\{a_1,a_3\}$ is the other absolute reduction of R too. It can be seen that the absolute reduction of the information system is not the only.

From the above analysis, removing unnecessary property does not change the original classification ability of the information system because this attribute is not able to provide new information for further subdivision to the objects of the domain. And the results are the same on the contrary. So seeking absolute reduction process can be carried out by dividing the refinement. At first any of property is selected to make division according to their different values by scanning information system vertically. Then adding the remaining property individually will divide refinement in equivalence class set until the division does not change.

An absolute reduction set contains minimum attributes for all objects described on the field. But the relative reduction issues tend to be more concerned in the application process. This problem is what conditions would lead to the decision situation occurred.

3.2 RELATIVE REDUCTION BASED ON PARTITION

Both condition attribute set and decision attribute set will be formed division on the domain for special information system like decision table. At this time the relationship between one classification and another tends to be more concerned. At this point the attribute reduction goal is to focus on finding some necessary properties from condition set. The classification capability of these properties is same as all conditions relative to decision attribute. This leads to the concept of relative reduction.

In a decision table, P is condition attribute set and Q is decision attribute set. According to the definition 7 refining division will lead to changes in the positive region $POS_P(Q)$. The attributes that does not belong to the positive region originally are likely to fall in the region. When all equivalence classes refined fall within the equivalence classes corresponding decision this condition set is a reduction. The following theorem will be founded.

Theorem 2 The information system $S=(\tilde{X},R,V,f)$. $R=C\bigcup D$. The domain $\tilde{X}$ is consistent with respect to the decision attribute set D, $C^{'}\subseteq C$, π_D is a partition formed by decision attribute. $\pi_{C^{'}}$ and π_C are division formed by indistinguishable relationship on the condition attribute set $C^{'}$ and C. If both of conditions are true as following that the attribute set $C^{'}$ is a D reduction of C.

1) $\pi_{C^{'}}$ is a subdivision of π_D.

2) $\neg\exists r((r\in C^{'})\wedge\pi_{C^{'}-\{r\}}$ is a subdivision of π_D).

Proof:

Let $\pi_{C^{'}}=\{X_1^{'},X_2^{'},\cdots,X_m^{'}\}$, $\pi_C=\{X_1,X_2,\cdots,X_n\}$. $\pi_D=\{Y_1,Y_2,\cdots,Y_k\}$. The equation $POS_C(D)=\tilde{X}$ is founded because of the domain $\tilde{X}$ is consistent with respect to the decision attribute set D. So $\pi_{C^{'}}$ is a subdivision of π_D.

For any $X_i^{'}\in\pi_{C^{'}}$ there is $Y_j\in\pi_D$ making the equation $X_i^{'}\subseteq Y_j$ established because $\pi_{C^{'}}$ is a subdivision of π_D. At the same time knowing from Definition 4 that $X_i^{'}\bigcap Y_l=X_i^{'}$ or $X_i^{'}\bigcap Y_l=\varnothing$ is founded for any $Y_l\in\pi_D$. So $p(Y_l|X_i^{'})=1$ or $p(Y_l|X_i^{'})=0$. From the Equation (5) and $C^{'}\subseteq C$,

$H(D|C^{'})=-\sum_{i=1}^{n}p(X_i)\sum_{j=1}^{k}p(Y_j|X_i)\log(p(Y_j|X_i))=0$. In the same way $H(D|C)=0$ because $\pi_{C^{'}}$ is a subdivision of π_D.

Assuming there is a property $a\in C^{'}$ making the equation $H(D|C^{'})=H(D|C^{'}-\{a\})$ established. In other words the conditional entropy of attribute set $C^{'}$ is equal to the entropy of $C^{'}-\{a\}$ with respect to the decision attribute set D. And because the domain $\tilde{X}$ is consistent with respect to the decision attribute set D that the attribute a is unnecessary by Lemma 2. a in $C^{'}$ does not affect its classification with respect to D. Then $\pi_{C^{'}}=\pi_{C^{'}-\{a\}}$ or $\pi_{C^{'}-\{a\}}$ is a subdivision of π_D. This conflicts to the condition (2) that $\neg\exists r((r\in C^{'})\wedge\pi_{C^{'}-\{r\}}$ is a subdivision of π_D). So the assumption does not hold. And any $r\in C^{'}$ the formula $H(D|C^{'})\neq H(D|C^{'}-\{r\})$ is founded. By Lemma 3 it is shown that $C^{'}$ is independence. So $C^{'}$ is a reduction by Lemma 4.

Theorem 2 illustrates that the attribute reduction is a subset of the condition attribute set C with respect to the decision set D. And the result of the reduction is relatively consistent with the division to the domain forming by all attributes of C. But the reduction does not include redundant attributes. Therefore, the attribute reduction based on the partition can be expressed as to strike a subset $C^{'}$ of the condition attribute set C. This subset $C^{'}$ is consistent with C for classification relative to the decision D.

4 The description of the reduction quality for data classification based on the equivalent division

In general case, the attribute information table containing more attributes of the universe is more detailed for object description. But too much attributes will influence the

comprehensive feature extraction for domain objects. Attribute reduction to facilitate the comprehensive knowledge extraction will lead to a quality decline on the object description in the domain. At present the property set of the absolute reduction forms smaller classification to the universe objects. This reduction is more detailed to the object description. In contrast the description to relative reduction on the domain object is rough. The data description quality for relative reduction is defined as follows.

Definition 12 The information system $S=(\tilde{X},R,V,f)$. $R^{'}$ is absolute reduction set and $C^{'}$ is relative reduction set, $\pi_{R^{'}}=\{X_1,X_2,\cdots,X_n\}$, $\pi_{C^{'}}=\{Y_1,Y_2,\cdots,Y_m\}$. The definition description of the quality of the classification to the domain as follows:

$$r_{C^{'}}(R^{'})=\left|\pi_{C^{'}}\right|/\left|\pi_{R^{'}}\right|. \tag{7}$$

It is shown in Table 2 by adding a row of decision attributes to Table 1.

TABLE 2 Information table of sample (2)

$\tilde{X}$	a_1	a_2	a_3	d
x_1	1	1	1	0
x_2	0	0	0	1
x_3	2	1	3	0
x_4	1	0	3	0
x_5	1	1	1	0
x_6	3	2	2	1
x_7	3	0	0	1
x_8	0	0	0	1

In Table 2, $R=\{a_1,a_2,a_3,d\}$. The division is constructed with the beginning of the property a_1 with respect to the decision attribute $\{d\}$. Part of the division is shown as following:

$$\tilde{X}/\{d\}=\{\{x_1,x_3,x_4,x_5\},\{x_2,x_6,x_7,x_8\}\},$$

$$\tilde{X}/\{a_1\}=\{\{x_1,x_4,x_5\},\{x_2,x_8\},\{x_3\},\{x_6,x_7\}\},$$

$$\tilde{X}/\{a_1,a_2\}=\{\{x_1,x_5\},\{x_4\},\{x_2,x_8\},\{x_3\},\{x_6\},\{x_7\}\},$$

$$\tilde{X}/\{a_1,a_3\}=\{\{x_1,x_5\},\{x_3\},\{x_4\},\{x_6\},\{x_7\},\{x_2,x_8\}\}.$$

The results can be drawn from the result. The absolute reduction generated by Table 2 is $\{a_1,a_2\}$ or $\{a_1,a_3\}$. The partition $\tilde{X}/\{a_1,a_2\}$ or $\tilde{X}/\{a_1,a_3\}$ is finer than $\tilde{X}/\{a_1\}$. But $\tilde{X}/\{a_1\}$ is subdivision of $\tilde{X}/\{d\}$ also and the classification can be done with respect to the decision attribute $\{d\}$. It is shown that the relative reduction results of Table 2 is $\{a_1\}$ by Theorem 2. The description classification quality of $\{a_1\}$ can be calculated by the Equation (7). $r_{\{a_1\}}(\{a_1,a_2\})=r_{\{a_1\}}(\{a_1,a_3\})=0.67$. Therefore striking minimum relative reduction of decision table is in the cost of the relative decline of description quality for classification. To improve the quality described on the domain objects some of the properties need to be increased on the results of the relative reduction for further refinement. The finer division are more specific for domain description.

Striking minimum attribute reduction and seeking higher classification description quality of the decision table cannot be taking into account. In the actual application this will be weighed in accordance with the characteristics of the field.

5 Conclusions

In classical rough set theory, attribute reduction is on the basis of positive region, distinguish matrix and information entropy. However calculating the distinguish matrix is excessive. And calculating equivalence classes is important basic steps for positive region or information entropy. The determination and proof for refinement reduction are given from absolute and relative reduction. It is shown that striking minimum relative reduction of decision table is in the cost of the relative decline of description quality for classification. These results must be processed according to the knowledge of specific fields.

A path planning algorithm research for seeing eyes robot based on visibility graph algorithm

Chao Chen, Jian Tang, Zuguang Jin*

School of Mechanical Engineering, Jiangsu University of Science and Technology, Zhen Jiang 212003, China

Received 1 March 2014, www.cmnt.lv

Abstract

This paper presents a new indoor path planning algorithm for seeing eyes robot using the RFID system. Through combination of UHF radio frequency identification system and low radio frequency identification system to realize accurate positioning for robot. New algorithm combines the idea of visibility graph algorithm with A* search algorithm, which not only improves the efficiency of searching but also guarantees the feasibility of path planning at the same time. The simulation verify the effectiveness and feasibility of the method.

Keywords: path planning, seeing eyes robot, visibility graph algorithm

1 Introduction

Path planning is an important element of seeing eyes robot system, which can fall into two types: First, global path planning, information on the surrounding environment is completely known for path planning; Second, local path planning, information on the surrounding environment is completely unknown or part unknown for path planning. In this paper, we objective is to build an indoor robotic guide for the visually impaired, so the best choice for us is global path planning. Global path planning involves two basic problems are environment modelling and search strategy. For environment modelling the typically method is visibility graph, which need less modelling time and Smaller storage space. When accurate localization information is obtain hardly, this algorithm can made robot to achieve the target point. Visibility graph use similar polygon instead of obstacles which in surrounding environment to make a map, and then utilize straight lines that not intersection with obstacles polygon in map to connect initial point, target point and obstacles polygon vertex. These lines are "lines-of-visibility" and the endpoint of lines-of-visibility are "points-of-visibility". The visibility graph is consist of lines-of-visibility. Once the map is generated, the robot computes and follows the optimal path to destination autonomously with search strategy. But visibility graph algorithm lack of flexibility and have highly complexity. When initial point and target point changed, the robot need to reconfiguration the map [1]. In our strategy, the new algorithm combines the idea of visibility graph algorithm positioning with A*, which not only improves the efficiency of searching but also guarantees the feasibility of path planning at the same time. It is used heuristic means to enhance the environment adaptability and improve the real-time of visibility graph algorithm. The simulation verify the effectiveness and feasibility of the new algorithm.

2 Environment model

2.1 HARDWARE

In this paper, we use a independent design seeing eyes robot for the application object, which consist of four layers yakeli board. The robot has three wheels, one universal wheel in front and two driving wheel in the back, 8 ultrasonic sonars in the front, two infrared sensor on the both sides, a Siemens PLC, a voice module, a radio frequency identification module, and is equipped with two stepping motors that control by PLC. Figure 1 shows the integral structure of seeing eyes robot.

2.1 ENVIRONMENT MODEL CREATION

We use a radio frequency identification (RFID) module to obtain rang data of the surroundings. The RFID module consist of a radio frequency identification reader and several RFID tags. The radio frequency identification reader mounted on top of the robot. These RFID tags can be attached to obstacles in the environment and stored the information of the obstacles such as global coordinates, feature points and so on. They do not require any external power source or direct line of sight to be detected by the RFID reader. They are activated by the spherical electromagnetic field generated by the RFID reader with a radius of approximately 1.5 meters. Each tag is programmatically assigned a unique ID.

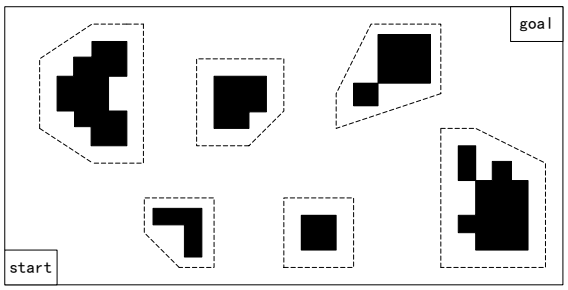

FIGURE 2 Mapping of environment model

As it can be seen in Figure 2, we use similar polygon instead of obstacles in the environment. Because of seeing eyes robot simplified to a point of 2D coordinates, obstacles polygon should be enlarge the object regions by $\omega/2 + a$, where ω is the robot width and a is the positional uncertainty of the robot (currently, 15cm) [2]. We only consider the obstacle polygon which is convex polygon and edge number less than seven. Those complex obstacles, such as concave polygon or roundness and so on, should be expansion to the convex polygon which accord with the requirements. Once the feature points of the obstacle polygon are known, we can record the information of the obstacle. During this process, we can record the information of the obstacles in environment to make a map. We should storage all points-of-visibility which in addition to itself of each feature point for path planning.

3 Indoor of robot localization

Because of the superiority to obtain the information of environment, the RFID system is very suitable for robot localization. But this system gained accurate localization information hardly, that it is easy by environmental influences [3]. In our method, we combine the uhf RFID module with low-frequency module, which reduce uncertainty of localization information due to effect of environment. We will introduces this method for the following aspects. First, the uhf RFID tags were attached to obstacles in the environment and stored the information of obstacles and the global coordinates of label. Second, the uhf RFID reader which mounted on the robot get the environment information, such as feature points of obstacles global coordinates of labels and received signal strength indicator (RSSI), by read the RFID tags in environment [4]. Because of the environmental influences is largely for RSSI, median strategy used to reduce this influences. By this strategy, the RFID reader collect n values of RSSI for a tag, and then these values be accorded to order of from big to small. The intermediate value is considered as the measurement result. Once the measurement result were obtained, we can make the RSSI value into distance value:

$$d = 10^{(ABS(RSSI)-A)/(10*n)}, \quad (1)$$

where A is the RSSI value when the distance from the reader to the tag one meter (currently, –45.8), and n is the attenuation coefficient of signal which because of the environmental influences (currently, 3). At a time, the reader receive many information of the tags in the environment. We choose three tags as nodes for localization which distance from the robot more recently, that the relative distance between tag and the robot is closer, the influence to robot localization is greater. Because of the complexity of environment, the estimated of distance between tag and the robot is greater than the actual one [5]. As can be seen in Figure 3, if three nodes' coordinates are $p_1(x_1, y_1)$, $p_2(x_2, y_2)$, $p_3(x_3, y_3)$, the estimated of distance values between tags and the robot are r_1, r_2, r_3, we used p_1, p_2, p_3 as the center of circle and used r_1, r_2, r_3 as the radius to painting circle.

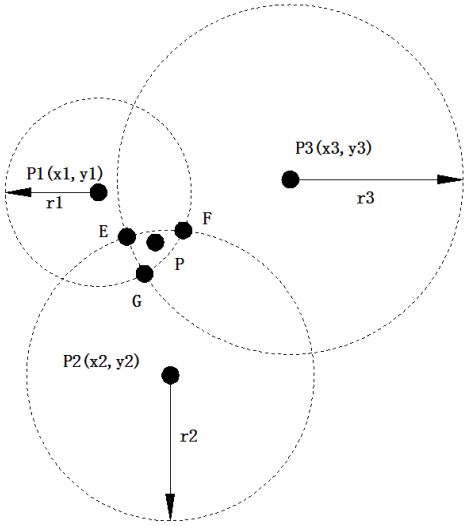

FIGURE 3 Location method

We were use triangle centroid localization algorithm to get the global coordinates of the robot in environment. In this method, the robot location is in two phases: First, we should calculation the three feature points coordinates which are the points of intersection of three circles and must in the overlap area of the three circles at the same time. And then, the position of robot is the centre of mass of tri-angular, which the three vertices of the triangular are the three feature points. To sum up, we can find out the

global coordinates of point $E(x_e, y_e)$ using the Equation (2). In a similar way, we can obtain the global coordinates of point $F(x_f, y_f)$ and point $G(x_g, y_g)$. As indicated above, we can get the global coordinates of the point $P\left((x_e + x_f + x_g)/3, (y_e + y_f + y_g)/3\right)$, which is the position of seeing eyes robot:

$$\begin{cases} \sqrt{(x_e - x_1)^2 + (y_e - y_1)^2} \le r_1 \\ \sqrt{(x_e - x_2)^2 + (y_e - y_2)^2} = r_2 \\ \sqrt{(x_e - x_3)^2 + (y_e - y_3)^2} = r_3 \end{cases}. \quad (2)$$

In the similar way, we can obtain the global coordinates of the point $P_1\left((x_{e+1} + x_{f+1} + x_{g+1})/3, (y_{e+1} + y_{f+1} + y_{g+1})/3\right)$ in other time. If the direction of the robot is θ. We can get this value as follows:

$$\theta = arctan\frac{(y_{e+1}+y_{f+1}+y_{g+1})/3-(y_e+y_f+y_g)/3}{(x_{e+1}+x_{f+1}+x_{g+1})/3-(x_e+x_f+x_g)/3}. \quad (3)$$

Then, we can layout low-frequency RFID tags in the environment which as a signpost. The low-frequency RFID reader were installed in the bottom of the robot for read the global coordinates which stored in the low-frequency RFID tags as the current coordinates of the robot, that reduce the location error which produced by the above localization algorithm and the robot move. Figure 4 show the layout of the low-frequency RFID tags in each intersection, that the read rang of the low-frequency RFID tags is small (currently, 10cm). In this manner, each tag apart to 20cm, and like this the robot can read the tags whether direction it passed through the intersection. If the robot read only to a tag, we used the global coordinates of this tag as the current coordinates of the robot. If the robot read two tags at the same time, we used the midpoint of the two tags as the current coordinates of the robot, for example, the robot read tag 1 and tag 2, the coordinates of the robot are $\left((x_1 + x_2)/2, (y_1 + y_2)/2\right)$. And if the robot read three tags, we used the center of mass of tri-angular, which the three vertices of the triangular are the three tags, as the current coordinates of the robot. For example, the robot read tag 2, tag 3 and tag 5, the coordinates of the robot are $\left((x_2 + x_3 + x_5)/3, (y_2 + y_3 + y_5)/3,\right)$. The location error of the robot were control within 10cm by this strategy.

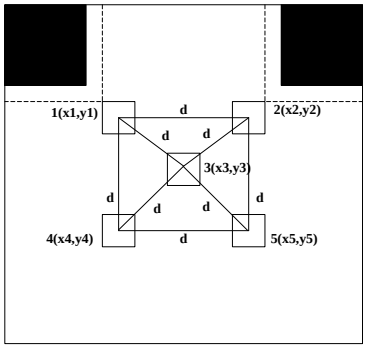

FIGURE 4 Mapping of low frequency tags

4 Description of the algorithm

4.1 THE RELATIVE POSITION OF LINE SEGMENT AND OBSTACLES

In the path planning process, we need to determine whether the desire line in conflict with obstacles in the environment [6]. In our strategy, as can be seen in Figure 5, if the desire line is the line segment SG which the starting point is S and the end point is G, we need to judgment whether S in conflict with the obstacle $ABCDE$. First, we should to work out the distances which between point S and the each feature of the obstacle are d_1, d_2, d_3, d_4, d_5 Second, we will make this distances to sorting by length and choose two feature points which distance from the S recently. Then, we need to judgment whether the line SG in conflict with the obstacle boundary line which the endpoint contain the two feature points. As shown in Figure 5, we need to judge whether the line SG in conflict with the lines AE, AB and ED. Obviously, if they are conflict that the line SG is in conflict with the obstacle; and if they are not intersect that the results is on the contrary. Therefore, the problem that whether the line SG in conflict with the obstacle is transformed into judge whether the line in conflict with the lines AE, AB and ED. As shown in Equation (4), the lines SG, AE, AB and ED were depicted as linear equation:

$$Ax + By + C = 0. \quad (4)$$

We can get the distance between points x, y and a line as follows:

$$d = (Ax + By + C)/\sqrt{A^2 + B^2}. \quad (5)$$

We can find it easily, in the coordinate system which as shown in Figure 5, that if the point is located in the top of the line, the value of d is less than zero, and if the point is located in the below of the line, the value of is greater than zero. Using the above relationship, if d_a is the distance between point A and line SG and d_e is the distance between point E and line SG, when $d_a * d_e < 0$ that the line SG is in conflict with the line AE; when $d_a * d_e = 0$ that the line SG is in conflict with the line AE and the node is the obstacles feature points, because of the line SG and AE only intersection one point and the obstacles were enlarged, so that the line AE not to interfere in the line SG; when $d_a * d_e > 0$ that the line SG is not in conflict with the line AE. In the similar way, we can judge whether the line SG in conflict with the line AB and line ED. Then we can judge whether the line SG in conflict with the obstacle.

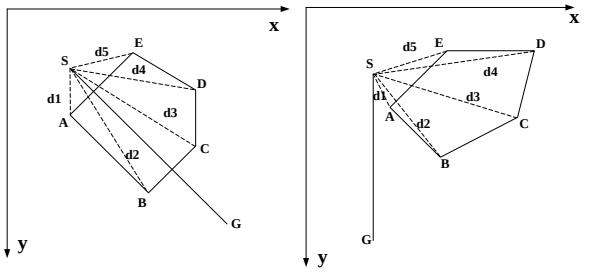

FIGURE 5 Verdict for relative of line SG and obstacle

4.2 VERDICT FOR POINTS-OF-VISIBILITY

In path planning process, when the change of the starting point and goal point, we need to search out new points-of-visibility for it. Therefore, we proposes a judgment method to judge whether a feature point of obstacles is the points of visibility for any point in space. We can find it easily that when obstacles polygon edge number less than seven, the number of the feature points of obstacle which can be the points of visibility for any point in space are no more than four, and the four points that distance from the point in space recently. Obviously, when without taking into consideration other obstacles in the environment, if the distance between the point in space and the feature point is shortest, and this feature point must be the points of visibility for the point in space [7]. In our strategy, the verdict for points of visibility in two phases: First, we only considerate one obstacle, if one feature point of the four points are not the points of visibility for the point in space, that the line of the feature point attach to the space point must be in conflict with the obstacle boundary line which the endpoints contain the nearest feature points. Therefore, we get the relative position which the line of the feature point attach to the space point and the obstacle boundary line which the endpoints contain the nearest feature points by the above method, and choose the feature points which are the points of visibility for the space point. Second, we need to judge whether the lines of this feature points attach to the space point in conflict with other obstacles in environment. If they are intersect, the feature point is not the points of visibility for the space point, and if they are not intersect that the results is on the contrary.

For example, as can be seen in Figure 6, the four points are point E, point F, point D and point A. Then, we need to judge whether the lines MF, MD and MA in conflict with the lines EF and ED. We can find that point E, point F and point D are the points of visibility for point M. And then, we should to judge whether the lines MF, MD and ME in conflict with other obstacles in the environment. Finally, we find that the points of E and D are the points of visibility for point M.

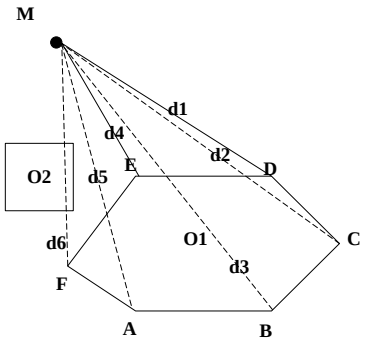

FIGURE 6 Verdict for points-of-visibility

4.3 THE ALGORITHM OF PATH PLANNING

A^* is a typical heuristic search algorithm in artificial intelligence, which uses a valuation function to estimate the weights of each node of the best, and work out the shortest path in the state-space [8]. In this paper, we should collect environment information by radio frequency identification module and voice module, and then combined with A^* algorithm for proposed a path planning algorithm. The algorithm processes as the following:

1) Create a two-dimensional environment model.

2) By UHF radio frequency identification module combined with low-frequency radio frequency identification module, the robot gets the current coordinates as starting point of S, and then obtain the information of the target point G by voice input functionality of voice module.

3) Search the feature points which can be the points of visibility for point S in the environment model.

4) Starting point of S joined the open list (open list is like a shopping list, and the path may through the point of it contain or may not be), as the current point. This article begins to search by formula 6 which as the valuation function.

$$f = g + h, \tag{6}$$

where the value of g is the actual value which is the travelled distance of from the starting point along the path to the current point. The value of h is the estimated value which is the euclidian distance of the current point to the target point. If the current point coordinates are (x_d, y_d) and target point coordinates are (x_m, y_m), you have:

$$h = \sqrt{(x_m - x_d)^2 + (y_m + y_d)^2}, \tag{7}$$

5) The current point was switched to the closed list (closed list saved all points that do not need to check again), and removed from the list of open. Then, we need to judge whether the feature points of obstacles which are the points of visibility for current point in the closed list. If in, we should skip over this point. Instead judge whether the feature points of obstacles which are the points of visibility for current point in the open list. If does not in, we are to the current point as its parent node for calculation

out its value of g, h and f and this feature point will joined in to the open list. If in, we should check new path whether more excellent by g value (g value is smaller, the path is better). If more excellent that we should change the parent node of the point to current point and update its value of g, h and f.

6) Judge whether the open list is empty, and if the open list is empty that the path does not exist, the algorithm ends.

7) Take the point which in the open list and the value of f is minimum as current point. And judge whether current point is the points of visibility for target point, if it is, we are to the current point as the parent node of target point for calculation out its value of g, h and f, and the target point joined in to the open list, the path is finding, end of the algorithm; otherwise go to step 5.

8) Save the path. Along every point of the parent point from the target point move until it is back to the starting point, and save the experienced points into the form of an array, reverse the order of the array, and then the array is the path.

4.4 PERFORMANCE ANALYSIS OF ALGORITHM

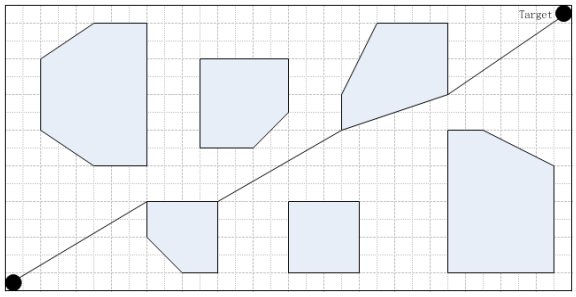
In this paper, we focus on the advantages and disadvantages of visibility graph algorithm, that proposed a path planning algorithm for the seeing eyes robot. This algorithm provides the method for judge the relative relationship of arbitrary points and the feature points of obstacles. The method ensure that path planning without need to refactor visual map when the starting point or target point is changed. Real time the path planning algorithm based on visibility graph are poor [9]. Such as the typical path planning algorithm of Dijkstra [10] based on visibility graph, it calculates the shortest path to each node to all other nodes, the main characteristics are use the starting point for the centre to the outer layers expand, until the expansion until the target point. Because of traverse a lot of nodes, its efficiency is very low. The new algorithm combines the idea of visibility graph algorithm with A^* search algorithm, and use of heuristic search approach greatly reduces the number of search nodes, that not only improves the efficiency of searching but also guarantees the feasibility of path planning at the same time.

5 Experimental debugging

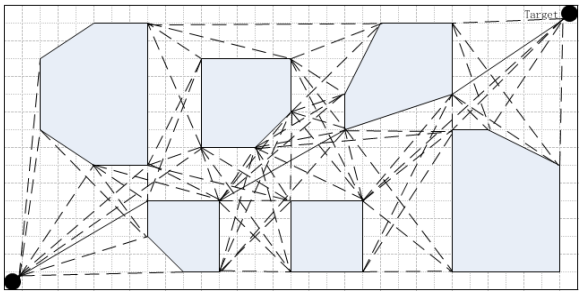
In the same of environment, we conducted simulation contrast test for the new algorithm and Dijkstra algorithm in MATLAB. We get the same path, but the new algorithm search time obvious is less than Dijkstra algorithm and the efficiency superior than the latter. And that the new algorithm can immediately again planning out effective path without need to refactor visual map when the starting point or target point is changed, but Dijkstra algorithm can't. As shown in Table 1 for the survey results of many experiments, Figure 7 are the find path of this article algorithm and Dijkstra algorithm, thus it can be seen that the new algorithm is better than Dijkstra algorithm.

TABLE 1 The time of search path

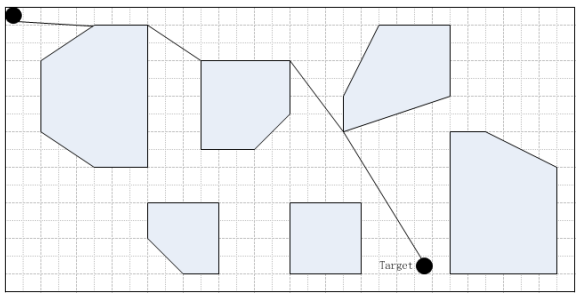
	minimum	**maximum**	**average**
New algorithm	0.4560s	0.8650s	0.6605s
Dijkstra algorithm	1.3550s	1.9460s	1.6505s



a) The path were found by the new algorithm



b) The path were found by Dijkstra algorithm



c) The path were found when the starting point or target point is changed

FIGURE 7 search path

Using the programming to the new algorithm to do the experiment, test sites and seeing eyes robot such as shown in Figure 8. In the process of moving, the robot getted the target point information by voice module, the system of robot will immediately planned an optimal or sub-optimal path which from the current position of the robot to the target point, and moving along the path until it reach the target point. Through the experiments that generate the executable path, meet the run-time requirements of robot, verify the viability and effectiveness of the algorithm.

FIGURE 8 Indoor environment experiment of robot

6 Conclusion

This article combines advantages of RFID module and voice module which on the data acquisition, first the robot gets the orientation of itself by UHF radio frequency identification module combined with low-frequency radio frequency identification module; then create the obstacles map by the idea of obstacles expansion and visibility graph; and then obtained the information of target point by voice module; finally use the search algorithm of *A** to search out the path which connection the starting point and target point. Experiments have shown that, the new algorithm which not only improves the efficiency of searching but also guarantees the feasibility of path planning at the same time.

Received 1 October 2014, www.cmnt.lv

Abstract

With the development of Internet, software has more and more collaborative trends. Collaboration application is becoming a new hotspot. Development of collaborative application process is complicated and need many technologies to realize it. It is difficult for an ISV (Independent Software Vendor) or a business department to provide all application modules of a whole collaboration application. Moreover it is difficult to integrate heterogeneous application module developed by different organizations (ISV or business department). According to the problems mentioned above, this paper proposes a PaaS platform framework to build collaboration application dynamically and flexibly. Such PaaS platform can provide the ability of application delivery deployment for organizations and provide the ability of collaboration application customization for end users.

Keywords: cloud computing, PaaS, collaboration application, process

1 Introduction

With the development of Internet, software has more and more collaborative trends. Collaboration application is becoming a new hotspot. Industry-specific functionality software has huge demand for complex collaborative applications. Collaboration is based on existing business organizations, through information exchange between applications and resource sharing, to achieve a unified business objective. For example, in the field of e-commerce, collaboration between different organizations is very obvious. For an e-commerce application collaboration system, it needs to achieve integration of many e-commerce applications, like online shop system, electronic payment systems, logistics systems. Resources and services that belong to different organizations and business execution is cross-organizational collaboration. It needs a lot of the underlying implementation technology to building such a huge complex process information systems. Currently it is lack of support for collaborative applications dynamically build support platform.

PaaS (Platform as a Service) [10] as a cloud computing [1, 2] service model that provides a new kind of software development, delivery, deployment and usage patterns, but also bring new technical support for designing, developing large-scale network collaborative applications. However, most studies on the PaaS focused on the delivery, deployment and on-demand of single application at present. In this paper, we propose a PaaS to support dynamically building collaboration applications and scheduling methods. The platform is notable feature is support dynamically building collaborative applications.

The key business capabilities of platform include:

1) Application delivery management. Platform supports rapid development, delivery and deployment of software applications with standard of platform. Software delivered by organizations will be resolved, reconstruction of cloud services which can be customized and deployed in the application runtime environment for the users by platform.

2) Collaboration applications customizing. Platform provides rapid collaboration applications customization, development capabilities. Users through leasing rather than invest to build collaboration applications. Moreover, collaboration applications can be customized to meet users' business needs.

3) Collaboration application scheduling. Platform can schedule customized collaborative applications.

4) Cross-cloud services called. Platform supports organization register local service to the platform to achieve cross-cloud service call.

By supporting dynamically building collaboration applications, users only need care about their own business logic implementation, without considering the complex collaboration in ecological changes. On the other hand, users can choose on-demand cloud services by dynamically building collaboration platform. Users do not need a separate investment to build its business collaboration applications. On the contrary users can quickly build the characteristics of the enterprise business processes only using a variety of software services provided by others. The platform can effectively use resources, reduce costs, and ultimately improve the enterprise's core competitiveness to meet the user demand

* ***Corresponding author*** e-mail: lqz@sdu.edu.cn

on business collaboration by supporting rapid collaboration applications building.

The following e-commerce example illustrates users to build collaboration application using PaaS. Entire e-commerce collaboration applications are so complex that no one organization can provide complete application. On the other hand, it is difficult for SMEs to have the economic strength to invest in construction of such a huge information system. Various types of e-commerce applications (such as the portal system, online payment systems, online e-commerce logistics system core applications), which are developed based PaaS can be delivered, deployed to the platform. E-commerce customers can browse, leasing, custom e-commerce software services, e-business collaboration applications quickly customize and development.

The rest of the paper is structured as follows: Related work is discussed in Section 2. Then section 3 describes the architecture of PaaS to support collaboration applications dynamically building. The method of dynamically building collaboration applications will be presented in Section 4. And Section 5 will show the customized approach of collaboration applications based PaaS. Finally Section 6 concludes.

2 Related works

PaaS is an Internet-based cloud computing service model that provides a novel software design, development, delivery, deployment and usage patterns. PaaS provides all the necessary resources, including virtual servers, storage, databases, and so on for software developers to build and deploy applications. PaaS hosted on web-based system through the application development platform, providing end to end development environment, or in some cases, all local online development environment [3].

Some PaaS currently exist, and different PaaS are technically differentiated:

1) One class is to provide application development and deployment container, which provide necessary resources to applications. A typical representative is AWS Elastic Beanstalk [7], on which developers can quickly deploy Java applications to Amazon's machine.

2) Another class is to provide an open API for third-party. A typical representative is Forec.com [5], which provides the necessary development tools and application services, so that software developers can use it to quickly build scalable applications and do not need to purchase, install, configure and manage hardware and software.

3) The last class is to provide the ability to generate the application's configuration. A typical representative is LongJump [9].

However, these PaaS less concerned about the collaboration of software services on the platform at present. Literature [11] presents a Service Delivery Platform for the telecommunications industry by using PaaS technology. It achieves develop value-added telecommunications services through the platform services and registered on the platform assembly of external services. Literature [12] studied how to improve information integration framework petrochemical execution efficiency through the cloud computing service model.

3 Architecture

The different software services are assembled together to form collaboration applications, in fact, is the process of software reuse. Researches show that software reuse in a specific domain is easier to achieve [13, 14]. With the same business objectives software delivered by different organizations typically form collaboration applications in specific domain. "Domain" refers to areas covered by a group application with similar functions [4]. For example, e-commerce or tax applications will be reflected in the relevant software applications and features in common. PaaS proposed in this paper can dynamically build collaboration applications in different fields. The application delivered to PaaS should be specified an area of software applications, so platform can dynamically build collaboration applications in specific areas of software services. During collaboration application development, the characteristics of the domain can be used, such as a common system architecture, which enhances the efficiency of collaboration application development.

PaaS which support dynamically building collaboration applications needs to provide application delivery, collaboration applications rapidly customize, instant deployment, external integration and other key operational capacity. By using the web-based development tools, dynamically build collaboration mechanism provided by the platform, in accordance with their specific business collaboration needs, users can quickly customize collaboration application system including personalized interface, business processes and data models. Moreover users do not need to focus on application deployment details and can ensure that applications can run stable.

The feature of PaaS proposed in this paper is the ability of dynamic building the collaboration of applications which is provided by different organizations within a specific domain and achieve personalized customization needs of users. Figure 1 shows the overall architecture of PaaS, including application delivery module, collaboration as a service, application customization module, resource management module, application runtime platforms, database as a service and PaaS operations management system. The following describes the role of each module.

3.1 APPLICATION DELIVERY MODULE

Application delivery module provides a Web-based application packaging, analytical, deployment, maintenance function and the necessary support of delivering the software for the ISV. It can achieve applications developed by ISV from the traditional

development environment to the platform. ISV can encapsulate the business logic, user interface, data model, and collaboration constraint in a compressed package for submission to the platform. The software developed by ISV can be expressed as App = <UI,BL,D,C>, where UI represents the application's user interface, including the interface of the function menu, the form layout, the optional background and Logo; BL is the core business logic of the application, which can be further divided into modules that can be customized by the user; D represents the data model of the application, including data objects and various data items of data objects; C represents the application collaboration constraints. These constraints can express which types of applications can be collaboration.

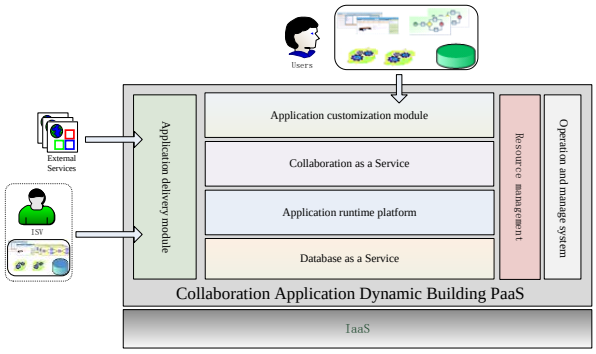

FIGURE 1 Overall architecture

PaaS will be responsible for the operation and maintenance work. Application Delivery module is responsible for parsing applications developed in accordance with the development standard and breaks it into the user interface, business logic, data models, and collaboration constraints. Then a service is built to enable users customizing collaboration applications. On the addition, PaaS can also accept registering local service on PaaS to enable cross-cloud service call capabilities. Use registration, organization needs maintenance its own software and infrastructure.

3.2 APPLICATION CUSTOMIZATION MODULE

Users can customize a single application on platform, including user interface, business logic, and data model and other aspects. Collaboration application customization module is shown in Figure 2. It includes UI customization module, collaboration application customization module, data customization module, cross-cloud service invocation interface module, custom verify module and custom isolation module. UI customization module supports the customization of menu, form layout, UI themes, interface colours, LOGO and other presentation layer.

Collaboration application customization module can implement customization on individual service and collaboration applications. Since collaboration constraints of each application are stored, platform will search, match, association, and recommend some abstract collaboration applications for users according to collaboration constraints.

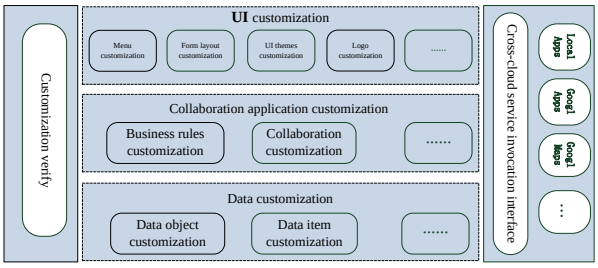

FIGURE 2 Application customization modules

Data customization module is responsible for the customization of data model, data object, and data item. It provides the ability to add, delete, edit and other customized functions of data objects and data items for tenants. Cross-cloud service call interface module is responsible for integrating a variety of cross-cloud applications. Custom verify module is responsible for verifying the user's customization results to ensure that the results did not violate the customization constraints.

3.3 COLLABORATION AS A SERVICE

The software delivered to PaaS is parsed and rebuilt as a standard cloud services by the application delivery module. There may be collaboration relationship between these services from different organizations. Collaboration as a service can discover the collaboration of services in services pool according to the collaboration constraints. Then it will link these services to form an abstract collaboration application. The abstract collaboration application refers each service node of abstract collaborative applications represents a class of services which have similar functions. For any service node, there may be many services from different organizations which can be chosen. The Collaboration as a Service is shown in Figure 3.

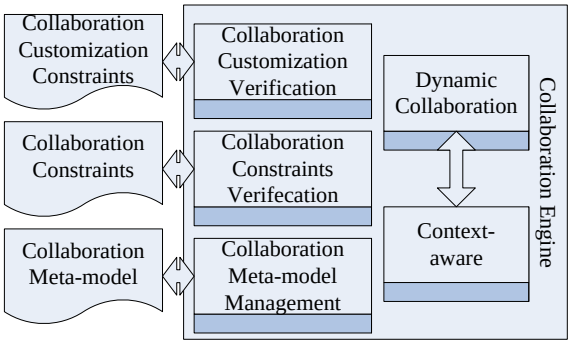

FIGURE 3 Collaboration as a service

3.4 APPLICATION RUNTIME PLATFORMS

Application runtime platform is the runtime environment, including UI engine, data engine and business process engine. These engines can interactive with application deliver module, application customization module, PaaS

operations management system. The collaboration applications generated by collaboration application customization module are deployed to the application running platform to provide services for users.

UI engine is responsible for UI presentation. It can rebuild, adjusted and displayed UI interface on the terminal. Data engine is used to parse data model of applications. Business process engine can parse and instantiate process of customized applications. It is responsible for creating and scheduling process instances, and process monitoring and exception handling. In addition, the application runtime platform can also call a Web service across cloud.

3.5 DATABASE AS A SERVICE

Database as a Service is responsible for managing data in the platform which include application data, meta-data of application, collaboration data and other data. Database as a Service can provide a uniform data model to all kinds of application which makes the manipulation of data more efficiently. On the other hand, applications can access their own data through different API. It is used as if only one was using the service. For example, application A can use MySQL database, while application B may use MongoDB.

3.6 RESOURCE MANAGEMENT MODULE

Resource management module can manage services according to its domain. The services which belonging to the same domain will be unified management, which will be beneficial for collaboration as a service dynamically building collaboration applications according to different domains. Services catalogue is also a part of it. The description of software delivered or registered to platform, including functional and non-functional information, will be in services catalogue. Services catalogue is available for user to find services satisfied his requirements. Besides resource management module is also responsible for data management and maintenance.

3.7 PAAS OPERATIONS MANAGEMENT SYSTEM

PaaS operations management system is used to manage the registration of tenants, as well as tenant directory structure, indexes, service access management. It is also used to coordinate between PaaS and tenants about QoS assurance. SLA requirements for different platforms QoS metrics to quantify dynamically adjusted based on quantitative indicators of shared resources, service monitoring, when the real understanding of custom applications running conditions and usage. Ensure that the platform's reliability, stability and robust to ensure tenants to meet SLA requirements. SLA-based resource dynamic adjustment strategy will meet two objectives: first, the SLA requirements for high-priority users will get the quality of service assurance; two SLA requirements is to ensure a high quality of service under the premise of the user, try to take care of low SLA requirements of users quality of service.

4 Building flexible application collaboration

Dynamically building collaboration applications rely on semantic rules. The rules of semantic description will be given in this section. Applications delivered by different organizations should follow these rules. When an application is delivered to PaaS, the application will be classified according to semantic information, and dynamically discover, associate, and build abstract collaboration applications according to the collaboration rules of the applications. The main roles of the semantic model are: first, it is the application development standards; second, it makes dynamically build collaboration applications possible.

4.1 BUILDING ABSTRACT COLLABORATION

An industry collaboration application will have its regular logic process models, such as e-commerce, collaboration applications in this area will involve electronic transactions, online payment, online logistics systems, etc. And the entire collaboration model is basically fixed. Differences between collaboration applications are also in framework of collaboration models. So an analysis can be made by domain experts to extract the business collaboration process to obtain collaboration application model for a specific domain. In addition, as more and more applications are delivered to platform, the potential collaboration between applications will be auto-discovery, association to form a new collaboration application model, or add new applications to the existing collaboration model. Users can customize the collaboration model according to their own needs.

Definition 1: Each service node of collaboration model represents one class of services but not a specific service instance in which all services have similar functions. Each service class contains many service instances which can achieve this functionality. The collaboration model is defined as BP = <SC,E>, where:

1) SC = {sc1, sc2, ..., scn} is set of the service classes, sc1 .... scn are the n classes of services that participate in abstract collaboration applications.

2) $E \subseteq SC \times SC$ is the set of connections between the service classes, in which $X \in E$ is the structure control operator. A number of basic services can be combined into a service workflow through some control structures. The control structure operators used by workflow are sequence, selection, cycle, and parallel.

Definition 2: The service class is a class services with same or similar function. Any service in the class which can meet the performance requirements of a specific application can be candidate service as a service node of abstract collaboration application.

Definition 3: Collaboration constraints C is defined as C = <Sd,F,Q,Dom>, where Sd represents the basic definition

and description of the application, including the service ID, a basic description of the application name. F represents the functional description of the application, including application interface parameters, preconditions and postconditions; Q is the non-functional attributes descriptions of the service, including time, cost, reputation, etc. Dom represents an application domain.

Users can cut, configure and build abstract collaboration applications which meet their own needs based on collaboration model. After building abstract collaboration applications, the next step is to bind service. The candidate services for each service node will be sorted according to their function by platform. Users can choose service to meet their non-functional requirements. Non-functional requirements include prices, response time, etc.

4.2 CUSTOMIZING COLLABORATION

Users can customize the application from the user interface, business logic, business process and data models four levels. This article focuses on the process logic customization of the collaboration application, i.e. users based on the abstract collaboration applications, according to their needs customize personalized collaboration applications. Platform provides the following custom methods:

Users select one collaboration application model, delete unnecessary path and change the service relationship based on this model. For example, for e-commerce collaborative applications, the user can adjust according to demand whether pay after shipping or shipping after pay. Eventually the abstract collaboration application is formed. Each service node of abstract collaboration application corresponds to many service instance, user can choose one service instance which meet his needs. For example, although many organizations have developed electronic payment applications, but there are some differences, user can choose on-demand according to their actual business conditions.

When there are a lot of collaboration models on platform, it is very difficult that users make choice manually. So a recommendation algorithm is proposed to quickly select the collaboration model.

Definition 4: Let ReqS is the services set of collaboration applications, Cm is a domain collaboration model, CmS is services included in the Cm , if ∀si∈ReqS, then si∈CmS, called ReqS match with Cms.

Definition 5: If ReqS match with CmS, and |ReqS| = |CmS|, called ReqS exactly match with CmS.

From the above definition, as long as ReqS match with CmS, the collaboration model will contain all functional requirements of user. But there may be some unwanted features. So the best case is the user needs and collaboration model exactly matches. If there is no exactly match, then find out the collaboration model with minimum difference.

Definition 6: Let C(ReqS, CmS) = $\frac{|\{si\,|\,(si \in \mathrm{Re}\,qS) \wedge (si \in CmS)\}|}{|\,\mathrm{Re}\,qS\,|}$ as the degree of collaboration model CmS cover user needs ReqS.

Definition 7: Let R(ReqS, CmS) = $\frac{|\,CmS - \{si\,|\,(si \in \mathrm{Re}\,qS) \wedge (si \in CmS)\}|}{|\,\mathrm{Re}\,qS\,|}$ as the degree of collaboration model CmS redundant of user needs ReqS.

Algorithm 1 recommendation algorithm:

```
Input: ReqS, userCov, userRed
Output: M

Ms= Ø //set candidate model null
for each m in M
  cov= C(ReqS, m)
  red =R(ReqS, m)
  If(cov>=userCov∧red<=userRed)
  M.add(m);
end for
Return M;
```

5 Scheduling Collaboration and Simulation

5.1 SCHEDULING COLLABORATION

Collaboration applications scheduling has two layers. The first layer maps the abstract collaboration application to the executable collaboration application. The second layer schedules the task to the appropriate computing nodes according to load balance.

Users customize the personalized collaboration applications based on the abstract collaboration applications. Then customized results are submitted, and will be scheduled by platform. The collaboration application scheduling model is shown in Figure 4.

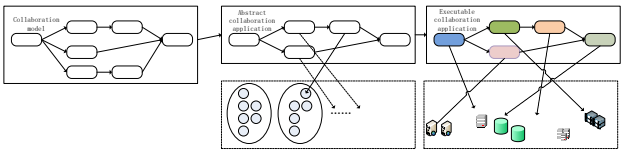

FIGURE 4 Collaboration application scheduling model

The first layer scheduling algorithm:

1) Process engine first reads the user's personalized needs, then the abstract collaboration is cut into customized collaboration application, i.e. removing the service node which user does not need.

2) The abstract customized collaboration applications bind services. The binding process is to find the corresponding services set (service instances set) based on the type of service. Then the services which are not satisfied QoS are deleted according to the user's QoS constraints.

3) After the above calculation, the service nodes of abstract collaboration application are mapped to specific service instance.

4) After executable collaboration applications generated, services is called and platform will monitor the execution of collaboration applications.

Taking into account the load balance, a service will not only deploy on one server, but have several copies on multiple servers. Then an executable collaboration application is scheduled, the appropriate server should be selected to make server load balancing. PaaS will receive a lot of request to execute applications the in a period of time, so multiple collaboration applications jointly scheduling should be considered. The strategy proposed in this paper is: first all executable services (execution condition is satisfied) is inserted into an execution queue according to the arrival time. Then try to do the following steps: a) remove the first task; b) schedule this task to a most appropriate server; c) If there is no appropriate server, this task is inserted into the tail; d) When the task is completed, notify scheduler task execution is completed.

Definition 8: The server load function is defined as $L(s) = \frac{C_{\max}(s) - C_{cur}(s)}{C_{\max}(s)}$, where $C_{\max}(s)$ is max load of server, i.e. the maximum execution server capacity, $C_{cur}(s)$ is the server's current load.

If the current server is idle, that is $C_{cur}(s) = 0$, then $L(s) = 1$. If the current server load reaches the maximum value, that is $C_{cur}(s) = C_{\max}(s)$, then $L(s) = 0$. So the second layer of collaboration applications scheduling algorithm is as follows:

1) For an executable collaboration application, all executable tasks will be inserted into a queue.

2) Take out each task, assign it to execution node. Execution node selection is based on its load function value. The value of the minimum execution node is selected. If all nodes load are full, i.e. L (s) <= 0, then this task is inserted into the tail.

3) Repeat steps 1 and 2 until the queue is empty.

5.2 SIMULATION

To verify the efficiency and scalability of the framework, an experiment is conducted. Five different test sets are used in the experiment. The collaboration time and result are recorded and shown in Table 1. If the collaboration which is generated dynamically by the framework in this paper can be executed and in accordance with the requirements, we call the collaboration is correct. And the accuracy in Table 1 is the correct rate of the collaborations. From Table 1, we can see that the execute time increases with the number of services linearly and the accuracy is always 100%.So we can conclude that the framework propose in this paper is effective and scalable.

TABLE 1 Collaboration time and accuracy

Test Set	Number of services	Time(ms)	Accuracy
Test Set 1	800	35	100%
Test Set 2	1000	52	100%
Test Set 3	400	116	100%
Test Set 4	1500	528	100%
Test Set 5	4000	1860	100%

6 Conclusion

Based on IT development and the demand of business collaboration, a PaaS for business collaboration is proposed that supports business collaboration applications quickly build and deployment. First, the platform provides a new application delivery model. The application can be parsed and rebuilt the services for the user customization. Secondly, platform provides automatic matching technology. The collaboration relationship between services can be matched and automatically generates business collaboration model. It simplifies the process of collaboration application customization. Moreover, the platform provides collaboration applications for deploying, runtime environment, including the UI engine, data engine and workflow engine.

Received 1 October 2014, www.cmnt.lv

Abstract

Rich symmetries have been found in many real networks, which is an extensive structural of networks. We study the relationships between synchronization and symmetry of network. One of fascinating problems related to symmetry network is how to optimization phase synchronization by employing symmetric structure. For this purpose, we optimize the network structure by symmetry properties of network, which is statistics the orbits of network. Nodes in the same orbit have similar properties, and then we reduce the network size by nodes in same orbit. We simulate the BA and SW model. The simulations result show that symmetry structure can optimize the network topology and can enhance phase synchronization of network.

Keywords: synchronization, symmetry network, orbit

1 Introduction

The topologies of network have been extensively studied and some common architecture has been discovered [1-3]. The small-world property [4-6], the scale-free [7], communication structure [7-9], network motif [10], modular network [11] any symmetric network [12, 13]. From this viewpoint, systematically understanding the network structural effects on their dynamical processes is of both theoretical and practical importance. Synchronization behaviour, in particular, as a widely observed phenomenon in network systems, has received a great deal of attention in the past few decades [14, 15]. The effects of average distance [16, 17], heterogeneity [14, 18], clustering [19, 20] and weight distribution on network synchronizability have been extensively investigated [21, 22]. Since the synchronizability is correlated with many topological properties, but these properties affected the synchronization maybe is not a proper answer. Perhaps a good index, which can characterize the synchronizability, has not been found. In recent years, graph-theoretic were used to analyse the network synchronizability, e.g., degree sequences were discussed [23], complementary graph and subgraph techniques were used [24-26]. But using the automorphism of symmetry graph to study the synchronization has not been fully investigated. Motivated by the above of work, this paper focuses on the relationships between the network synchronization and the orbit of automorphism of symmetry network. We know that it is difficulty all nodes achieves the synchronization in whole network, the finding shows that the network size is smaller and achieving the synchronization is easier. From this, we know that we may optimize the network topology to enhance the network synchronizing through symmetric structure. In symmetry network nodes in same orbit are similar and we view the nodes in same orbit as one node and reduce the network size. We found that the nodes in same orbit are also very easy to achieve the synchronization. The results show that the optimized networks enhance the network synchronism.

2 Symmetry network and synchronization

2.1 SYMMETRY NETWORK

A graph or network is denoted by $H=(V,E)$, where V is the set of vertices and E is the set of edges. To any node $v\in V(G)$, $\varepsilon(v)=v$, obviously, there has a isomorphism to identity map $\varepsilon:V(H)\to V(H)$ [28]. We illustrate the concept through Figure 1. There has a map $\alpha_1:V(H)\to V(H)$ defined by $\alpha_1(v)=v$, which is a isomorphism from H to itself [27-29].

An automorphisms of a graph H is a isomorphism from H to itself. We denote the set of automorphisms of graph H under composition operation as $Aut(H)$. Figure 1 shows $Aut(H)=\{\alpha_1,\alpha_2,\alpha_3,\alpha_4\}$. The automorphisms group also is a permutation group. The set of all of permutation group base on n called symmetric group S_n. The network is considered as symmetry if its underlying graph contains not only an identity permutation.

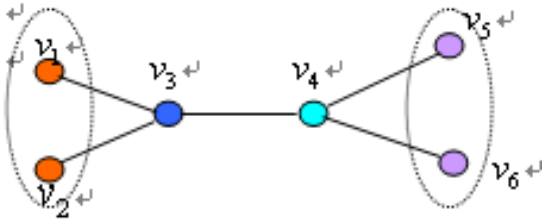

FIGURE 1 Symmetry network

*Corresponding author e-mail: shtao_2008@126.com

Next, we will introduce the concepts of automorphism partition and orbit. Given the automorphism group acting on vertex set V, we can get a partition $\pi = \{V_0, V_1, ..., V_k\}$, $x R y$ if and only if $\exists \alpha \in Aut(H)$, s.t. $\alpha(x) = y$. Such partition is called automorphism partition, each cell of the partition is called an orbit of $Aut(H)$, denote as $orbit(H)$. An orbit is trivial if it only contains a single vertex, otherwise, the orbit is non-trivial. The vertex u, v called similar if they are in same orbit. Figure 1 shows the automorphism partition $\pi = \{\{v_1, v_2\}, \{v_3\}, \{v_4\}, \{v_5, v_6\}\}$ and the orbits. Nodes in same orbit are marked with the same colour, shown as Figure 1. The nodes in same orbit have similar structure information [28]. We view them as one node, e.g.:

$$\{v_1, v_2\} \to v_1, \{v_3\} \to v_2, \{v_4\} \to v_3, \{v_5, v_6\} \to v_4 .$$

We reduce the network structure, shown as Figure 2. We call this reduction network as optimization network in this paper.

FIGURE 2 Optimization network.

2.2 SYNCHRONIZATION

To settled the natural frequencies of the oscillators, Kuramoto worked out a mathematically model to tackle this problem and each of the oscillators in the system are [30-31]:

$$\dot{\theta}_i = \omega_i + \frac{K}{N}\sum_{j=1}^{N} \sin\left(\theta_j - \theta_i\right), \ (i = 1, ..., N), \tag{1}$$

where N is the factor and $N \to \infty$, ω_i is the frequency of oscillator i, K is the coupling constant.

To deal with the synchronization on complex networks, the Kuramoto model can be reformulated to Equation (2): The synchronization of Kuramoto model [30, 31]:

$$\frac{d\phi_i}{dt} = \omega_i - \frac{\delta}{N}\sum_j a_{ij} \sin\left(\phi_i - \phi_j\right), \tag{2}$$

where ϕ_i and ω_i are the phase and the intrinsic frequency of vertex i, respectively. ω_i is chosen from the Gaussian distribution with unit variance. The summation runs over j, the nearest neighbours of vertex i. The coupling strength is used as δ. To study synchronization, each node in complex topologies is considered an oscillator, such as WS networks and BA graphs.

The order parameter M is defined as:

$$M = \left\langle \left| \frac{1}{N}\sum_{j=1}^{N} e^{i\phi j} \right| \right\rangle, \tag{3}$$

where $\langle ... \rangle$ is the ensemble average over different configurations and N is the total number of vertices. M is $0(1)$ in the fully incoherent (coherent) phase.

The dynamics of synchronization on symmetry networks through a modified Kuramoto model, where $orbit[i]$ is the vertex i in the same orbit.

$$\frac{d\phi_i}{dt} = \omega_i - \frac{\delta}{Orbit[i]}\sum_j a_{ij} \sin\left(\phi_i - \phi_j\right), \tag{4}$$

3 Scale-free network

To scale-free network our numerical simulations are based on the SF model. The model starts from m_0 nodes, at every time step adds a new node with $m(\le m_0)$ edges that link the odd node already existing in network. We assume that the probability connecting to an existing node i is proportional to $i's$ degree k_i. The algorithm of the BA model is [35]:

1) Growth: starting with a small number m_0 of nodes, each step adds a new node with $m(\le m_0)$ edges connect new node with different old nodes in network.

2) Preferential growth: when choosing old nodes which the new node connects to, and assuming that the probability depends on the degree k_i of node i. The link probability is:

$$\prod = \frac{k_i}{\sum_j k_j} . \tag{5}$$

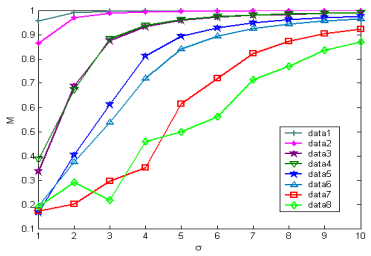
By using the rate equation, we can easily obtain the degree distribution of the whole network, $p(k) \sim k^{-2.8}$. In simulation, there are totally 200 nodes in the network. According to the new node m which added to the network, we assumed $m = 2, m = 3, m = 4, m = 5$, respectively. When $m = 2$, the $Aut(m_2) \approx 6.8 \times 10^6$, so the network is richly symmetric [10]. We only simulated the synchronization of non-trivial, because the nodes in non-trivial at lease are 2. In the 11th and 17th orbit, the node number is 14, respectively. In the 16th orbit, the node number is 17. In the 20th orbit, the node number is 8. In the 25th orbit, the node number is 9. In the 37th and 38th orbit, the node number is 3, respectively. In other orbit, the node numbers also are 2. To get the synchronization property of network, we investigate how the order parameters in different orbits, a network and quotient network change with the coupling strength. According to the Equation (2), Figure 3a shows the simulation results. From top to bottom, the node numbers in different orbits 2, 3, 8, 9, 14, and 17, corresponding to more and more node numbers in same orbit. In the case $orbit[i] = 2$, with the increasing of coupling strength, the order parameter of

$orbit[i]$ soon reaches 1, indicating the synchronized state within one orbit. With the further observed, an interesting phenomenon appears: for different $orbit[i] = 2,3,8,9,14,17$, order parameter for different $orbit[i]$ all reach 1 soon, which indicated oscillators belong to the different $orbit[i]$ are synchronized. We call this phenomenon orbit synchronization clustering.

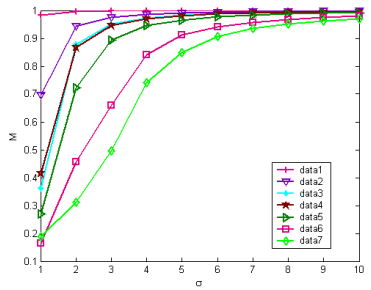
However, the phases of oscillators in different $orbit[i]$ are different, in the case $orbit[i] = 17$, the order parameter of $orbit[i]$ reaches 1 slower than $orbit[i] = 2$, which indicating more node within one orbit, slower reached synchronized state.

Similarly, to enhance the synchronization of the whole network, we defined the node in the same orbit as one node, like this may reduce the node number in the network greatly and enhances the network synchronism. Synchronization of the optimized network and original network shown as Figure 3a, the red square represents optimized network, indicated as $data8$, the green diamond represents the whole network, indicated as $data9$. In Figure 3a, obviously, the order parameter for the whole network is the lowest one. Optimization network reach 1 sooner than the whole network. That is, optimized network's topology may enhance the network synchronized performance.

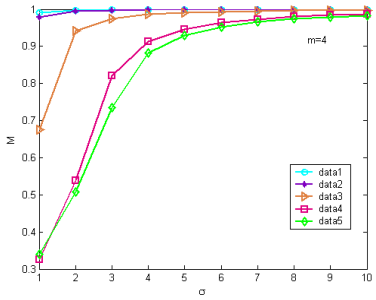
At the same time, we simulated the synchronism of $orbit[i]$, the optimized network and the whole network with $m = 3, m = 4, m = 5$, shown in Figures 3b-d. The simulation show that different m values form different network structure, but each network $orbit[i]$ may achieve the synchronization and forms the synchronized clustering. The synchronization of optimization network with different m values surpasses the original network.



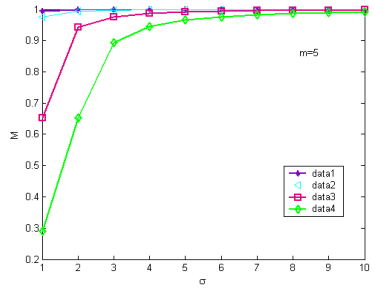
a) m=2



b) m=3



c) m=4



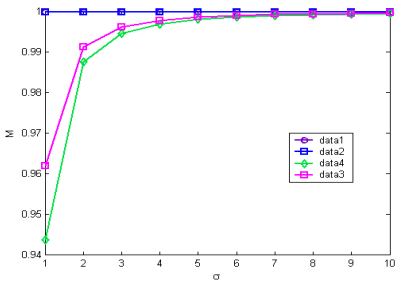
d) m=5

FIGURE 3 Synchronization of BA network

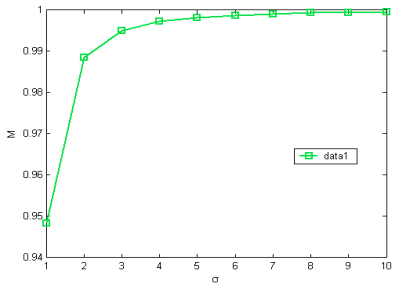
4 Small world network

The WS model was proposed by Watts and Strogatz. The WS model start from regular loop network with n nodes. Assuming that each node on loop links K edges with two sides nodes on it, then restart a new link with the probability p to each edge. This new network has small world character, which has smaller average path and bigger cluster. The degree distribution of small world obey the Possion distribution.

We made the synchronization simulation of small world network similar to BA network. Network has 200 nodes in simulation same as BA network size. When network connection probability smaller than $p = 0.49$, network has not non-trivial orbit, only trivial orbit. Hence, assuming that WS network connection probability is $p = 0.49$ and $p = 0.5$ separately. When the connection probability is bigger than $p = 0.5$, all of nodes in the same orbit. When $p = 0.49$, $Aut(H)$ is very small and has a few non-trivial orbit. We simulated the synchronization of non-trivial orbit and the optimization network when $p = 0.49$, shown as Figure 4a. When $p \geq 0.5$, $Aut(H) \approx 7 \times 10^5$ the network has richly symmetry and all of the node in same orbit. Although the topology of network has not optimized, the whole network reached 1 very soon, that is the network has better synchronization, shown as Figure 4b.



a)



b)

FIGURE 4 Synchronization of SW network

We found that the synchronization of SW reaches 1 sooner than BA model with the same scale. In BA, the network symmetry is richer, different non-trivial orbit are more and enhance the network synchronism. In SW, The network symmetry is richly, the node in the same orbit and the network is very completely easy to achieve the synchronization.

5 Conclusion

The paper captured the synchronization of symmetric network and introduced the concept of symmetry network. The more automorphism of a network have and the more symmetry of a network and the orbit constitutes the partition of automorphism. On the other hand, the nodes in orbit have similar properties, hence, we viewed the nodes in orbit as a node to optimize the network topology, and we called this network as optimization network. We simulated the synchronization of orbit clustering, the whole network and the optimization network using revised Kuramoto model. We discussed the relationship of synchronization and symmetry of BA network. In BA model, the different m values and the network topology are also different. According the different network topology formed by different m values, we simulated the synchronization of orbit clustering, the whole network and the optimization network of BA model. The results show that the optimized network topology can enhance the synchronization of network. Finally, we discussed the SW model, the synchronization of network is different according to different linking probability. All node in the orbit when $p \geq 0.5$, the network has the better synchronization. In BA model, the nodes in different orbit can reduce the network scale to optimize the network topology, and the optimization network has the better synchronization than the original network. To SW model, the nodes of the network in the same orbit when $p \geq 0.5$, and it can't optimize the network structure. But the results show that the SW model is more easy reach the synchronization than BA model to the same network scale if BA model is not optimization.

Solution of compressed sensing for wide angle EM scattering analysis based on MFIE

Xinyuan Cao*, Mingsheng Chen, Bingbing Chen, Liangliang Cheng, Qi Qi

School of Electronics and Information Engineering, Hefei Normal University, Hefei, Anhui, China

Received 1 June 2014, www.cmnt.lv

Abstract

Fast analysis of electromagnetic scattering problems over a wide incident angle is always a difficult problem in computational electromagnetics. Up to the present, almost all of the traditional numerical methods need to solve one discrete angle after another to finish calculating this kind of problem. In this paper, we propose a new method, which can fix it effectively by applying compressed sensing into method of moments for magnetic field integral equation. The theory and calculation process of the solution are described in detail in the paper, and by numerical experiments of different three dimensional objects, the accuracy and the efficiency of the algorithm are also discussed.

Keywords: compressed sensing, method of moments, magnetic field integral equation

1 Introduction

As an important research field of computational electromagnetics (CEM), up to the present, electromagnetic (EM) scattering problems can already be computed by a lot of solutions [1-3]. However, fast analysis of wide angle EM scattering problems is still a difficult task for all traditional numerical methods, almost all of them need to solve one discrete angle after another to finish calculating this kind of problem [4-6]. It means iterative operations are adopted as incident angle changes, which must result in low efficiency. Aiming at this difficulty, we propose a new method, which can solve it effectively by applying compressed sensing (CS) into method of moments (MoM) for magnetic field integral equation (MFIE).

CS is called as 'a big idea' in the field of signal processing [7]. One of the most interesting advantages in CS is that it breaks the restriction of Nyquist-Shannon sampling theorem [8] - it can capture and represent compressible signals at a rate significantly below the Nyquist rate. MoM is a classical numerical method of electromagnetic field integral equation, which is applied extensively in solving EM scattering problems [9]. MFIE, as is well known to all, is considered to have some advantages by its smaller condition number and faster iterative convergence speed [10], so we choose it as the basic integral equation. In this paper, the theory and implementation of the new solution are elaborated, and numerical simulation for different three dimensional objects is presented and discussed - it is shown that the new method can obtain accurate results by only several measurements and the efficiency can be improved greatly.

2 Traditional MoM for MFIE

For a closure perfect electric conductor (PEC) whose surface is S radiated by electromagnetic waves, MFIE could be represented as:

$$\mathbf{J}(\mathbf{r}) = 2\hat{\mathbf{n}} \times \mathbf{H}(\mathbf{r}) + 2\hat{\mathbf{n}} \times P.V. \int_{S'} \mathbf{J}(\mathbf{r}') \times [\nabla' G(\mathbf{r}, \mathbf{r}')] \mathrm{d}S' , \quad (1)$$

where $\mathbf{J}$ represents induced current density on S, $\hat{\mathbf{n}}$ represents unit normal vector of the surface of object, $\mathbf{H}(\mathbf{r})$ represents incident magnetic field, $G(\mathbf{r}, \mathbf{r}') = \mathrm{e}^{-\mathrm{j}kR}/4\pi R$, $P.V.\int$ means principal value integral.

Calculation process of traditional MoM for MFIE is as follows:

Step 1: Use RWG vector basis functions $\mathbf{f}_n^S$

$$\mathbf{f}_n^S(\mathbf{r}) = \begin{cases} \dfrac{l_n}{2A_n^{\pm}} \boldsymbol{\rho}_n^{\pm S} & \mathbf{r} \in \mathrm{T}_n^{\pm} \\ 0 & \text{else} \end{cases} , \quad (2)$$

to expand $\mathbf{J}(\mathbf{r})$.

Step 2: Make inner product operation by Galerkin's method:

$$< \mathbf{f}_m^S(\mathbf{r}), \hat{\mathbf{n}} \times \mathbf{H} >= \sum_{n=1}^{N} I_n [< \mathbf{f}_m^S(\mathbf{r}), \frac{\mathbf{f}_n^S(\mathbf{r}')}{2} > - < \mathbf{f}_m^S(\mathbf{r}), \hat{\mathbf{n}} \times \int_{S'} (\mathbf{f}_n^S(\mathbf{r}') \times \nabla' G(\mathbf{r}, \mathbf{r}')) \mathrm{d}S' >], \quad (3)$$

that is:

$$\mathbf{Z}_{n \times n} \mathbf{I}_n = \mathbf{V}_n , \quad (4)$$

* ***Corresponding author*** e-mail: xycaoBL@163.com

where:

$$Z_{mn} = \frac{1}{2}\int_S \mathbf{f}_m^S(\mathbf{r})\cdot\mathbf{f}_n^S(\mathbf{r}')\mathrm{d}S - \int_S \mathbf{f}_m^S(\mathbf{r})\cdot\hat{\mathbf{n}}\times \int_{S'}\mathbf{f}_n^S(\mathbf{r}')\times\nabla' G(\mathbf{r},\mathbf{r}')\mathrm{d}S'\mathrm{d}S, \quad (5)$$

$$V_m = \int_S \mathbf{f}_m^S(\mathbf{r})\cdot[\hat{\mathbf{n}}\times\mathbf{H}(\mathbf{r})]\mathrm{d}S. \quad (6)$$

Step 3: Solve the matrix equation with gauss integration, mean value theorem and treatment of singularities.
Step 4: Numerical result of **J**(**r**) will be finally calculated as:

$$\mathbf{J}(\mathbf{r}) = \sum_n I_n \mathbf{f}_n^S(\mathbf{r}). \quad (7)$$

While the angle of incident wave is not certain but in a wide range, traditional MoM for MFIE has to compute the matrix equations at each small discrete angle repetitively, so the efficiency is low.

3 Basic CS theory

CS is based on sparse representation of signals, its mathematical model [11-13] can be formulated as follows:

$$\mathbf{\Phi}_{M\times N}\mathbf{X}_{N\times 1} = \mathbf{\Phi}_{M\times N}\mathbf{\Psi}_{N\times N}\boldsymbol{\alpha}_{N\times 1} = \begin{pmatrix} s_1 \\ s_2 \\ \vdots \\ s_M \end{pmatrix} = \mathbf{s}_{M\times 1} \quad (M \ll N), \quad (8)$$

where **X** stands for original signal, **α** is the sparse projection of **X**, **Ψ** stands for sparse basis, **Φ** stands for measurement matrix and it is incoherent with **Ψ**. From the *M*-dimensional measurement **s**, the approximation of **α** can be calculated from a *L*-minimization problem as:

$$\hat{\boldsymbol{\alpha}} = \min\|\boldsymbol{\alpha}\|_L \quad s.t.\ \mathbf{\Phi\Psi}\boldsymbol{\alpha} = \mathbf{s}, \quad (9)$$

finally, the original signal can be approximated as:

$$\hat{\mathbf{X}} = \mathbf{\Psi}\hat{\boldsymbol{\alpha}}. \quad (10)$$

4 Solution of CS introduced to MFIE

We introduce CS into traditional MoM for MFIE to fasten calculating wide angle EM scattering problems, the procedure is as follows:
Step 1: Assume the discrete angles of incident waves are $\theta_1,\theta_2...\theta_n$, accordingly, the excitations could be denoted as $\mathbf{V}(\theta_1)$, $\mathbf{V}(\theta_2)$, ..., $\mathbf{V}(\theta_n)$, construct a new group of excitations as:

$$\mathbf{V}_i^{\mathrm{CS}} = \alpha_{i1}\mathbf{V}(\theta_1) + \alpha_{i2}\mathbf{V}(\theta_2) + \cdots + \alpha_{in}\mathbf{V}(\theta_n), \quad (11)$$

where $i = 1, 2, ...m$ and $m \ll n$.

Step 2: Substitute these new excitations into the matrix equation of MFIE, that is,

$$\mathbf{Z}\mathbf{I}_i^{\mathrm{CS}} = \mathbf{V}_i^{\mathrm{CS}}, \quad (12)$$

solve these matrix equations as the way of traditional MoM, then $\mathbf{I}_1^{\mathrm{CS}}, \mathbf{I}_2^{\mathrm{CS}}, ..., \mathbf{I}_m^{\mathrm{CS}}$ can be obtained.
Step 3: Since the impedance matrix **Z** does not vary with the angle of incidence, $\mathbf{I}_i^{\mathrm{CS}}$ can be expanded as

$$\mathbf{I}_i^{\mathrm{CS}} = \alpha_{i1}\mathbf{I}(\theta_1) + \alpha_{i2}\mathbf{I}(\theta_2) + \cdots + \alpha_{in}\mathbf{I}(\theta_n) \ (i = 1, 2, ...m), \quad (13)$$

thus $\mathbf{I}_1^{\mathrm{CS}}, \mathbf{I}_2^{\mathrm{CS}} ... \mathbf{I}_m^{\mathrm{CS}}$ are *m* measured values of $\mathbf{I}(\theta_1), \mathbf{I}(\theta_2) ... \mathbf{I}(\theta_n)$.
Step 4: According to the theory of CS, from these measured values, current coefficient vectors over the wide angle can be reconstructed accurately by the recovery algorithm and sparse basis, so we get the relation:

$$\begin{bmatrix} \mathbf{I}_1^{\mathrm{CS}} \\ \vdots \\ \mathbf{I}_m^{\mathrm{CS}} \end{bmatrix} = \mathbf{\Phi}_{m\times n}\begin{bmatrix} \mathbf{I}(\theta_1) \\ \mathbf{I}(\theta_2) \\ \vdots \\ \mathbf{I}(\theta_n) \end{bmatrix} = \mathbf{\Phi}_{m\times n}\mathbf{\Psi}_{n\times n}\begin{bmatrix} \mathbf{s}_1 \\ \mathbf{s}_2 \\ \vdots \\ \mathbf{s}_n \end{bmatrix}, \quad (14)$$

where $\mathbf{\Phi}_{m\times n}$ represents measurement matrix, $\mathbf{\Psi}_{n\times n}$ represents sparse basis, $[\mathbf{s}_1\ \mathbf{s}_2\ ...\ \mathbf{s}_n]^{\mathrm{T}}$ is sparse projection of $[\mathbf{I}(\theta_1)\ \mathbf{I}(\theta_2)\ ...\ \mathbf{I}(\theta_n)]^{\mathrm{T}}$.
Step 5: Calculate the optimization problem:

$$\begin{bmatrix} \hat{\mathbf{s}}_1 \\ \hat{\mathbf{s}}_2 \\ \vdots \\ \hat{\mathbf{s}}_n \end{bmatrix} = \min\left\|\begin{bmatrix} \mathbf{s}_1 \\ \mathbf{s}_2 \\ \vdots \\ \mathbf{s}_n \end{bmatrix}\right\|_L \quad s.t.\ (\mathbf{\Phi\Psi})\begin{bmatrix} \hat{\mathbf{s}}_1 \\ \hat{\mathbf{s}}_2 \\ \vdots \\ \hat{\mathbf{s}}_n \end{bmatrix} = \begin{bmatrix} \mathbf{I}_1^{\mathrm{CS}} \\ \vdots \\ \mathbf{I}_m^{\mathrm{CS}} \end{bmatrix}. \quad (15)$$

Step 6: Finally, current coefficient vectors over the wide angle can be reconstructed as:

$$\begin{bmatrix} \hat{\mathbf{I}}(\theta_1) \\ \hat{\mathbf{I}}(\theta_2) \\ \vdots \\ \hat{\mathbf{I}}(\theta_n) \end{bmatrix} = \mathbf{\Psi}_{n\times n}\begin{bmatrix} \hat{\mathbf{s}}_1 \\ \hat{\mathbf{s}}_2 \\ \vdots \\ \hat{\mathbf{s}}_n \end{bmatrix} \quad (16)$$

and the induced current density **J** will be solved by Equation (7).

Above all, based on $m(m \ll n)$ times of calculation of MoM, $\mathbf{I}(\theta_1), \mathbf{I}(\theta_2) ... \mathbf{I}(\theta_n)$ are solved. Compared with *n* times of calculation of matrix equations needed by traditional MoM, the amount of computation is reduced.

5 Numerical results

Take different three dimensional objects as numerical examples. Experimental electromagnetic parameters are set as follows: the frequency of incident wave f=1.35×10^{9}Hz, permittivity ε=1/(4π×9×10^9)F/m, permeability μ=4π×10^{-7}H/m. Consider 360 angles of incidence (from 1° to 360°, the angle of the wave which is propagating along y axis and E-polarized in the x direction is defined as 0°). Choose Gauss random matrix [14] as the measurement matrix, Hermite basis [15] as the sparse basis and orthogonal matching pursuit (OMP) [16,17] as the recovery algorithm, take 35 times of measurement as example. Compare the calculation results of our method with the ones of traditional MoM.

5.1 NUMERICAL EXAMPLE 1

Consider a PEC cuboid with size of 0.2×0.1×0.05m, as shown in Figure 1.

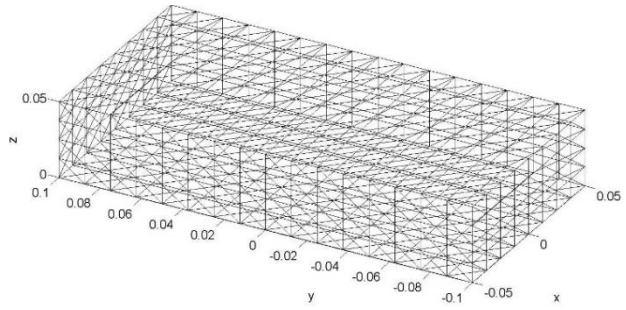

FIGURE 1 The PEC cuboid model

Calculate the current coefficients over 1°, 2°, ..., 360° by both traditional MoM and our solution, and compare the results of two methods. Figure 2 shows the comparison of the current coefficients over the wide angle on an arbitrary RWG basis (take basis number 327 which is centered at (0.025,-0.056,0) as example).

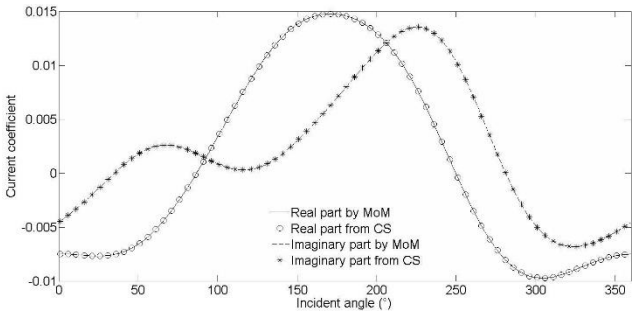

FIGURE 2 Comparison of the calculation results of the current coefficients over the wide angle on basis 327 of the cuboid

From Figure 2, we can see that the results of our method are completely consistent with the ones of traditional MoM.

5.2 NUMERICAL EXAMPLE 2

Consider a multi-objective model which consists of a PEC sphere, a PEC cube and a PEC rectangular pyramid, as shown in Figure 3 (assume the radius of the sphere is 0.05m, the edge-length of the cube is 0.1m and the size of the rectangular pyramid is 0.1×0.1×0.1m.).

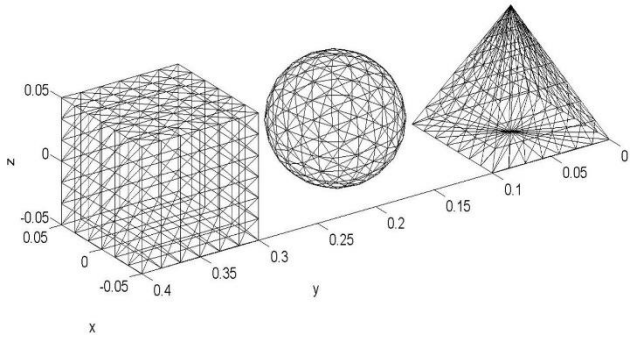

FIGURE 3 The multi-objective model

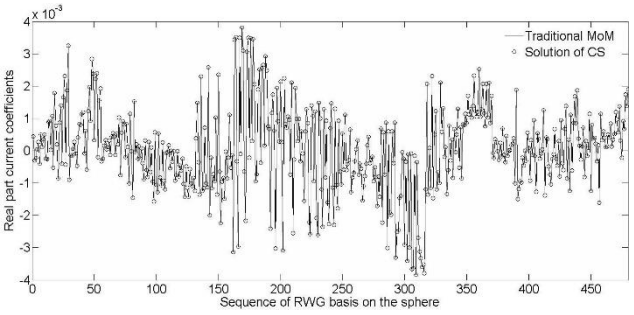
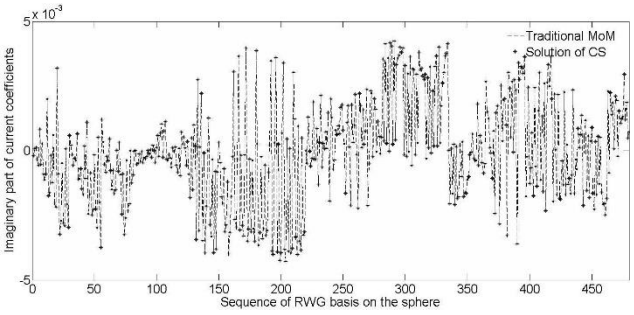
Figures 4-6 show the comparison between the current coefficients of all RWG basis on the sphere, the cube and the rectangular pyramid over an arbitrary incident angle (take 100°, 200°, 300° as examples) of the wide range calculated by our method and the results of traditional MoM respectively.

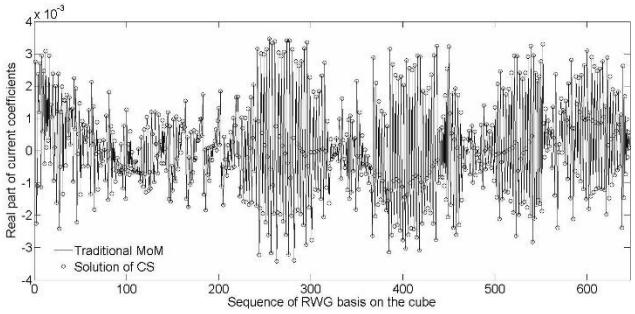


a)

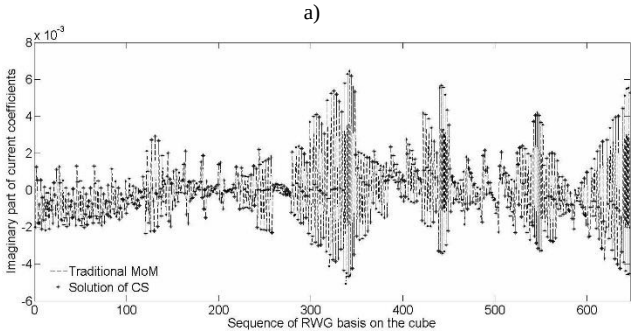


b)

FIGURE 4 Comparison of the calculation results of the current coefficients on the sphere (incident angle=100°): a) Real part, b) Imaginary part

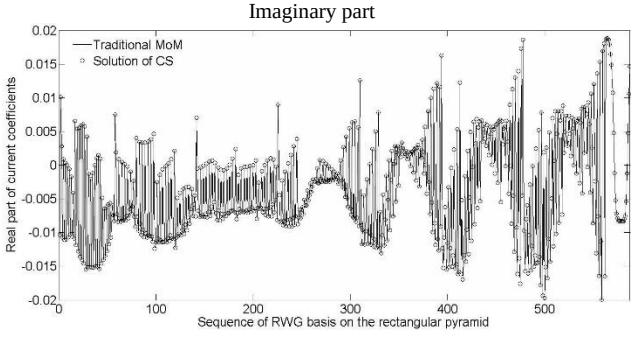


a)

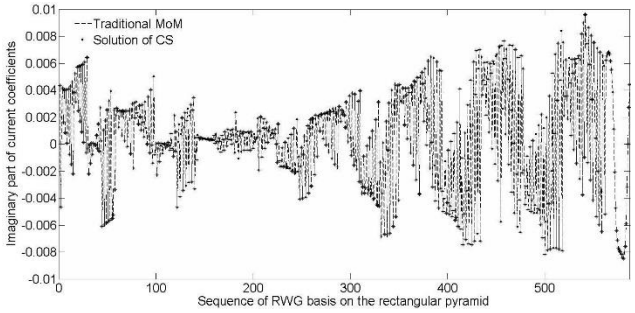


b)

FIGURE 5 Comparison of the calculation results of the current coefficients on the cube (incident angle=200°): a) Real part, b) Imaginary part



a)



b)

FIGURE 6 Comparison of the calculation results of the current coefficients on the rectangular pyramid (incident angle=300°): a) Real part, b) Imaginary part

From Figures 4-6, one can see that the results of our method are also accurate for the multi-objective model.

5.3 NUMERICAL EXAMPLE 3

Consider a simple missile-like model, as shown in Figure 7.

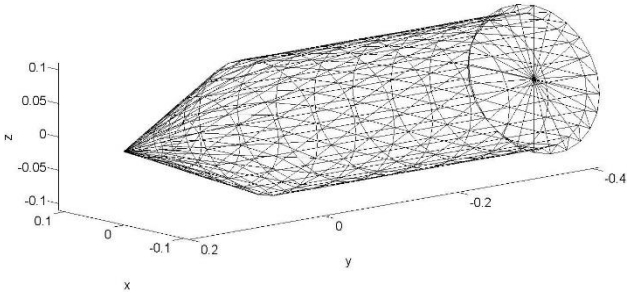


FIGURE 7 The simple missile-like model

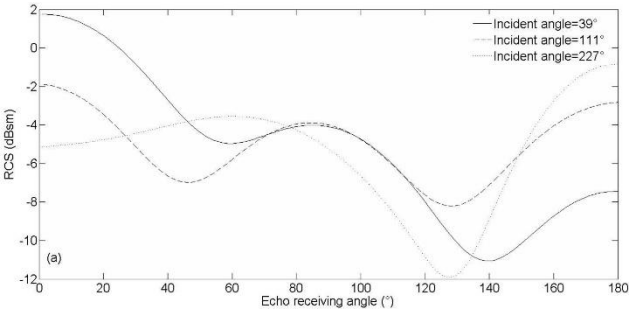
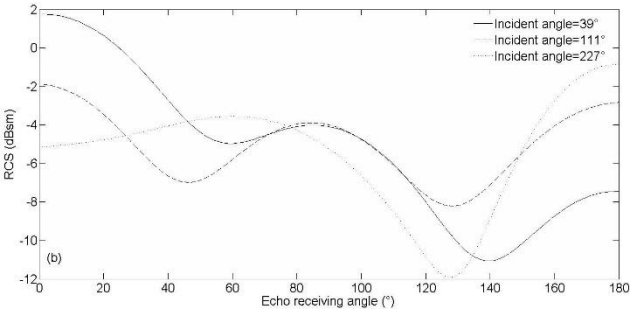
Calculate the values of RCS (take *E* surface as example) of this simple missile-like model over some discrete angles among the wide range (take 39°, 111°, 227° as examples) based on both our method and traditional MoM, comparisons of the results of the two solutions are shown in Figure 8.



a)



b)

FIGURE 8 Comparison of the RCS results of the simple missile-like model by a) traditional MoM and b) our method

From Figure 8, one can see that the numerical results calculated by our method are still accurate.

5.4 ERROR STATISTICS

Define the calculation error as:

$$\Delta = \frac{\left\| \hat{\mathbf{I}}_\theta - \mathbf{I}_\theta \right\|_2}{\left\| \mathbf{I}_\theta \right\|_2} \times 100\% , \tag{17}$$

where $\mathbf{I}_\theta$ stands for the current coefficient matrix over the wide angle calculated by traditional MoM, $\hat{\mathbf{I}}_\theta$ stands for the one calculated by our method. The calculation error statistics for the cuboid, the multi-objective model and the simple missile-like model are shown in Table 1.

TABLE 1 The calculation error statistics

Object	Example 1	Example 2	Example 3
Calculation Error	2.7374×10^{-5}	6.1254×10^{-5}	1.8901×10^{-6}

5.5 COMPARISON OF OPERATION TIME

Table 2 shows the comparison between the computational time of our method and the one of traditional MoM. (The operation environment of the programs is Mathworks Matlab7.0, Pentium(R) Dual-Core CPU at 2.10GHz and an internal memory with capacity of 2GB.)

TABLE 2 Comparison of the computational time (s)

Object	Example 1	Example 2	Example 3
Traditional MoM	402.5571	431.6213	510.1818
Solution of CS	93.6437	99.1613	111.7152

From the tables above, we can see that the calculation results of our method relative to the ones of traditional MoM are still accurate highly but the operation time is reduced a lot.

6 Conclusion

Overall, aiming at fast analyzing wide angle EM scattering problems, this paper proposes a new solution by applying CS into MoM for MFIE, and the feasibility of the method is verified by numerical experiments -- the expected effect of fastening calculating EM scattering problems over a wide angle is achieved.

The influence and improvement of scanning speed to the line width in fused deposition manufacturing

Zili He, Tingchun Shi*, Biaobiao Gao

School of Life information and Instrument Engineering, Hang Zhou Dianzi University, Hangzhou, Zhejiang, China

Received 1 October 2014, www.cmnt.lv

Abstract

During the process of fused deposition manufacturing, the extruding speed and the scanning speed of nozzle don't match in some path of large change in direction may lead the extrusion of material more or less than demand too much which causes accumulation of material or the lack of line width. The method of controlling FDM's forming accuracy which is under the restrictions of the mechanical structure of the work platform is studied. By adjusting the extruding speed and measuring the line width on the work platform the width of forming line in process can be controlled in allowed range. The experiment results indicate that through controlling the speed of extruding motor the extrusion of material is controlled efficiently and the accuracy of molding is improved.

Keywords: movement theory of nozzle, scanning speed, extruding motor controlling, measure of line-width

1 Introduction

The Fused deposition manufacturing (FDM) is one of the rapid prototyping manufacturing technology and is today the second most common commercial layered manufacturing system [1]. The FDM without the need of laser is lower cost and has a simpler structure compared to SLA, LOM, SLS and other rapid prototyping manufacturing technology. So the maintenance is more convenient, too. But the accuracy of line width is the constraint to the FDM's further improvement [2].

2 Theory of scanning speed

The manufacturing accuracy of the FDM is influenced by many factors including the temperature of the nozzle, material viscosity, the contraction size of material's solidification [3], the accuracy of the equipment, the performance of software system and so on. Besides, the manufacturing is also restricted by working platform. The movement of the FDM mainly depends on the three motors of *X* axis, *Y* axis and *Z* axis. The *Z* axis motor controls the height while the *X* and *Y* axes motors controls the nozzle's movement in horizontal direction. That means the nozzle's horizontal scanning speed is composed of motors speed of *X* and *Y* axes. As shown in Figure 1.

It's hard to form when the scanning speed is faster than the extruding speed which causes the line broken due to the lack of the material. Instead, when the scanning speed is slower than the extruding speed will lead to the extrusion of the material too much and it causes the material on the working platform spreading non-uniform, which will affect the model's quality [4]. The set scanning speed of the nozzle matches the appropriate extruding speed can make the line width of the material on the working platform in a stable range.

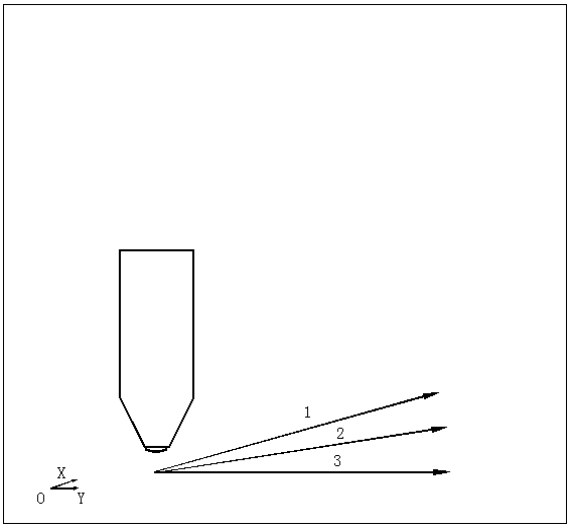

FIGURE 1 The velocity of the nozzle 1. The speed of the *X* axis 2. The actual speed of the nozzle 3. The speed of the *Y* axis

However, in some path, such as right-angled path, the scanning speed will change substantially while the extruding speed doesn't change which may cause accumulation of the material on the working platform. Although the scanning speed that is set by PC in different paths, which the PC cannot tell the difference, the motor speed of X and Y axes will change anyway. The most paths during FDM's working process are the straight line path, the right-angled path and the curved path. Here is an experiment between the line width and them. The right-angled path takes the bevel width, which is the critical point of the velocity's change, as the line width. The motor

* ***Corresponding author*** e-mail: stc@hdu.edu.cn

speed of *X* and *Y* axes don't change when it comes the straight line path. The Table 1 shows the line width of straight line path doesn't change much. The line width in curved path is wider than it in straight line path but the difference between them is not big in generally even the motor speed of X and Y axes are changing all the time. The scanning speed couldn't keep the same when its direction is about to change 90 degree. Because the scanning speed is composed of 2 phase motors' speed and the change in direction of the nozzle need both change of the two motors substantially in a very short time.

TABLE 1 The line-width in different trajectory (mm)

	straight line path	the curved path	right-angled path
d	0.65	0.7	1.10
	0.62	0.69	1.05
	0.61	0.72	1.07
	0.59	0.71	0.99
	0.62	0.75	1.08
	0.63	0.7	1.09
$\bar{d}$	0.62	0.71	1.06

Nozzle's temperature: 200°C the scanning speed: 10mm/s material: Polyurethane

The change of the shaft's speed is accomplished by changing the speed of the servo motor. In normal case, the starting of the no-load servo motor is very quick and the time of it can be ignored compared to the while working process. Even it may cost longer when it is loaded. The right-angled path is done by the nozzle instantly which makes time of the servo motor's acceleration not be ignored and it can be proved by Table 1.The acceleration of the servo motor in the starting and stopping stays the same, which is showed by Figure 2, thus, the relation between the velocity of servo motor and the velocity of the shaft can be calculated. The rotation of the shaft driven by servo motor makes the nozzle move in the direction of X(Y) axis. According to relation between the spiral and the helical pitch in mechanical transmission, the equation can be got as follows:

$$L = M \times P_h . \tag{1}$$

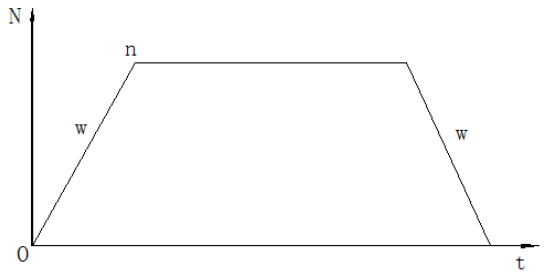

FIGURE 2 The process of motor's starting and stopping. *n* is the rated speed of the motor, *w* is the acceleration of the motor

The *L* represents the distance moved by the nozzle in the direction of *X*(*Y*) axis, the *M* represents the number of rotations of the shaft driven by servo motor, the P_h represents the helical pitch. Both sides of the Equation (1) are divided by the time, the relation between the velocity in axial of the nozzle and the velocity will be:

$$v = \frac{L}{t} = \frac{M}{t} P_h = n \times P_h , \tag{2}$$

and both sides of Equation (2) are differentiated, the relation is as follows:

$$a = \frac{dv}{dt} = \frac{dn}{dt} P_h = w \times P_h , \tag{3}$$

a represents the axial acceleration, the *w* represents the servo motor's acceleration.

Establish a model and analysis it for the process when the nozzle is going through a righted-angled path (Figure 3). The direction of the scanning speed is assumed to parallel the *X* and *Y* axes (For the convenience of analysis, the same conclusion can be got in other angles).

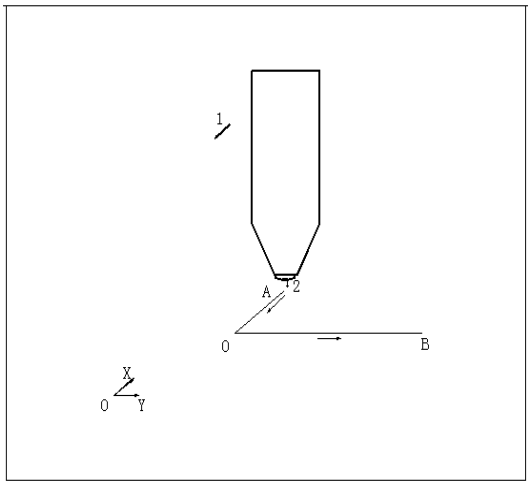

FIGURE 3 The scanning path 1. The scanning speed v_2. 2. The extruding speed v_1

As the scanning speed of the nozzle is composed of the motors' speed in the *X* and *Y* axes, The scanning speed in path AO means the speed of the motor in *X* axis. The nozzle decelerates in path AO and the deceleration can be deduced by Equation (3).The scanning speed of the nozzle is v_1,The extruding speed is v_2,the distance of decelerating is *S*, the time of nozzle spending in the decelerating distance is t_1.

The time spent in path AO with decelerating speed:

$$t_1 = v_1 / a . \tag{4}$$

The time spent in path AO with uniform speed:

$$S = v_1 \times t_2 ,$$

$$S = v_1^2 / 2a ,$$

$$t_2 = v_1 / 2a . \tag{5}$$

The different time between them:

$$\Delta t = t_1 - t_2 = v_1 / 2a . \tag{6}$$

Analysing the process of extruding material and the condition of the material on the working platform, as shown in Figure 4.In the circumstances of uniform speed, the quantity *m* of the material comes out of the nozzle in unit time *t*:

$$m = v_2 \times t \,. \tag{7}$$

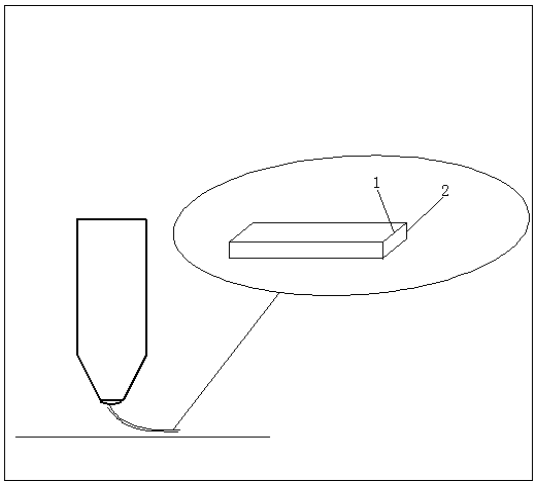

FIGURE 4 the amplification of line-width 1. Line width *d*. 2. Height of layer *h*

The quantity of the material extruded by nozzle on the working platform (ρ is the density of the material) [5]:

$$m = v_1 \times d \times h \times t \times \rho \,. \tag{8}$$

The quantity of the material stays the same from the nozzle to the working platform because there is no loss, the following formula can be got combining Equations (7) and (8) [6]:

$$v_2 \times t = v_1 \times d \times h \times t \times \rho \,. \tag{9}$$

If the line width and line height are wanted to keep the same when scanning speed v_1 is decelerating, the v_2 should be decelerated along with the v_1, which can be known from Equation (6).

$$\Delta m = \rho \times v_2 \times \Delta t = (v_1 \times v_2 \times \rho) / 2a \,. \tag{10}$$

Therefore, there is 2 times of quantity extruded when the nozzle goes through a righted-angle path combining the path AO and path OB. Substituting Equations (2) and (3) into Equation (10), the quantity extruded more than the standard is $(\mathrm{n} \times v_2 \times \rho) / w$.

There are two mainly filling ways in rapid prototyping technology presently which are straight filling and offsetting filling. The way of the straight filling (Figure 5a) working is moving back and forth in a straight direction and has nothing to do with the outline of the model to be done. The outline is added after each layer is done. But the offsetting filling (Figure 5b) is working in a way, which is close to the outline of each layer. The scanning path from inside to outside parallels the outline related to each layer of the model [7].

It fills perpendicularly to the working path between the two back and forth in order to keep the material continuous although the straight filling is not complex. The nozzle always meets the condition of big change in direction which causes the accumulation of the material no matter the simple straight filling or the complex offsetting filling. There are more than dozens and hundreds of layers in a model and each layer's error will be accumulated which may affect the accuracy of the model even destroy the structure.

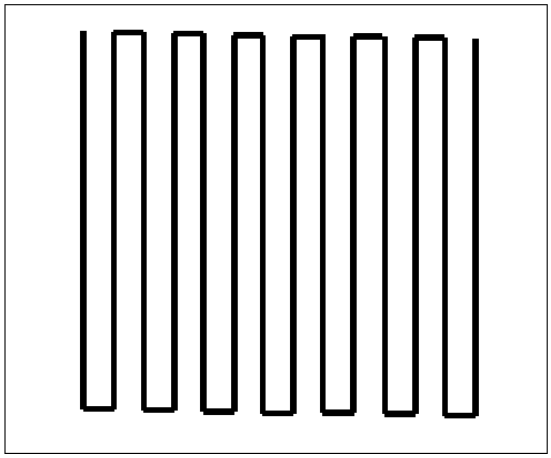

FIGURE 5a straight filling

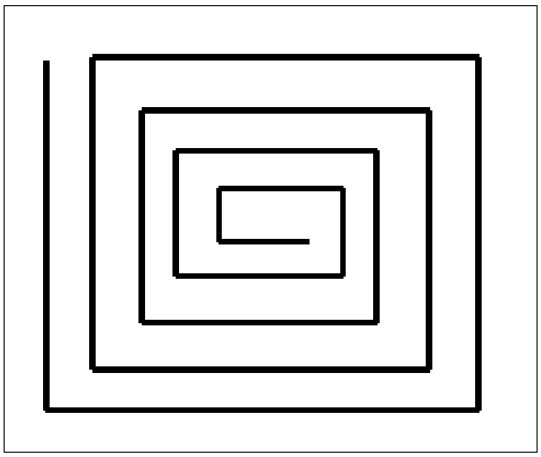

FIGURE 5b offsetting filling

3 The measures of improvement

The paper takes the nozzle of fused deposition molding machine the MEM-300 (Figure 6) of Tsinghua University as the experimental object and bring a method to improve the controlling. The screw extruder which simplifies the process and reduces the cost of the trial [8] is one of the main extruder in the field of FDM presently. The main factor affecting the extruding speed is the balance between the flowing resistance and driving force of the extruding motor in liquefaction pipe and nozzle where the liquid material goes through [9]. The extruding motor is the only problem to be considered to the extruding speed because the model is made by one material. The motor driver transmits the fixed frequency of pulse to the extruding

motor in order to make the material out of the nozzle with an unchanged speed in the whole process once the machine starts working. According the above analysis, the reason to the error is that the extruding speed does not match the scanning speed when the nozzle is going to have a big change in direction.

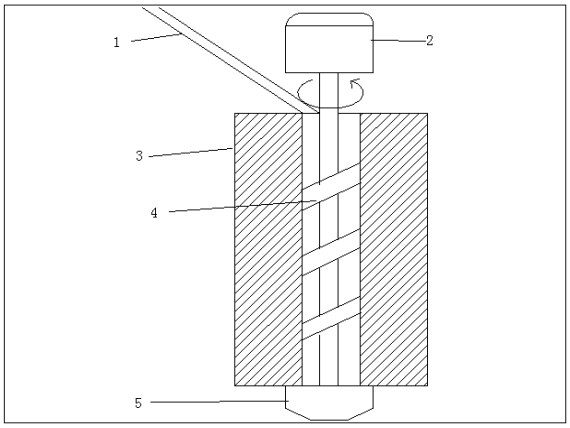

FIGURE 6 The structure of the nozzle 1. Feeding channel. 2. The extruding motor. 3. The heater. 4. Screw arbour. 5. The nozzle

If the extruding speed is reduced during the changing through controlling the extruding motor, the error will be decreased. The purpose of the study is to measure the line width in the different working frequency of the extruding motor. The reasonable speed could be chose when the nozzle is going to have a big change in direction. It may lay the foundation of the whole process's automation. The extruding motor is controlled by the PC software in normal condition and the extruding motor works with a set frequency once the software is started. The set speed is suitable which is based on a large number of experiments and the experiment is much significate based on the speed above.

After the oscilloscope detects the signal which is sent out by the PC to control the stepper motor driver, it could found the frequency of the signal is 1000Hz.

The external equipment of extruding motor is composed of step motor drive controller YJ01, stepper motor driver DM422C and the DC power to the driver.

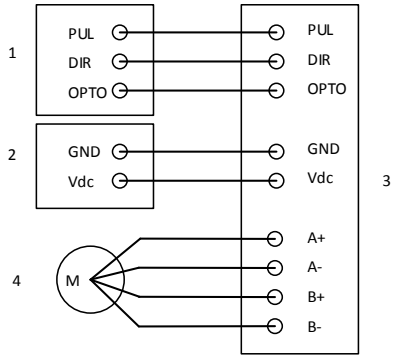

FIGURE 7 The connection of equipment 1. Stepper motor drive controller. 2. DC power. 3. Stepper motor driver. 4. Stepper motor

The Figure 7 is the connection of the equipment. The Figure 8 is the analysis of the righted-angle path. The line width D is the right line to be measured because the line width D is the critical place of the velocity's change and the maximum variation of the line width.

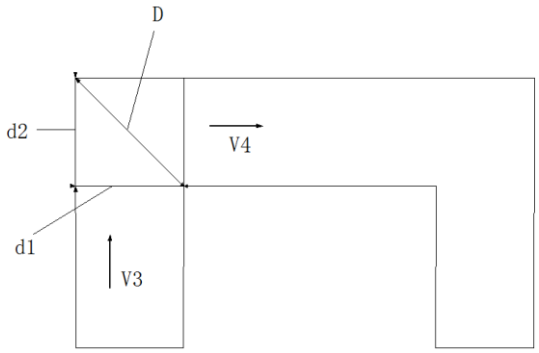

FIGURE 8 The amplification of the right-angled path

The scanning speed of the nozzle is changeless in the ideal condition, $v_3 = v_4$, according to the Equation (8):

$$v_3 \times d_1 \times h \times t \times \rho = v_4 \times d_2 \times h \times t \times \rho , \quad (11)$$

$$d_1 = d_2 = d . \quad (12)$$

So, $D = \sqrt{2}d$.

TABLE 2 The line-width under different frequency of the motor (mm)

Motor's frequency(Hz)	500	550	600	650	700
Line-width in right-angled d	0.85	0.82	0.84	0.89	0.89
	0.86	0.81	0.85	0.83	0.93
	0.82	0.83	0.89	0.86	0.90
	0.81	0.87	0.86	0.90	0.95
	0.78	0.86	0.86	0.92	0.95
	0.78	0.88	0.91	0.91	0.94
	0.75	0.88	0.93	0.88	0.93
	0.87	0.83	0.84	0.89	0.91
$\overline{d}$	0.815	0.8475	0.8725	0.885	0.925

Nozzle's temperature: 200°C the scanning speed: 10mm/s material: Polyurethane

According to the Table 1, the average of the straight line width d is 0.62mm and the bevel width D of righted-angle should be 0.87mm. The accuracy of the model is only controlled in the range of 0.1~0.2mm due to many factors' influence in the FDM process at present [10]. It is known from Table 1 the range of straight line width d is from 0.59mm to 0.65mm and the range of bevel width D should be from 0.83mm to 0.91mm.

TABLE 3 The percentage of the different frequency

motor's frequency (Hz)	500	550	600	650	700
percentage	37.5%	75%	87.5%	87.5%	50%

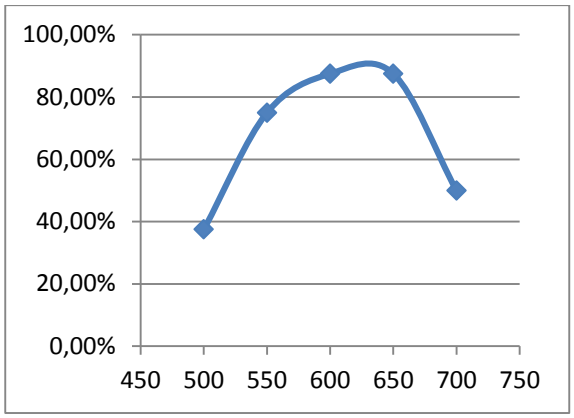

FIGURE 9 Scatter diagram of Table 2

Table 3 is percentage of Table 2 and Figure 9 is scatter diagram of Table 3.The data of line width is most in range of 0.83~0.91mm when the extruding motor's frequency is 550Hz,600Hz and 650Hz after analysing the above charts. The line width meets the requirement when the frequency of the extruding motor is between 550Hz and 650Hz during a righted-angle path according to Figure 9. In order to get rid of the limitation of the machine's structure, the frequency of the extruding motor should be changing along with the different path in the whole working process.

4 Conclusions

This paper has deeply analysed the accuracy of the FDM from the mechanical structure of the nozzle and brought a new method to improve the accuracy with the proof by experiment. The model's accuracy is still restricted by the structure of the working platform even the nozzle and other factors which affect the FDM's accuracy have been improved and it still may not meet the requirement. The accuracy of FDM will be much improved if the intelligent control system which makes the controlling of extruding motor automatic rapidly was taken.

Query semantic data from relational database: an on-demand mapping approach

Haifei Zhang*

School of Mechanical and Electrical Engineering, Nantong Textile Vocational Technology College, CN-226007 Nantong, China

Received 1 March 2014, www.cmnt.lv

Abstract

One of the tasks for semantic web is to integrate large amounts of current information in relational database, which behind Web into machine-understandable RDF data model to form a "web of data". So relational database semantic query namely RDF access to relational database is an important issue in semantic web research. To realize the query is to build mapping relation between relational database schema and ontology. However, there is natural isomerism between them. The traditional method to eliminate the isomerism is to convert relational database schema into a similar ontology form and then to build all concepts and attributes mappings between conversion ontology and input ontology. This paper realized an on-demanding mapping method when users request query, avoided building all concepts and attributes mappings between conversion ontology and input ontology and improved mapping efficiency.

Keywords: relational database, semantic data, conversion ontology, input ontology, on-demanding mapping

1 Introduction

Relational database semantic query namely RDF [1] access to relational database is an important issue in semantic Web research. There are two access approaches: one is to build mapping between relational database schema and known ontology [2], the other is to issue or transform existing relation schema into RDF ontology [3, 4]. With the development of semantic Web, the number of ontology increases, thus we can make full use of existing known ontology to realize the RDF access to relational database that is the first access method is discussed in above. However, there is natural isomerism between relational database schema and ontology. The isomerism can be eliminated by converting relational database schema into similar ontology (we call the conversion ontology) and then building mapping between conversion ontology and input ontology (that is known ontology mentioned above). The basic graph pattern of input ontology SPARQL query reflects ontology classes and attributes that users need to query. This paper realized an on–demanding mapping method when users request query, avoided building all concepts and attributes mapping between conversion ontology and input ontology and improved mapping efficiency.

2 Relational database schema

Definition 1: A relational database schema can be described as $D=(N,attr,pk,fk,datatype)$, and is pentad, where name set $N=ET\cup RT\cup DT$ is a finite set composed of pairwise disjoint sets, including set *ET* of entity relation name, set *RT* of relationship relation name, and set *DT* of data type name, each data type name is data type name predefined by RDBMS. For $\forall T\in ET\cup RT$, the $Rel(T)$ denotes the *T* is a relational table.

In $\forall T\in ET\cup RT$, T has a non-empty set of attributes $attr(T)$ and each attribute $A\in attr(T)$ has a relevant predefined data type $datatype(A)\in DT$ as its range, $datatype(*)$ denotes the predefined data type of "$*$".

In $\forall T\in ET\cup RT$, T has only a single attribute or attribute set determining its tuple, called primary key $pk(T)$ of *T*. If $pk(T)\in attr(T)$, $pk(T)$ is called as single primary key, while if $pk(T)\subseteq attr(T)$, $pk(T)$ is composite primary key.

In $\forall T\in ET\cup RT$, if there is relation attribute quotes the primary key $pk(G)$ of other entity relation $G\in ET$ in T, then this attribute is called foreign key, satisfying $fk(T,G)\subseteq attr(T)$ and:

$$value(fk(T,G))\subseteq value(pk(G))\cup\{null\},$$

$value(*)$ denotes the range of "*", and "*null*" denotes null value. *T* may have $n\,(n\geq 0)$ foreign keys.

3 Ontology and semantic modelling

An ontology is an explicit specification of a conceptualization [5], which can be formalized as O(C, R, F, A, I), where C is the set of concepts/classes; R is the set of relations over elements of C; F is the set of functions; A is a set of axioms; and I is a set of instances.

* ***Corresponding author*** e-mail: zhanghaifei@nttec.edu.cn

Concepts can be used to describe anything, concrete or abstract. The ontology engineer analyzes relevant entities and organizes them into concepts. The backbone of ontology consists of a generalization/specialization hierarchy of concepts, i.e., taxonomy. Relations between concepts of a domain are a subset of the Cartesian product: C×C, which describe the relationships between two entities of the entities in C; Functions are special relations, which presents a functional property on pair entities. For example, mother(x, y) presents that x has a mother y, so, x determines y, like a function: y=mother(x); A is a set of axioms which are tautology assertions; and I is a set if instances of the concepts in C.

In the perspective of Semantic Web, the ontology can be used to model the knowledge about a specific domain, which requires a terminology to represent the concepts and the relations between these concepts. What's more, these concepts and the relations are organized as a hierarchy form. Ontology provides the Semantic Web a formal model of domain knowledge, on which we can use some logic to inference. In Semantic Web, the logical foundation of ontology is the Description Logic (DL) [6].

Based on the concept of ontology, W3C recommends a set of specifications to model the information on the Web of data. RDF (Resource Description Framework) [1] is a lightweight ontology language, which originally designed as a metadata data model. RDF is based upon the idea of making statements about Web resources in the form of triple (subject, predicate, object) expressions. The subject denotes the resource, and the predicate denotes traits or aspects of the resource and expresses a relationship between the subject and the object. Therefore, RDF can be used to describe the entities and the relationships between these entities. However, RDF has limited weak semantics, and we need a rich-semantic ontology language. OWL (Web Ontology Language) [7] is another proposal which is recommended by W3C. OWL is designed for use by applications that need to process the content of information instead of just presenting information to humans. It can facilitate greater machine interpretability of Web content than that supported by RDF and RDFS by providing additional vocabulary along with a formal semantics. OWL has three increasingly-expressive sublanguages: OWL Lite, OWL DL, and OWL Full.

Semantic data modelled with OWL described in RDF is the foundation of Semantic Web applications, how to get the RDF data is an emergency question for many environments. So, lots of researchers have focused on the fields of mapping the existing traditional data to the RDF data [8]. W3C also recommends a language to map the relational data to RDF data, the R2RML (RDB to RDF Mapping Language) [9]. It can be used to express customized mappings from relational databases to RDF datasets. With R2RML, we can view existing relational data in the RDF data model. The target RDF data is modelled in an existing ontology and different distributed relational data can be mapped to the unified semantic data which implements a data integration application.

4 Relational database semantic query

Traditional database semantic query is as follows: First generating conversion ontology from relational database schema by semantic wrapper, then building mapping relation from input ontology to conversion ontology. So SPARQL query on input ontology can be transformed into conversion ontology according to the mapping relation. Lastly submitting conversion ontology to semantic wrapper for transforming into SQL query of relational database. The construction of semantic wrapper refers to the author's previous work [10]. And the key function is to generate conversion ontology and rewrite from conversion query to SQL query and SQL query results transform into RDF data. Relational database semantic query is shown as Figure 1. This paper mainly describes mapping on query, so query results are not discussed here and there is no hint of query results in the graph. All these are realized in the author's previous work [10].

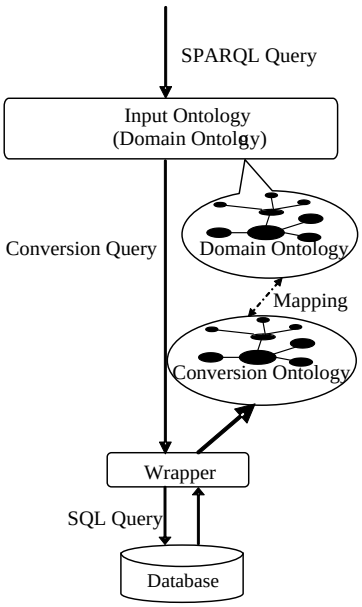

FIGURE 1 The structural diagram of relational database semantic query system

5 SPARQL basic graph pattern

SPARQL is the query language of semantic Web and is matched on graph patterns. Complex graph patterns can be obtained by combining simple patterns. Combining methods include: 1. Basic graph pattern; 2. Group graph pattern; 3. Optional graph pattern; 4. Alternative graph pattern.

Definition 2: A SPARQL query graph pattern *GP* is defined as the following expression:

$GP \to TP \mid GP\ AND\ GP \mid GP\ OPTIONAL\ GP \mid GP\ UNION\ GP \mid GP\ FILTER\ \exp$, where

$GP\ AND\ GP$ is namely group graph pattern, which could be the combination of any other graph patterns.

TP namely basic triple graph pattern, which could be the set consists of many RDF triples.

GP OPTIONAL GP stands for alternative graph pattern, the latter *GP* of which is the range of optional graph pattern.

GP UNION GP means that query graph pattern contains alternative graph pattern.

GP FILTER exp stands for value constraint, in which exp is the expression of value constraint.

Basic graph patterns (abbreviated to BGP) are sets of triple patterns. SPARQL graph pattern matching is defined in terms of combining the results from matching basic graph patterns. A sequence of triple patterns interrupted by a filter comprises a single basic graph pattern. Any graph pattern terminates a basic graph pattern [11].

Figure 2 shows the SPARQL query statement pattern, in which ?x, ?y and ?z respectively stand for instances of Class A, Class B and Class C. Class A has value property A1 and relationship property has B; Class B has value property B1 and B2 and relationship property has A and has C. Among them, A1 is value property variable with value constraint Exp(?A1); B2 is value property variable under OPTIONAL pattern; B1 is value property variable and takes the Value(B1); C1 is value property variable. From this SPARQL query statement pattern, it is known that this query covers basic graph pattern, optional graph pattern, value constraint and so on; for alternative graph pattern (UNION), its query rewriting result can be regarded as union of two SQL statements; SPARQL query statement of UNION graph pattern is not given.

```

FIGURE 2 SPARQL query statement pattern

6 On-demanding mapping on query request

In addition to the above described SPARQL basic graph patterns that are composed of triples, ontology is also composed of triples. Inputting the basic graph patterns of ontology SPARQL query in relational database semantic query reflects ontology classes and attributes that users need to query. This chapter presents how to realize the on-demanding mapping method when users request query by examples to illustrate how to build the mapping between the basic graph patterns in SPARQL query and conversion ontology.

Assuming conversion ontology generated from relational database schema is shown as Figure 3.

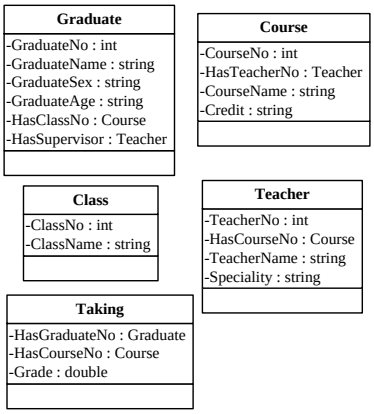

FIGURE 3 Graduate ontology

Obtain corresponding(matching) concept P_{oi} of O_i from conversion ontology; 14. $P_{ti} \leftarrow P_i$; 15. Return *Match*(P_{ti}, P_{oi}) 16. END 17. END FOR

7 Conclusion

This paper describes an on-demanding method when users request query by building mapping between basic graph patterns in SPARQL query and conversion ontology. To compared with the method described in classic literature [2] of the first access approach in section 1, this method avoid constructing all concepts and properties mapping between input ontology and conversion ontology, thus the efficiency is obviously.

The match between basic graph pattern and conversion ontology is similar to directly regarding input ontology SPARQL query as query on conversion ontology. But this query term (class and attribute) is not an exact match and needs to establish matching relation by using lots of similarity calculation algorithm in existing mapping of basic graph patterns and terms on conversion ontology. The on-demanding mapping method using basic graph patterns of SPARQL query statement in relational database semantic query avoided building all concepts and attributes mapping between conversion ontology and input ontology and undoubtedly improved query efficiency.

The study and design on the campus network surveillance

Xu Bing*, Yizhi Zhang

Chongqing Three Gorges University, Wanzhou Chongqing, China

Received 1 August 2014, www.cmnt.lv

Abstract

In order of improving the efficiency of network administration, one of the most useful methods is to inspect and measure of the network traffic. By introducing technology relevant to network flow monitor and analysing monitor system of campus network flow, this paper brings forth collection of Campus network flow and statistic of network flow, adopting Visual C++ 6.0 technology to design structure of this plan. This paper also points the key technology and means to realize monitor system of campus network flow and monitor system of campus network flow. It is reliable and extensible to for realization of system to improve administrative function. It is easy to realize the function of collection of campus network flow and flow statistic.

Keywords: network monitor, network flow, collection of flow, data statistic, VC++ 6.0

1 Introduction

With the rapid development and wide application of computer network, network has been interfered into various fields of social life. Similarly, as an important infrastructure establishment so as to innovate education in high colleges, improve managing level and educational quality, campus area network has been elevated correspondingly. However, the secure problems consisted in its operation and management has become prominent. Therefore how to establish sophisticated secure system of campus area network has become a crucial problem to be faced and tacked by network managers.

Network will determine our life style; the quality of network will have direct influence on various respects of social and economic life. With the increase of users' demand on network property, stable operation and efficient development of network cannot be guaranteed without efficient managing system and network system. With the rapid development of infrastructure technology of constructive network and network application and increase of demand on network property, network management has become an issue to be solved immediately. Efficient network management can guarantee stable operation and lasting development of network. What is more important, due to enlargement of network scale and development of hacker technology, the number of cases about invasion and attack become large, which takes challenge to stable network service and information security and internet rule, so internet security has become an important role in the whole system of internet management. At present, P2P, mainstream media and network game and some new application has occupied above 60 percent of network flow [1], and hostile attack on network has become more and more. Thus identification of network flow is quite important, which is helpful for network manager to timing supervise and manage various business flows and for supplier of network service to understand condition of each business flow of network when lay outing and constructing and for internet researchers to understand character of each flow of network and correspondent users' action. Therefore supervision on network flow has attached wider attention from academic and applicative fields.

2 Adopting relevant technology

2.1 NETFLOW

NETFOLW is a network exchanging technology stipulated by CISCO Company [2], which classify and handle network flow by concept of data flow. The definition of data flow given by NETFPLOW is consisted with seven key words marked by one- way network data assemblage of two communication terminals. The seven keywords are original IP, target IP, original terminal, target terminal, negotiation type, service type and interface search. In the case of traditional network interchange, each input subgroup is handled separately, then router will take series of independent consultation for each subgroup and check visiting list, obtain charging data and exchange subgroup by resort of series of functions, after that send {exchange}it to destination. These checks include whether to adopt secure visit to infiltrate and renewing network charging record. On contrary, in terms of NETFLOW exchange, in the process of consultation, it only works on the first subgroup of the first data flow. When a data flow is identified and determined its relevant service, the later subgroups will be treated as a part of this data flow and handle it on the base of linkage. In this case, it can avoid check on visiting list and can exchange subgroups in turn.

* ***Corresponding author*** e-mail:xb_2316@163.com

Besides exchange of data, important applications of NETFLOW are count information of data flow and supervise network flow. The information of data flow counted by NETFLOW is sent to address of preset information collector in the form of UDP data packet. Information collector will receive NETFLOW data packet constantly, then analyze various flow information.

The applicative model of NETFLOW (illustrated by Figure 1), NETFLOW exchange or route equipment analyze and count flow, then send information to information collector. NETFLOW information of various information collectors will be assembled to NETFLOW SERVER, after that it will handle flow information in accordance with need of application.

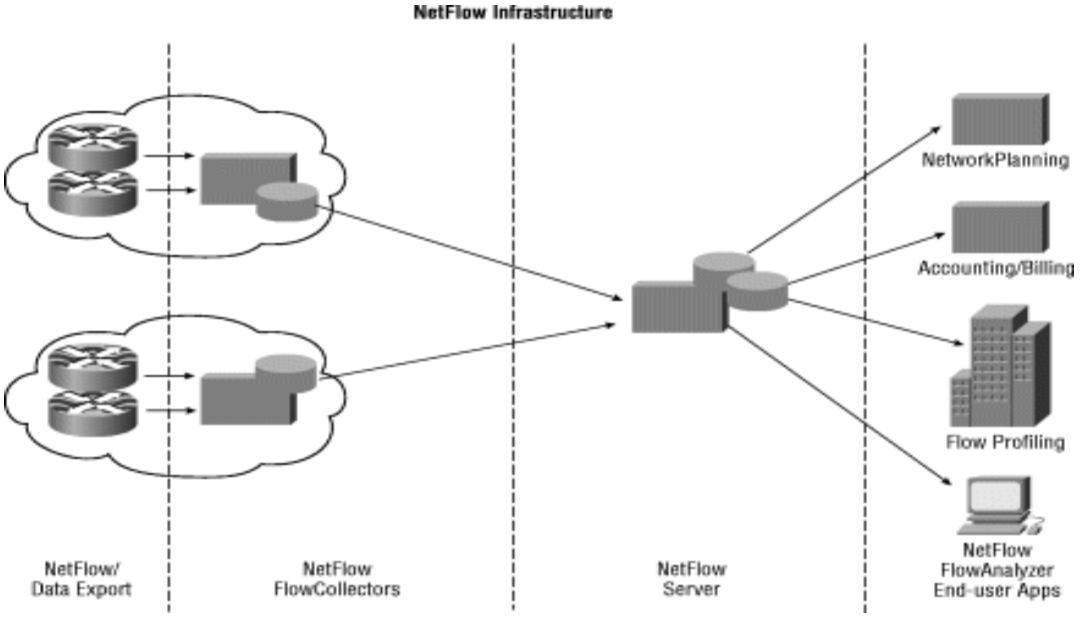

FIGURE 1 Netflow application structure diagram

2.2 PROGRAMMING INTERFACE OF TRANSPORT LAYER (WINDOWS SOCKET PROGRAMMING TECHNOLOGY)

2.2.1 The concept of Window socket

Window socket - SOCKET, as a foundation of network communication, which is suit of standard API supporting network negotiation data communication for exploration of Windows system. That is TCP/IP network programming interface. In 1994 after set as network programming standard, it experienced Winsock 1.1 and Winsock 2.0, with the final aim to adapt to the demand of explorer of applicative programmer and network servicer, and the process of communication is completed by socket communication domain. Socket is charge of input and output of data in transport layer and network layer so that shield data link layer and physic layer.

2.2.2 Type of socket

According to the nature of communication, the socket can be divided into stream socket and data gram socket. Their differences mainly are that stream socket offers bidirectional, regular, unrepeated data flow service. By contrast with data gram socket, the expense of its system is high. Data gram socket also supports bidirectional data flow ignoring reliability of transportation, unrepeated and regulation. However, it retains record delimitation. Owing to high efficient transportation of data gram, it is still used widely.

2.2.3 Sequence of byte, block and unblock

In terms of sequence of byte, different computer will adopt their own sequence to deposit data, thus when these data are used to communicated, sequence of byte need to be transferred. IP addresses and terminal numbers of network sockets functions should be arranged according to network sequence constructed by sockaddr_in. To be more cautious, before applicative procedure constructs applicative procedure, users need to transfer system- unit series number to network sequence (use htons function, on the contrary ntohs function).

Block and unblock, socket possesses synchronization block and a synchronization; in the case of block model, socket only to be finished when operation is accomplished; when socket are in unblock model, socket is marked by whether new data is up to block. Block model socket is simple, convenient, but is inefficient, by contrast, unblock model is complicated by efficient. To be mentioned, Winsock provides several I/O model to solve a synchronization issue, such as “selection”, “overlap”, “event selection”, “async selection” and so on.

3 Designing goal

Supervision of network flow and analysis tool mainly aims to timing collect network data constantly and do statistic

to obtain nature index of main opponents. Combined with theory of network flow, we can observe network situation by counted nature index and analyse changing tendency of network and find factors affecting network nature. It will realize following functions:

1) Adopting Winsock to compile original socket, socket- Raw collects data packet.

2) Analysing obtained data packets

3) Visiting parameter interface of network nature offered by operative system, obtaining total amount of flow of network card, input flow and output flow;

4) System will provide various ways to show result, such as curve graph, list and so on; it mainly adopt curve to show.

5) Adopting IP to help API obtain statistic information of network.

6) Realizing part of common alarms to continue exploring function of alarm.

4 Realization of system of network flow supervision

4.1 REALIZATION OF OBTAINING ORIGINAL DATA PACKETS

Obtaining system of data packet in network mainly relies on operative system; there are different realizing ways in different operative systems. In Window environment, we can realize the obtaining function of network data packet by network driver interface specification (NDIS), SOCK-RAW of WinSock or driving technology of virtual equipment and so on.

According to above account, original socket can avoid functions suffered by Socket, use and explore bottom negotiation, and generate needed data sheet in accordance with their own desire. I start to introduce some technical knowledge relevant to exploring catch data packet by use of original socket.

4.1.1 Before using socket, we need to understand working principle of receiving data of network card

In normal condition, network interface only correspond two kinds of data frame, one kind is just match their hardware, the other one is applied to all computer broadcast. In system, the send and reception of data frame is completed by network card. Network procedure receives data packet sent by network, and judges whether to match with hardware by hardware address. If it works, it will take notice CPU to stop to respond, then it calls network card set by driver procedure to stop procedure address to call driver procedure to receive data, after all put it into stack to do systematic handle, if not, this data packet will be discarded directly.

In the case of network interface, it possesses four receiving models of data that are broadcast, multicast, and direct and mix. Only when we set interface as mixed model, network interface can receive all data, ignoring whether addresses match, thus only we set mixed model when designing, and we can realize collection of data.

4.1.2 Working procedure and usage of socket

Generally speaking, exploring network procedure by adopting socket will be experienced by following steps: start, establishment, binding, monitor (receiving connection), connection, sending/receiving data, and close, unload and so on.

4.1.3 Designing how to obtain network data by means of original socket in windows

1) Starting socket;
2) Establishing a original socket;
3) Binding socket to local address
4) Setting operative parameter
5) Setting network interface as mixed model
6) Starting monitoring thread to receiving data
7) Quitting and closing socket.

4.2 KEY FUNCTIONS OBTAINED BY ORIGINAL DATA PACKET

4.2.1 Start function WSAS startup

int PASCAL FAR WSAStartup (DWORD wVersionRequested, LPWSADATA lpWSAData).

Each socket applicative procedure must do series of initialization work by calling this function, and this socket only can be used when call is accomplished and returned. Parameter wVersionRequested among them is the version number, high byte is the minor version, low byte is the major version, and parameter lpWSAData is the guiding principle of WSADATA structure.

4.2.2 Socket establishes function socket

SOCKET socket (int af, int type, int protocol).

All communications must be established on starting up a socket, the function of socket function is establishing socket, parameter af among them refers to address family. When socket established based on UDP or TCP, we need set af as AF_ INET and adopt IP negotiation. Function type is one type of negotiation socket. When we adopt stream socket, we use SOCK_ STREAM. When we adopt data gram socket, we use SOCK_DGRAM. When adopting original socket, we use SOCK_ RAW. Function protocol can set as 0 in the situation of default.

4.2.3 binding function bind

int bind (SOCKET s, struct sockaddr_in name, int namelen).*

The next step is bind local network interface with socket after establishing socket, function s is the established socket, parameter name is the guide of information structure of communicative object needed to be bound, namelen is the length of this structure. We should pay more attention to structure of sockaddr_in:

```
struct sockaddr_in{
short sin_family;    / address family, set as AF_INET
unsigned short  sin_port;      //pointed terminal number
struct in_addr   sin_addr;     //IPaddress
```

char sin_zero
};[8].

Due to relationship between System- unit serial number and network number, in the procedure we need to use htons and some functions to transfer.

4.2.4 Setting function WSAIoctl of interface model

int WSAAPI WSAIoctl(SOCKET s, DWORD dwIoControlCode, LPVOID lpvInBuffer, DWORD cbInBuffer, LPVOID lpvOutBuffer, DWORD cbOutBuffer, LPDWORD lpcbBytesReturned, LPWSAOVERLAPPED lpOverlapped, LPWSAOVERLAPPED_COMPLETION_ROUTINE lpCompletionRoutine).

s is a handle of socket, dwIoControlCode is the code of operative control, lpvInBuffer is the address of input block, cbInBuffer is the size of input block, lpvOutBufferis the address of output block, cbOutBuffer is the size of output block, lpcbBytesReturned is the address of the number of practical output byte, lpOverlapped is the address of structure of WSAOVERLAPPED, lpCompletionRoutine is a called routine guide after finishing guiding operation.

After finishing call, WSAIoctl return to 0, or will return to INVALID_SOCKET, applicative procedure can obtain wrong code by WSAGetLastError [5]

4.2.5 Recv

int recv (SOCKET s, char buf, int len, int flags);*

4.3 DATA STATISTIC

By use of API function in IP assistant of software, network manager can, to some extent, find bottom neck of network nature by statistic data. Main relevant functions are:

GetUdpStatistic, GetTcpStatistic, GetIcmpStatistic, GetIStatistic, we should pay more attention to IPHelpapi.lib needed to load in the project. The result of function calling can show directly by list that network managers can supervise network nature by observing change of statistic, the design of statistic interface is following.

5 Conclusions

On the basis of network flow supervision system, this essay introduces in detail main technology of network flow supervision, collection of campus network flow and statistic of network flow. This system can improve reliability and flexibility of flow supervision by measure of VC++ 6.0. In the light of operation test of campus network shows that system works stably to basically satisfy designing requirement, setting foundation of research and realization of exploring further campus network flow supervision system.

Abstract

Cloud computing is a new computing service mode, and virtualization is a key technology of it. A self-aware strategy (SAST) for Virtual machines (VMs) management on clouds is proposed which is multi-attributed weighted on the resources. It manages the virtual resource basing on the requests of users and the real-time state of the system dynamically. It consists of three phases: (1) monitoring the cloud performance including VMs and Physical Machines (PMs), with the data standardized; (2) measuring the cloud load balance value with the attribute weighted measurement model; (3) using the placement algorithm to choose the best appropriate PM to place the VM requested. The main contribution of the paper is that a cloud load balance measurement model is introduced and a VM scheduling strategy is proposed which includes the VMs placement optimization algorithm and the VMs dynamic migration algorithm. The SAST is tested on the simulation platform comparing with other traditional ones. As a result, we concluded that it guaranteed the SLA and achieved better load balance of cloud. And at the same time, it minimized the number of the started PMs on clouds to reduce energy consumption.

Keywords: cloud computing, virtualization, placement, scheduling

1 Introduction

Cloud computing [1] is considered a new computing service model and has got a lot of attentions. Cloud computing provides the infinite shared resources to the customers via the Internet. The customers would get them with not understanding the fundamental technology and the application running environment. The more quickly the demand of cloud computing grow, the larger data centre is needed. As most of all know, the user requirement for cloud platform is often heterogeneous and irrelevant, so the unreasonable resource distribution will lead to the waste of resources inevitably. In order to improve the utilization rate of resources, cloud computing platform also needs the dynamically balanced load of various kinds of services. On the other hand, large-scale computing infrastructure consumes a lot of power resources, and the power consumption increased year by year. FORREST W [2] has predicted that the data centre power consumption would reach 2% of the world's total energy consumption in 2020. So, how to dynamically and effectively manage the cloud computing platform resource becomes a key problem.

Virtualization technology [3, 4] provides an effective method to manage the resources of the cloud computing platform dynamically, and it has broken the tight coupling between the computing and the hardware. Customers use Virtual Machines (VMs), based on SLA; cloud providers take advantages of VM's flexible management on PMs to optimize resources allocation so as to meet customers' requests. Server virtualization technology enables multiple VMs running on a physical node at the same time. It has greatly improved the utilization of computing resources and implemented the on-demand deployment [5, 6]. In addition, the VM migration technology makes that cloud computing platform can be dynamically adjusted to deploy the VM to the less physical machines according to the changes of the service load, and as a result, it will achieve energy saving.

Since different resource utilization is caused by different mapping between VMs and PMs, for cloud providers, the key issue is how to effectively manage and schedule VMs to meet the customer's requests, and at the same time reduce the energy consumptions to minimize the cost. Nowadays, the algorithm for building the mapping from the customer's requesting VMs sets to the servers in the resource pool is becoming a hot issue. The algorithm will choose the most appropriate PM as the host for the requested VM and establish the specific mapping.

The number of the VMs requested on cloud is increasing with the development of cloud computing, and then the deployment of VMs becomes more important. A VM will be bound a PM for a lifelong under simple managing strategy, which will lead to a load imbalance. In the same way, the managing and scheduling strategy based on single attribute will also cause uneven load, such as a VM with demand for network could be deployed in a PM with sufficient CPU residue but poor network resource, resulting the VMs on the same PM competing for bandwidth. At the same time, the quantity and load of VMs and PMs will vary over time with the demand of the customer and application, static management of VMs will cause waste or shortage of resources, and the artificial scheduling is an obvious lag one.

[*]***Corresponding author*** e-mail: csguofen@scut.edu.cn

For VM management, one major direction is to minimize the number of the PMs for reducing energy consumption. Such problems are usually to be interpreted as packing problem [7-9]. These studies are usually only consider how to reduce the number of physical, but does not take into account the needs of customers (for example, now more and more customers have specified requirements about the network).What's more, it will lead SLA violation. Some studies [10-22] considered the needs of customers and applications. However, the optimization of load balancing is less concerned, and some studies do not consider the dynamic performance of the cloud. In view of this, the VMs management strategy should not only consider the utilization rate of resources but also the overall load balancing combining with the dynamic demand of customers.

Therefore, our paper presents a dynamic managing strategy for VMs on cloud. It is concerned chiefly with meeting the customer requirement, keeping the system load balancing and saving power. With meeting the constraints of PM resources(CPU, network, etc.), the strategy managed the VMs on PMs to achieve cloud's load balancing for reducing SLA violation, which allows the idle PMs in a sleeping state so as to reduce energy consumption on cloud finally.

Based on the above, we proposed a self-aware strategy (SAST) for VMs management on clouds which is called as SAST. The strategy is based on the user requests of virtual resources and the real-time system status. And it is composed of three phases: Firstly, to monitor the cloud load performance including VMs and physical machines, with the data standardized; secondly, to measure the cloud load balancing value with the proposed measurement model. Thirdly, to use the managing and deploying algorithm to choose the best appropriate PM to deploy the VM requested. In addition, the batch requests are treated in accordance with the single application process in order in SAST.

Our paper is divided into six major sections as follows. Section 1 introduces the related work. Section 2 opens with the description of the SAST. Section 3 shows the load balance measurement method. Section 4 introduces the main scheduling algorithm, while section 5 provides experimental result and analysis, and section 6 draws a conclusion.

2 Related work

There are two focuses on VM managing strategy for reducing energy consumptions. One is to consider how to place VM to the PMs in cloud. Eucalyptus [10, 11] has proposed round robin and greed algorithm to deploy the VMs. While OpenStack [12] takes a random scheduling strategy as the default one. However, the match-making scheduler [13] of OpenNebula achieved the ranking algorithm. Varma et al. [14] dynamically readjust server's location and consider the cost of migration and energy, with a simple algorithm; it shows that dynamic migration technology realizes low energy cost. Norman Bobroff et al. in [15] put forward a VM deployment algorithm using the forecasting techniques and heuristic algorithm, and ensured the SLA with minimizing the physical machine number. Singh et al. formed the question into a multi-dimensional knapsack problem, and treated the constraints of the deployment as a separate dimension [16]. Tsakalozos [17] used a two-phase mechanism for mapping problem of VM for large heterogeneous infrastructure: First, to synthesize the physical machine set which can be used at this stage; second, to determine the approximate optimal VM-to-PM mapping with satisfying constraints. Breitgrand et al. formalized the problem to be a multi-unit combinatorial auction model in [18]. Zhang Wei et al. of [19] proposed a kind of strategy for deploying and scheduling VMs based on multiple attributes analysis for the uneven loads between physical machines in the cloud computing.

The strategies or algorithm above consider the energy consumption, and they neglect the user requests and the load balancing of the cloud. The other type [20-22] is to consider the dynamic factor of the cloud. Nik Bessis [20] explored two configurations, the static case in which VMs are generated according to the cloud orchestration, and the dynamic case in which VMs are reactively adapted according to the job submissions, using migration, for optimizing performance time metrics. Yang Xing [21] proposed the Performance Matching-Load Balancing (PM-LB) algorithm of VM deployment. In [22] Zhao Hongwei put forward a kind of efficient resource management strategy based on the domain. Studies above covered various aspects, and they emphasized with the merchant's profits or only one single aspects of the optimization. But the study didn't consider how to achieve best load balancing. So they are also different from our objective.

3 Description of the SAST

3.1. SYSTEM ARCHITECTURE

The framework of the SAST is shown in Figure 1. It includes: central controller; VMs scheduling strategy generator, cloud monitor, VMs placement module.

The central controller is responsible for the overall system, including receiving the requests from the client layer, sending alarm information from the monitor and sending command to the VMs scheduling generator, etc.

The scheduling generator would build the load balance model of the cloud, and judge whether the node is overloaded or low load by analyzing the real-time data from the monitor. And then, it will calculate the best VMs placement scheme using the proposed algorithm in SAST combining with the requests of the alarm queue and the user's optimizing request queue.

The monitor will receive the load performance of each VM and PM periodically, the requests of the migration, the usage of the storage and the network of the cloud. If it found a PM load had exceeded the specified threshold, it would alarm. And at the same time, it would add this PM

into the alarm queue, and informed the central controller triggering the VMs scheduling generator to deal with it.

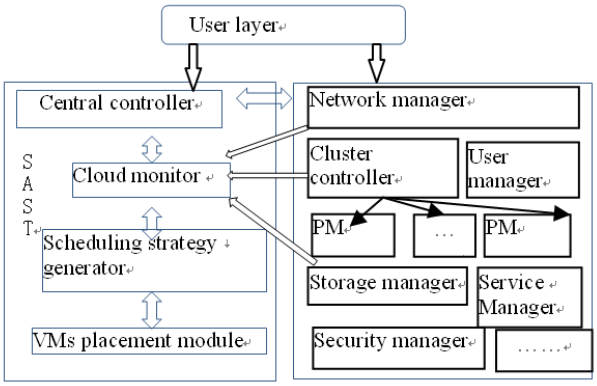

FIGURE 1 The system architecture

3.2 THE OBJECTIVE

The details of our objective are as follows:

Meet the existing customer's request, and maximize the load balancing degree on each physical server scheduling domain.

Minimize the number of PMs to start on IaaS on the basis of 2 to save energy.

Control the load rate of each PM in the scheduling domain not higher than the threshold

3.3 MONITORING STRATEGY

The traditional distributed systems often use the passive monitoring strategy. The node does not only need to exchange information between each other, but also report the status to the information centre regularly. Consequently, it will affect the overall performance of the platform.

1. The monitoring contents are shown in Table 1.

TABLE 1 The monitoring contents

CPU	Memory	Hard disk	Network
1-usage	1-usage	1-usage	1-usage

2. The sampling method.

The average sampling method is used to collect the monitoring data. The monitor collects every node's (including PMs and VMs) load data from the system for every *T* seconds, and defines the average value of the last N data as the load value of the node, which is denoted as $X = \sum_{i=1}^{N} X_i / N$. The value of *T* and *N* can be dynamically set by the monitor according to the individual request, the default value of *T* is 10 seconds, and the *N* is 5.

3. The monitor saves the latest load data vector $\boldsymbol{S}_x$ as the real-time load information of each *X* as follows(*X* can be a VM or a PM).

$$\boldsymbol{S}_x = (C_X, M_X, H_X, N_X). \quad (1)$$

C_x, M_x, H_x, N_x, respectively represents the monitoring data of CPU usage, memory usage, hard disk usage and bandwidth usage of the *X*.

3.4 SCHEDULING STRATEGY

The scheduling strategy is the core of the SAST, and it will be detailed in the below. This scheduling strategy combined with users' requirements to overcome the shortcomings of existing technology:

1) A cloud platform load balance measurement model is introduced with setting the weigh vector and matrix referring to the customer requirements and the monitoring data.

2) A VM scheduling algorithm is proposed, which includes the VM deployment optimization strategy and the VM dynamic migration strategy.

4 Load balance value measurement method

4.1 DEFINITION AND LEMMA

Suppose the number of the PMs in the scheduling domain is *m*, and the one of the VM types is *t.*

Definition 1. Let *P* stands for the PMs Set. *P* is defined as follows.

$$\mathrm{P} = \left\{ \mathrm{G}_i | \mathrm{i} \in (0, n) \, and \, \mathrm{G}_i P \right\} ,$$

$$\mathrm{G}_i = \left\{ p_{i1}, p_{i2}, ..., p_{ij} | \mathrm{j} = \mathrm{Num}(\mathrm{G}_i) \, \mathrm{and} \sum_{i=1}^{n} Num(G_i) = \mathrm{m} \right\},$$

$$p_i = \{SC_i, SM_i, SH_i, SN_i\} .$$

G_i stands for the i^{th} group on cloud, and p_i stands for the configure vector of the PM *i*. SC_i, SM_i, SH_i, SN_i respectively stands for the CPU size, the memory size, the disk size and the bandwidth size of P_i.

Definition 2. Let VT stands for the VM type's set. VT is defined as follows.

$$\mathrm{VT} = \{vt_1, vt_2, vt_3, \ldots \ldots, vt_t\}),$$

$$vt_i = \{sc_i, sm_i, sh_i, sn_i).$$

vt_i stands for the configure vector of the VM of type *i*, and sc_i, sm_i, sh_i, sn_i respectively stands for the CPU size, the memory size, the disk size and the bandwidth size of vt_i.

Definition 3. $v_i = \{sc_i, sm_i, sh_i, sn_i)$ can be deployed on $p_i = \{SC_i, SM_i, SH_i, SN_i\}$ only when

$$sc_i \le SC_i \ ; sm_i \le SM_i; sh_i \le SH_i; sn_i \le SN_i.$$

Definition 4. $p_j \le p_i \ (i, j \in (0, m])$

$$\text{s.t. } SC_j \le SC_i \ ; SM_j \le SM_i; SH_j \le SH_i; SN_j \le SN_i$$

Definition 5. Let V be the set of the VMs vectors which are deployed in cloud.

$$\mathrm{V}=\left\{\begin{matrix}V_1,V_2,\ldots\ldots,V_m|V_j=\{v_{j1},v_{j2},\ldots\ldots,v_{jk}\},\\ k\in N\ and\ \ j\in[1,\ \ m]\end{matrix}\right\}$$

Definition 6. V_j represents the set of the VMs on the PM p_j, the v_{ji} represents the i^{th} VM on the PM p_j.

Let W_v be the pre-supposed weighted matrix of the VMs, W_p be the pre-supposed weighted matrix of the PMs. The W_v and W_p are stored in the VM scheduler as follows.

$$\boldsymbol{W}_v=\begin{bmatrix}wv_{11} & wv_{12} & \ldots & wv_{14}\\ wv_{21} & wv_{22} & \ldots & wv_{24}\\ \ldots & \ldots & \ldots & \ldots\\ wv_{t1} & wv_{t2} & \ldots & wv_{t4}\end{bmatrix}$$

$$\boldsymbol{W}_p=\begin{bmatrix}wp_{11} & wp_{12} & \ldots & wp_{14}\\ wp_{21} & wp_{22} & \ldots & wp_{24}\\ \ldots & \ldots & \ldots & \ldots\\ wp_{m1} & wp_{m2} & \ldots & wp_{m4}\end{bmatrix}$$

$$\mathrm{W_{v_s}}=(\mathrm{wv_{s1}},\mathrm{wv_{s2}},\mathrm{wv_{s3}},\mathrm{wv_{s4}})$$

$$\mathrm{W_{p_j}}=(\mathrm{wp_{j1}},\mathrm{wp_{j2}},\mathrm{wp_{j3}},\mathrm{wp_{j4}})$$

$$\mathrm{wv_{s1}}+\mathrm{wv_{s2}}+\mathrm{wv_{s3}}+\mathrm{wv_{s4}}=1$$

$$\mathrm{wp_{j1}}+\mathrm{wp_{j2}}+\mathrm{wp_{j3}}+\mathrm{wp_{j4}}=1$$

$\boldsymbol{W}_{v_s}$ stands for the weighted vector of v_s, while the $\boldsymbol{W}_{p_j}$ stands for the weighted vector of p_j. And $wv_{s1},wv_{s2},wv_{s3},wv_{s4}$ respectively represents the pre-supposed weight of CPU, memory, hard disk, network for the v_s, while $wp_{j1},wp_{j2},wp_{j3},wp_{j4}$ has the similar meaning. So we can use $\boldsymbol{W}_x$ (X can be a VM or a PM) to represent the performance weight vector of X.

4.2 LOAD VALUE MEASUREMENT MODEL

Let $bl(j)$(j∈[1,m]) be the load value of the PM p_j, O as the load balance value of the scheduling domain. Function $f_n(j)$ returns the number of the VMs deployed on the PM p_j, while $H_p(p_j)$ represents the load value of PM p_j, and $H_v(j,i)$ stands for the load value of the VM v_{ji}. The performance weighted strategy calculates the load value according to the following Equations. σ is a systematic parameter which can be set by the system administrator.

$$H(x)=\boldsymbol{W}_x\times\boldsymbol{S}_x, \tag{2}$$

$$bl(j)=\sigma\times H_p(p_j)+(1-\sigma)\times\sum_{i=1}^{f_n(j)}H_v(j,i)/\ f_n(j). \tag{3}$$

$$O=\sqrt{\sum_{j=1}^{m}\left(bl(j)-|bl|\right)^2}/m\ ,$$

$$\sigma\in(0,1)\ ,\qquad\left(|bl|=\sum_{i=1}^{m}bl(i)/m\right). \tag{4}$$

Lemma 1. Based on the definitions above, we can deduce that the smaller the O is, the higher the cloud load balance degree is.

Lemma 2. Based on the configure set of PMs and VMs, we can get the VM number matrix $\boldsymbol{R}$, while the r_{ij} represents the max number that the vt_i can be deployed on the p_j. The detail is as follows:

$$\boldsymbol{R}=\begin{bmatrix}r_{11} & r_{12} & \ldots & r_{1m}\\ r_{21} & r_{22} & \ldots & r_{2m}\\ \ldots & \ldots & \ldots & \ldots\\ r_{t1} & r_{t2} & \ldots & r_{tm}\end{bmatrix}.$$

$$r_{ij}=min\{l_1,\ l_2,\ l_3,\ l_4\}\ (\ i\in[1,\ t],\ j\in[1,\ m]).$$

$$l_1=\ SC_{p_j}/sc_{v_i},l_2=\ SM_{p_j}/sm_{v_i}.$$

$$l_3=\ SH_{p_j}/sh_{v_i}\ ,l_4=\ SN_{p_j}/sn_{v_i}.$$

Lemma 3. When a new VM q_x is requested whose type number is be k, we can find the corresponding weighted vector in W_v. Suppose $H'_v(v_x)$ returns the presupposed load value for q_x, while $H'_p(p_j)$ returns the pre-supposed load value of the PM p_j if the v_x is deployed on it, and $\boldsymbol{S'}_{p_j}$ returns the pre-supposed load data vector of the PM p_j. Then we can deduce the following Equation.

$$\boldsymbol{S'}_{p_j}\approx\boldsymbol{S}_{p_j}+1/r_{kj}\ ,$$

$$H'_p(p_j)=\boldsymbol{W}_{p_j}\times\boldsymbol{S'}_{p_j}\approx H_p(p_j)+\boldsymbol{W}_{p_j}\times100/r_{jk}, \tag{5}$$

$$H'_v(v_x)=\sum_{i=1}^{f_n(j)}H_v(j,i)/f_n(j). \tag{6}$$

Lemma 4. Given $bl'(j)$ returns the pre-supposed load value of the PM p_j. Then we can deduce it as follows basing on Equation (5) and (6).

$$bl'(j)=\sigma\times H'_p(p_j)+$$
$$1-\sigma\cdot\left(\sum_{i=1}^{f_n(j)}H_v(j,i)+H'_v(v_x)\right)/\left(f_n(j)+1\right)\ . \tag{7}$$

Lemma 5. Suppose $\Delta bl(j)$ as the changes in the load values of p_j if the v_x is deployed on itself, then we can deduce as follows.

$$\Delta bl(j)=bl'(j)-bl(j)$$
$$=\sigma\times H_p(p_j)+\sigma\times100\times\overline{W_{p_j}}/r_{jk}+\ . \tag{8}$$
$$(1-\sigma)\times\left(\sum_{i=1}^{f_n(j)}H_v(j,i)+H'_v(v_x)\right)/\left(f_n(j)+1\right)$$

When $f_n(j)$ is very great, we can deduced the below Equation.

$$\Delta bl(j) \approx \sigma W_{p_j} / r_{jk} + (1-\sigma) H'_v(v_x) / f_n(j). \quad (9)$$

Lemma 6. Suppose $\Delta O(j)$ as the changing value in the load balance value of the cloud scheduling domain if the v_x is deployed on itself, then we can deduce as follows.

$$|O'| = \left(\sum_{i=1 \text{ and } i \neq j}^{m} bl(i) + bl'(j) \right) / m, \quad (10)$$

$$\Delta O(j) = \sqrt{\sum_{i=1 \text{ and } i \neq j}^{m} \left(bl(i) - |O'|\right)^2 + \left(bl'(j) - |O'|\right)^2 / m - O}. \quad (11)$$

5 Scheduling algorithm

5.1 ALGORITHM SUMMARY

Suppose there are n VMs which the user layer has requested, while the request set is called Q:

$$Q = \{q_1, q_2, q_3, \ldots\ldots, q_n\} | qi \in VT.$$

Then the main work of the deploying and scheduling for VMs is to find the mapping f:

$$f: Q \xrightarrow[q_i \longrightarrow p_j]{deployed} P \quad (q_i \text{ is deployed on } p_j).$$

The details are as follows.

Adding all the alarm tasks into the alarm queue Q_R, and invoking the alert processing module to process each PM in queue sequentially.

Adding the user-specified optimization tasks into the optimization queue Q_O, and calling the optimization module to optimize each PM in queue.

Adding new requested task into the new task queue Q_N, and calling the VM deployment scheduling module to treat each request in order.

5.2 PREREQUISITES AND RESTRICTIONS

Never deny the user's request ($v = \{sc, sm, sh, sn\}$) except when:

$c \leq \sum_{i=1}^{m} SC_i$ or $sm \leq \sum_{i=1}^{m} SM_i$

or $sh \leq \sum_{i=1}^{m} SH_i$ or $sn \leq \sum_{i=1}^{m} SN_i$.

Only allow the user to request one of the VM types among the given VT.

Each PM and VM can be monitored, and when there was a PM or VM load had exceeded the specified threshold, the monitor would alarm.

The first group G_1 is the default initial scheduling domain on the cloud.

5.3 THE DETAILS OF THE ALGORITHM

5.3.1The main process

Input:

$P = \{G_i \mid i \in (0, n) \text{ and } G_i P$

$P = \{p_1, p_2, \ldots, p_m \mid m \in N\}$

1) V, W_v, R, W_p;
2) $S = \{S_x \mid x \in P \text{ or } x \in V\}$;
3) The queues Q_R, Q_O, Q_N.

Output: $f: Q_N \xrightarrow[q_i \longrightarrow p_j]{deployed} P$; finish status.

Steps

```
1)  while(QR!=NULL)
    {
    q=QR->head;
     if (dynamicsheduler (q->id, q->threshold, (P-QR))= = SUCCESS)//
process PM q
     {QR->head=q->head; delete (q);}
     else
     go to 4);
     }
2)  while(QO !=NULL)
    {     q=Qo->head;
      if (dynamicsheduler (q->id, S, (P-Qo))= =SUCCESS) // process
      PM q
        {Qo->head=q->head;
         delete(q);
         }
      else
      go to 4);
    }
3)  while(QN !=NULL)
    {q= QN->head;
     if (staticsheduler (q->id, P)= =0)
        // process PM q
       go to 4);
     else {QN->head=q->head;
        new p;
        p->id= staticsheduler(q-> id, P);
        insert(q ⟶ p) to f;
        Update(V, q ⟶ p);
        deploy(q,p);//deploy q on p
        delete(q);
        }
    }
4)  if (Num(the current Gi)= =m)
    //if all the PMs in the current scheduler domain
         return FAIL;
    else {
    start Gi+1;merge(Gi, Gi+1);
    }
```

5.3.2 The VM placement module

staticscheduler

Input: the requested new VM q; ()

Output: the id of the target PM (0 stands for failure)

Steps:

```
1)  for(i=1;i<=num(G);i++)
    {p=G(i);
     if(S(p) ≈0) return i;
    }
```

2) for(i=1;i<=num(G);i++)
if (G(i)>q) insert (G(i),Q_L);
{if(Q_L!=NULL)
{Scan Q_L orderly;
if (m> system threshold number)
//if m is very large
return the first j in $\{j|j \in \min_{j\in[1,num(Q_L)]} \Delta bl(j)\}$;
else
return the first j in $\{j|j \in \min_{j\in[1,num(Q_L)]} \Delta O(j)\}$;
}
else
return dynamicsheduler (q->id, the specific threshold, G);
}

5.3.3 The dynamic migration scheduling module

dynamicsheduler

Input: ID (PM id or new VM type number);
The default threshold of PM load; the current schedule domain G;
Output: FAIL or SUCCESS

Steps:

1) Make *P* to *P'*(*P'* is in descending order according to the available size of resources);
2) if the module is invoked by Q_O or Q_R
{delete p whose id = =ID from *P'*;
v=Max (V_{id}); //v is the max VM on p;
}
else v=vt_{id}; //v is the requested VM;
3) for(x=1;x<num(*P'*),x++)
{
if (there is *V'* on V_x which meet the following condition:
a); (V_x- *V'*)>*v*
b) for each $v' \in V'$
staticsheduler (*v'*->id, P')! =0
)
{
for each $v' \in V'$ deploy (*v'*, *P'*);
return SUCCESS;
}
else return FAIL;
}

6 Experimental result and analysis

This section shows that the SAST is feasible and exact. This experiment is simulated with Java programming language, using a set of simulated experiment set to compare the performance of the round robin algorithm, the best fit heuristic packing algorithm and the SAST.

6.1 CONFIGURATION

1. The configuration of the PMs and VMs is described in Table 2. The PMs consists of 10 nodes and 2 kinds of configuration. There are 6 PMs about node1, and 4 PMs about node 2; The VMs has two types, one is the high computing (HC), another is the high storage (HS). Each type is divided into big, medium and small class, so there are six different VM configurations. Clusters are divided into 10 groups, each group of only one PM. Each CPU has a core (Intel(R) Xeon (R) E5606). There are 10 PMs with two types of configuration.

TABLE 2 Experiment configuration

Type	CPU (G)	Memory (G)	Storage (GB)	Network (MB)
node1	16	96	20*1024	1000
node2	16	96	10*1024	1000
VM_A	8	8	200	100
VM_B	8	4	100	100
VM_C	8	2	50	100
VM_D	4	8	200	100
VM_E	4	4	100	100
VM_F	4	2	50	100

2. All strategies using the same set of monitoring data.

3. In each strategy the VMs are requested at random for 15 times.

4. When talking about round robin strategy, let's suppose that Wp=(0.25,0.25,0.25,0.25), and for SAST, σ=0.6,and the setting of Wv is shown as Table 3.

TABLE 3 W for six VMs

w	VM_A	VM_B	VM_C	VM_D	VM_E	VM_F
w_1	0.3	0.2	0.4	0.2	0.5	0.2
w_2	0.25	0.25	0.2	0.2	0.15	0.15
w_3	0.2	0.3	0.2	0.4	0.2	0.5
w_4	0.25	0.25	0.2	0.2	0.15	0.15

6.2 RESULTS AND ANALYSIS

The number of PMs started of the SAST is the same with the best fit heuristic packing algorithm at each application as shown in Figure 2, and the early number were less than the largest PM number. But when the system entered into a stable state, the load balance degree of cloud of the SAST is relatively high, particularly as shown in Figure 3. The abscissa represents the number of VMs, and the ordinate represents the value of load balance value of the cloud.

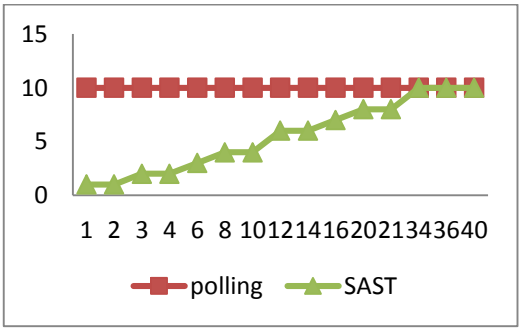

FIGURE 2 The PMs started

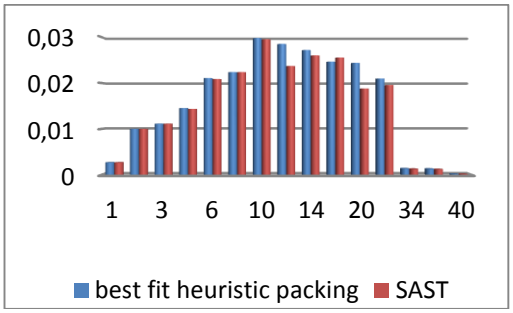

FIGURE 3 The load balance value

We let two strategies applied 20 VMs at random for 4 times, the total number of migration at the steady state of the cloud platform was compared and shown in Table 4.

TABLE 4 The total number of migration

Strategy	Random Equilibrium	SAST
the number of test 1	4	2
the number of test 2	4	3
the number of test 3	3	0
the number of test 4	5	2

7 Conclusions

Considering the user requests of virtual resources and setting the weight of performance parameters to calculate the load balance value of the cloud, we present a self-aware strategy for VMs placement on clouds. It achieved better load balance of cloud, and at the same time, it minimized the number of the started PMs on clouds to reduce energy consumption. However, the time complexity of the SAST is relatively high when it is compared with the round robin algorithm and other traditional algorithms. We will emphasize with the security on cloud in the future work.

Abstract

To improve the efficiency of policy searching, a method based on the use of a weighted directed graph is studied. Regarding security states as vertices and trigger conditions as edges, the security policy knowledge base can be described as an acyclic weighted directed graph. Firstly, the graph is divided into some areas with just has an initial state node and a termination state node. Secondly, weights for each edge are set according to trigger condition frequencies, and then the optimal path from the initial state node to the termination state node is found using the A* algorithm. Finally, all state nodes are reordered on the basis of their optimal path to build an adjacency matrix and conduct depth-first traversal to search policies. Experiments showed that this method improved policy search efficiency.

Keywords: security policy search, acyclic directed graph, A* algorithm, adjacency matrix

1 Introduction

With the expansion of computer networks and increases in their complexity, information systems face serious security threats. Reasonable and effective security policy can ensure that network devices work together, so that an information system can deal with a series of security incidents. The security policy is event-driven and enforced by changing the configuration of security devices. Based on the model of a state machine, security devices or their related functions can be regarded as security states, and the security policy can be described as changes in these security states under special trigger conditions. Combined with the frequency of these trigger conditions, the set of security policies can be created as an acyclic weighted directed graph. On the basis, this paper discusses improvements to the efficiency of search policy rules on a directed graph.

The complexity of searching a security policy depends on how its description. A security policy can be expressed as a Datalog program [1], by using the Datalog semantic query algorithm to implement searched thereon. Based on first-order logic, a security policy can also be expressed by well-founded semantics [2], by introducing the SLG algorithm [3, 4] to realise policy searching. In this research, a direct graph was used to express the policy knowledge base instead of creating a logical system through well-founded semantics. The method of searching policies by traversing the graph was simpler and more efficient.

2 Definition of the security policy and system operation principle

A security policy is a set of rules, which control the security management of people and resources [5]. A security policy expresses multiple requirements related to system security while not all these requirements can be characterised by security models [6]. This paper describes a security policy with $P =< D, C, R >$, where D represents the security domain. C represents the trigger condition which consists of a security incident and a system incident (only security incidents are shown in the acyclic directed graph). R represents the rule set (each rule represents a configuration action described by $r =< i, o, s_{0,} l >$). i represents the former state. ^{o} represents the output state (state transition can be described as $i(C) \to o$). s_o represents the initial state of the security domain, and l represents whether the output state of policy is a final state or not. All state transition rules in the system constitute the policy knowledge base, which can be described as an acyclic directed graph containing one initial state node and some termination state nodes: it is shown in Figure 1, which shows part of the rules as based on policy within the policy knowledge base.

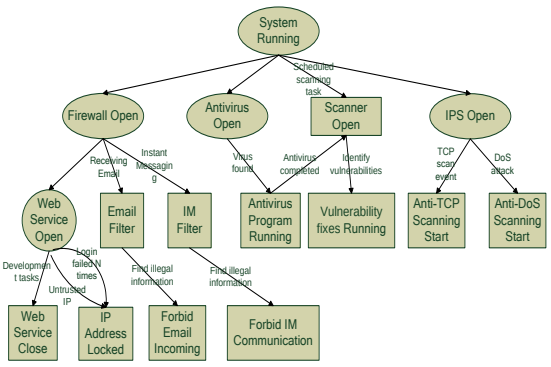

FIGURE 1 Part of the rules in the knowledge base described as a directed graph

[*]***Corresponding author*** e-mail: cheng3100@sohu.com

There is a current state set in the system, which is used to save the active states, and a state will be deleted from the current state set when it changes under the conditions imposed by the security incident. The system operation principle is shown in Figure 2. When the system receives notification of a security incident, it searched the former state and determined whether the former state belonged to the current state set. If the current state set contained the former state, then system distributed the security policy to related devices and enforced it, otherwise no action was taken. When policy enforcement was complete, the output state of the policy was merged into the current state set. Sometimes the trigger condition would be a system incident such as "system running" provided that the trigger condition continued in the system, then its output state would always remain in the current state set.

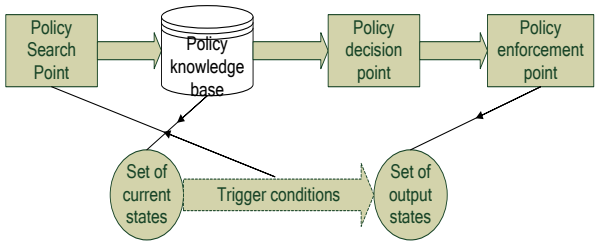

FIGURE 2 System operation principle

As shown in Figure 2, policy searching plays an important role in system operation: it is the premise of policy enforcement. In the direct graph, depth-first traversal or breadth-first traversal can be used when searching policies: both methods required an adjacency matrix. A path from the initial state node to the termination state node forms a workflow, considering the association among states in the same workflow; depth-first traversal was a better choice. When building the adjacency matrix, the sequence of nodes determined the nodal access order in depth-first traversal. To give priority to nodes, which stand for high frequency security incidents, the weights of the graph and the method of arranging the nodes were combined: this was feasible when building the adjacency matrix as proposed.

3 Method of searching security policy based on weighted direct graph

3.1 INSTANCE OF WEIGHTED DIRECTED GRAPH

There is no loop in the directed graph, which is created according to the knowledge base. The graph only has an initial state node (the in-degree of the node is zero) and some termination state node (the out-degree of the node is zero). With a small-scale knowledge base (e.g. Figure 3), V1 represents the initial state node, V10, V11, and V12 are termination state nodes, c1 to c16 are trigger conditions, the frequency of trigger conditions is described by an integer from 1 to 10, where 10 stands for the highest occurrence probability and 1 the lowest.

Using an adjacency matrix to describe this directed graph, each item in the matrix was represented by the name of its trigger condition and event frequency. In accordance with the sequence from V1 to V12, the weighted direct graph was transformed into a matrix as follows:

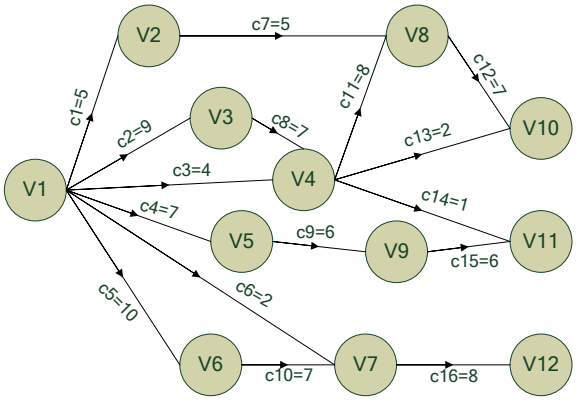

FIGURE 3 A small-scale policy knowledge base represented by a weighted direct graph

$$A=\begin{bmatrix}
null & c1,5 & c2,9 & c3,4 & c4,7 & c5,10 & c6,2 & null & null & null & null & null \\
null & null & null & null & null & null & null & c7,5 & null & null & null & null \\
null & null & null & c8,7 & null & null & null & null & null & null & null & null \\
null & null & null & null & null & null & null & c11,8 & null & null & c13,2 & c14,1 \\
null & null & null & null & null & null & null & null & c9,6 & null & null & null \\
null & null & null & null & null & null & c10,7 & null & null & null & null & null \\
null & null & null & null & null & null & null & null & null & null & null & c16,8 \\
null & null & null & null & null & null & null & null & null & c12,7 & null & null \\
null & null & null & null & null & null & null & null & null & null & c15,6 & null \\
null & null & null & null & null & null & null & null & null & null & null & null \\
null & null & null & null & null & null & null & null & null & null & null & null \\
null & null & null & null & null & null & null & null & null & null & null & null
\end{bmatrix}$$

If the frequency of the trigger condition was not taken into account when building the adjacency matrix, then depth-first traversal would not be conducive to a timely response to high frequency events, especially when the scale of the directed graph were large. As shown in Figure 3, the frequency of c16 was relatively high in all trigger conditions while almost all state nodes needed to be traversed to find the former state (V7) of c16. So the sequence of nodes when building the adjacency matrix was important when improving the efficiency of a policy search. Early detection, early implementation methods of arranging the nodes entailed two key steps: division of the graph into sub-areas, each containing one initial state node and one termination state node and discovery of the optimal path for each area using the A* algorithm. On the basis of each optimal path, all state nodes were reordered.

3.2 DIVIDE THE DIRECT GRAPH

Starting with one of the termination state nodes, the previous state of that node was successively searched until reversion to its initial state node. All state nodes were visited from the termination state to initial state node to

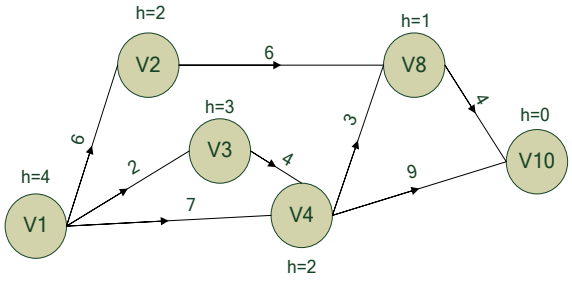
form a division of the directed graph. The number of termination state nodes on a graph was the number of areas after sub-division. This was realised by a recursion method.

For a direct graph with n nodes and e edges, the time complexity of the algorithm was $\Omega(n+e)$. By executing the algorithm, all relevant state nodes from the initial state node to the termination state nodes can be found. The graph was sub-divided as shown in Figure 3 into three areas, and the node sequence was output in reverse order as follows:

{{V1,V2,V3,V4,V8,V10},{V1,V3,V4,V5,V9,V11},{V1, V6,V7,V12}}

3.3 FIND THE OPTIMAL PATH OF EACH AREA AND REORDER ALL STATE NODES

The optimal path was that most likely to have been chosen from the initial node to the termination node corresponding to a series of higher frequency security events. Using the A* algorithm to find the optimal path required alteration of the optimal path to the minimum dissipation path. In the weighted direct graph, value of arcs represented the frequency of security events, the higher the frequency, the smaller the dissipation. The frequency values ranged from 1 to 10, so the conversion formula from frequency to dissipation value was set to $g_i = 10 - c_i + 1$ where g_i represents the dissipation value and c_i represents the frequency. Meanwhile, to reduce the number of nodes in this extended search, a heuristic function was required. The value of this heuristic function h was set to encompass the maximum number of steps to a given termination node. One of the sub-areas of the graph shown in Figure 3 was chosen, marking the heuristic function value of each node and the dissipation value of each arc, as shown in Figure 4.



FIUGRE 4 One graph sub-division showing its heuristic function value and dissipation value

The A* algorithm [7] was used to find the optimal path from initial node V1 to termination node V10: Table 1 shows such the search table thus created.

TABLE 1 A* algorithm search table

OPEN`	CLOSED
Initialisation(V1(4))	()
1 (V2(8) V3(5) V4(9))	(V1(4))
2 (V2(8) V4(8))	(V1(4) V3(5))
3 (V4(8) V8(13))	(V1(4) V2(8) V3(5))
4 (V8(10) V10(15))	(V1(4) V2(8) V3(5) V4(8))
5 (V10(13))	(V1(4) V2(8) V3(5) V4(8) V8(10))
End of search	

According to the search result, the optimal path was V1 →V3 → V4 →V8 → V10, and the dissipation of the path was 13. Similarly, for the division from V1 to V11, the optimal path was V1 → V5 → V9 → V11, the dissipation value was 14, and for the division from V1 to V12, the optimal path was V1 → V6 → V7 → V12 and the dissipation value was 8. According to the dissipation value of each optimal path, the division of nodes was arranged in ascending order:

{{V1,V6,V7,V12}, {V1,V3,V4,V8,V2,V10}, and {V1,V5,V9,V3,V4,V11}}.

The first node was removed from each set to form the final node arrangement, if the node was already in the final arrangement, then the original node was overwritten to give the termination nodes for each division. After nodal arrangement the set was:

{V1,V6,V3,V5,V7,V4,V9,V8,V2,V12,V10,V11}.

According to this nodal arrangement, the adjacency matrix was rebuilt as follows:

$$A' = \begin{bmatrix}
null & c5,10 & c2,9 & c4,7 & c6,2 & c3,4 & null & null & c1,5 & null & null & null \\
null & null & null & null & c10,7 & null & null & null & null & null & null & null \\
null & null & null & null & null & c8,7 & null & null & null & null & null & null \\

null & null & null & null & null & null & null & null & null & null & null & null \\
null & null & null & null & null & null & null & null & null & null & null & null
\end{bmatrix}$$

A depth-first traversal was run using the adjacency matrix above: nodes representing high frequency events were always searched first so the method could improve the overall efficiency of a policy search.

4 Experimental verification

An experiment was designed to verify the advantages of this policy search method. The experiment was run with the Java programming language on a computer with a Core 2 Duo processor and 2 GB of random access memory. Some 26 sample of security incidents were generated according to frequency. The 26 trigger conditions were searched in the original adjacency matrix of the directed

graph and in the adjacency matrix after nodal reordering. The time required under both cases was recorded (see Figure 5). It was seen from the result of this experiment that, with the expansion of the direct graph, the advantages of the proposed policy searching method were obvious.

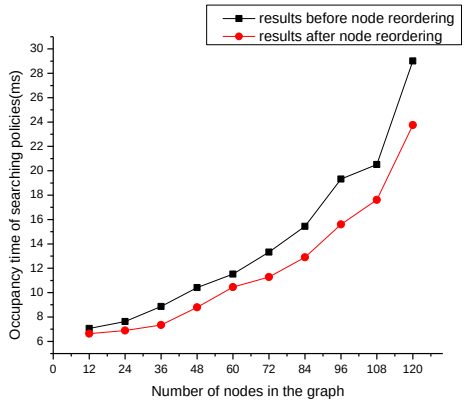

FIGURE 5 Comparison of the times required for searching the security policy: the case for nodal reordering

5 Conclusions

This research into methods of improving the efficiency of searches in a security policy based on direct graph depth-first traversal was successful. By means of a state machine, the policy knowledge base could be described as an acyclic weighted direct graph with a single initial state node and some termination state nodes.

Combined with the reverse topological sorting algorithm and the A* algorithm, and according to the frequency of each trigger condition, all state nodes were reordered before creating the adjacency matrix for a given graph. As a result, nodes associated with high frequency security events could be searched first. The experimental result showed that the proposed method could improve search efficiency within a security policy.

Abstract

Based on the shortcomings of poor compatibility, weak practicality, and low accuracy in current linkage systems, this paper designed a gradation of event correlation model with real-time response mechanism. It will be analyzing technology in data mining association rules is introduced to analyse the processing of security incidents. Then the system through the analysis of a large number of real-time data collecting all kinds of security devices found hidden in the data and related information to improve detection precision and safety accident treatment work. At last, apply this model into the system, to demonstrate the effectiveness of the model and priority.

Keywords: linkage system, event correlation model, correlation rule, security event

1 Introduction

With the rapid development of the Internet and the widespread use of e-commerce, the importance of computer communication networks in all aspects of society is increasing; computer and Internet technologies are changing the face of society. Security and reliability issues [1, 2] have become the main problems facing network security operations. To ensure that critical network information is always complete and confidential, to protect against attacks from external and internal networks, security products, such as firewalls [3], intrusion prevention systems [4], antivirus systems for all aspects of internal and external networking were developed. On the one hand, they guarantee the safety of system, on the other hand they generate many security events. These events are multifaceted in nature, vary considerably, take different formats, are sometimes false alarms, or are not be able to be used fully.

How to effectively manage all kinds of heterogeneous security devices, extract important information from massive information sets (and do so timeously), forecast system attacks that may occur accurately and efficiently, has become the urgent problem facing network security linkage systems.

By associating various security events, an event correlation [5] model matches security events with other of the same type, large quantities, different formats, and false alarms mixed with genuine cases, can not only be greatly reduced in number, and unified in format, improved in readability, and ultimately produce more real event reports, but also allow a system administrator to discover intrusive behaviours timeously and take effective measures to reduce loss.

2 Design of the event correlation model

2.1 OVERALL DESIGN OF THE MODEL

The overall structure of the event correlation model is shown in Figure 1.

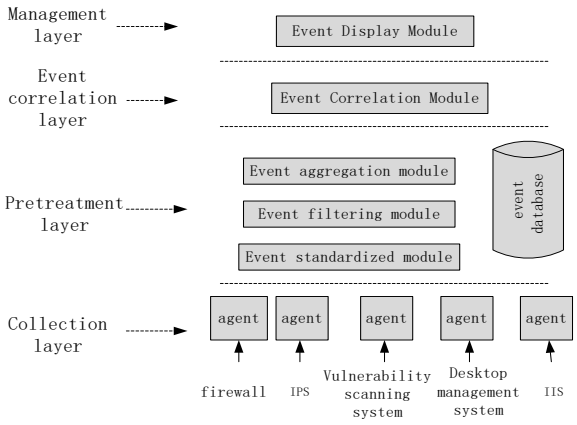

FIGURE 1 Structure of the event correlation model

The basic composition of the event correlation model included: a security event information collection module, an event standardised module, an event filtering module, an event aggregation module, an event correlation module, an event display module, and a security event database. The entire model was divided into four levels: the event collection layer, the pre-treatment layer, the event correlation layer, and the event management layer.

The lowermost layer was the collection layer, which comprised various types of information collection agent. These agents can run on a variety of operating systems and

[*]***Corresponding author*** e-mail: 867038858@qq.com

are responsible for collecting all kinds of security event information, such as IDS alarm logs, firewall logs, host logs, vulnerability information, *etc*., from different security devices.

The event pre-treatment layer included the event standardised module, event filtering module, event aggregation module, and the event database. The event standardised module unified the format of the information collected for subsequent processing. The event filtering and event aggregation modules were used to remove useless information for data mining, reducing the number of original data items. The security event database was mainly used to store all kinds of security event information produced by pre-treatment.

The event correlation layer was to uncover specific, potentially threatening, security event information through associating/matching events: this was a core part of the network security event correlation system and a critical section of the system.

The uppermost layer was the management layer, which was responsible for displaying security events, so that administrators can query, delete, or browse current network conditions.

2.2 DESIGN OF EACH MODULE IN THE MODEL

In this section, the design of the function of each module is considered at four levels, and the corresponding implementation method is introduced.

2.2.1 Event collection layer

This layer was mainly used to collect event information generated by various types of safety equipment. Here Agent is used to collect information. Agent can be installed on all kinds of safety equipment or on the router in the network where the devices sit. Agent can fully capture event information generated by the security equipment which it has been monitoring. The flowchart through the event collection layer is shown in Figure 2.

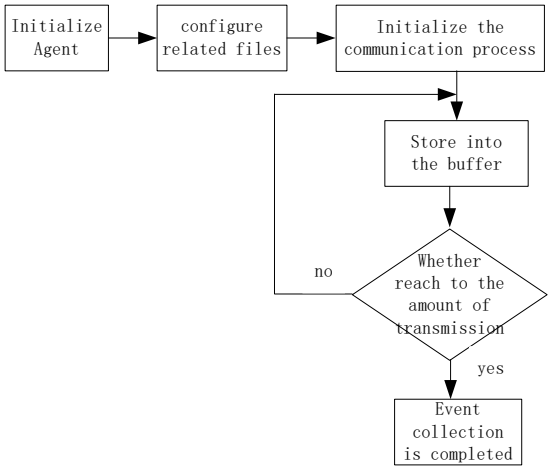

FIGURE 2 Flowchart for security event information collection

As seen in Figure 2, before collecting a certain type of security event, the information collection agent had to be initialised; secondly, we configured related files, specifying the server's IP address, port number, file location including security event/information, and the quantity of data sent each time. Then the communication process was initiated and a communication connection with the server-side established; thirdly, the specified information was collected, and finally sent from agent to server.

The event collection process mainly depended on each information collection agent which was developed independently in this research and cross-platformed, including host log collection agents, IIS service log collection agents, intrusion detection alarm collection agents, firewall log collection agents, vulnerability scan results collection agents, *etc*.

2.2.2 Pre-treatment layer

The flowchart through the event pre-treatment process is shown in Figure 3. In the pre-treatment process, firstly, we normalised and unified the formatting of various events. A security event correlation process may receive security events of different types or of one type but from different devices: there are certain differences between the formats of these events, such as security events from different types of firewall which can be compiled into different formats. A standardised module aimed to put all security events into a unified format, filter the events, removing those with nothing to do with system security, to get events that are real threats to system security. Finally, aggregation and incorporation of repeat events to reduce the number of data were undertaken and the output stored in the event database.

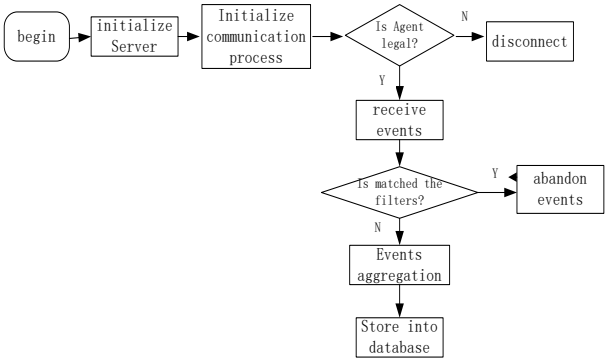

FIGURE 3 Flowchart through the pre-treatment process

2.2.2.1 Event standardised module

Security events refer to the original security event information produced by all kinds of security equipment, including log events produced by the firewall, intrusion alarm events generated by intrusion detection systems, system vulnerability events produced by vulnerability scanners, host system log events, router log information,

IIS Service log events, etc. These network security events are the main analysis objects in this research, they not only have different characteristics, but contain different content and record formats. The following is a simple introduction to some type of events:

1) Properties included in firewall logs.

int log_id
time createtime
string type
string src
string dst
string protocol
string service
string operation
int severity
int probability
int priority

2) Properties included in intrusion alarm events.

int analyzeid
time createtime
string classification
string src
string dst
string protocol
string suggestion
int probability
int priority

3) Properties included in vulnerability scanning events.

string name
string owner
time release_time
int cve_id
string request
string consequence
int severity
string solution

From the above, it can be seen that the formats of security events differed: therefore to facilitate the unified analysis of all kinds of security incidents, it was necessary to carry out the standardisation, to derive a unified format capable of expressing diversified event information from all relevant security devices.

To facilitate event correlation, events will be expressed in the following octuple form: (ID, Time, Host name, Type, Src, Dest, PRI, MSG). Among them, ID is a unique identifier of the information; Time is the production time; Host name is the device name of the recorded information; Type describes the information type; Src is the description of the source of invasion; Dest describes the purpose of the invasion; PRI refers to the priority of the event; and MSG is a description of the log.

2.2.2.2 Event filtering module

Network security events which occur in large numbers and are of low quality, contain both real events corresponding to attacker intrusion behaviour and false events with little or nothing to do with system security. The purpose of filtering for all kinds of network security events is to filter out false information as well as event information that had no relationship with the system security, at the same time, obtain only those events which posed a real threat to system security. The work included: excluding false information from detection and revealing event information corresponding to attacker intrusion behaviour from a large event log dataset.

Filtering rules mainly includes two aspects:

1) Filtering based on priority: we read PRI values of the event, and compared them with the pre-set threshold *k*. If PRI > *k*, this data had to be dealt with instantly, then sent to the next process. Otherwise it was abandoned with further processing.

2) Filtering based on key field: we included two methods:

a) Ignorance. Treat security events lacking key parameters as illegal event information, and delete it directly. For example, event information with empty log types had no analytical value and was filtered out. In addition, we deleted events with obvious error messages. For example, each part number of an IP address is an integer between 0 and 255, if the attribute value of a certain security event lay outwith that range it was clearly erroneous and was filtered out.

b) Filling. When missing only a few attributes of a record event, linear prediction, a global constant, or the average of the local properties were used to provide the missing attributes. A flowchart through the filtering process is shown in Figure 4.

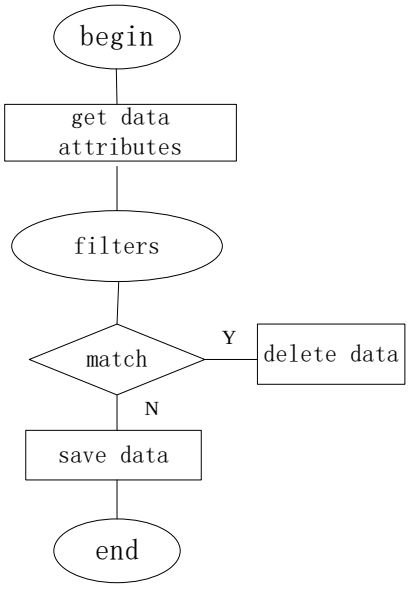

FIGURE 4 Filtering flowchart

2.2.2.3 Event aggregation module

Event aggregation aimed to merge a large number of duplicate events and reduce data redundancy. The main causes of a large number of repeats in security events were

that: the same attack, which is from the same place at the same time, often triggered different security equipment items to generate security incident records respectively; attackers often test different attack methods against specific targets or run the same attack multiple times to evaluate some parameters (such as, the offset and memory address of cache attack). Generally, all attributes or key attributes of these events are the same, and if we stored all of them in the database, they would not only occupy a large amount of storage space, but also the database grew too large, which was not conducive to the follow-up work and affected system efficiency: merging was therefore necessary.

2.2.3 Event correlation layer

After pre-treatment, the number of security events was reduced significantly. Analysing the processed results with the event correlation analysis algorithm and finding the association rules that may exist behind these data, while predicting potential dangerous events in the network, provided decision-making information for system managers.

2.2.4 Event management layer

The event management layer was responsible for displaying the data in the event database to the administrator in a pre-set way: at this time, the alarm information presented to the administrator was concise and clear, which made it convenient for the system administrator to respond to the current display and take appropriate precautionary measures. The main function of this layer included: security event querying: according to specific requirements, administrators can search associated event information by typing the appropriate query condition in the query box; and statistical analysis, for example the statistical analysis tables of various security events over a certain period (flow statistics or attack type statistics) making it easier for administrators to have an overall grasp of the current security situation.

3 Implementation of the event correlation model

To evaluate this correlation model, a strategy-based network security equipment linkage platform was used as the experimental platform and logs generated by the Venus firewall and user were taken as the data source for this experimental trial.

3.1 EXPERIMENTAL PROCEDURE

Specific steps were as follows:

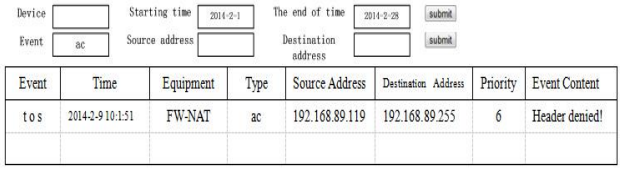
1) Pre-process the data collected by Agent to unify formats and streamline the data, store the results were then stored in the event database;

2) Discretise the data (correlation rules only deal with logical data, while these data had both numeric and class properties), thus necessitating their translation into logical data;

3) Analyse the data in the event database with an improved FUP [6] algorithm and automatically mine the dangerous events that may exist behind these data. Mining results were as follows:

TCP SYN scan => SYN flood attacks 0.8
Ftp, Telnet password detection => Trojan 0.6

Network administrators searched correlated event information through the management interface, part of which looked as follows:



Event	Time	Equipment	Type	Source Address	Destination Address	Priority	Event Content
tos	2014-2-9 10:1:51	FW-NAT	ac	192.168.89.119	192.168.89.255	6	Header denied!

FIGURE 5 Information query interface

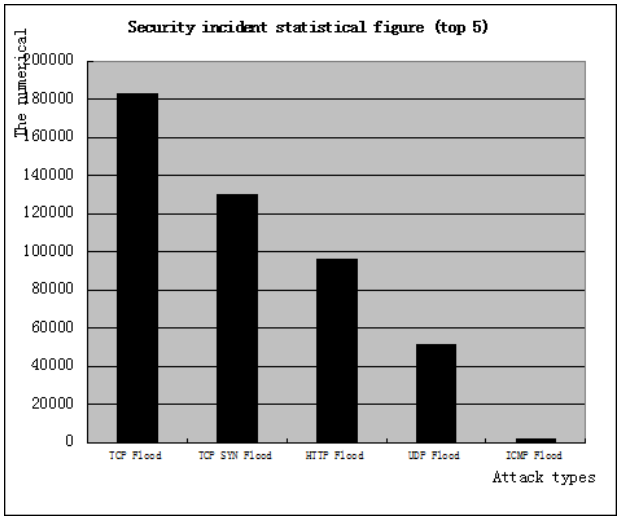


FIGURE 6 Security event statistics chart

3.2 EXPERIMENTAL RESULTS ANALYSIS

As the policy-based network security equipment linkage platform was still in its research stage, we just tested it simplistically: from the test results, this event correlation model was seen to effectively analyse alarm events, reducing the number of alarms significantly. Compared with traditional correlated systems, this event correlation model had the following advantages:

1) As it was the core module of a real-time network security equipment management system, it could process security events immediately for a timeous response.

2) The associated security events came from various heterogeneous security devices; therefore it could also improve the accuracy of correlation operations.

3) It undertook a series of processes to deal with the original security event(s) before executing correlation operations, including event normalisation, event filtering

and event consolidation, which improved the quality of the security event management and reduced the number thereof significantly. It was therefore deemed to have improved the efficiency of correlated events.

4 Conclusions

This research first introduced the overall design of the model, and then elaborated each module hierarchically. This model collected event information from agents, formatted the data into a unified event form; then eliminated redundant duplicate data with filtering and aggregation rules, stored the processed security event into an event database, and uncovered association rules hidden behind data by mining security events with an improved FUP algorithm. It then notified the system administrator thus allowing timeous preventative measures to be taken to prevent possible dangerous events. The system administrator can query the specific security event, current network status, *etc*. Finally, this model was applied to a network security equipment linkage system, using a firewall log and a user log as its data sources, and, according to the data processing flow of the model, realised the prediction of abnormal behaviour and attack behaviour, verified the effectiveness of the model, and so further improved overall system performance.

Abstract

In the process of medicine grain production may generate many kinds of defects. If these unqualified medicine granules are not timely detected, it will not only affect the company's reputation but also the health of the patient. This paper mainly studied how to detect the unqualified medicine grain base on machine vision. It mainly consists of three kinds of common defects segmentation and defect area calculation. Firstly, preprocess the medicine grain image for the following procedures. Secondly, obtain the defect region by improved segmentation algorithm, in order to deal with three different drugs grain defects this paper improved three segmentation algorithms, for the damaged tablets propose a local edge detection algorithm that based on grey level difference, for the irregular-shaped tablets adopts the ellipse detection algorithm, which based on Hough transform technology, for the Capsule has air uses the multi-scale Canny edge detection operator. Finally, adopt Chain code contour tracking algorithm and Three-point method calculate the area of the damaged tablets, determine whether the tablets meet the requirements. Experiments show that the system can detect unqualified medicine granule quickly and accurately, it is of great practical value.

Keywords: image processing, median filtering, defect detection, region segmentation, area calculation

1 Introduction

In recent years, many developed countries in Europe and America have carried out deeply research on product quality real time detection, and have made a great progress in the online quality detection and production control [1, 2]. But the technical details strictly confidential to the outside world. In china, due to the research starts late, the domestic pharmaceutical testing is mainly relay on manual that production efficiency relatively low, so there often comes out error detection or misses detection and other undesirable phenomena. It does not be able to satisfy the efficient industrial automation requirements. So study on the drug quality inspection has a very good social significance [3-5].

Three common unqualified medicine granules are: damaged tablets, irregular-shaped tablets, Capsule has air bubbles. The medicine grain defect detection is to detect the unqualified medicine grains on the production line. This task includes two main parts: the granule region segmentation and the damaged areas calculation. Image segmentation is dividing image into non-overlapping regions which based on the image grey, texture, shape and colour. According to the prior knowledge separate the target area and background. Through analysis three types of medicine grain image find that each type has their own characteristics. Because of the tablets interior region high connectivity features, it can use the SUSAN edge detection algorithm get edge information. But SUSAN operator is sensitive with threshold lead to edge detection unstable. Therefore, based on the grey level difference propose a local edge detection algorithm. This algorithm can effectively solve the problem. For the irregular-shaped tablets detection, it adopted the ellipse detection based on Hough transform technology. For the bubble capsule, this paper mainly uses the multi-scale Canny edge detection operator [6]. After obtained the defect region, in order to quantify the damage rate [7], this paper mainly uses a method based on Freeman chain code [8]. Because the medicine grains image has the connectivity characteristics, so adopt the algorithm that chain code combined with pixel count to calculate the area. In order to prevent misjudge, in this paper for first time proposed the “three point method” to calculate the area.

2 Image preprocessing

2.1 IMAGE GREY PROCESSING

Dealing with colour images is complicated and needs a long operation time. RGB image does not reflect the morphological characteristics. It is better to convert the colour image into grey image, which only contains brightness information with 256-level grey scales. The conversion Equation for grey image and colour image is:

$$Y = 0.299R + 0.587G + 0.114B, \quad (1)$$

**Corresponding author* e-mail: missjiangyueqiu@sina.com

2.2 MEDIAN FILTER

In the process of collection and transportation, the image may be added noise, so there will be influence the image quality [9]. Median filter can smooth the image to reduce the noise effects.

When the noise is rarely and evenly distributed, median filter can better reduce noise in the image [10]. But the noise distribution in the image is relatively concentrated, traditional median filtering effect obviously cannot meet the requirements of the system [11, 12].

In order to meet the requirements that the median filter not only effectively remove the concentrated distribution noise, but also preferably preserve medicine grain image detail [13]. We propose an improved median filter algorithm. The main idea is to get rid of the maximum and minimum values in the sliding window, get the median of the two pixels, denoted m_p . Then get the difference between m_p and the value of the corresponding pixel within the window, values Δ_p . If Δ_p is within a predetermined range of threshold ΔTH , use the mean value m_p replace the grey value of the pixel point.

Let $W_n(\mathrm{i,j})$ window size is $n\times n$ its centre $(\mathrm{i,j})$. Improved filtering algorithm detailed steps are as follows:

Step 1: First assign $n=3$, find out the maximum and minimum grey value $p_{\max}$ and $p_{\min}$ in window $W_n(\mathrm{i,j})$.

Step 2: Statistics the number of pixels value is not equal to $p_{\max}$ or $p_{\min}$ in the window and make it as c_n.

Step 3: If c_3 less than or equal to 1, then let $n=5$ execution Step 2.

Step 4: If c_5 equal to 0, then let $n=7$ execution Step 2.

Step 5: Within the sliding window, calculate the median of all elements pixel values:

m_{p3} = median (the number of pixels in the window $W_3(\mathrm{i,j})$ and the grey does not equal $p_{\max}$ or $p_{\min}$;

m_{p5} = median (the number of pixels in the window $W_5(\mathrm{i,j})$ and the grey does not equal $p_{\max}$ or $p_{\min}$);

m_{p7} = median (the number of pixels in the window $W_7(\mathrm{i,j})$ and the grey does not equal $p_{\max}$ or $p_{\min}$).

Step 6: Calculate the overall average m_p .

$$m_p=\begin{cases} m_{p3} & c_3\ge 2 \\ m_{p5} & c_5>0, c_3<2 \\ m_{p7} & c_5=0 \end{cases}. \tag{2}$$

Step 7: Filtering result $F(\mathrm{i,j})$ is calculated by the original pixel values and median values according to the Equation (3).

$$F(\mathrm{i,j})=\mathrm{a}_1\cdot E(\mathrm{i,j})+\mathrm{a}_2\cdot m_p, \tag{3}$$

Where a_1 and a_2 are the weighting coefficients satisfy the condition $\mathrm{a}_1+\mathrm{a}_2=1$, wherein a_2 is determined by the Equation (4).

$$a_2=\begin{cases} 0 & \left|E(\mathrm{i,j})-\mathrm{m}_p<TH_1\right| \\ \dfrac{E(\mathrm{i,j})-m_p-TH_1}{TH_2-TH_1} & TH_1\le\left|E(\mathrm{i,j})-\mathrm{m}_p\right|\le TH_2 \\ 1 & \left|E(\mathrm{i,j})-\mathrm{m}_p\right|>TH_2 \end{cases}, \tag{4}$$

where parameters TH_1 and TH_2 are preset threshold.

Step 8: Go Step 1, processing the next target pixel.

3 Medicine grain of region segmentation algorithm research

Because there is no segmentation algorithm can adapt to all situations [14, 15]. According to the characteristics of each medicine grain image it proposes three different image defect detection segmentation algorithm based on machine vision.

3.1 REGIONAL SEGMENTATION FOR DEFECT TABLETS

Image edge is often accompanied by grey mutation that is to say the grey value of edge pixels satisfy discrete criteria [16, 17]. According to the principle, this paper put forward the improved edge detection algorithm based on local greyscale difference. The core of the algorithm includes computing greyscale differences, selecting candidate point, determining threshold value and refining edge. Details as follows:

Firstly, obtain candidate edge pixels. It can use the formula to quantify the grey step.

$$\delta=A-B. \tag{5}$$

Before determine *A* and *B*, first define a constant metric *n*. When use a 3×3 template traverse the image, *n* can measure the number of valid point in the template. According to the actual circumstance of medicine grain of image detection, here $n=3$. Sort the pixels within the coverage area of the template, taking the top *n* larger pixels summation assigned to *A*, taking *n* smaller pixels summation assigned to *B*. For each pixel x_i, difference in local greyscale δ constantly changes with different x_i position. When x_i is located in the edge, δ is larger. So edge candidate can be selected according to the size of the value of δ , the greater of the value, this point the more likely is edge pixel.

After traversing the whole image, local differences in per-pixel can be respectively calculated. According to the ideas of the SUSAN algorithm, here need to set a threshold to determine the candidate edge points. In order to avoid the shortcoming that SUSAN algorithm is affected by the threshold is too big. It can get the adaptive threshold according to the Equation (6):

$$T_{hr} = \frac{1}{M}\sum_{i=1}^{M}\delta_i \,. \tag{6}$$

If a pixel is the centre of 3×3 area and its greyscale difference δ is greater than T_{hr}, and then the pixel is the candidate edge point, otherwise not edge point.

Secondly, get the ultimate edge.

While get a set of candidate edge points, it still need to further refine the edge. Refinement idea as follows:

1) Use a sliding window size 3×3 traverse the whole image.

2) If the pixels is the candidate edge points, Calculate as Equation (7):

$$t = \delta\frac{x_i}{x_M} \tag{7}$$

where x_M is the average of the three largest grey value in the 3×3 neighbourhood which centre is x_i.

(3) Set the mean of t in the whole image as the threshold, if t is greater than the threshold, this point as edge points.

3.2 REGIONAL SEGMENTATION FOR IRREGULAR-SHAPED MEDICINE TABLETS

According to the detection index of a pharmaceutical company, irregular drug testing need not quantify different degrees, only need to detect whether medicine grain of aliens.

This section is mainly to detect the ellipsoid medicine granule whether irregular, so it can use Hough transform to determine the centre coordinate. According to the results of the Hough transform locate the tablets centre. When we got ellipse parameters, plug the tablet edge point coordinates into elliptic equations to calculate its value, if get the value greater than 1 means that the oval medicine grain is qualified, or medicine granule irregular.

The main idea of Hough transform is to map the point of original image space to the line of parameter space, or do the opposite process. If directly using the Hough principle testing ellipse centre, in the image space $(\mathrm{x,y})$, elliptical Equation (8):

$$\frac{(\mathrm{x}-\mathrm{a})^2}{m^2}+\frac{(\mathrm{y}-\mathrm{b})^2}{n^2}=1, \tag{8}$$

where m, n, a and b can be obtained by the production design specification. There are four parameters in the Equation above: (a,b) is the centre coordinates of the ellipse, oval semi-major axis m semi-minor axis n. According to the idea of Hough Transform, there need to create a cumulative four-dimensional array $A(\mathrm{a,b,m,n})$. For each a must traverse all the possible values of b, m and n, this calculation is too large to detect in real time. So in this paper, we propose an improved method.

Using gradient information, when $dy/dx = \tan\theta$, for x do derivate, get the following equation:

$$\frac{(\mathrm{x}-\mathrm{a})^2}{m^2}+\frac{(\mathrm{y}-\mathrm{b})^2}{n^2}\tan\theta=0, \tag{9}$$

$$a = x \pm \frac{\sqrt{m^2\tan\theta}}{\sqrt{m^2\tan^2\theta+n^2}}, \tag{10}$$

$$b = y \pm \frac{n^2}{\sqrt{m^2\tan^2\theta+n^2}}. \tag{11}$$

Through comparing the Equations (10), (11) with (8) can found that the number of parameters reduced from the original four to three, so just set up two three-dimensional accumulation array $A_x(\mathrm{a,m,n})$ and $A_y(\mathrm{b,m,n})$ can meet the requirements. Every point in the image, in turn, change m and n calculate the corresponding a and b, then respectively for m, n accumulation, after the improved algorithm it obviously reduce amount of calculation.

3.3 THE SEGMENTATION ALGORITHM OF BUBBLES INSIDE THE CAPSULE

This section is mainly to detect capsules whether containing bubbles. Because of the bubbles within the capsule have a clear boundary and its colour significantly different with the surrounding, so the bubbles boundary can be clear detected. Canny operator detects the edge of the more complete and connection degree is also very good, but the result is sensitive to noise, so this paper proposed an adaptive multi-scale Canny edge detection algorithm. Specific steps are as follows:

1) Combined with capsule medicine grain images to determine the scale collection.

If σ represent one scale of the image, then $0\le\sigma\le\sigma_{\max}$, the scale of the image edge is always in a range, so assume medicine granule image edge contains K scale. It can use $\{\sigma_k\}_{k=0,1,\ldots,K-1}$ represent the scale collection, the collection can cover all of the image edges scale, it's element is monotonic distribution and scale difference between the two adjacent elements within the set should be less than the scale interval $\Delta\sigma$, generally $0<\Delta\sigma<0.5$. $\sigma_{\max}$ is the maximum edge scale. $\sigma_{\max}=2^{n-1}\sigma$, After sampling at equal intervals on the scale space $0\sim\sigma_{\max}$ can get the scale set.

2) Use Canny edge detection operator [11] to detect the capsules image edge information on multiple scales.

In the course of capsules edge detection, first with a Gaussian function for image smoothing, then derivative of capsules image get the original image edge information on various scales. The edge information at the scale σ_k can be expressed as

$$f_k'(r,c), k=0,1,\ldots,k-1.$$

3) Through fusion the information of scale edge to determine the edge.

After obtaining the information of each scale on the capsule image edge, complete the synthesis of various scale edge information to get the new multi-scale image edge information. In this paper, use the weighted summation algorithm.

$$f_k'(r,c) = \sum_{k=0}^{k-1} w_k f_k'(r,c), \quad (12)$$

where w_k represents the weight factor of each scale edge information. If ignore the noise it can use mean-weighted factor. However, due to uneven illumination bring significant noise effect to the capsule image, so the mean-weighted does not meet the requirements. The weights of different scales case determined by the following steps:

Step 1: On the scale σ_k use a Gaussian function which standard deviation is σ smooth the capsules image to reduce noise, $f_k = f \cdot G(x,y,\sigma_k)$.

Step 2: In various scales of the capsule image, calculate the difference $\Delta_k = |f - f_k|$ and variance $\Delta_k^2 = |f - f_k|^2$.

Step 3: Calculates the difference and variance of image and the weight can be determined by the ratio of the two parameters.

4) The Non-maxima Suppression method to extract the edge points.

When using non-maxima suppression to get edge, mainly in order to find the ridge of the original image from the gradient image, that is to say our target point is maximum gradient, so discarded the edge is not a maximum, set $a_1,...,a_8$ are the 3×3 neighbourhood pixels of a:

$$\begin{matrix} a_1 & a_2 & a_3 \\ a_4 & a & a_5 \\ a_6 & a_7 & a_8 \end{matrix}$$

If a satisfy one of the following conditions it could as the edge points, otherwise use $\min(a,a_1,...,a_8)$ instead of a.

1) $a_1 + a_4 + a_6 < a_2 + a + a_7$ and $a_2 + a + a_7 > a_3 + a_5 + a_8$, a is vertical ridge.

2) $a_1 + a_2 + a_3 < a_4 + a + a_5$, and $a_4 + a + a_5 > a_6 + a_7 + a_8$, a is horizontal ridge.

3) $a_1 + a_2 + a_4 < a_3 + a + a_6$, and $a_3 + a + a_6 > a_5 + a_7 + a_8$, a is 45-degree angle ridge.

4) $a_2 + a_3 + a_5 < a_1 + a + a_8$, and $a_1 + a + a_8 > a_4 + a_6 + a_7$, a is 135-degree angle ridge.

4 The area calculation of the damaged tablets

Calculate the area of the damaged tablets is mainly used it quantify the damage rate. In the process of drug quality inspection need to pick out the tablet damage rate more than 3%. In this paper, the basic unit of area is pixel, by calculating the number of valid pixels in the target area to obtain the damaged area and other geometric characteristics. Since the area calculation methods all have their advantages and disadvantages and application scope. We combine with the actual situation of medicine grain of defects, proposed two methods to calculate area.

The first method: Combined chain code contour tracking algorithm [18], devised an effective multi- region contour area calculation method.

Chain code element of the contour is determined by a line segment which has both the length and direction, and each direction has a sequential number, shown in Figure 1.

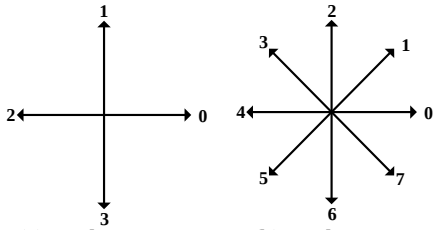

FIGURE 1 Chain code

After medicine grain image segmentation and binarization, the target region and the background region were respectively marked as 0 and 1. According to the idea of chain code contour tracing, use eight to the chain code tracking medicine grain of image boundary specific steps are as follows [19]:

1) Set the starting point b_0 as the first marked black dots of picture. Use c_0 represents b_0 neighbouring point on the left side. Figure 2b, c_0 always background points. Starting from the c_0 along the same sequence inspect b_0 eight adjacent points, find the first black adjacent points b_1 and set c_1 (background) as the point in front of the sequence of b_1. Save the location of the b_0 and c_0, in order to use in step 4.

2) Set $b = b_1$ and $c = c_1$, Figure 2c.

3) Starting from the c travels clockwise, set b eight adjacent points as $n_1, n_2, ..., n_8$ respectively. Find the first n_k marked 1, set $b = n_k$ and $c = n_{k-1}$.

4) Repeat step 3, until $b = b_0$ and find the next boundary point b_1.

In Figure 2, the next point to be processed is marked in black, has been processed pixels marked grey, c is always background points in step 3, because n_k is the first point value is 1 when clockwise scanning. But the algorithm also can further improve in boundary description. After finding target area, the area is marked as grey, follow-up point may also be judged, which will be duplicate detection. Mark the point has been detected as a boundary pixel can reduce

unwanted detection can further accelerate the processing speed.

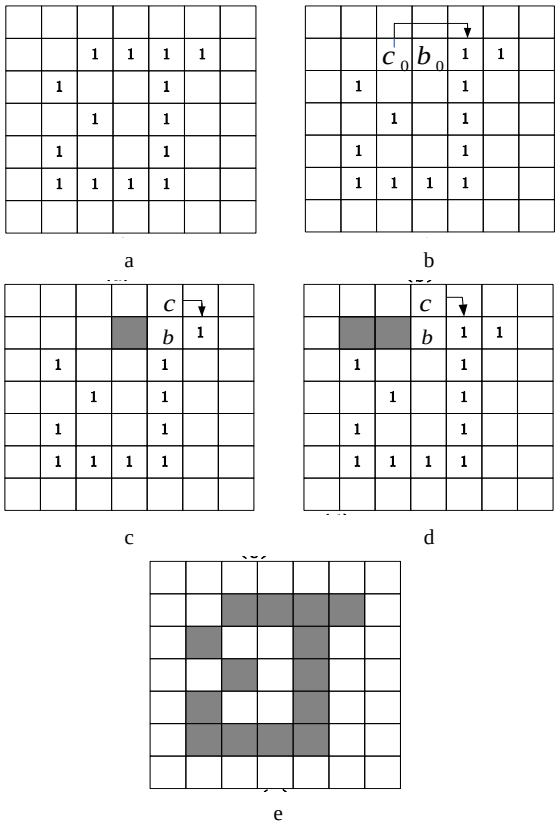

FIGURE 2 Boundary tracing algorithm description

The second method: "three point method"

"Three point method" is mainly for round tablets, because its approximate circle area after image segmentation, regional boundary has good connectivity, traverse the medicine image, and select the outermost (uppermost, lowermost, leftmost and rightmost) "point". Make straight line in the direction of maximum gradient points, it is vertical line. Calculate the intersection point of straight line, the intersection is the circular medicine circle, finally statistical the number of pixels that centre to each point (up, down, left and right edge point), calculated their average that is the drug tablet radius r, according to the area Equation $S = \pi \cdot r^2$, we can get the medicine grain area. Set four points $p_1(x_1, y_1)$, $p_2(x_2, y_2)$, $p_3(x_3, y_3)$, $p_4(x_4, y_4)$ as shown in Figure 3, after detection $p_1(x_1, y_1)$ is the rightmost edge point, but in theory, the rightmost point should be $p_1'(x_1, y_1)$. So according to the criterion, the point of $p_1(x_1, y_1)$ should be discarded. Choose the remaining three points for subsequent calculation. Determining whether the detection point is an edge point by the following criterion as in Equation (13):

$$\begin{cases} |x_2 - x_4| < c \\ |y_1 - y_3| < c \\ |y_2 - y_4 + x_3 - x_1| < 2c \\ |y_1 - y_3 + x_4 - x_2| < 2c \end{cases}, \tag{13}$$

where c is the preset threshold, it is determined whether the point is a valid edge point.

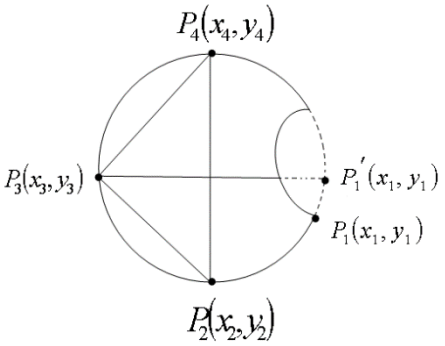

FIGURE 3 Three-point method schematic

Based on the above ideas and combined with the specific circumstances of this topic, set target pixel is white, background pixels is black. Three point method measuring area details in the following five steps:

Set P_1, P_2 are two one-dimensional arrays.

Step 1: Detecting started from the top and left of the image and gradually went on towards the down and the right, until detect the first white pixels; this point is edge point record the pixel coordinates $p_1(x, y)$.

Step 2: After obtain the first white pixel, scanning a new line and put the first met white point (the leftmost edge points) in the array P_1. At the same line when a black pixel is scanned again to put its front white pixel coordinates into the array P_2.

Step 3: When there is no white pixel to be detected in the whole row, means the end of detecting. Then the last element of the array P_2 is the most under the lowermost edge point.

Step 4: Extract the horizontal ordinate component of the each object in the array P_1, P_2 to sort. Determining the minimum and maximum of the horizontal component, thus the left-most, rightmost, uppermost, lowermost edge point coordinates are obtained.

Step 5: According to the Equation (13), determine whether the detection point is required edge point.

5 Experimental results and analysis

5.1 REGIONAL SEGMENTATION RESULTS

The improved segmentation algorithm was respectively applied to the medicine grain image, to test the effect of image segmentation and edge detection.

Figure 4 shows the damaged medicine grain region segmentation results obtained by the improved edge detection algorithm based on local greyscale difference.

Figure 4a shows the noise free image segmentation Figure 4b the image adding 3% of Gaussian noise and 2% salt and pepper noise.

Through the experimental results it can be seen that in the case of less noise, the algorithm can segment the region of medicine grain clearly. The second group is the result of edge detection after adding noise, common medicine grain image quality is much better than that situation. The improved algorithm detects the edge more complete and clear than SUSAN algorithm detected.

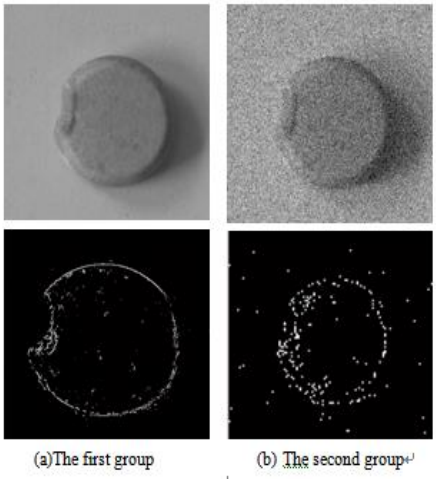

FIGURE 4 The original and add noise image region segmentation results

Figure 5 shows the irregular-shaped medicine tablets region segmentation results obtained by modified ellipse detection algorithm based on Hough transform.

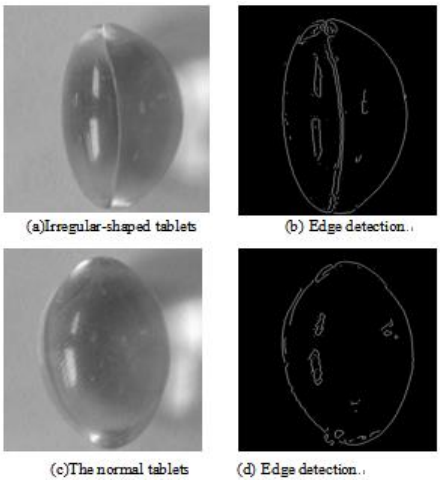

FIGURE 5 Irregular-shaped and normal tablets region segmentation results

Medicine grain qualified analysis: after dealing with the various steps above a single medicine area has to be designated. At the same time the elliptic equation is obtained by Equations (9-11), so it only needs to traverse each element of the $A_x(a,m,n)$ and $A_y(b,m,n)$, if get the value greater than 1 means that the oval medicine grain is qualified, or medicine granule irregular.

Figure 6 shows the bubble region segmentation in capsules results obtained by Multi-scale adaptive Canny edge detection algorithm.

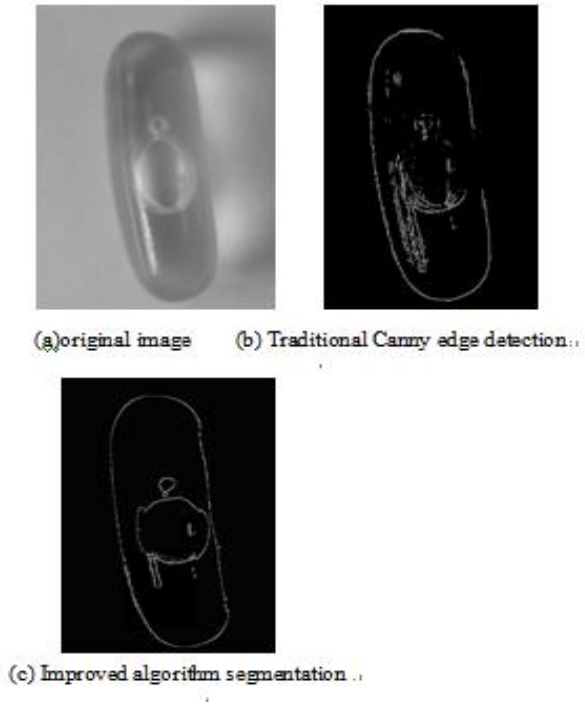

FIGURE 6 Multi-scale adaptive Canny edge detection

5.2 MEDICINE GRAIN OF DEFECT QUANTITATIVE RESULTS

First, use the Freeman chain code area algorithm processing the image, for the damage medicine grain of defect areas can be detected, quantification of the defect region, obtained theoretical defect area and actual detection area. According to the drug quality specification, damage rate more than 3% the tablet is unqualified. So that can further calculate damage rate and judge whether the drug tablets are qualified. The experimental results are shown in Table 1.

TABLE 1 Freeman chain code area algorithm of quantitative results (pixels)

No.	Theoretical area	Actual area	Damage rate	Qualified
1.	147730	137813	6.71%	no
2.	151327	147476	2.54%	yes
3.	150968	146682	2.84%	yes
4.	149978	136597	8.92%	no
5.	161468	154567	4.27%	no
6.	146798	136892	6.75%	no
…	…	…	…	…

In order to better compare the reliability and accuracy of the two algorithms, both methods deal with the same group of tablet images. The quantitative results are shown in Table 2.

TABLE 2 Three point method of quantitative results (pixels)

No.	Theoretical area	Actual area	Damage rate	Qualified
1.	153863	139867	9.09%	no
2.	157638	153433	2.67%	yes
3.	149863	145658	2.81%	yes
4.	151267	139685	7.66%	no
5.	161468	153534	3.85%	no
6.	160357	147586	7.96%	no
…	…	…	…	…

Quantitative results obtained from two algorithms can be seen: although the algorithm implementation have differences lead to concrete numerical value different, it has same results.

6 Conclusions

The experimental results show that the segmentation result satisfies the requirement of experiment, in order to quantify the damage of drug, we use the Freeman chain code area algorithm and "three point method" respectively calculated the defect area. Although the algorithm implementation have differences lead to concrete numerical value different, it has same results. But this article is just study the area of damaged medicine grains, other types without quantitative treatment, might exist misjudgments, so the algorithms also need to be improved. The system cannot achieve complete automation, there still needs a further improvement and enhancement.

Research on a regional innovation system: viewed from the degree distribution of complex networks theory

Jiangbo Zheng*

School of Management, Jinan University, Guangzhou, China

Received 1 March 2014, www.cmnt.lv

Abstract

A Regional Innovation Systems is viewed as a special type of complex network in this paper, and the complex features of the entities in the system as well as the interactions between the entities are discussed in detail. Based on the Degree Distribution of Complex Networks theory, firstly this paper proves the feasible degree distributions in practical networks through mathematical reasoning and analysing. Then, an empirical case of degree distribution characteristics for the Regional Innovation System is tested by mean of calculating the Correlation Coefficient with the statistical data of Guangdong Province. Coupling Complex Networks Theory with these data and the practical conditions of Guangdong province, this paper sheds light on the insight of the calculating results. Such research shows that the methodologies and conclusions of this paper are proper.

Keywords: regional innovation system, degree distribution, complex networks, data calculation, Pearson correlation coefficient

1. Introduction

Since the early 1990s, the concept of regional innovation systems has obtained considerable attention for advancing the understanding of the innovation process in regional economies. The increasing popularity of this concept has been impelled partly by the intense international competition in globalizing environment, as well as the deficiencies of traditional regional development models and policies in many regions around the world. Although it is typically understood to be a set of interacting private and public institutions or organizations that function according to organizational arrangements and relationships conducive to the generation, use, and dissemination of knowledge, the concept of regional innovation systems has no generally accepted definitions. The basic argument is that such a set of actors produce pervasive and systemic effects that encourage firms within the region to develop specific forms of capital that are derived from social relations, norms, values, and interactions within the community in order to reinforce regional innovative capability and competitiveness [1].

The original concept can be found in two main bodies of relative research. The first is systems of innovation. Built on evolutionary theories of economic and technological change, the literature [2] conceptualizes innovation as an evolutionary and social process. In the literature [3], innovation is stimulated and influenced by many actors and factors, both internal and external to the firm. In the literature [4], the social aspect of innovation refers to the collective learning process between several departments of a company (for example, R&D, production, marketing, commercialization, etc.) as well as to external collaborations with other firms, knowledge providers, financing, training, etc. The second body is regional science and its explanations about the social environment from which innovations emerge. From this point of view, innovation is localized and a locally embedded, not placeless, process [5, 6]. Namely, a regional innovation system is characterized by cooperative innovation activities for knowledge creation and diffusion between firms and organizations, such as universities, training organizations, R&D institutes, technology transfer agencies, and so forth.

A fundamental problem in all studies of regional innovation systems is that we cannot yet determine how a regional innovation system might appear in reality [7]. For instance, how much and what type of innovation must occur within a region for it to be considered a regional innovation system? Do all regions that aspire to take a lead in organizing and innovating become regional innovation systems by default? If something like a regional innovation system already exists, but the extant literatures on the subject are not clear. We contend that the interactions between actors in regional innovation systems have not been sufficiently explored, while the institutional context of these interactions has been largely overlooked. As a result, the validity of recommendations for innovation policy making based on the current analyses of regional innovation systems is somewhat questionable. Therefore, it is very necessary to analyse a regional innovation system from new viewpoint to obtain substantial insight.

2 The definition of a regional innovation system in the sight of network

The innovation theory initially emphasizes on the technological innovation within corporations. For instance, American economist Joseph Alois Schumpeter's book The Theory of Economic Development: An inquiry into profits, capital, credit, interest and the business cycle pointed out that technological innovation is a linear process including developing, designing, manufacturing and selling [8]. However, as researches deepened, innovation was no longer confined to a linear model within corporations or between corporations. People generally consider it in a higher level--regional innovation system. In 1987, British economist Christopher Freeman introduced the concept of "National Innovation System" [9]: the network of institutions in the public and private sectors whose activities and interactions initiate, import, modify and diffuse new technologies. The OECD report "Managing National Innovation Systems" [10] in 1999 pointed out: "Innovation performance depends on the way in which the different components of the 'innovation system' -- businesses, universities and other research bodies - interact with one another at the local, national and international levels, and concludes that the public authorities must change their approach to the promotion of innovation." Throughout the researches published, although regional innovation systems have drawn great attention in the academic fields, there is no plausible explanation about it given by mainstream Economics, Industrial Economics, or Evolutionary Economics [11]. The researches in managerial fields are even in a worse situation.

The world-famed physicist Stephen Hawking once said that the 21st century would be the Century of Complexity. This statement is widely recognized, and the researches on complexity have been carried out in many fields in recent years. Among many new researches on complexity science, one of the most representative theories is Complex Networks Theory. According to this theory, a complex network is a highly abstract complex system. In fact, complex networks can be found in natural, engineering, and even our social fields [12,13]. For instance, the metabolism in cells, neural networks in brains, food chain networks forming the ecological system, social relationship networks, science research cooperation networks, trade networks, internet, and electric power networks, etc [14-19]. Recent years, with the rapid development of network and computer technologies, researchers are able to obtain abundant data from major real networks to conduct statistical analysis. Such results show that complex networks are not homogeneous; on the contrary, they are heterogeneous. Their degree distribution does not follow Poisson distribution, but power-law distribution. A network that follows power-law distribution is called a scale-free network [20]. Because of the scale-free feature possessed by complex networks, its degree distribution is completely determined by its power-law index (degree distribution index). For instance, the degree distribution indexes of most artificial networks are between 2 and 3. And some key natures (like transmission threshold) of network dynamics (like transmission of infectious disease or virus) are directly related with degree distribution index.

All of the achievements have shown the successful application of complex networks theory. However, there are not yet specific researches utilizing this theory into the important academic field-regional innovation. Based on the previous researches, this paper defines a regional innovation system as a complex network constituted by corporations, research institutions, universities and colleges, government and institutions with intermediary functions within a given region, which develop the ability of regional innovation by interacting with each other. Based on the definition, this paper first analyses the connotation of the degree distribution based on complex networks theory. Then, taking Guangdong Province of China as the object of demonstration, this paper calculates the degree distribution with the related data and tries to explain the calculation results. It is believed that this paper will offer important reference for future research related to regional innovation.

3 The complex network's features of a regional innovation network

Based on the complex networks theory, both the characteristics of the subjects in regional innovation networks and interactions between subjects have embodied complex network features.

3.1 FEATURES OF THE SUBJECTS

There are many categories of subjects building a regional innovation system. These subjects have different forms and abilities. Furthermore, each type subject can be described in different accurate degrees. Such subjects have different layers and scales, and play different roles in the innovation systems. This paper has classified subjects into 4 following categories.

Creative Subjects: this paper considers that the sources of innovation are ideas, which produce new knowledge. In a regional innovation network the subjects that produce new knowledge are research institutions, universities, R&D departments of enterprises. They are in the one edge of the frontier in the innovation network. And the aggregates of these subjects are creative ones. These subjects should be depicted according to the layer of the network studied or the particular characteristics of data.

Supportive Subjects: if creative, informational new knowledge can be transformed into economic interests, it has to gain support and coordination from material elements. That is why we think governments (political supports), banks (financial credits), venture capitals, etc. are on the other edge of the frontier in the innovation network. They are supportive subjects.

Flowing Subjects: in an innovation network system, the combinations and flows from source boundary (inputs of economic interests) to department boundary (outputs of economic interests) of every elements related to innovation cannot fulfil the transmission function. They need corresponding channels, patterns and drivers as inter-mediums. We see intermediaries in technical markets and related government sectors that perform communicative functions and resource allocation are in the middle area of the innovation network. They are flowing subjects.

Productive Subjects: in an innovation network, many innovation elements finally come together and transform into economic interests. This process need to be performed by a specific category of subjects. In this paper I view corporations as the elements that produce outputs of innovation networks. They are in the last area of an innovation network and can be defined as productive subjects.

As *we* can see, different kinds of subjects in a regional innovation network not only have important effects on themselves, but also have corresponding attributes and features that can directly affect the whole innovation network. Based on the description of different accurate degree, therefore, if we see the subjects in an innovation network as nodes in the network, they have obviously embodied the features of nodes in the complex network.

3.2 FEATURES OF THE INTERACTIONS BETWEEN SUBJECTS

In a regional innovation network, interactions between subjects substantially reflect the interactive relations between material, energy and information. These interactions are non-linear synergistic actions. With these interactions, subjects can modify their behaviors to response to the changes of environment. In other words, every subject can gain innovative ability through information sharing, mutual complementarities of abilities, diffusion effect of knowledge and cumulative effect of innovation accumulation. Therefore, theoretically speaking, the interactions between subjects have features like direction and intensity (or weight). In practice, of course, they can be dealt as undirected and weightless interactions.

The Directions of the Interactions: almost every interaction between subjects specifically directs from one to another. For example, an action which directs to a corporation from a research institute means that the researches flow from the latter to the former, while an action directing to universities from government financial sectors means the flows of financial expenses to the universities. Therefore, the in-degree and out-degree of every subject should be considered respectively. And also we can study the ratio of input to output (like innovation effectiveness), the proportion of patent, etc. about the corresponding innovative behavior.

The Multiple-characteristics of the Interactions: the interactions between subjects in an innovation network have different characteristics. Take universities as an example, an action directing the university from government means the government supports the university financially; an action from a corporation means it supports the university financially as well. The former is much more policy behavior, while the latter is more business cooperation.

The Weights of the Interactions: in innovation networks, the interactions not only differ in quality, but also in quantity - it means that the interactions have weights. Furthermore, in this paper weight means the intensity of *interactions* between subjects.

The Dynamics of the Interactions: the interactions between subjects in innovation networks are not static, but dynamic. In other words, every action happens only in a specific time, being a function of time.

Therefore, if we see the interactions between different subjects in an innovation network as the "edges", they will obviously reflect the features of edges in complex networks.

4 Theoretical analyses on degree distribution

Based on the principles of complex networks, the degree of a node refers to the number of the edges to which link the node. Suppose that there is no isolated node in a network, no self-circled phenomenon, and there is at most one edge between any two given nodes, then the definition of degree distribution should be:

$$P(k) = \frac{\text{the number of nodes whose degrees are k}}{\text{the total number of nodes}}$$

($\forall$ positive integer k).

Set the total number of nodes as N, and the total number of edges as W. Then the minimum degree of every node is 1, the maximum is N-1. So the relationship of degree distribution can be expressed as Equation (1) which is called completeness:

$$\sum_{k=1}^{N-1} P(k) = 1. \tag{1}$$

For a scale-free network [12~13], $P(k)$ is a power function, namely $\gamma > 0$ and $C_N > 0$, making:

$$P(k) = C_N \cdot k^{-\gamma}. \tag{2}$$

In the equation above, γ is called degree exponent; C_N is a Power law coefficient, whose value can be calculated according to the completeness of degree distribution in Equation (3).

$$C_N = 1 \Big/ \sum_{k=1}^{N-1} k^{-\gamma}. \tag{3}$$

In order to further discuss degree distribution, set the fist moment and second moment of degree distribution as d_{M1} and d_{M2} respectively, expressed as followed:

$$d_{M1} = \sum_{k=1}^{N-1} k \cdot P(k) = C_N \cdot \sum_{k=1}^{N-1} k^{1-\gamma}, \quad (4)$$

$$d_{M2} = \sum_{k=1}^{N-1} k^2 \cdot P(k) = C_N \cdot \sum_{k=1}^{N-1} k^{2-\gamma}. \quad (5)$$

Set the average value and standard deviation as μ and σ respectively, let $\mu = d_{M1}$, then:

$$\sigma^2 = d_{M2} - \mu^2 = d_{M2} - d_{M1}^2. \quad (6)$$

Obviously, with γ increasing, both d_{M1} and d_{M2} will decrease. When reflecting on network topology, that means the network transits from heterogeneity to homogeneity. When $\gamma \to +\infty$, there would be $\mu \to 1$, $\sigma \to 0$, which means the network is completely homogeneous. Since the length of this paper is limited, only one situation is discussed to demonstrate the relations between the range of γ and network topology.

When $0 \le \gamma < 1$, there is:

$$\sum_{k=1}^{N-1} k^{-\gamma} = O\left(N^{1-\gamma}\right), \sum_{k=1}^{N-1} k^{1-\gamma} = O\left(N^{2-\gamma}\right), \quad (7)$$

$$d_{M1} = O\left(N^{2-\gamma} / N^{1-\gamma}\right) = O(N). \quad (8)$$

Obviously, when N is abundantly large, d_{M1} is divergent. The same:

$$d_{M1} = O\left(N^{3-\gamma} / N^{1-\gamma}\right) = O\left(N^2\right) \quad (9)$$

So d_{M2} is also divergent. Therefore based on the Equation (6), it can be proved that the average and variance of degree distribution are divergent. The total number of edges in the network is:

$$W = N \cdot \mu = N \cdot d_{M1} = O\left(N^2\right). \quad (10)$$

The Equation (10) shows that the number of edges in the network is of the same magnitude with $N \cdot (N-1)/2$, the number of edges in a complete network. The calculation does not quite fit the real evidence obtained by other researchers since many researches with real evidence show that large networks are almost sparse networks, therefore the network where γ is in the range of [0,1] does not exist in the real world.

Specially, when $\gamma = 1$, there will be:

$$\sum_{k=1}^{N-1} k^{-\gamma} = O[\ln(N)], \sum_{k=1}^{N-1} k^{1-\gamma} = O(N), \sum_{k=1}^{N-1} k^{2-\gamma} = O\left(N^2\right)$$

and we can yield:

$$d_{M1} = O\left[N / \ln(N)\right], \; d_{M2} = O\left[N^2 / \ln(N)\right], \quad (11)$$

$$W = N \cdot \mu = N \cdot d_{M1} = O\left[N^2 / \ln(N)\right]. \quad (12)$$

Based on the principles above, a large network with $\gamma = 1$ does not exist in the real world either.

5 Demonstration and analyses based on data calculation

According to the complex networks theory, different types of degree distribution of networks can reflect the nature of the whole structure. Moreover, nodes with different degrees have different status and functions within the network. Besides, the degree distribution of complex network theory is built on the hypothesis that edges and weights are equal. But in practice, what matters is the overall weight. In examining the degree distribution, we can ignore the source of the edges (in the case of in-degree) and the direction of the edges (in the case of out-degree), just focus on the calculation of input and output distribution of nodes.

5.1 DEFINITION OF NODES AND EDGES IN THE NETWORK

Ideally speaking, universities, corporations and government sectors can be identified as the innovation subjects in a region because these subjects meet with the requirements of complex network theory well. But since data that completely fits theoretical requirements is unavailable, we instead employ rough method to define nodes. That is, to view Guangdong Province as an innovation network and the 21 cities of Guangdong as nodes.

Some other measuring methods are often subjective when defining whether there are relationships between nodes or not. In general, those arbitrary weights will affect the result of the measurement. To eliminate the subjectivity in defining the edges, this paper applies Pearson Correlation Coefficient as an objective indicator to measure the relationship between nodes. Pearson correlation coefficient is a statistical measure of the degree of linear dependence between two variables, explaining the strength of linear relationship between two phenomena (X and Y). Sample correlation coefficient is commonly represented by the letter *R*, giving a value between -1 to 1 inclusive, where *R*>0 indicates positive correlation, *R* <0 indicates negative correlation, and *R*=0 is no correlation. The Equation is:

$$R = \frac{\sum (X - \overline{X})(Y - \overline{Y})}{\sqrt{\sum (X - \overline{X})^2 \sum (Y - \overline{Y})^2}} = \frac{\sum XY - \frac{\sum X \cdot \sum Y}{n}}{\sqrt{[\sum X^2 - \frac{(\sum X)^2}{n}][\sum Y^2 - \frac{(\sum Y)^2}{n}]}} . \quad (13)$$

Then we choose some statistics data with temporal continuity of nodes, and calculate its relevance with time, to gauge whether and at what degree they are related. The method is to subjectively define the critical value of the correlation coefficient between any two cities as R_0, then to analyze the correlation between every two different nodes. When the correlation coefficient is larger than R_0, we consider there is a edge between the two nodes. This assumption is built on such theoretical basis: if two cities, at a particular time period, have a relatively consistent development trend, it means that they have similar policies and other internal and external elements. The reason they have such similarities is generally due to communications and interactions between cities (for instance, one city often learns some patents from other cities to promote the experience of development). Therefore, this method avoids subjectivity, as well as better reflecting the connections between cities.

5.2 DATA SELECTION AND CALCULATION RESULTS

Table 1 shows the statistics of the number of patents of 21 cities of Guangdong Province (data from statistics yearbook, only part of the data is shown below), which is calculated to see if an edge is formed between any 2 cities. When the given R_0 =0.97, the degree distribution (by computing programming) is shown in Figure 1.

Make sure that you have used Type 1 or True Type Fonts (check with the Acrobat Reader or Acrobat Writer by clicking on File>Document Properties>Fonts to see the list of fonts and their type used in the PDF document).

In Figure 1, the network built by numbers of patents in Guangdong cities is scale-free. It is found that the degree distribution is negative power law distribution with $2 < \gamma \leq 3$. Based on the complex network theory, its network architecture is highly self-similar and divergent, meaning that most nodes' degree have low values, but a minority of nodes are central nodes with pretty high degree values. Therefore, these central nodes with high degree values are obviously of great importance, like Guagzhou, Shenzhen, Zhuhai and Foshan. The results fit the actual situation of Guangdong Province quite well, in a way demonstrating the correctness of our research.

6 Conclusions and future research

The following conclusions can be drawn from the research:

1) A regional innovation system can be considered as a complex network. The definitions of nodes and sides reflect its features as a complex network.

2) The calculations show that the Guangdong Province regional innovation network follows the negative power law distribution and the degree index is between 2 and 3.

3) The calculation results show that degree distribution theory is able to reflect the status of subjects and their relations with one other.

4) The complex networks theory brings new view, new tools and new methodologies for regional innovation researches. Relative researches worth going even further.

Abstract

In study of deep space targets recognition, infrared images of deep space targets are needed for repeat testing and evaluating. Since the limitation of deep space flight experiments, it is difficult to obtain sufficient infrared images under different conditions. Infrared image simulation technology is brought up to solve this problem efficiently. The principle of deep space targets infrared imaging was studied. Based on the infrared sensor's optical properties, a hierarchical imaging model was built. The infrared camera and all the effects were simulated respectively, including motion trail of target and space objects, blurring, dispersion, blind elements, and noise. A mixed noise model was introduced by combining the random noise and Perling noise model. In the image simulating process, Graphic Processing Unit was used to produce noise image in real time. According to the reference photo of infrared sensors, infrared simulated images were evaluated using histogram distribution, the trend of intensity, and Signal to Noise Ratio, and the results show these images satisfied targets recognition algorithm.

Keywords: deep space targets, infrared optical properties, infrared imaging, graphic processing unit, Perling noise

1 Introduction

According to the infrared radiation characteristics of the target and the background, infrared image simulation technology produces infrared thermal image, this is very significant for the target tracking and recognition algorithm. The first principle model, proposed in 1988, considers infrared features of objects in different conditions, by solving equations to get radiation intensity distribution on the surface of the object [1]. But as solving the first principle model is very complicated and unpractical, a semi-empirical first principle model is proposed.

With the development of the infrared image simulation technology, the reality of infrared image becomes more and more strong. In 1996, in order to overcome the problem in lack of reality sense and measured infrared data, people rendered the scene and identified the target by the synthesis of real images and artificial images. In 2005, Gaussian proposed an infrared imaging simulator IRISIM, which can simulate the complete imaging process of the broadband and multispectral infrared imaging system, and evaluate the reliability of the simulation image [2].

Currently, the domestic research adopts the mature semi-empirical first principle model. In studying the effect of the infrared detector on imaging, domestic researchers have obtained certain achievements, including optical dispersion, detector noise, etc, and set up some models and methods [3]. Based on these models and methods, fully considering the influence of various infrared detectors imaging effect, this paper proposes the hierarchical model of imaging, and mixed noise model is established. The whole process implemented with the GPU, provides an effective way for the study of deep space target detection recognition algorithm.

2 Layered model for infrared detector imaging

Different from the traditional scanning detectors, the infrared staring detectors' imaging lack some factors such as blur, which is essential in the real world. To generate the final infrared image, the dispersion effect, blur, noise and blind pixel need to be added to the image.

Therefore, imaging can be layered in modelling, to simplify the modelling process. A complete infrared image can be divided into six layers. As shown in Figure 1.

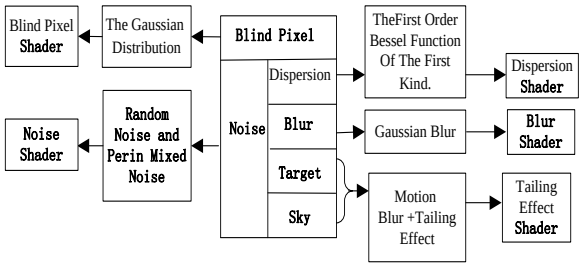

FIGURE 1 Layered model of infrared detector

The top is blind pixel, which will cover all the lower objects. The blind pixel conforms to the Gaussian distribution. The closer to the neutral, the lower the risk of producing blind pixel is. The blind pixel is achieved by blind pixel Shader. The blind pixel is divided into two branches, the relationship between which is not covered

*Corresponding author-e-mail: li_weiqing@139.com

with each other, but for a certain pixel, the larger brightness value of two branches is obtained as the final brightness value. The left branch is noise. The noise of infrared image is simulated in the way of mixing random noise and Perling noise, and produced by the noise Shader. The right branch is top-down with four levels: blur, dispersion, target and stars. The dispersion phenomenon conforms to the trend of the first-order the first kind of Bessel function, which is implemented by blur Shader; blur phenomenon is simulated with Gaussian blur function, and implemented by blur Shader; Target and stars produce tailing effect, which is simulated by the motion blur algorithm and OpenGL camera Settings for the calculation of the interaction, and implemented by the tailing effect Shader.

3 Simulation of infrared characteristics for deep space target

Due to the difficulty of the deep space target intercept test in the reality, which spends high cost and a lot of manpower, the way of simulation experiment is adopted.

3.1 THE TARGET TEMPERATURE FIELD CALCULATION WITH FINITE VOLUME METHOD

Deep space target temperature directly determines the target radiation condition. Target surface temperature is affected by many factors. To study the influencing factors, a deep space target surface thermal equilibrium relation is established and the equation is solved. Therefore, the target surface element temperature and the target surface temperature field distribution is obtained.

The system mainly uses the finite volume method [4] for target temperature field calculation. The basic idea of finite volume method is a series of grid in the calculation area, which does not overlap with each other, is divided, and each grid point is surrounded by a control volume. Each control volume of the differential equation is integrated, and then a set of discrete equations are obtained. The biggest advantage of the finite volume method is that even in the condition of coarse grid; the accurate integral conservation is also shown.

The main source of external thermal radiation that the target in the deep space environment received is as follows:

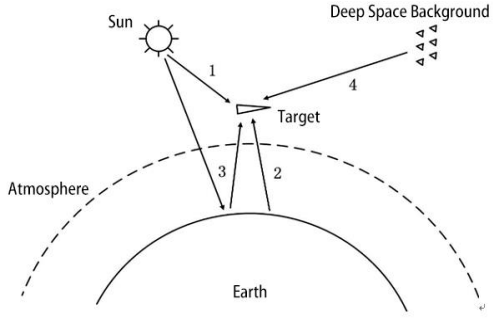

FIGURE 2 Thermal environment of the deep-space targets among them

Among them:

1 is the direct radiation from sun to target Q_{sun}, 2 is the radiation from earth to target Q_{earth}, 3is the reflection of the sun from the earth radiation Q_{ErefS}, 4 is the deep space background radiation Q_{space}.

When a target surface unit receives the radiation and is regarded as the research object, it also exchanges the heat source $Q_{exchange}$ with the nearby unit and internal heat source Q_{inside} of heat. Target surface unit, at the same time, under the influence of various thermal itself, also radiate heat energy, remember to Q_{self}. All of them are factors that make effects on the change of the target surface internal energy Q_{tempr}. The thermal balance equation is established by selecting a binning on targets.

Because deep space background in addition to the sun and the earth's makes little effect on the target radiation Q_{space}, it will be ignored and a balance Equation is obtained:

$$Q_{self}+Q_{tempr}=Q_{sun}+Q_{earth}+Q_{ErefS}+Q_{exchange}+Q_{inside}. \quad (1)$$

Then, balance Equation is established for each binning. As there is T4 factors in the thermal factors of binning, the difference method [5] is used in the linearization of equations, and solution is obtained according to the linear equations. There are many methods of solving linear equations. The methods often used are: Jacobi iteration method, the fourth-order Runge-Kutta method and Gauss-Seidel iterative method. Gauss-Seidel iterative method is used in the system, to calculate the temperature field distribution on the surface of the target on every moment.

3.2 TARGET RADIATION CALCULATION

From the perspective of deep space detector on target, the radiation it receives is related with energy and radiation on the surface of the target, the target reflection, and the target distance, detecting angle and so on. Thus these factors will be analysed.

3.2.1 The radiation factor of itself

The radiation of target unit is related with the temperature of the unit. When the temperature of the target is high, the radiation increases. When the temperature reduces, the radiation will be reduced accordingly. Since infrared radiation of the target is distributed at different wavelengths, it only needs to study the radiation of observed wavelengths. With an optical variable to describe the target, using Planck's law to describe the spectral distribution of blackbody radiation E_λ:

$$E_\lambda=\frac{c_i\lambda^{-5}}{\exp(\frac{c_2}{\lambda T})-1}, \quad (2)$$

among them: T is temperature; λ is wavelength; c_1 is the first radiation constant, value is 3.742×10-6 W m2; c_2 is the second radiation constant, value is 1.4388×10-2 m K.

With the integration of the infrared sensors from floor to ceiling, effective radiation flux for sensor of the target unit itself outward radiation can be obtained:

$$E_{Self} = \int_{\lambda_1}^{\lambda_2} \varepsilon_\lambda E_\lambda d_\lambda , \tag{3}$$

where λ_1 is infrared wavelength floor; λ_2 is infrared wavelengths ceiling; ε_λ is the surface spectral emissivity of target unit.

3.2.2 Reflection radiation factors

The calculation of target unit reflection from the external radiation is complicated. The direct radiation of the sun on the target Q_{sun}, the radiation of the earth on the target Q_{earth}, the sun radiation from the reflection of the earth Q_{ErefS}, and the radiate on from the other units Q_{others}.At the same time the effective receiving band range of the detector is also taken into account. The target unit calculating formula for the reflection of radiation is:

$$E_{reflect} = \rho_s K_s \left(Q_{sun} + Q_{ErefS}\right) + \rho_l K_e (Q_{ErefS} + Q_{others}) , \tag{4}$$

among them: ρ_s is the reflectivity of the target unit to the infrared solar radiation; ρ_l is the reflectivity of the target unit to the infrared earth radiation; K_s is the proportion of the total radiant energy from solar radiation in the infrared radiation of the detector; K_e is the proportion of the total radiant energy from earth radiation in the infrared radiation of the detector.

3.2.3 Detector factor

Detector receives the radiation flux associated with the target and the radiation flux, also with the environment, and the target distance and Angle. That is:

$$H = \sum_{i=1}^{N} \mu_i A_i E_{Mi} , \tag{5}$$

among them: N is the total number of factors, μ_i is the pupil coefficient of unit normal and the angel of the detector; E_{Mi} is the radiation flux of target unit, the value is:

$$E_{Mi} = E_{self} + E_{reflect} \tag{6}$$

Using optical device to focus infrared energy of objects in the scene's on the infrared detector, and then transforming infrared data from each detector element into standard video formats, they can be displayed on the standard video detector, or recorded on videotape. As a result that the infrared detector is heat rather than light, they can be used all-day long.

4 Infrared image simulation based on GPU

4.1 INFRARED DETECTOR IMAGING

Temperature change rate of the object is reflected in the image grayscale change rate. When the temperature of the object changes, the imaging grayscale of warhead target and decoy change over time, then we can obtain the grayscale time series and grayscale change rate.

4.2 INFRARED IMAGING EFFECTS

4.2.1 Tailing

In the real world, the infrared detector exposure is not instantaneous, this will result in that images it captured have tailing phenomenon. In addition, as interceptors constantly do orbit adjustment and attitude adjustment, Astronomical do back and forth motion relative to the infrared detector, this also produces tailing phenomenon.

To simulate tailing phenomenon, there are two approaches as follows:

1) Directly tailing phenomenon is seen as Motion blur to deal with. This method is simple, in each frame captured image, apply motion blur algorithm to target point to achieve the trailing effect. As shown below:

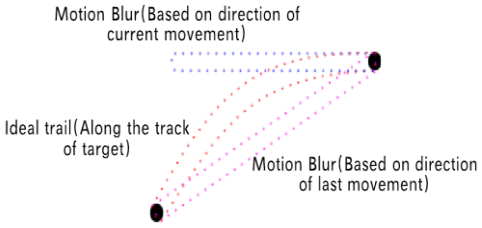

FIGURE 3a Tailing simulated by Motion blur

2) Set the camera so as not to remove the previous frame image when drawing the next frame image. This approach is slightly more complicated. Firstly several intermediate frames need to be inserted between each two frames. Provided frame A_1, A_2, A_3 are inserted between the original frame A and frame B. When rendering frame A_1, frame is not output to the screen, instead is output to a separate frame buffer to store until A_2, A_3 and B rendering are completed, then the image in the frame buffer is displayed on the screen. As shown below:

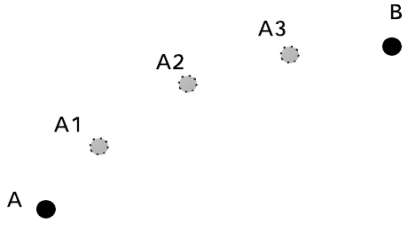

FIGURE 3b Tailing simulated by camera features

We combine the above two methods, namely firstly use Method 2 to insert intermediate frames, and each frame image output to the frame buffer, while use Method 1 to do motion blur for each frame image. This guarantees that the images were real enough.

4.2.2 Blur

Blur mainly refers to the Gaussian blur. Noticing that images outputted by the computer simulation are too sharp, but in real life there is always some blur exciting in the edges of the image captured by camera. In order to simulate this phenomenon, we need to apply a slight Gaussian blur to the image, so that the edge of objects in the image is slightly soft, close to the effect of the real world.

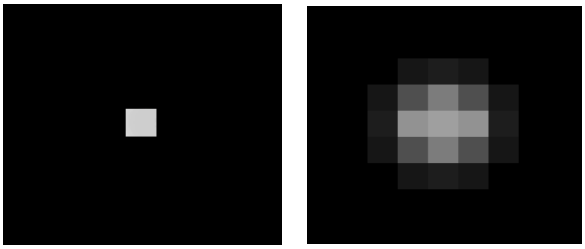
Gaussian blur uses probability density function of normal distribution to calculate the weight of the surrounding pixels, which is defined as follows:

$$f(x)=\frac{1}{\sqrt{2\pi}\sigma}\exp(-\frac{(x-u)^2}{2\sigma^2}). \tag{7}$$

We use the standard normal function to generate natural effect, when $\mu=0$, $\sigma=1$ this is probability density function of standard normal distribution as follows:

$$f(x)=\frac{1}{\sqrt{2\pi}}\exp(-\frac{x^2}{2}). \tag{8}$$

Point target in infrared image before and after joining blur is displayed as follows:



a) before adding blur b) after adding blur

FIGURE 4 Blur effect

4.2.3 Dispersion

In the background of deep space, the main impact on the size of dispersion circle is the diffraction and aberrations. Aberrations can be weakened as much as possible by improving the optical system. But the diffraction phenomenon is the inevitable result of the spread of radiation, cannot eliminate.

Optical instruments generally use circular aperture [6], for dispersion energy of circular aperture diffraction calculation Equation is:

$$I(\omega)=|U(\omega)|=I_0\left[\frac{2J_1(k\alpha\omega)}{k\alpha\omega}\right]^2, \tag{9}$$

where I_0 is the centre intensity of dispersion circle, $k=2\pi/\lambda$ is wavelength constant, α is the diameter of incident aperture, ω is the angle, $J_1(\ )$ is the first order the first kind of Bessel function.

Assuming the radius of incident aperture is α , the radius of reflector is $\varepsilon\alpha$, the diffraction energy distribution is:

$$I(\omega)=|U(\omega)|=\frac{I_0}{(1-\varepsilon^2)^2}\times \left\{\frac{2J_1(k\alpha\omega)}{k\alpha\omega}-\varepsilon^2\left[\frac{2J_1(k\in\alpha\omega)}{k\in\alpha\omega}\right]\right\}^2. \tag{10}$$

The second factor impacting dispersion circle is aberration. In the simulation, we can simply use uniform optical defocus to simulate the impact caused by aberration by adding defocus coefficient μ in the above function. For reflection system can be written as:

$$I(\omega)=|U(\omega)|=\frac{I_0\mu^2}{(1-\varepsilon^2)^2}\times \left\{\frac{2J_1(k\alpha\mu\omega)}{k\alpha\mu\omega}-\varepsilon^2\left[\frac{2J_1(k\in\alpha\mu\omega)}{k\in\alpha\mu\omega}\right]\right\}^2. \tag{11}$$

This can reflect the diffusion phenomena caused by aberration without changing the basic distribution of the diffraction. The implementation of dispersion phenomenon is estimated and simplified in the system, Dispersion effect as shown below:

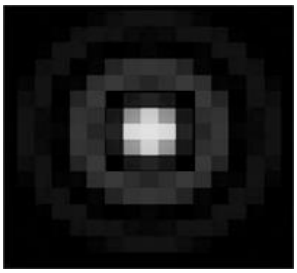


FIGURE 5 Dispersion effect

4.2.4 Blind pixel

Blind pixel is also known as failure, including death pixel and overheating pixel. Performance on the infrared image, death pixel is a black spot for all time, while overheating pixel is white dot forever. According to the project demand, system just simulate white dot.

Central area of infrared detectors undertakes main task of recording the target position. Therefore, blind pixels of central area are less and obey the Gaussian distribution, namely the closer from the centre, the smaller odds of blind pixel. However, the peripheral blind pixels are more and obey uniform distribution. Blind dollar rate for the entire focal plane is about 0.1%.

4.2.5 Noise

Noise can be divided into two parts to simulate. One part is the white noise shown in the uniform distribution. The other part use Perling to simulate the lower image noise of "piece" light and dark areas. Then the brightness values of the upper is remapped around 1.0, and superpose the brightness values of the lower image again to get close to the true noise pattern.

1) Random Noise

The upper noise is easier, regarded as the effects of white noise. Then the white noise has nothing to do with the frequency, and is even distributed on the whole infrared image. The brightness range of your white noise is set as the maximum and the minimum brightness, and the two values are between 0 and 1. The implementation only needs to produce the brightness value of the image between the maximum value and the minimum value with the random number generator.

Because generation of the noise is accomplished in the GPU Shader language and Shader does not directly provide random noise function, this system uses the following hash function to generate pseudo random numbers:

```
float rand(vec2 seed){
return fract(sin(dot(seed.xy, vec2(12.9898,78.233))) * 43758.5453);
}
```

When called, the *x*, *y* coordinates of points on the image are introduced to the function as a seed vector, to get the brightness values of point. Then we obtain the more-random image.

2) Perling noise

It needs to use Perling noise function to generate the lower noise. Perling noise is mainly used to simulate real objects, to replace the general random number generator to produce hard and rough result.

Ken Perling proposed a simple method of one-dimension noise function in 1985, called as classical Perling noise. It can be generalized to the two-dimensional case. The implementation steps are as follows:

1) A value and a gradient is specified for all integers (x, y) coordinates, and the space is divided into many squares;

2) In the plane, to coordinate for integer points, the value specified for it is set as a value of a point; for points inside square, we make the interpolation with four vertices values and gradient in squares.

For example, for point (x, y), i and j are integers which x and y are respectively made down. The square four vertices are: (i, j), $(i+1, j)$, $(i+1, j+1)$, $(i, j+1)$ .Make $u = x - i$, $v = y - j$, and then the contribution of the four vertices to the point (x, y) can be achieved with the dot product in the gradient $(g_{00}, g_{10}, g_{11}, g_{01})$ and (x, y) point and the direction of the four vertices $((u, v), (u-1, v), (u-1, v-1), (u, v-1))$. But in the case of two-dimension interpolation is more complex, and the number of interpolation grows as the growth of the dimension exponential growth.

In order to simplify the calculation and use the hardware implementation easier, Ken Perling improved his method in 2001 and the improved noise is called Simplex noise. The algorithm of Simplex noise effectively reduces the number of interpolation.

As mentioned above, the two-dimensional classic Perling noise makes that the two-dimensional space is filled with a square, using four vertices used with three interpolations, and Simplex noise makes that the two-dimensional space is filled with an equilateral triangle, using three vertices with interpolation.

4.3 INFRARED IMAGE GENERATION BASED ON GPU

We use GPU programming, specifically Shader programming for image simulation. The Shader can't save intermediate results in memory, we can use a technology known as the "render to texture" (RTT), to save the intermediate results rendered in a certain extent, and used to image transmission in the multiple Shader.

Concrete implementation steps are shown in the Figure 6 below:

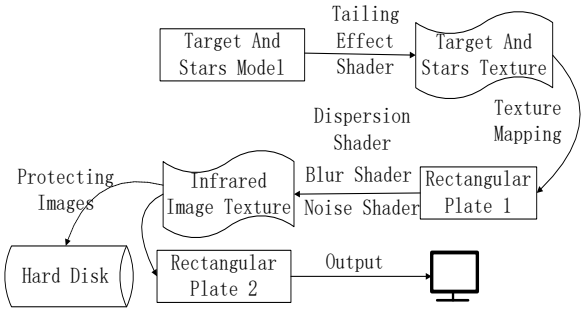

FIGURE 6 Implementation steps based on Shader

Because in the middle dispersion and blur effect needs to be based on the current coordinate view around the point, and the dispersion is to check a certain distance from the current point on the existence of a target. If any, the current point assignment is set; Blur is according to the brightness of the points around and reset the brightness of the current point. So we need to save target and star to join the tail effect to a texture, that it is convenience to check dispersion and blur query Shader. And noise Shader does not need to use the result of a step, so the noise Shader does not introduce another texture.

We can notice that a system is a requirement to save and read infrared image, or store it in hard disk, or sent to the network, so the above is the two nodes "infrared image texture" and "rectangle plate 2". If there are not the two nodes, the infrared image directly output to the screen, and cannot be read.

5 Simulation results evaluation

5.1 SIMULATED PICTURES OF INFRARED TARGETS

The following figures show the real-time infrared simulation images (the original image is too big, the picture is cropped):

a) The 100th frame b) The 800th frame c) The 900th frame

FIGURE 7 Simulation of infrared images

These pictures show the change of the target in infrared image after the start of the simulation. Target is getting closer, and the target point is also growing. Noticed that the tiny white spot in the background is blind pixel, the noise also can be clearly seen.

5.2 THE EVALUATION OF INFRARED IMAGE

In the literature [7], it gives a deep space infrared background image by a certain type of infrared detector:

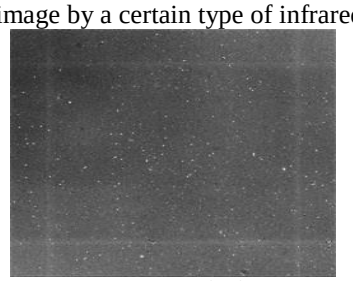

FIGURE 8 Real images of infrared detector

Considering the final goal of the system is target recognition, the infrared image generated by our system should meet an indicator, which is suitable for an ideal target recognition algorithm. We can assess simulated images based on it. As shown in Figure 8, using infrared background image as a reference image, compare it with the simulation image, thereby assess the simulation results.

1) The assessment about characteristics of histogram distribution.

What target recognition algorithm first need to do is eliminating noise in the background. However, filtering background noise is related to the histogram of images. The histogram of referential image as shown below:

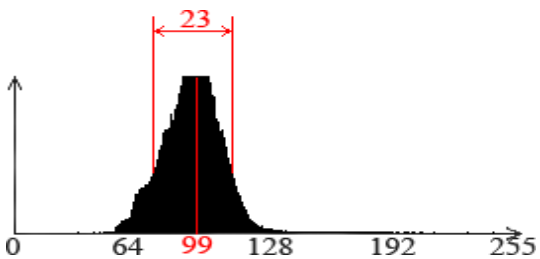

FIGURE 9 Histogram of real deep space infrared background image

The luminance values of reference image is trapezoidal distribution, middle value is 99. Among the pixels, whose luminance value is more than the half of middle value, the difference between max luminance value and min luminance value (hereinafter referred to as "the width of the ladder") is 23.

Histogram distribution of simulation image is as follows:

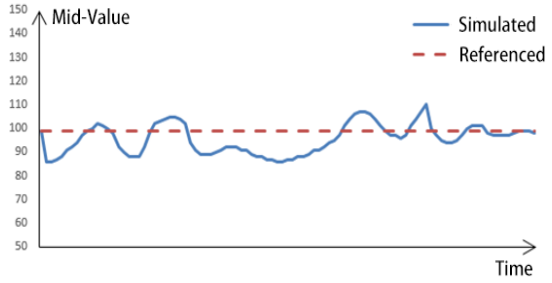

FIGURE 10 Comparison of middle value

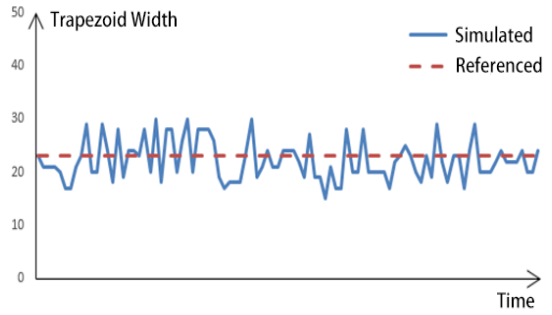

FIGURE 11 Comparison of trapezoidal width

In the simulation image, the histogram changes along with the noise. But the change is always kept within a certain range. The middle value of the simulation image has always been in the vicinity of 99, the maximum deviation is -13.13%, average deviation is -3.43%. The standard deviation of the difference was 0.05; Keystone width of simulated image is always around 23. The maximum deviation is -34.78%, average deviation is -3.52.%, the standard deviation of the difference was 0.13. The histogram distribution of simulation image is close to reference image, we can consider that the simulation image truthfully reflects the infrared image.

2) SNR evaluation of infrared images

In this experiment, we assume the point target is a pixel, and the luminance value is 255. We have a random sample of ten in a series of simulation images to compare with the real image, SNR of real images is 27.74 dB and SNR of simulation image is shown as below:

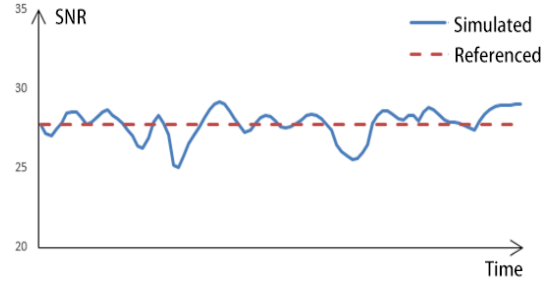

FIGURE 12 Comparison of SNR

The SNR of simulated image fluctuated around 27.74dB, the maximum deviation is -9.73%, average deviation is 0.27%, the standard deviation of the difference was 0.02. The SNR of simulated image is close to the reference image, and we can consider that the simulated image is close to real infrared image.

6 Conclusions

In this paper, according to the imaging principle of infrared detectors, we set up a hierarchical imaging model and give a method for simulation of targets, stars, blur, dispersion, blind pixel, as well as noise. The modelling of noise is discussed in detail. We implementation this method based on GPU to generate more realistic infrared images. According to reference image of an infrared detector, the histogram trend of infrared simulation images, and the signal to noise ratio were evaluated. Simulation results verify the modelling method and show these images satisfied targets recognition algorithm.

Abstract

The development and application of computer graphic design and visual communication design greatly changes people's life. Designers can use design tools, which are highly-advanced and professional to create a broader scope of design and design theme works. In our daily life, computer graphics technology is widely applied into various fields, such as the military, medical, communication, art etc. Computer graphics and image technology has been emphasized in the visual field, which improves the overall effect and the level of visual communication design to a large extent. This article mentioned the definition of the technology of computer graphics and the visual communication, then described the significance of realizing the visual communication design elements, and hoped the results will be helpful to relative fields.

Keywords: computer graphics, visual communication, the overall effect, the significance

1 Introduction

Since the computer generated, the software technology has gradually penetrated into every corner of people's life with further extension and development of modern technology. From the visual communication way, the whole concept of visual communication design elements appeared for a long time, but the theory of visual communication design elements and computer graphics technology proposed in recent decades. If the technology of computer graphics and visual communication design elements are well-linked, it will be more convenient and easily for the viewer to understand the concept and the intrinsic meaning. Therefore, we can say that the computer graphics technology has important significance for the design of the visual communication elements.

2 The definition of computer technology graphics and visual communication design

Technology of computer graphics and visual communication design refers to use a sort of computer technology as a means to do design data processing in its dram, and show the design drawings in the display or in the drawing software. From the perspective of the angle of visual communication design, it refers to the basic elements of text, colour, graphics, layout and other information through the computer technology to create, and we usually call it the computer graphics technology [1]. Visual communication refers to the visual symbols as the channel of information transfer, use visual language as expression and transmission way, which means people use "view" as a means to communicate with others. Visual communication design aims at processing the design content and let it have the visual function. Visual communication design mostly refers to the graphic design, and printed matter as the media, which include book design, corporate image design, logo design, packaging design, advertising design etc. Visual communication design is mainly aimed at colour, graphics, layout, text and other elements of artistic creation, which plays an extremely important role in people's life. Graphics is a kind of visual symbol, and the intonation is intuitive and conscious. Computer graphics and image processing technology have been fully applied in the visual communication fields, and its prosperous development has brought a breakthrough in the visual communication design field.

The rapid development in computer technology today, which can not only enrich people's cultural and spiritual world with applying the computer graphics and image technology in visual communication design, but also play an important role which should not be ignored in the development of the art design [2, 3].

3 The significance of computer graphics technology to the visual communication design elements

3.1 THE SIGNIFICANCE OF COMPUTER GRAPHICS TO REALIZE THE LAYOUT ELEMENTS

It is of great significance of computer graphics technology in the layout elements of visual communication, and the layout elements includes a wide range of fields, such as advertising design, creative imagery which has a close contact with it. Perfect layout on the advertising and image picture can bring extraordinary creative effects. One of the main branches of the art design is the creative visual design, which has obvious business purpose; but it provides people who appreciate design with a broad design space, consequently, a growing number of designers become interested in designing the computer graphics, and their creativity and innovation make the visual communication more creative and has obvious personal characteristics. It is a particular demanding job in advertising photography and hand-painted for the visual communication arrangement elements. The purpose is to use the visual communication design to make the company's packaging style, the behaviour of enterprise idea, management idea, management characteristics, marketing strategy and guidelines into a complete and unified image, and it hopes to make the product layout satisfactory through computer graphics technology [4]. In addition, the imagination and creativity of computer image design is very rich, and it can make the totally unrelated things united by using the powerful graphics processing software, the image can be totally changed by using a variety of replacement and modification technology. For example, we can achieve the effect which exceed our expectations by designing the layout of fruit juice beverage bottles, and we often see the pattern design character with tick juice fall into the mouth, thus it is not only enhance the realistic visual effect, but also make people feel fresh and lovely. There are a number of such graphic design and bring great economic benefits for manufacturers.

3.2 THE SIGNIFICANCE TO REALIZE COMPUTER GRAPHICS AND IMAGE PROCESSING TECHNOLOGY ON COLOR ELEMENTS

Colour is the first feeling for eyes when receive the visible light, so in visual communication, colour element is one important element among them. Computer can adjust and grasp the colour, brightness and purity, then reproduce the three dimensional effect so as to let people observe a thing more intuitively. Consequently, computer designers can make use of the computer graphics and image technology to transmit the rich and colourful life to the viewers, then viewers can know more about the world by the information created by the computer, and applied this information into all works of life. For example, the packaging design is always the first thing to attract consumer's eyes, so we would see the novel and unique packaging design in our daily life. The garment packaging, and food packaging are closely related to communication design of computer graphics [5]. The packaging of goods is the means to realize the value and the use value of goods, and whether we see posters, brochures, or the book cover we are reading, these graphic printings have rich visual effect. To arouse people's interest, the first thing to do is to design the novel colour through computer graphics design software. Only by doing this can arouse more interest, and enhance the understanding of the cultural, intellectual and ideological aspects. As long as we set the product different transparency and colour, different visual effects will be created.

3.3 THE SIGNIFICANCE OF REALIZING GRAPHIC ELEMENTS AND TEXT ELEMENTS

The adjustments and division of the graphics and image are two main parts in terms of the significance of computer graphics and image technology. The acquisition images can be adjusted and processed by computer graphics technology in two aspects. One is good for the design need, which can do effects of filters, colour adjustment and image synthesis processing. The second is to draw with the computer drawing technology, for example, a graphic or image can achieve large number of scattered in vertical and horizontal by technical parameter settings, meanwhile, more changes in colour, transparency, shape ,and these changes are finished in a few seconds. It is impossible to achieve it in such a short time if hand- painted is used. The graphics and image are clear divided into vector graphics and bitmap by using computer graphics and image technology. The bitmap is bit by bit to draw Icon, but vector record and plot the various elements of the geometric figure painting in the digital form. The former can design the rich colour and brightness of the image, while the latter can show things the original contours and lines. In addition, the computer graphic design can also be applied to character design, and it is easy to operate. In the commonly used software, and in the toolbar, as long as you choose to design "front colour" "typeface" "font size", then input the text, then you can do the art-processing. The text will experience a sort of changes after processed by the computer graphic design technology, and it is not only enhancing the visual effect, but also improve the work demand rate. For instance, a variety of text design is not only enhance the advertising effect but also transmit the happiness atmosphere; therefore, computer graphics design can make any form of words realize its potential image value.

4 The field of computer graphic design with visual communication application

4.1 TEXT DESIGN

Character design is the most basic application of graphic design, software operation is simple/ Such as Photoshop, as long as one choose to design "typeface" "font size" "font colour", then select areas on the selected input text box, you can input the text and word [6]. Afterwards, you can do the art processing. When the text encounter image design processed, everything will be changed. It is stressed that the hotkey settings is very skilled in software tools, and some sets of data should be noted. Set the word adjustment ratio of 0，and select the pixels "Ctrl+ Shift+ Q". When we want to trim the Kerning decrease or increase to 20 -1000 ems, please use "Alt+ /".However, we should use "Ctrl+ Alt+ /"to trim the kerning decrease or increase to 100-1000 ems. Computer graphics design can let the text or words have a variety of changes, and improve the work demand, and in addition, it can also enhance the communication visual effect. For instance, a variety of text design is not only enhancing the advertising effect but also transmit the happiness atmosphere.

4.2 PACKAGING AND ADVERTISING DESIGN

When we walk in the market, a shopping canter or a small supermarket, all kinds of packaging of various commodities, and its novel and unique design can often attract the attention of consumers. The packaging of food or clothing cannot exist without the visual communication design of computer graphic image. Packaging is a means to realize the value of the commodity. Whether we are reading the book cover, or see posters, brochures in the street, these graphic paintings have rich visual communication effects. Most of them need computer graphic design to do art processing to let more people interested in it, then achieve a deep understanding of the ideological, cultural and intellectual nature. Different colours and different opacity can convey different visual effect. Creative advertising design and image cannot do without a computer graphic image processing, and it will bring out different creative effect if we do reasonable and exaggerated treatment on the picture. Visual creative design is a branch of the art design, such design usually does not have obvious business purpose, but because it provides a broad space for the general design enthusiasts, so more and more designers began to learn computer image design, creative visual communication and add the individual characteristic and style [7]. Advertising photography and hand-painted are very strict work for visual communication. It is a means that make enterprise business philosophy, behaviour concept, management characteristics, packaging, marketing style guidelines and strategies reach an overall image, the final product can get a satisfied effect after image design modification. In addition, image innovation is the specialty of computer image design, we can make the objects which have no relevance together through the powerful computer graphic image software, moreover, the replacement technology can make the image totally changed. The design of tick coffee falling into the mouth of the characters that enhances coffee cup visual vivid effect, and make people feel fresh and lovely, so graphic design will bring great advertising benefits and economic benefits to the coffee cup manufacturers.

4.3 PAINTING INTERFACE DESIGN

Many illustration design producers often use the pencil to draw a draft, then use the colouring method of graphic design software to draw illustrations, since the software has good function of computer image design and colour painting [8]. In addition, pixel art is very popular in recent years also for designers to use image design works, these works have strong visual impact. The success of IPhone, which is largely attributed to the exquisite interface design, and show the most incisive visual performance, details decide the excellence! The interface of IPhone design is solemn and elegant, and let a person feel it with quality. Computer graphics interface design is no longer an emerging field, which attracts more and more attention, and most designers use the computer graphic software to design the visual communication.

5 Conclusions

This research made a brief analysis and research mainly in computer graphics and image processing technology to realize the significance of visual communication design elements and other aspects. The graphic design and visual communication design can be effectively improved with the help of computer image processing software and provide sufficient design content to the designers, and allow designers to use more processing techniques and processing method on the design of the works to adjust or perfect. In addition, the combination of graphic images and visual communication design is able to create a more vibrant, more appealing works of art, and constantly promote people to use modern tools to show their own thinking and innovative ability

Content of smart wireless sensor network security and its network security policy

Xiehua Yu*

Minnan Science and Technology Institute, Fujian Normal University, Fujian, 362332, China

Received 1 October 2014, www.cmnt.lv

Abstract

Wireless sensor network is generally composed by plenty of micro-sensors that arranged on designated area. The supervision of these sensor nodes is used to finish the collecting, disposing and uploading of vast information. However, the security of wireless sensor network has many problems, since the sensor node itself exists plenty of limitation. Aiming at the problems of smart wireless sensor network security as well as the analysis of wireless sensor network node easy been attacked, wiretapped and forged without safeguard, this paper put forward a security policy of smart wireless sensor network. Simple and useful intrusion detection policy was realized from a series of improvement of LEACH protocol of low-energy self-adaptation cluster routing protocol.

Keywords: Smart wireless sensor network security, secure routing, key management, intrusion detection

1 Introduction

According to characteristics of limited self resource, poor computing power and small storage space of wireless sensor network, this paper put forward a security policy of smart wireless sensor network. Through the improvement of LEACH protocol of low-energy self-adaptation cluster routing protocol, and the requirement of low-energy and real-time needed for intrusion detection of wireless sensor network, it also put forward whole network cooperated intrusion detection policy. Low–energy and real-time intrusion detection policy is realized by effectively using base station energy and setting up dynamic parameter.

2 Introduction of Wireless Sensor Network

Wireless sensor network technology is an inter-discipline, which involves in many fields, like computer, micro-electronics, sensor, network, communication, signal processing, etc. With the development of many relevant new technologies, this technology is also rapidly booming [1]. Sensor node is made up of data acquisition module, data processing module, data communication module and energy supply module [2], as shown in Figure 1. Data acquisition module is used for monitoring the collection of information within formulation range and the transformation of information data. Data processing module is used for controlling the disposal operation, routing protocol, synchronization, location, energy management, task management and data infusion of all nodes. Data communication module is used for node to collect data and transmit data. Energy supply module provides the needed energy for the above three modules.

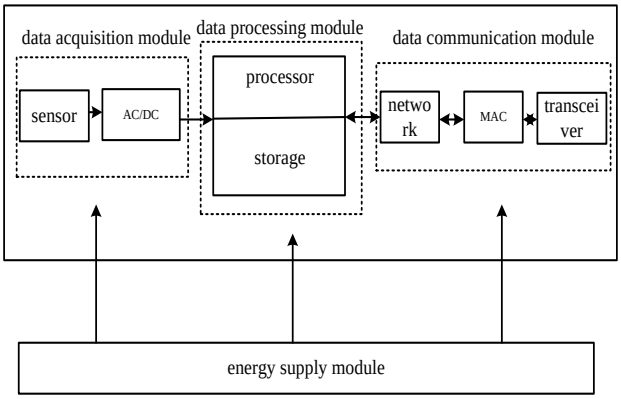

FIGURE 1 Architecture of sensor node

Structure of wireless sensor network is shown in Figure 2 [3]. Wireless sensor network is the newly developing network, which consists of many sensors, reactors and base stations. It finishes the corresponding reaction task and distribution induction with the cooperation of infinite medium. Such kind of wireless sensing actor network must be extensively used in society [4].

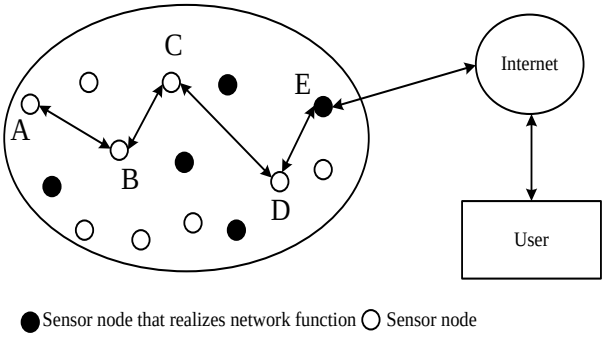

FIGURE 2 Architecture of wireless sensor network system

3 Contents of wireless sensor network security and its technologies

3.1 SECURE ROUTING

The routing algorithms of wireless sensor network are mainly put forward based on characteristics of network itself and energy problems. However, these routing algorithms are not taking security issue into consideration. In order to solve problems like network failure caused by misuse of routing protocol, insecure information transmission, etc, this paper will put forward a safe and reliable routing protocol. Generally, routing security protocol is designed from two large aspects: aspects of message encryption, intrusion detection, identity authentication, etc; the application of multiple path transmissions for providing reliable transmission path.

3.2 KEY MANAGEMENT

Based on wireless sensor key management, the authentication mechanism, confidentiality mechanism, integrity, usability, secure routing, secure localization, etc of wireless sensor network are guaranteed. Key managements based on deployment knowledge, multipath reinforce key, random key and non-symmetric cryptography algorithm are all currently common key management plans [5].

3.3 CRYPTOLOGY

The characteristic of limited energy of wireless sensor network itself will be the main problem of cryptology of wireless sensor network. Low-energy and light weight key algorithm is the characteristic of self-organizing network. More security mechanisms of wireless sensor network are designed based on the key algorithm of wireless sensor network. Many scholars are trying to effectively use public key algorithm on wireless sensor node. With the improvement of technology and the development of wireless sensor technology, the previously not utilized key algorithms begin to be widely accepted and used in wireless sensor network.

3.4 AUTHENTICATION TECHNOLOGY

The authentication technology of wireless sensor network is made up of entity authentication and message authentication. Entity authentication refers to identify user status through method of key management. E-G algorithm and LeaP algorithm are the main representatives of authentication protocol of symmetric key, which are based on the authentication of symmetric cryptography and authentication of identity key mechanism. TinyPk authentication plan is the main representative of the authentication of identity key mechanism. μTESLA protocol is the main protocol of message authentication, of which the function is the guarantee that message is not been forged or falsified [6].

3.5 INTRUSION DETECTION TECHNOLOGY

Intrusion detection includes two kinds of detection models: anomaly detection and misuse detection. The process of intrusion detection is divided into three parts: information collection, information analysis and result processing. Wireless sensor network is subject to be larger intruded, since wireless sensor is generally located in the easily intrusive environment and resource is limited. Intrusion detection is also just emerging. The current intrusion detection technology based on active defense cannot be realized because of the characteristics of wireless sensor itself. Currently, traditional intrusion detection technology cannot apply to wireless sensor network [7].

4 Security Policy of Smart Wireless Sensor Network

4.1 SECURITY POLICY MODEL OF SMART WIRELESS SENSOR NETWORK

Based on the relay node routing protocol of smart energy detection, this model put forward efficient group secrete protocol encryption communication of smart identity authentication matched with it based on cluster structure. In addition, it also added the intrusion detection plan based on smart intrusion detection recognition. This security policy model of wireless sensor network integrated the network security technology of these three aspects together, thus to make this network security policy model more comprehensive, safe and reliable. The model structure is shown in Figure 3.

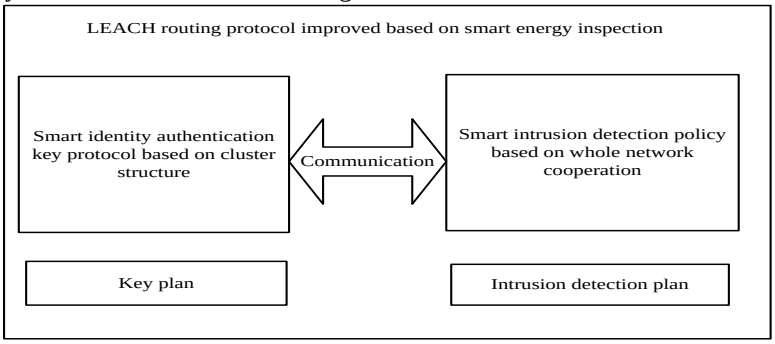

FIGURE 3 Security policy model of smart wireless sensor network

4.2 LEACH ROUTING PROTOCOL IMPROVED BASED ON SMART ENERGY INSPECTION

Routing protocol of wireless sensor network is the carrier of whole network communication, which determines the energy consumption of wireless sensor network and security of network. The current common sensor network routing protocols are all wireless routing protocol. The characteristics of wireless sensor network are greatly different from those of wireless network, thus a more appropriate routing protocol is needed.

The application of this protocol to wireless sensor network may cause the network paralysis with exhausted energy, since LEACH routing protocol consumes large energy on cluster head node. The primarily solved problem is energy consumption that the application of this protocol is needed. This paper put forward the improvement plan based on the routing protocol of smart energy inspection transmission relay mode. Its main content is to set up a relay node and sensor node, which locate on designated detection area. This relay node serves as transit of communication between cluster head node that far away from base station and base station, and it also reveal itself independently in the whole network. This protocol has a kind of smart detection mechanism, and all nodes are equipped with voltage and current detection ability (including relay node). As shown in Figure 4.

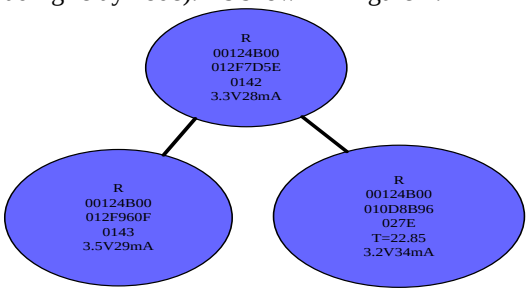

FIGURE 4 Communication mode of wireless sensor

Relay node will detect and record data of cluster head at fixed time. When it detects that cluster head node has little energy, then it will select another node with more energy as cluster head, which will effectively solve problem of energy exhaust of cluster head node. In addition, an independent relay node is established to decrease the intrusion degree of node after been intruded.

4.3 SMART IDENTITY AUTHENTICATION EFFICIENT GROUP KEY AGREEMENT PROTOCOL MODEL BASED ON CLUSTER STRUCTURE

Key management protocol plays an important role in secure communication of sensor. It is responsible for the management task of key, for the development of wireless sensor network also needs larger guarantee for network security. In addition, the application of group key protocol in wireless sensor network has strong reliability. The calculated amount, communication traffic and security of group key agreement protocol also meet the characteristics of wireless sensor network. However, the group key agreement protocol proposed by Burmester and Desmedt (or BD protocol) needs only two round of communication, and its calculated amount is small. BD protocol can resist passive attack brought by the wiretap of external node, but it cannot resist attack from internal node. Based on the above analysis, the application of BD protocol in wireless sensor network is feasible. As for the characteristics of not able to resist internal node attack, this paper put forward a kind of group key agreement protocol of logical key hierarchy in hierarchical structure through the improvement of BD protocol [8].

4.4 SMART INTRUSION DETECTION POLICY MODEL BASED ON WHOLE NETWORK COOPERATION

General intrusion detection model cannot adapt to wireless sensor network, since wireless sensor network have the characteristics of small calculated amount. A da Silva, et al put forward distributed wireless sensor network intrusion detection system, which has synthesized anomaly detection and misuse detection. These two models conducted feature library contrast on attack in network and analysed abnormal data through cooperative work, then found new intrusion feature [9]. These models provided integrated intrusion detection plan, but the plan consumed more energy. Based on the improvement of distributed wireless sensor network intrusion detection model, this paper put forward the intrusion detection plan that suit to cluster wireless sensor network model. Base station implemented complex analysis and detection algorithm through each cluster head node and terminal node. The communication method among nodes was provided through the secure routing protocol of wireless sensor network. At the same time, a simple and lo-energy algorithm was also set up based on intrusion feature comparison for cluster head node as small-scale communication network rendezvous point.

4.5 OVERALL WORKING MODE OF POLICY MODEL

The security policy of wireless sensor network is integrated security architecture. Taking the improved LEACH routing protocol as carrier, an information transmission path is provided for data that need to be send through the networking and information transmission protocol provided for routing protocol, thus to transmit information. In the process of information transmission for routing protocol, key agreement protocol of smart identity authentication and smart intrusion detection policy of whole network cooperation were added to guarantee the security of information transmission, which provided a low-energy security plan of secure transmission for whole information transmission based on smart identity authentication, encryption and decryption of information and smart intrusion detection policy of nodes. The main procedure is shown in Figure 5.

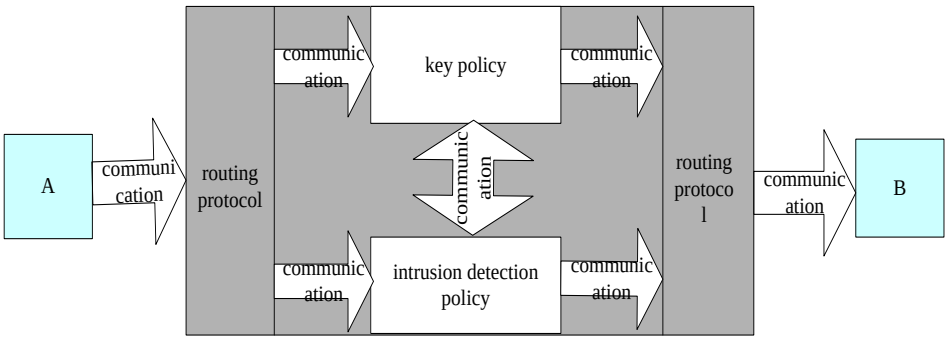

FIGURE 5 Diagrammatic figure of the overall working mode of policy model

5 Implementation of smart wireless sensor network security policy

5.1 IMPLEMENTATION OF LEACH ROUTING PROTOCOL IMPROVED BASED ON SMART ENERGY INSPECTION

According to the analysis and thought of routing protocol based on the relay mode of smart energy inspection, the idea in this paper was realized and verified through experiment and design. Therefore, node was considered based on routing protocol of smart detection relay node. In order to realize the protocol, we also need to provide feasible hardware and interface design plan. The component of wireless sensor are mostly made up of hardware, thus the most of application protocols also need the support of bottom hardware. The analysis was on the need of application layer of network, other communication network layer and physical layer and data link layer that supply hardware support. In addition, communication requirement was also analysed, since communication of protocol has many modules. The primary programming mode of design aid software based on Zigbee protocol was C procedure. Each communication module defines the corresponding function.

5.2 SMART IDENTITY AUTHENTICATION GROUP KEY AGREEMENT PROTOCOL BASED ON CLUSTER STRUCTURE

Burmester and Desmedt put forward the efficient key agreement protocol that only needs two wheel communication processes (BD protocol) [10]. However, this protocol is a non-authenticated group key agreement protocol, which cannot provide authentication function. Zheng Minghui [8] put forward the improved function that added message authentication, which proved the security of protocol under ROM. The identity authentication group key agreement protocol based on cluster structure applied BD protocol that has authentication function to wireless sensor network, which has improved the existing problem of protocol itself. At the same time, it also met the low-energy requirement of wireless sensor network. The requirement of small calculated amount and storage space has met the requirement of wireless sensor network security on data security and node security.

5.3 IMPLEMENTATION OF SMART INTRUSION DETECTION POLICY BASED ON WHOLE NETWORK COOPERATION

Based on smart intrusion detection model, the provided methods for model was analysed and solved according to the detection requirement of wireless sensor network, which verified the idea proposed by the model. According to the characteristics of wireless sensor network, the wireless sensor network security policy that integrated active intrusion detection policy and passive intrusion prevention key policy together was realized with secure routing policy as carrier. It put forward the corresponding implementation method and process of secure routing, key policy and intrusion detection plan.

6 Conclusions

Wireless sensor network is extensively used in modern society. However, such kind of network has many security problems because of the characteristics of wireless sensor network. In order to solve these problems, this paper put forward a security policy of wireless sensor network that integrated three aspects together. Each policy of this module cooperates mutually, and through a set of smart analysis, recognition, authentication and detection mechanism to form a comprehensive security defense and problem solving model for the overall wireless sensor network.

Received 1 June 2014, www.cmnt.lv

Abstract

In this paper, some nonsmooth generalized convex functions called uniform $K-(F_b,\rho)-$ convex function, uniform $K-(F_b,\rho)-$ pseudoconvex function, uniform $K-(F_b,\rho)-$ quasiconvex function are defined using $K-$ directional derivative and $K-$ subdifferential. Nonsmooth multi-objective semi-infinite programming involving these generalized convex functions is researched, some Mond-Weir type duality results are obtained.

Keywords: Nonsmooth, Multi-objective Semi-infinite Programming, Mond-Weir type duality, Uniform $K-(F_b,\rho)-$ Convex Function

1 Introduction

The convexity theory plays an important role in many aspects in mathematical programming. In recent years, to relax convexity assumption involved in sufficient conditions for optimality or duality theorems, various generalizations of convex functions have appeared in the literature. Hanson and Mond introduced type I and type II function [1]. Reuda and Hanson extended type I function and obtained pseudo type I and quasi type I function [2]. Bector and Singh introduced $b-$ convex function [3]. Bector, Suneja and Cupta extended $b-$ convex function and defined univex function [4]. Mishra discussed the optimality and duality for multi-objective programming with generalized univexity [5]. Preda introduced $(F_b,\rho)-$ convex function as extension of $F-$ convex function and $\rho-$ convex function [6, 7, 8].

In this paper, we introduce a new classes of generalized convex functions, that is, uniform $K-(F_b,\rho)-$ convex function, uniform $K-(F_b,\rho)-$ pseudoconvex function, uniform $K-(F_b,\rho)-$ quasiconvex functioned. Then we consider nonsmooth multi-objective semi-infinite programming involving these generalized convex functions and obtain some Mond-Weir type duality results.

2 Definitions

Throughout this paper, let R^n be the $n-$ dimensional Euclidean space and R^n be its non-negative orthat. Now we consider the following multi-objective semi-infinite programming problem:

$$(VP)\begin{cases}\min f(x)=(f_1(x),f_2(x),\cdots,f_p(x))\\ s.t.g(x,u)\le 0, x\in X, u\in U\end{cases},$$

where X is an open subset of R^n, $f:X\to R^p$, $g:X\times U\to R^n$, $U\subset R$ is an infinite parameter set.

Let

$A=\{x\mid g(x,u)\le 0, x\in X, u\in U\}, \Delta=\{i\mid g(x,u^i)\le 0, x\in X, u^i\in U\}$, $I(x^*)=\{i\mid g(x^*,u^i)\le 0, x^*\in X, u^i\in U\}$, $U^*=\{u^i\in U\mid g(x,u^i)\le 0, x\in X, i\in\Delta\}$ is any countable subset of U, $\Lambda=\{\mu_j\mid \mu_j\ge 0|, j\in\Delta,$ there is only finite μ_j such that $\mu_j\ne 0\}$.

Notations. If $x,y\in R^n$, then $x\le y\Leftrightarrow x_i\le y_i$, $i=1,2,\cdots,n$, and there exists at least one $i_0\in\{1,2,\cdots,n\}$ such that $x_{i_0}<y_{i_0}$.

Definition 2.1 [9] Let $K(\cdot,\cdot)$ is a local cone approximation, the function $f^K(x,\cdot):X\to R$ with $f^K(x;y):=\inf\{\xi\in R\mid (y,\xi)\in K(epif,(x,f(x)),y\in R^n)\}$ is called $K-$directional derivative of f at x.

Definition 2.2 [9] A function $f:X\to R$ is called $K-$subdifferentiable at x if there exists a convex compact set $\partial^K f(x)$ such that $f^K(x,y)=\max\limits_{\xi\in\partial^K f(x)}<\xi,y>,\forall y\in R^n,$ where $\partial^K f(x):=\{x^*\in X^*\mid <y,x^*>\le f^K(x;y),\forall y\in R^n\}$ is called $K-$subdifferential of f at x.

Definition 2.3 A functional $F:X\times X\times R^n\to R$ ($X\subset R^n$) is called sublinear with respect to the third variable, if for any $x_1,x_2\in X$,

* ***Corresponding author*** e-mail: yhxy888@sina.com

(i) $F(x_1,x_2;a_1+a_2)\le F(x_1,x_2;a_1)+F(x_1,x_2;a_2),\forall a_1,a_2\in R^n$;

(ii) $F(x_1,x_2;ra)=rF(x_1,x_2;a),\forall r\in R, r\ge 0, a\in R^n$.

Definition 2.4 $x^*\subset X^0$ is called an efficient solution for (VP) if and only if there exists no $x\subset X^0$ such that $f(x^*)\le f(x)$.

In the following definitions, we suppose $C\subset R^n$ is a nonempty set, $x_0\in C$, $f:C\to R$ is a local Lipschitz function at x_0, $F:C\times C\times R^n\to R$ is sublinear with respect to the third variable, $\phi:R\to R$, $b:C\times C\times[0,1]\to R_+$, $\lim_{\lambda\to 0^+} b(x,x_0;\lambda)=b(x,x_0)$, $d(\cdot,\cdot)$ is a pseudo-metric in R^n. In [9], Elster and Thierfelder defined $K-$ directional derivative and $K-$ subdifferential and pointed out that $K-$ subdifferential is most generalized. Now we will define some new generalized convex functions using $K-$ directional derivative and $K-$ subdifferential.

Definition 2.5 A function $f:C\to R$ is said to be uniform $K-(F_b,\rho)-$ convex at x_0 with respect to F,ϕ,b,d, if for all $x\in C$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]\ge F(x,x_0;\xi)$
$+\rho d^2(x,y),\forall\xi\in\partial^K f(x_0)$.

Definition 2.6 A function $f:C\to R$ is said to be strictly uniform $K-(F_b,\rho)-$ convex at x_0 with respect to F,ϕ,b,d, if for all $x\in C, x\ne x_0$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]>F(x,x_0;\xi)$
$+\rho d^2(x,x_0),\forall\xi\in\partial^K f(x_0)$.

Definition 2.7 A function $f:C\to R$ is said to be uniform $K-(F_b,\rho)-$ pseudoconvex at x_0 with respect to F,ϕ,b,d, if for all $x\in C$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]<0\Rightarrow$
$F(x,x_0;\xi)+\rho d^2(x,y)<0,\forall\xi\in\partial^K f(x_0)$.

Definition 2.8 A function $f:C\to R$ is said to be strictly uniform $K-(F_b,\rho)-$ pseudoconvex at x_0 with respect to F,ϕ,b,d, if for all $x\in C, x\ne x_0$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]\le 0\Rightarrow$
$F(x,x_0;\xi)+\rho d^2(x,y)<0,\forall\xi\in\partial^K f(x_0)$.

Definition 2.9 A function $f:C\to R$ is said to be uniform $K-(F_b,\rho)-$ quasiconvex at x_0 with respect to F,ϕ,b,d, if for all $x\in C$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]\le 0\Rightarrow$
$F(x,x_0;\xi)+\rho d^2(x,y)\le 0,\forall\xi\in\partial^K f(x_0)$.

Definition 2.10 A function $f:C\to R$ is said to be weak uniform $K-(F_b,\rho)-$ quasiconvex at x_0 with respect to F,ϕ,b,d, if for all $x\in C$, there exists $\rho\in R$ such that

$b(x,x_0)\phi[f(x)-f(x_0)]<0\Rightarrow$
$F(x,x_0;\xi)+\rho d^2(x,y)\le 0,\forall\xi\in\partial^K f(x_0)$.

3 Mond-Weir type duality

We consider the following Mond-Weir type dual programming for (VP):

$$(VD)\begin{cases}\max f(y)\\ s.t.0\in\partial^K(\sum_{i=1}^p\lambda_i f_i)(y)+\sum_{j\in\Delta}\mu_j\partial^K g(y,u^j),\\ \sum_{j\in\Delta}\mu_j g(y,u^j)\ge 0,\\ \lambda_i\ge 0, i=1,2,\cdots,p,\sum_{i=1}^p\lambda_i=1,\\ \mu_j\in\Lambda.\end{cases}$$

Let $W=\Big\{(y,u^j,\lambda,\mu)\,|\,0\in\partial^K(\sum_{i=1}^p\lambda_i f_i)(y)$
$+\sum_{j\in\Delta}\mu_j\partial^K g(y,u^j),\sum_{j\in\Delta}\mu_j g(y,u^j)\ge 0,\ \lambda_i\ge 0,\ i=1,2,\cdots$
$,p,\sum_{i=1}^p\lambda_i=1,\mu_j\in\Lambda,u^j\in U^*,U^*\subset U\Big\}$.

Theorem 3.1 (Weak duality) Assume that $x\in A$, $(y,u^j,\lambda,\mu)\in W$, if for any $\lambda_i>0,i=1,2,\cdots,p$, $\mu_j\in\Lambda, j\in\Delta$, there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1$, $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^p\lambda_i f_i$ is uniform $K-(F_b,\rho_1)-$ convex or strictly uniform $K-(F_b,\rho_1)-$ convex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\ge$
$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)$,
$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*,j\in I(y)$;

(iii) $\alpha<0\Rightarrow\phi_1(\alpha)<0,\alpha\ge 0\Rightarrow\phi_2(\alpha)\ge 0$,
$b_1(x,y)>0,b_2(x,y)\ge 0$;

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\ge 0$.

Then the following inequality cannot hold: $f(x)\le f(y)$.

Proof

Suppose that $f(x)\le f(y)$, then there exists i_0 such that $f_{i_0}(x)<f_{i_0}(y)$, $f_i(x)<f_i(y),\forall i\ne i_0$.

Since $\lambda_i>0,i=1,2,\cdots,p$, we have $\sum_{i=1}^p\lambda_i f_i(x)<\sum_{i=1}^p\lambda_i f_i(y)$.

By hypothesis (iii), we have

$b_1(x,y)\phi_1[\sum_{i=1}^{p}\lambda_i f_i(x)-\sum_{i=1}^{p}\lambda_i f_i(y)]<0.$

By hypothesis (i), we get

$$F(x,y;\xi)+\rho_1 d^2(x,y)<0,\forall\xi\in\partial^K(\sum_{i=1}^{p}\lambda_i f_i)(y), \qquad (1)$$

observe that $\mu_j\in\Lambda$ and $g(y,u^j)=0, j\in I(y)$, we have $\sum_{j\in I(y)}\mu_j g(y,u^j)\geq 0.$

By hypothesis (iii), we have $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0.$

By hypothesis (ii), we get $F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)\leq 0,$

$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in I(y).$

Let $\mu_j=0, \quad j\notin I(y),$ we have

$$F(x,y;\sum_{j\in\Delta}\mu_j\eta_j)+\sum_{j\in\Delta}\mu_j\rho_2^j d^2(x,y)\leq 0,$$

$$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in\Delta. \qquad (2)$$

adding (1) and (2) ,using the sublinearity of F, we can obtain $F(x,y;\xi+\sum_{j\in\Delta}\mu_j\eta_j)+(\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j)d^2(x,y)<0.$

By hypothesis (iv), we have $F(x,y;\xi+\sum_{j\in\Delta}\mu_j\eta_j)<0.$

So $\xi+\sum_{j\in\Delta}\mu_j\eta_j\neq 0$, which contradicts the first subjective condition of (VD).

Theorem 3.2 (Weak duality) Assume that $x\in A$, $(y,u^j,\lambda,\mu)\in W$, if for any $\lambda_i>0, i=1,2,\cdots,p$, $\mu_j\in\Lambda, j\in\Delta$, there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1$, $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^{p}\lambda_i f_i$ is uniform $K-(F_b,\rho_1)-$ pseudoconvex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0\Rightarrow$

$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)\leq 0,$

$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in I(y);$

(iii) $\alpha<0\Rightarrow\phi_1(\alpha)<0,\alpha\geq 0\Rightarrow\phi_2(\alpha)\geq 0,$

$b_1(x,y)>0,b_2(x,y)\geq 0;$

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\geq 0.$

Then the following inequality cannot hold: $f(x)\leq f(y).$

Theorem 3.3 (Weak duality) Assume that $x\in A$, $(y,u^j,\lambda,\mu)\in W$, if for any $\lambda_i\geq 0, \quad i=1,2,\cdots,p$, $\mu_j\in\Lambda, j\in\Delta,$ there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1$, $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^{p}\lambda_i f_i$ is strictly uniform $K-(F_b,\rho_1)-$ pseudo-convex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0\Rightarrow$

$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)\leq 0,$

$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in I(y);$

(iii) $\alpha\leq 0\Rightarrow\phi_1(\alpha)\leq 0,\alpha\geq 0\Rightarrow\phi_2(\alpha)\geq 0,$

$b_1(x,y)\geq 0,b_2(x,y)\geq 0;$

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\geq 0.$

Then the following inequality cannot hold: $f(x)\leq f(y).$

Theorem 3.4 (Weak duality) Assume that $x\in A$, $(y,u^j,\lambda,\mu)\in W$, if for any $\lambda_i\geq 0, \quad i=1,2,\cdots,p$, $\mu_j\in\Lambda, j\in\Delta,$ there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1$, $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^{p}\lambda_i f_i$ is uniform $K-(F_b,\rho_1)-$ quasiconvex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0\Rightarrow$

$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)<0,$

$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in I(y);$

(iii) $\alpha\leq 0\Rightarrow\phi_1(\alpha)\leq 0,\alpha\geq 0\Rightarrow\phi_2(\alpha)\geq 0,$

$b_1(x,y)>0,b_2(x,y)\geq 0;$

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\geq 0.$

Then the following inequality cannot hold: $f(x)\leq f(y).$

Theorem 3.5 (Weak duality) Assume that $x\in A$, $(y,u^j,\lambda,\mu)\in W$, if for any $\lambda_i>0, \quad i=1,2,\cdots,p$, $\mu_j\in\Lambda, j\in\Delta,$ there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1$, $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^{p}\lambda_i f_i$ is weak uniform $K-(F_b,\rho_1)-$ quasiconvex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0\Rightarrow$

$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)<0,$

$\forall\eta_j\in\partial^K g(y,u^j),u^j\in U^*, j\in I(y);$

(iii) $\alpha<0\Rightarrow\phi_1(\alpha)<0,\alpha\geq 0\Rightarrow\phi_2(\alpha)\geq 0,$

$b_1(x,y)>0, b_2(x,y)\geq 0$;

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\geq 0.$

Then the following inequality cannot hold: $f(x)\leq f(y)$. The proofs of Theorem 3.2 —Theorem 3.5 are similar to Theorem 3.1.

Theorem 3.6 (Strong duality) Assume that x^* is an efficient solution for (VP), if for any $\lambda_i>0,\ i=1,2,\cdots,p,$ $\mu_j\in\Lambda,\ j\in\Delta,$ there exist $F,\phi_1,\phi_2,b_1,b_2,\rho_1\in R^1,$ $\rho_2^j\in R^{|I|}$ such that

(i) $\sum_{i=1}^{p}\lambda_i f_i$ is uniform $K-(F_b,\rho_1)-$ pseudoconvex at y;

(ii) $-b_2(x,y)\phi_2[\sum_{j\in I(y)}\mu_j g(y,u^j)]\leq 0\Rightarrow$

$F(x,y;\sum_{j\in I(y)}\mu_j\eta_j)+\sum_{j\in I(y)}\mu_j\rho_2^j d^2(x,y)\leq 0,$

$\forall\eta_j\in\partial^K g(y,u^j), u^j\in U^*, j\in I(y)$;

(iii) $\alpha<0\Rightarrow\phi_1(\alpha)<0, \alpha\geq 0\Rightarrow\phi_2(\alpha)\geq 0,$

$b_1(x,y)>0, b_2(x,y)\geq 0$;

(iv) $\rho_1+\sum_{j\in\Delta}\mu_j\rho_2^j\geq 0.$;

(v) The *Kuhn-Tuker* condition is hold at x^*, that is, there exist $\lambda^*\in R_+^p,\mu^*\in R_+^{|I|}$ such that

$$0\in\partial^K(\sum_{i=1}^{p}\lambda_i^* f_i)(x^*)+\sum_{j\in I(x^*)}\mu_j^*\partial^K g(x^*,u^j),$$

$$\mu_j^* g(x^*,u^j)=0,\ j\in\Delta,$$

$$(\lambda^*,\mu^*)\geq 0,\sum_{i=1}^{p}\lambda_i^*=1.$$

Then there exist (λ^*,μ^*) such that $(x^*,u^j,\lambda^*,\mu^*)$ is an efficient solution for (VD), and the optimal values of (VP) and (VD) are equal.

Proof

Since x^* is an efficient solution for problem (VP) and the *Kuhn-Tuker* condition is hold at x^*, therefore, for any $u^j\in U^*$, there exist $\lambda_i^*>0,\ i=1,2,\cdots,p,$ $\sum_{i=1}^{p}\lambda_i^*=1$, $\mu_j^*\in\Lambda, j\in\Delta$ such that

$$0\in\partial^K(\sum_{i=1}^{p}\lambda_i^* f_i)(x^*)+\sum_{j\in\Delta}\mu_j^*\partial^K g(x^*,u^j),$$

$$\sum_{j\in\Delta}\mu_j^* g(x^*,u^j)\geq 0.$$

So $(x^*,u^j,\lambda^*,\mu^*)$ is a feasible solution for (VD).

Suppose that $(x^*,u^j,\lambda^*,\mu^*)$ is not an efficient solution for (VD), then there exist (y,u^j,λ,μ) and i_0 such that $f_{i_0}(x^*)<f_{i_0}(y),\ f_i(x^*)\leq f_i(y),\forall i\neq i_0.$ that is,

$$f(x^*)\leq f(y),\qquad (3)$$

which contradicts the conclusion of Theorem 3.2. Therefore, $(x^*,u^j,\lambda^*,\mu^*)$ is an efficient solution for (VD). Obviously, the optimal values of (VP) and (VD) are equal.

4 Conclusions

In this paper, we introduce a new classes of generalized convex functions, that is, uniform $K-(F_b,\rho)-$ convex function, uniform $K-(F_b,\rho)-$ pseudoconvex function, uniform $K-(F_b,\rho)-$ quasiconvex function, etc. Then we consider nonsmooth multi-objective semi-infinite programming involving these generalized convex functions and proved some weak and strong duality theorems of Mond-Weir type duality.

Abstract

Security is an important component of a grid, and it directly affects the development of the grid and the practical application of the grid system software. According to the practical application problem (namely realization of the role-based management) in the role management occurring in the information application system of my school, a role-based security information flow model is proposed from the point of view of guaranteeing the information security. In this paper, the object concept in the general network environment is expended, and the organization security classification of an object and relation between the security classification and the role set are used to classify the security and define the strategy for information flow, finally a security information flow model based on the grid environment is presented. The safe classify of the object is divided by the related information of role set, the organization security classifications, and classifications etc. At the same time, the information flow role is described. A new secure information flow model based on rules and grid environment is described using these methods. It is proven from strict mathematical justification that the new model satisfies properties of the finite lattice and least upper bound operator, and it is reasonable and safe. Furthermore, it is an extension of the BLP model and the role-based information flow model as well as extension of the security information flow model in the general network environment. Therefore, it is significant to the study of grid security.

Keywords: Grid Security, BLP model, Rule, Information flow model

1 Introduction

With the rapid development of the internet technology, thousands of types of high-performance computers are distributed on the internet. How to expand and use these network resources has become the research direction of scientists in the future. This is development prospects of the grid.

The grid security is an important part of the grid, which directly affects development of the grid and practical application of the grid system software. To construct a reasonable information security model is not only the need of information security, but also the necessary means of completing an information security project. At present, there are various information security models, such as BLP model [1] and the information flow model [2]. They have different characteristics, and play a very important role in formal description of information security. Most of the existing [3-5] information flow models are developed based on the reference [2], and all are presented in the general network environment.

Current research on grid security mainly focuses on the security certificate, access control, data integrity, communication confidentiality, non-repudiation of user behaviour, as well as single sign-on [7-9] in the network environment. Grid workflow and other properties are discussed in the reference [10-11]. In the reference [12], the information flow in the network environment is studied. In this study, the information flow model proposed in the reference [12] in the network is modified. Furthermore, role and other concepts are introduced in combination with the reference [6], and information security flow in the network is discussed again from another perspective.

Content of this paper is as follows: the second section introduces related concept and known information flow models. In the third section, new concept introduced in the new model is first presented, such as role decomposition and security function; next security class, definition of expanded subjective & objective bodies, security policy, and definition of the symbol $\oplus$ are introduced finally the model description is given. In the fourth section, explanation of the model is given as well as proving of relevant properties. The fifth section summarizes the paper.

2 Related concept

2.1 GRID AND GRID SECURITY

In the grid environment, different autonomous domains or virtual organizations compose the entire grid computation environment capable of providing the service for the external, But resource nodes in each autonomous domain or virtual organization can cooperate to complete different services, if tasks submitted by the

* ***Corresponding author*** e-mail: zhangshuanghua1@126.com

grid user can not be finished in an autonomous domain or a virtual organization, then the grid server of this autonomous domain or virtual organization will request resource nodes of other autonomous domains or virtual organizations to complete it through cooperation. The physical view of grid security is shown in Figure 1 [13].

In this paper, the discussion is developed on the basis of the GSI security strategy [14] in grid Globus environment.

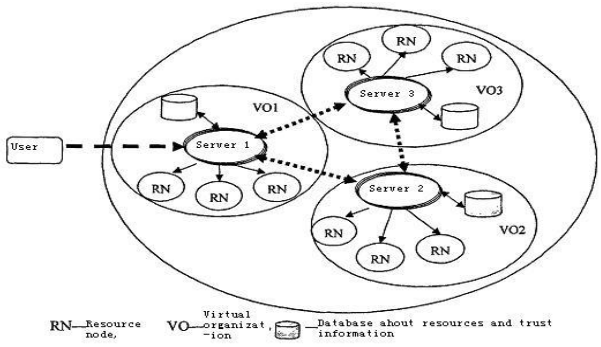

FIGURE 1 Physical view of grid security

2.2 BASIC SECURITY MODEL

2.2.1 Basic concept

Firstly, some known concepts are presented.

Subject and object: there exist a quantity of computer operation involved with the security. anything implementing operation is called the subject, such as process; they are expressed with s_1, s_2, …, s_i,…, or s, and their set is denoted as **S**. anything which is operated is called the object, denoted with o_1,o_2,…,o_j,…,or o, and their set is denoted as **O**.

Suppose there are m virtual organizations in the entire grid Globus environment, a subject represents a user or the user process in the environment. The local resource subject set corresponding to virtual organizations VO_i is denoted with S_VO_i, and the corresponding local resource object set is denoted with O_VO_i (i=1,2,…m).

Security classification: in this paper, security classifications (confidentiality grade) of the subject and object are measured in a specific way [4]. Confidentiality grade of the subject **s** is denoted with T(s), and T(o) indiactes that of the object **o**.

According to BLP model [1], the system is at security status (confidentiality), so the following needs to be satisfied: reading up and writing down are not allowed. For this reason, if T(s) is not less than T (o), then the subject **s** can read the object **o**, and if T(s) is not larger than T (o), then the subject **s** can write the object **o**.

2.2.2 Decomposition of subject and object

Decomposition of subject [12]: when the subject s needs to access simultaneously the virtual organizations VO_1, VO_2, …, VO_m, the resource proxy needs to map a Globus subject to one or more subjects belonging to the local resource, so decomposition of s in a virtual organization is expressed as $sj=(s\_VO_1,s\_VO_2,\ldots,s\_VOm)$, where the jth component indicates the subject in the jth virtual organization mapped from the Globus subject. if sj need not be mapped to the virtual organization VOj, then the corresponding component is noted with s_VOj_φ (j=1,2,..,m) .

Decomposition of Object [12]**:** when the object **o** needs to be decomposed to virtual organizations VO_1, VO_2, …, VO_m, o_j decomposed and expressed as $o_j=(o\_VO_1, o\_VO_2,\ldots, o\_VO_m)$ in the virtual organization, where the j^{th} component is the part decomposed from the object o to the virtual organization VOj, and if the object o need not be decomposed to the virtual organization VO_j, then the corresponding component may be denoted with $o_j\_VO_j\_\varphi$ (j=1,2., m).

When a subject or an object not in a virtual organization, with decomposition expression, the security classification of subject **s** /object o (T(s) /T (o)) is converted to a m-dimension vector function, in which a component can be defined like the related definition in the general network environment, such as: $T(s)=(T(s\_VO_1),T(s\_VO_2),\ldots,T(s\_VO_m))$.

2.2.3 Security classification of organization

Security classification of organization [12]: supposes the existing grid is divided into **m** independent virtual organizations VO_1, $VO_2 \ldots VO_m$ in accordance with the access request, and each virtual organization is given a different security grade, so this is called security classification of the organization, denoted with **net** (Net_name). A net (Net_name) corresponds to the organization classification of virtual organization Net_name, denoted with net (Net_name)=(net(VO_1),net(VO_2),…,net(VO_m)).

Suppose $net(VO_i)=\max_{\forall o \in O\_VO_i}\{T(o)\}$ and when $o=(o\_VO_1, o\_VO_2,\ldots, o\_VO_m)$, $net(o)=\max\{T(o\_VO_1), T(o\_VO_2),\ldots, T(o\_VO_m)\}$.

2.2.4 RBAC model

The basic idea of the RBAC model [5] is responsibility separation, and this is similar to an organization. In the RBAC model, the user is given a role, a role is awarded with permissions, and the permissions are associated with operations, the user gets the relevant permissions of the role through the role, so as to complete some operations. This paper is subject to the most basic concepts of the RBAC model.

Suppose the system has a role set $R=\{r_1,r_2,\ldots,r_n\}$;the role set of the object **o** is denoted with OR(o); While the user owned by the object o through the role is denoted OS (o).

2.2.5 Denning Information flow model

Denning's [2] information flow model is defined by FM=<N, P, SC, $\oplus$, →>, where N is an object finite set, P is a finite process set (subject set), SC is a security class set, the class-combining operator $\oplus$ is an associative and commutative binary operator. For classes of any two operands, $\oplus$ demonstrates the class to, which the result operand generated from any binary function of the two operands belongs. A flow relation → indicates information flow between pairs of security classes. For classes A and B, we write A → B, only if information in class A is permitted to flow to class B. Information is said to flow from class A to class B.

The security requirements of the model are simply stated: a flow model FM is secure if and only if execution of an operation sequence cannot produce a flow that violates the relation →. Under certain assumptions, <SC,→, $\oplus$ > forms a finite lattice:

(1) <SC,→> is a partially ordered set.(2) SC is a finite set.(3) SC has a lower bound of L such that $\forall$ A∈SC, L→A.(4) $\oplus$ is a least upper bound operator on SC.

Where the class-combining operator $\oplus$ is also a least upper bound operator, it has the following properties for all A, B, C∈SC:

(a) A→A$\oplus$B and B→A$\oplus$B.

(b) A→C and B→C$\Rightarrow$ A$\oplus$B→C.

3 A new information flow model based on grid environment

3.1 NEW MODEL DESCRIPTION

In order to give new information flow model under the grid environment, we give some new definitions in the following.

3.1.1 Role decomposition

Similar to decomposition of the object, decomposition of the role set OR (o) owned by the object o may be expressed as follows:

$$OR(o)=(OR(o)\_VO_1, OR(o)\_VO_2, \ldots, OR(o)\_VO_m).$$

Similar to decomposition of the subject,decomposition of the subject OS (o) owned by the object **o** through the role may be expressed as follows:

$$OS(o)=(OS(o)\_VO_1, OS(o)\_VO_2, \ldots, OS(o)\_VO_m)$$

3.1.2 Security function

Object Security function: it is used to describe the ultra four-dimensional vector function relevant to security classification of the virtual organization, security classification, and related roles of the object, denoted as T(net(Net_name), T(o), OR(o), OS(o)) or T(net(o),T(o), OR(o), OS(o)).

The set U indicates the complete set consisting of all ultra four-dimensional security function vectors.

3.2 DESCRIPTION OF NEW MODEL

The grid security information flow model proposed in this paper is defined as follows:

FM=<O,S,SC, $\oplus$,→> is a security information flow model based on the grid environment, in which information flows only from the virtual organization with the low security classification to the one with the high security classification, where O and S are the object set and the process (subject) set of the whole grid. They are finite sets. SC is the security class of the model, defined in Section 3.2.1.The strategy → is defined in Section 3.2.3. The operation $\oplus$ is defined in Section 3.2.4.

The relevant concepts are described and discussed as follows.

Suppose that O' is an actual object set and S' is an actual subject set (processes set) of the whole grid, they are finite sets; SC' is the set of actual security classes.

U' is the set of all actual ultra four-dimensional security function vector defined in Section 3.1.2.

SC' is the set of security classes divided according to all actual ultra four-dimensional security function value, and obviously it is a finite set, and the U'$\subseteq$ U.

3.2.1 Security class #o

Definition 1: the security class of the object o, indicated #o, #o={ o| o∈O, #o={o| o∈O,T(net(o),T(o), OR(o), OS(o)) are invariable}, as $\forall$ o'∈#o, there are T(net(o'),T(o'), OR(o'), OS(o'))＝T(net(o),T(o),OR(o), OS(o)))

Hence SC'= {#o|o∈O'}, SC' is a finite set.

We will discuss U' and U, and expand the concept of O', S', SC'.

3.2.2 Empty object and empty subject

Empty object: $\forall$ α ∈ U, but α ∉ U'. Then we will expand a object **o,** which satisfies T(net(o),T(o), OR(o), OS(o)))= α . Except name and the ultra four-dimensional security function vector, the object has no other characteristics. When a subject accesses the object, no available information is leaked. For example, an empty file has only name and we say that the object is an empty object. An empty object set is denoted with O''.

Empty subject: any object performing operation related to the above empty object is called the empty subject and its set is denoted as S''.

$\forall$ o∈O'', then SC''＝{#o|o∈O''}.

The previously described $s_i\_VO_j\_\varphi$, $o_j\_VO_i\_\varphi$ can actually be considered empty subject and empty object

respectively.

$\forall$ o $\in$ O",then SC" = {#o|o$\in$O"}.O=O' $\cup$ O", S=S' $\cup$ S", SC=SC' $\cup$ SC".

When expanding the concept of O', S', SC', we make use of them together with the general concept, don't make any distinction between them.

Now they are denoted again: O=O' $\cup$ O'', S=S' $\cup$ S'', SC=SC' $\cup$ SC''.

Where O is a object set, S is a subject set (processes set) for total grid network, SC is a security classes set, and they are finite sets.

3.2.3 Description of security policy

Definition 2: security flow policy:

For any objects o_1 and o_2, if information can flow from o_1 to o_2, then the security class of o_1 is controlled by o_2's, or they are equivalent, namely:

Axiom: $\forall$ $o_1,o_2 \in O, o_1 \rightarrow o_2$ if and only if

$net(o_1) \leq net(o_2), T(o_1) \leq T(o_2), OR(o_1) \supseteq OR(o_2)$ and $OS(o_1) \supseteq OS(o_2)$, both of them are true.

Further explanation is presented as follows:

- Meaning of $\cdot \leq, \geq, \supseteq$ operations

$\leq, \geq$ were comparison operation of "less than or equal to" and "greater than or equal to" of real numbers, $T(o_1) \leq T(o_2)$ is defined as follows: corresponding components of two **m**-dimension vectors are used for computatoin through $\leq$ operation. $T(o_1) \geq T(o_2)$ has the similar definition.

The operator $\supseteq$ represents containing operation between two sets. $OR(o_1) \supseteq OR(o_2)$ and $OS(o_1) \supseteq OS(o_2)$ are defined as follows: the sets of the corresponding components of two m-dimension vectors are used for computation through "$\supseteq$" operation.

- **The object is not defined in the decomposition of a virtual organization**

When $o_1\_VO_i\_\varphi$ is a component of the source object O_1, the definition in this paper is presented as follows:

$$T(o_1\_VO_i\_\varphi) = \min_{j\neq i, j\in\{1,2,\cdots m\}}^{m} \{T(o\_VO_j)\}$$

$$OR(o_1\_VO_i\_\varphi) = \bigcup_{j\neq i, j\in\{1,2,\cdots m\}}^{m} OR(o_j)$$

$$OS(o_1\_VO_i\_\varphi) = \bigcup_{j\neq i, j\in\{1,2,\cdots m\}}^{m} OS(o_j)$$

When a component of objective object O_2_is VOj_φis the definition in this paper is presented as follows:

$$T(o_2\_VO_j\_\varphi) = \min_{j\neq i, j\in\{1,2,\cdots m\}}^{m} \{T(o\_VO_k)\}$$

$$OR(o_2\_VO_j\_\varphi) = \bigcup_{j\neq i, j\in\{1,2,\cdots m\}}^{m} OR(o_k)$$

$$OS(o_2\_VO_j\_\varphi) = \bigcup_{j\neq i, j\in\{1,2,\cdots m\}}^{m} OS(o_k)$$

3.2.4 The definition of "$\oplus$"

Definition 3: the operator "$\oplus$" is defined as follows:

$\forall$ $o_1,o_2 \in O$,

$\#o_1 \oplus \#o_2 = \{o \mid T(net(o), T(o), OR(o), OS(o))$

$= T(\max(net(o_1), net(o_2)), \max(T(o_1), T(o_2)),$

$OR(o_1) \cap OR(o_2), OS(o_1) \cap OS(o_2), o \in O\}$.

The max $(net(o_1), net(o_2))$ for a maximum of two real numbers, $\max(T(o_1), T(o_2))$ is defined as follows:

$\max(T(o_1), T(o_2)) = \{\max(T(O_1\_VO_1), T(O_2\_VO_1)), \max(T(O_1\_VO_2), T(O_2\_VO_2)), \ldots, \max(T(O_1\_VO_m), T(O_2\_VO_m))\}$.

$OR(o_1) \cap OR(o_2)$ and $OS(o_1) \cap OS(o_2)$ have similar definition.

On the basis of the above assumption, the model FM=<O,S,SC, $\oplus$,$\rightarrow$> described in this section is a security lattice model in the grid environment.

4 Discussion of new model

We discuss the rationality of the new model from the following aspects.

4.1 THE RATIONALITY OF "$\rightarrow$" DEFINITION

According to the first hypothesis, the subject **s** and the operating objects o_1 and o_2, s= (s_VO1, s_VO2,..., s_VOm), meet the condition $s\_VO_j \in S\_VO_j$, this shows that the subject is mapped to one or more subjects belonging to the local resource through relevant strategy. It accords with the most basic requirements for grid security.

When $o_1,o_2 \in O$ and belong to the same virtual organization, $net(o_1) = net(o_2)$, then flow directions of o_1 and o_2 are determined only according to the priority levels of security classification and role natures of the two objects. According to references [3] and [6], $T(o_1) \leq T(o_2)$, $OR(o_1) \supseteq OR(o_2)$, and $OS(o_1) \supseteq OS(o_2)$ are used to define $o_1 \rightarrow o_2$, which complies with security requirements of the general network environment. At the moment, because no information flows out of the virtual organization, so it meets design requirements of the entire network.

When $o_1,o_2 \in O$ and they don't belong to the same virtual organization, according to the relevant definition, only when $net(o_1) \leq net(o_2)$, $T(o_1) \leq T(o_2)$, $OR(o_1) \supseteq OR(o_2)$ and $OS(o_1) \supseteq OS(o_2)$ are true, $o_1 \rightarrow o_2$ is true.

The first condition is satisfied only when O_1 and O_2 are from the virtual organizations with the low-level and the high-level security classification respectively. Furthermore, O_1 and O_2 should meet the second condition which is necessary for the common information flow; otherwise they cannot flow from the virtual organization with the low-level security classification to the one with the high-level security classification. So they satisfy

design requirements of the general network security. Moreover, the third or the fourth condition complies with design requirements of the entire grid security in accordance with the description in the reference [5].

In addition, when the source object or objective object is not decomposed in a virtual organization, it meets the above security requirements as per definitions of security classifications of the subject and the object.

Thus, definition of "→" in Section 3.2 is reasonable.

4.2 <SC,→> IS A PARTIALLY ORDERED SET

Theorem 1: <SC,→> is a partially ordered set.

Proof: we verify it from reflexivity, transitivity and anti-symmetry of <SC,→> .

- Reflexivity: $\forall o \in O, o \rightarrow o$.

Suppose $T(o\_VO_i) \leq T(o\_VO_i)$, $OR(o)\_VO_i \supseteq OR(o)\_VO_i$, and $OS(o)\_VO_i \supseteq OS(o)\_VO_i$ (i=1,2,…,m), $net(o) \leq net(o)$, $T(o) \leq T(o)$, $OR(o) \supseteq OR(o)$ and $OS(o) \supseteq OS(o)$ are true, so is $o \rightarrow o$.

- Transitivity: $\forall o_1,o_2,o_3 \in O, o_1 \rightarrow o_2$ and $o_2 \rightarrow o_3$, here has $o_1 \rightarrow o_3$.

$\forall o_1, o2, o3 \in O, o1 \rightarrow o_2$ and $o_2 \rightarrow o_3$.

So $net(o_1) \leq net(o_2)$, $T(o_1) \leq T(o_2)$, $OR(o_1) \supseteq OR(o_2)$,$OS(o_1) \supseteq OS(o_2)$,

and $net(o_2) \leq net(o_3)$,$T(o_2) \leq T(o_3)$,$OR(o_2) \supseteq OR(o_3)$, $OS(o_2) \supseteq OS(o_3)$. The following can be derived accordingly.

$T(o_1\_VO_i) \leq T(o_2\_VO_i)$,$OR(o_1)\_VO_i \supseteq OR(o_2)\_VO_i$, $OS(o_1)\_VO_i \supseteq OS(o_2)\_VO_i$ and $T(o_2\_VO_i) \leq T(o_3\_VO_i)$, $OR(o_2)\_VO_i \supseteq OR(o_3)\_VO_i$, $OS(o_2)\_VO_i \supseteq OS(o_3)\_VO_i$ (i=1,2,…,m).

therefore $T(o_1\_VO_i) \leq T(o_3\_VO_i)$, $OR(o_1)\_VO_i \supseteq OR(o_3)\_VO_i$, $OS(o_1)\_VO_i \supseteq OS(o_3)\_VO_i$ (i=1,2,…,m) are true.

According to the definition of decomposition, $T(o_1) \leq T(o_3)$, $OR(o_1) \supseteq OR(o_3)$, $OS(o_1) \supseteq OS(o_3)$ are true, and obviously net $(o_1) \leq net(o_3)$ is true, and so is $o_1 \rightarrow o_3$.

- Anti-symmetry: $\forall o_1,o_2 \in O, o_1 \rightarrow o_2$, and $o_2 \rightarrow o_1$, $\#o_1 = \#o_2$.

Suppose $net(o_1) \leq net(o_2)$; $T(o_1) \leq T(o_2)$, $OR(o_1) \supseteq OR(o_2)$, $OS(o_1) \supseteq OS(o_2)$ and $net(o_2) \leq net(o_1)$,$T(o_2) \leq T(o_1)$,$OR(o_2) \supseteq OR(o_1)$, $OS(o_2) \supseteq OS(o_1)$, the following can be derived:

$T(o_1\_VO_i) \leq T(o_2\_VO_i)$, $OR(o_1)\_VO_i \supseteq OR(o_2)\_VO_i$, $OS(o_1)\_VO_i \supseteq OS(o_2)\_VO_i$ 且 $T(o_2\_VO_i) \leq T(o_1\_VO_i)$, $OR(o_2)\_VO_i \supseteq OR(o_1)\_VO_i$, $OS(o_2)\_VO_i \supseteq OS(o_1)\_VO_i$ (i=1,2,…,m).

$T(o_1\_VO_i)=T(o_2\_VO_i)$, $OR(o_1)\_VO_i=OR(o_2)\_VO_i$, $OS(o_1)\_VO_i= OS(o_2)\_VO_i$ (i=1,2,…,m).

So $T(o_1)=T(o_2)$, $OR(o_1)=OR(o_2)$ and $OS(o_1)=OS(o_2)$ are true. obviously $net(o_1)=net(o_2)$ is true.

It can be seen from the above, derivation that <SC,→> is a partially ordered set.

4.3 SC HAS A LOWER BOUND $\#O_{LOWEST}$

SC has a lower bound, denoted as $\#o_{lowest}$.

$\#o_{lowest}=\{o|T(net(o),T(o),OR(o),OS(o))=T(\min(net(o), \min(T(o)), \bigcup_{o' \in O} OR(o'), \bigcup_{o' \in O} OS(o')),o \in O\}$.

According to the above definition $\#o_{lowest}$ is always present and $\#o_{lowest} \rightarrow \#o$.

4.4 SOME PROPERTIES OF $\oplus$

Property 1: $\forall o_1,o_2,o_3 \in O, \#o_1 \rightarrow \#o_1 \oplus \#o_2, \#o_2 \rightarrow \#o_1 \oplus \#o_2$

Proof: (1) because of the definition of $net(o_1)$ and $net(o_2)$

So $net(o_1) \leq \max(net(o_1),net(o_2))$, $net(o_2) \leq \max(net(o_1),net(o_2))$ is true.

(2) because of the definition of $\max(T(o_1),T(o_2))$,

So $T(o_1) \leq \max(T(o_1),T(o_2))$, $T(o_2) \leq \max(T(o_1),T(o_2))$ are true.

(3) when i=1,2,…,m

$OR(o_1)\_VO_i \supseteq OR(o_1)\_VO_i \cap OR(o_2)\_VO_i$,$OS(o_1)\_VO_i \supseteq OS(o_1)\_VO_i \cap OS(o_2)\_VO_i$

so $OR(o_1) \supseteq OR(o_1) \cap OR(o_2)$ and $OS(o_1) \supseteq OS(o_1) \cap OS(o_2)$ are true.

Similarly, $OR(o_2) \supseteq OR(o_2) \cap OR(o_2)$ and $OS(o_2) \supseteq OS(o_2) \cap OS(o_2)$ are true.

On the basis of the definition of $\oplus$ and the above analysis, the following can be derived:

$\#o_1 \rightarrow \#o_1 \oplus \#o_2$, $\#o_2 \rightarrow \#o_1 \oplus \#o_2$.

Property 2: $\forall o_1,o_2,o_3 \in O, \#o_1 \rightarrow \#o_3, \#o_2 \rightarrow \#o_3$, **so** $\#o_1 \oplus \#o_2 \rightarrow \#o_3$

Proof: (1) Suppose $net(o_1) \leq net(o_3)$, $net(o_2) \leq net(o_3)$, Max $(net(o_1), net(o_2)) \leq net(o_3)$ is true.

(2) Suppose $T(o_1) \leq T(o_3)$, $T(o_2) \leq T(o_3)$,

$\max(T(o_1\_VO_i),T(o_2\_VO_i)) \leq T(o_3\_VO_i)$ (i=1,2,…,m) is true.

so is $\max(T(o_1), T(o_2)) \leq T(o_3)$.

(3) $\#o_1 \rightarrow \#o_3$

$OR(o_1)\_VO_i \supseteq OR(o_3)\_VO_i$, $OS(o_1)\_VO_i \supseteq OS(o_3)\_VO_i$ (i=1,2,…,m)

$\#o_2 \rightarrow \#o_3$

$OR(o_2)\_VO_i \supseteq OR(o_3)\_VO_i$, $OS(o_2)\_VO_i \supseteq OS(o_3)\_VO_i$ (i=1,2,…,m),

so the following can be derived:

$OR(o_1)\_VO_i \cap OR(o_2)\_VO_i \supseteq OR(o_3)\_VO_i$, $OS(o_1)\_VO_i \cap OS(o_2)\_VO_i \supseteq OS(o_3)\_VO_i$ (i=1,2,…,m).$OR(o_1) \cap OR(o_2) \supseteq OR(o_3)$, $OS(o_1) \cap OS(o_2) \supseteq OS(o_3)$

According to the definition of $\oplus$ and the above analysis, $\#o_1 \oplus \#o_2 \rightarrow \#o_3$ is true.

5 Conclusions

In this study, on the basis of elements of grid security, the concept of role decomposition, the ultra four-dimensional security function of the object are defined by means of the characteristics of the security formation flow model in general network environment.

A new information flow model based on the grid environment is described by defining the information flow strategy by means of the ultra four-dimensional safety function value of the object.

According to the analyses, it is proved that the model is safe and reasonable. The model can reflect the information flow in the grid environment well, and this is helpful for description of security information flow in the grid environment.

Because the grid environment is too complicated and the thesis length is limited, practical application of the information flow model in this study will be detailed in a separate paper.

Abstract

Fashion colour forecasting is a hot issue in fashion industry and also a hard problem because of much uncertain information. Utilizing strong mapping capability of BP Neural Network (BPNN) for nonlinear function, this paper investigated the forecasting model of fashion colour. Based on colour data of recent several years, the forecasting model for future colour trend is discussed and built. The historical data are input to train the Neural Network weights and the different parameters of BPNN were investigated to find how to affect the forecasting performance. The results demonstrate the algorithm is very efficient in colour forecasting and can approximate nonlinear relationship of fashion colour very close.

Keywords: Fashion colour, BP neural network, Trend forecasting, Network parameters

1 Introduction

Fashion colour is the colour or colours that the most people prefer in a given period of time. It is very important to forecast the future colour trend that will be popular in 24 months later during the fashion selling seasons and offer the trend palettes for clothing enterprises [1-2]. The obtained palettes will offer the industries useful information and guidance in marketing and manufacturing [3]. And it has long been considered as the most powerful driving forces. Therefore, accurate forecast of fashion colour is not only a marketing strategy of garment industry, but also a hot issue in international fashion market. If the market products do not meet pop elements, it would be unsalable or have to be withdrawn from the market [3-4].

Currently, many authoritative associations on colours release fashion colour palettes every year such as INTER-COLOUR, JAFCA CFCA, PANTONE®, and so on, but little detailed information is known about the forecasting methodologies dealing with this complex and uncertain process [5]. What's more, the lag and confidence of palettes during propagating restrict its commercial value, which stimulates the development of research on fashion colour forecasting. So far, several theories and methods have been applied into this field by using statistical analysis [6-7], grey theory [5, 8], artificial neural network [9-12] and hybrid models [13-14]. Although some achievements obtained, fashion colour prediction is still in exploring stage on the whole and few convincing forecasting systems had been established. Deficiencies and controversies are still existed and the validity of prediction has yet been a pressing problem of the day in the textile and clothing industries [15].

Fashion colour forecasting involves various factors such as sales psychology, geographical, social psychology, political situation, climate, season, skin colour, education level [2-3]. These factors are all interrelated to each other and the fashion colour palettes usually have non-linear features, so forecast of fashion colour becomes a very difficult task. Therefore, an effective forecasting system is required to be established. Utilizing strong function nonlinear mapping capability of Back Propagation neural network (called BPNN)[16], this paper carried out simulation and forecast of fashion colour and built the forecasting model. It is well-known that a single hidden layer BP neural network can approximate arbitrary nonlinear mapping relationship [9, 15-16]. The successive 6 years' fashion colour palettes, released by INTER-COLOUR, from 2007 to 2012 are taken as the objects in this study. The colours are pre-treated using PANTONE colour system and used as input parameters. In some degree, colour data of recent years reflect the trend and greatly reduce the uncertain character. Finally, the different parameters of BPNN were investigated to find how to affect the forecast performance.

2 Algorithm model

2.1 BP NEURAL NETWORK (BPNN)

The artificial Neural Network algorithm mimics biological neural networks, and it is composed of many neurons and adjustable weights connection [16]. Artificial neural network system is made with a large-scale parallel processing, distributed information storage, good self-organizing and self-learning ability and other characteristics. It is widely used in the information processing, pattern

* ***Corresponding author*** e-mail: nancykong@hist.edu.cn

recognition, intelligent control and system modelling and other areas to adapt systems to the environment, find the law of things and recognize or control object [9-12, 17-19]. In particular, the error back propagation algorithm can approximate nonlinear function with strong mapping ability and the colour forecasting is the case. In this network, data stream propagate forward and error signal back-propagation. The network can be represented by a directed acyclic graph $G=(N,W)$, where N is a set of neurons and W is a set of weights, corresponding to the data dependence among neurons. The weights are associated with the amount of data units to be transferred from one neuron to another neuron.

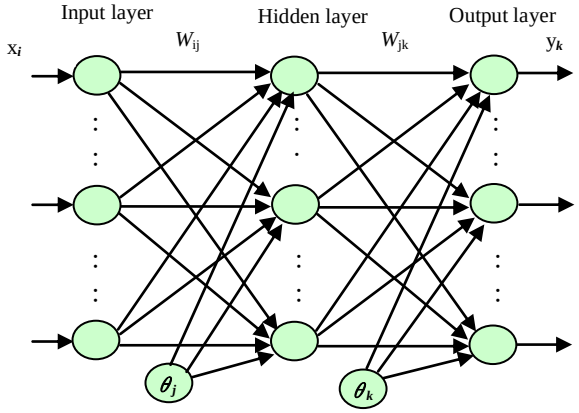

FIGURE 1 The architecture of a BPNN model

BP neural network is suitable to solve the problems of fuzzy and uncertain system and the most commonly used network is a three-layer feed-forward model shown in Figure 1 [16]. It consists of one input layer, one hidden layer and one output layer. The input layer has n inputs and the output layer m outputs, denoted as $x_i(i=1,\cdots,n)$, and $y_k(k=1,\cdots,m)$ respectively. Suppose the hidden layer has h neurons. The neurons of adjacent layers are fully connected with weights W_{ij} and W_{jk} and the data only flow from the input layer to output layer. The neurons of hidden layer and the output have different transfer function named as f_h and f_o. When the $x_i(i=1,\cdots,n)$ is input to network, $\sum_{i=1}^{n} w_{ij}x_i(j=1,\cdots,h)$ are applied to h neurons together with bias $\boldsymbol{\theta}_j$ of hidden layer. The transfer function determines the output of every neuron. The output layer has the same process and finally $y_k(k=1,\cdots,m)$ comes out. θ_k represents the bias of the output layer.

BP algorithm is a supervised learning algorithm. In this case, the weights are not known ahead and obtained from sample data. The main idea is: the BP model must be trained by input samples; During the training process, error back-propagation algorithm is used to adjust weights and the biases repeatedly, and it is ensured that the output vector and the desired vector is as close as possible; When the error of output layer is less than a specified error, the training is finished and the network weights and biases are saved for further forecasting. The specific steps are as follows [16]:

(1) Initialize the weights (W_{ij}, W_{jk}) and bias (θ_j, θ_k).

(2) Calculate the output of the hidden layer neuron according to Equation (1).

$$a_j = f_h\left[\sum_{i=1}^{n} w_{ij}x_i - \theta_j\right]. \tag{1}$$

(3) Calculate the output of output neuron according to Equation (2).

$$y_k = f_o\left[\sum_{j=1}^{h} w_{jk}b_j - \theta_k\right], \tag{2}$$

if the bias $\boldsymbol{\theta}_k$ is considered as $-1\times w_{0j}(w_{0j}=\theta_k)$, Equation (2) can be rewritten as $y_k = f_o\left[\sum_{j=0}^{h} w_{jk}b_j\right]$.

(4) Calculate the error between the desired output and network output according to Equation (3), t_k is the target output.

$$E=\sum_{k=1}^{m}(t_k-y_k)^2. \tag{3}$$

(5) Error back propagation and the weights are updated according to Equation (4).

$$\begin{aligned}\Delta W(t+1)&=\eta\delta[W(t),X(t),T(t)]X(t)\\ W(t+1)&=\Delta W(t+1)+W(t)\end{aligned}, \tag{4}$$

where W denotes the connection weight matrix, X denotes the input vector and T the target vector, $\boldsymbol{\delta}$ represents the back propagation error based on different learning rule and η denotes the learning rate, $\eta>0$.

(6) Repeat step (2) –step (5) until the error satisfy the performance.

2.2 BPNN MODEL FOR THE FASHION COLOUR PREDICTING

In this study, a BP neural network with three-layer is adopted. The neurons of the hidden layer use sigmoid transfer function and the output layer linear function [20]. The nonlinear transfer functions can represent nonlinear and linear relationships between input and output vectors of the network. The linear neurons of the output layer allow the network to produce values outside the range [–1,+1]. BPNN is a negative gradient descent algorithm. There are two ways to realize the gradient descent algorithm, incremental mode and batch mode. In the incremental model, the gradient is calculated and the weights are updated after each input is applied to the network. In the batch mode, only when the whole sample

has been trained, the weights and bias are updated. The negative error gradients of training samples determine the change of the weights and bias.

BPNN is powerful to distinguish the complex mode with its strong learning ability and generalization ability. The algorithm transform a set of the input/output samples into a nonlinear optimization problem by iterative learning method, but its convergence speed is slow and easy to fall into local minima. In order to solve the network instability of learning defects, many improved algorithms are raised. In this paper, several considered versions are shown in Equation (5).

$$\Delta W(t+1) = \eta\delta[W(t), X(t), T(t)]X(t) + \alpha\Delta W(t), \quad (5)$$

where α is the momentum factor, $\alpha \in (0,1)$ and $\alpha\Delta W(t)$ reflects the experience accumulated previously.

The learning rate is a multiple of the negative gradient to determine the changes of the weights and biases. An adaptive algorithm will be adopted and learning rate η will be adjusted during the training period. The weights are updated after all of the inputs are applied to the network. A flow chart of the BP is shown in Figure 2.

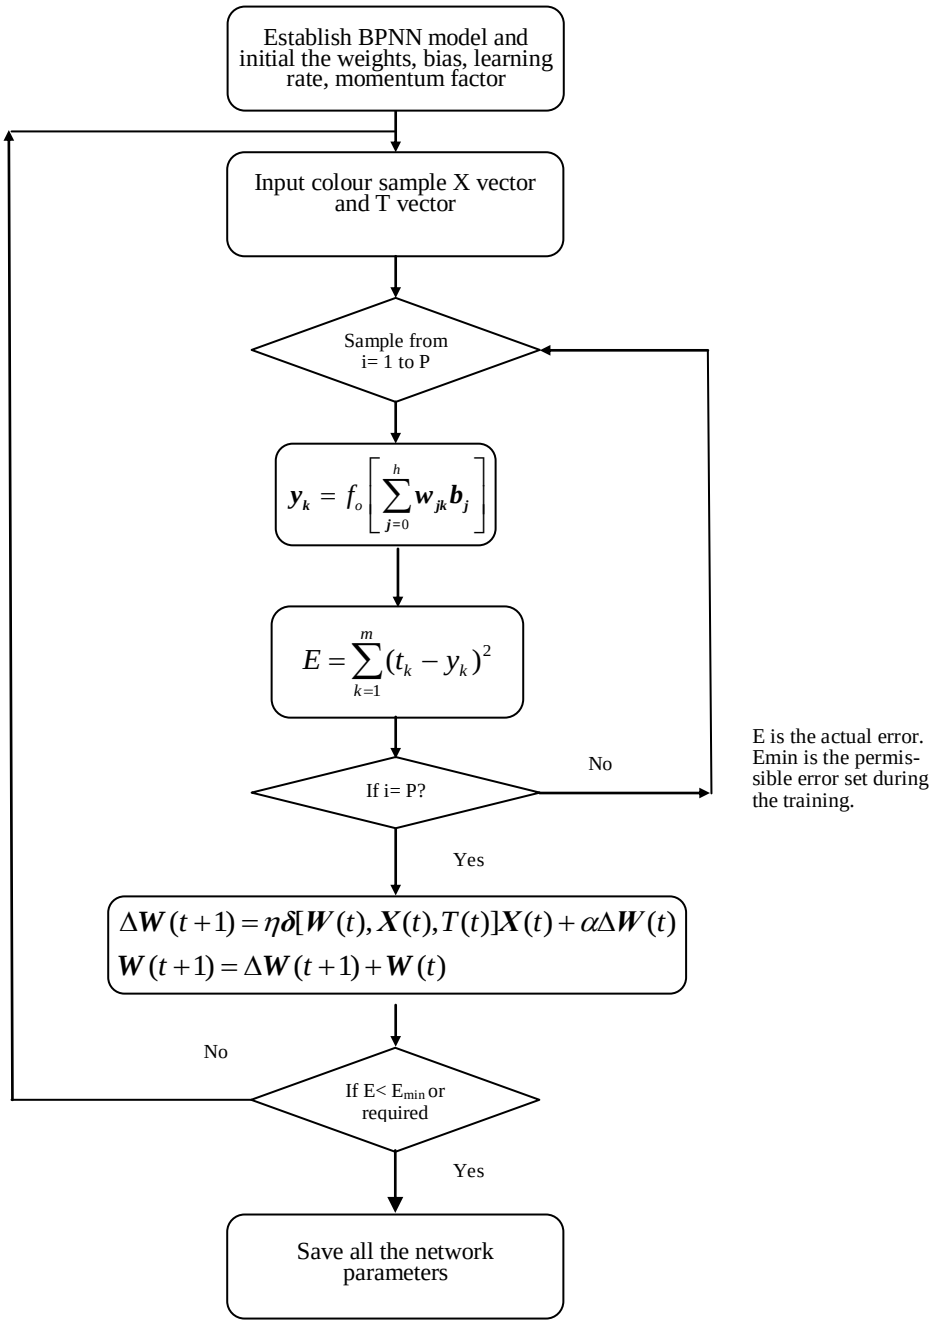

FIGURE 2 The algorithm flow diagram

3 Experiments based on BPNN algorithm

3.1 TEST BENCHMARK

Fashion colour conveys consumers a tendency of tones that will be widely accepted while not specific one or several colours. Generally, more than 40 colours can appear in every palette, and there is no exact corresponding colours in every year, therefore, the colours must be classified and quantified according to the colour theory on hue, lightness and chroma, respectively. Fashion Colour palettes for women's Spring/summer, released by INTER-COLOUR are taken as the test benchmark in this study. These successive fashion colour palettes from 2007 to 2012 were collected. In order to exploit the historical data in BP algorithm, the colours are quantified to numeric data by applying Pantone colour system by PANTONE INC, which is influential in colour specification. The detailed quantification theory and method can be seen in our previous research results [6, 11].

The study only discussed the hue feature. The colours are firstly reflected as their corresponding domains in the Pantone colour space, shown in Table 1[6]. And the colours are transformed further according to Equation (6) and here P_i represents the proportion in the palette.

$$P_i = \frac{n_i}{N}, \tag{6}$$

where n_i depicts the numbers of the colours reflected into the corresponding domains. i denotes the different colour domains; and N indicates the whole numbers of colours in every palette. The quantified results were listed in Table 2.

TABLE 1 Colour domain in the Pantone colour space

Domain	Colour	Domain	Colour	Domain	Colour	Domain	Colour	Domain	Colour
[6-10]	Yellow	[11-14]	Yellow/red	[15-16]	Red	[17-24]	Red/Purple	[25-33]	Purple
[34-38]	Blue /Purple	[39-47]	Blue	[48-52]	Blue /Green	[53-59]	Green	[60-64] [0-5]	Yellow /Green

TABLE 2 Colour ratio in the palettes from 2007 to 2012

Year	Yellow	Yellow/Red	Red	Red/Purple	Purple	Purple/Blue	Blue	Blue/Green	Green	Green/ Yellow
2007	0.242	0.069	0.104	0.034	0.103	0.034	0.242	0.034	0.034	0.104
2008	0.279	0.047	0.07	0.023	0.023	0.093	0.233	0.023	0.047	0.162

3.2 MODEL PARAMETERS SELECTION

The numbers of the hide layers, the number of processing units and network learning coefficient and other parameters have great flexibility and must be set depending on the circumstances. In many applications, these parameters play an important role. There is no theoretical guidance for selecting the hide layer of the network and the number of units. If BP neural network parameters are not fit, the network cannot guarantee convergence to the global optimal point.

The algorithm is implemented and simulated with neural network toolbox in Matlab 7 [20]. In order to investigate network performance, different parameters were considered as the following:

1) the weights (W_{ij}, W_{jk}) were randomly initialized between (-0.5, +0.5).
2) the learning rate η is adaptive with the training process.
3) the momentum factor α uses the default value.
4) Mean squared error performance function is chosen as target function and target error is set as 0.001.
5) maximum iterations =1000
6) The size of hidden layer neurons, denoted as *Nsize*. *Nsize* is determined by Equation (7).

$$Nsize = \sqrt{n+m} + (1 \sim 8). \tag{7}$$

Here, n and m represent the number of input layer neurons and output layer neurons.

Sigmoid and linear functions were selected as the transfer function of hidden layer and output layer. In Matlab environment, there are several variations of gradient descent algorithms Different training function and learning function were selected from the following functions [20]:

traingd – Gradient descent backpropagation.
Traingdm – Gradient descent with momentum backpropagation.
Traingda – Gradient descent with adaptive lr backpropagation.
Traingdx – Gradient descent w/momentum & adaptive lr back propagation.
trainlm – Levenberg-Marquardt back propagation.
Learngd – Gradient descent weight/bias learning function.
Learngdm – Gradient descent w/momentum weight/bias learning function.

3.3 TRAINING AND SIMULATING

When the BPNN was trained with the colour samples, the weights were modified continuously. The training stops if the number of iterations exceeds epochs or if the error $E < E\min$.

3.3.1 Single factor and single colour predicting

When the BPNN is trained, the three successive years' fashion colour data is input and the fourth year's data is the output. That is to say, the recent three years of data roll forecast the fourth year trends. In this mode, only one colour of the past three years influences the same colour of the fourth year. For example, the data of 2007, 2008, and 2009 is the input data and the data of 2010 is the output. And so on, the training samples of the yellow are listed in Table 3.

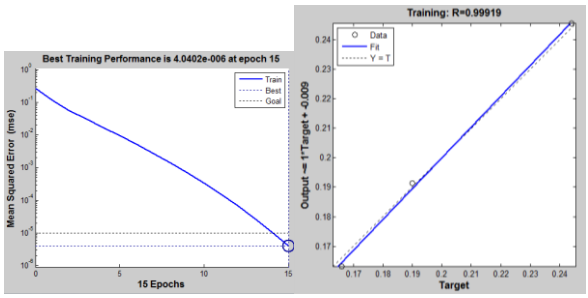
After training the network, the original input vectors were applied the trained network and the simulating results are listed as Table 4.

TABLE 3 Training samples of the hue yellow

Colour	Inputs			Output
Yellow	0.242	0.279	0.130	0.244
	0.279	0.130	0.244	0.190
	0.130	0.244	0.190	0.167

TABLE 4 Single factor forecast of the hue yellow

Value \ Year	2010	2011	2012
Actual value	0.2440	0.190	0.1660
Forecast value	0.2454	0.1914	0.1632
Error	-0.0014	-0.0014	0.0028



(a) (b)

FIGURE 3 (a) Performance plot; (b) Regression plot

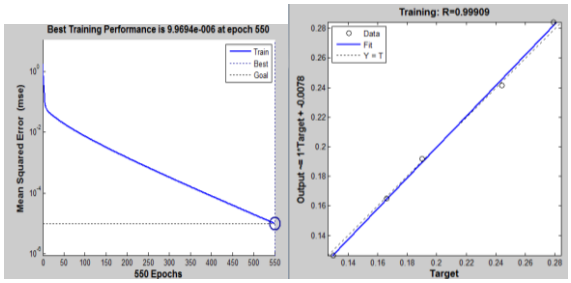
There are two plots in Figure 3 that describe the performance plot and the regression plot respectively. The performance plot shows the mean squared error of the network began with a large value and gradually decreased to a smaller value. It also shows the learning process. The regression plot illustrates regression analysis between the network output and the expecting targets. A dashed line indicates the best linear fit and the solid line shows the perfect fit (output equal to targets). In this example, the best linear fit line is very close to the perfect fit line and the algorithm is very good.

3.3.2 Multiple factors adjacent predicting

Colour forecast is a different task and is affected by many factors. It is not enough to use one colour data of the past three years. In this mode, the next year colour is determined by the ten colours of the former year. In this mode, initial η =0.1, *Nsize* =8, training function= 'traingd', learning function='learngdm' in first experiment. The simulation results were listed in Table 5 and Figure 4.

TABLE 5 Multiple factor forecast of the hue yellow

Value \ Year	2008	2009	2010	2011	2012
Actual value	0.2790	0.1300	0.2440	0.1900	0.1660
Forecast value	0.2841	0.1265	0.2416	0.1921	0.1649
Error	-0.0051	0.0035	0.0024	-0.0021	0.0011



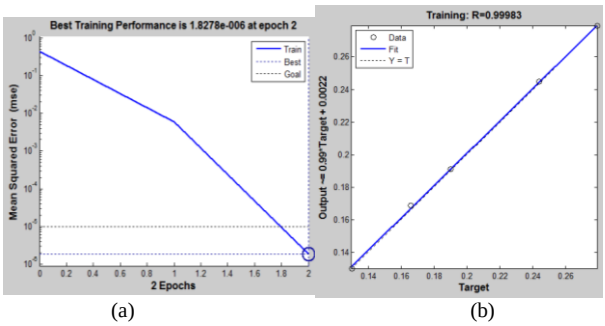
(a) (b)

FIGURE 4 (a) Performance plot; (b) Regression plot

In the second experiment, the training function is modified as 'trainlm' and the other parameters remain unchanged. The experimental results are shown in Table 6 and Figure 5.

TABLE 6 Multiple factors forecast of the hue yellow

Value \ Year	2008	2009	2010	2011	2012
Actual value	0.2790	0.1300	0.2440	0.1900	0.1660
Forecast value	0.2841	0.1265	0.2416	0.1921	0.1649
Error	-0.0051	0.0035	0.0024	-0.0021	0.0011



(a) (b)

FIGURE 5 (a) Performance plot (b) Regression plot

From the above results, the multiple factors forecast was not good as single factor forecast because the former only use one year data and the learning information was less.

3.3.3 Multiple factors and single colour predicting

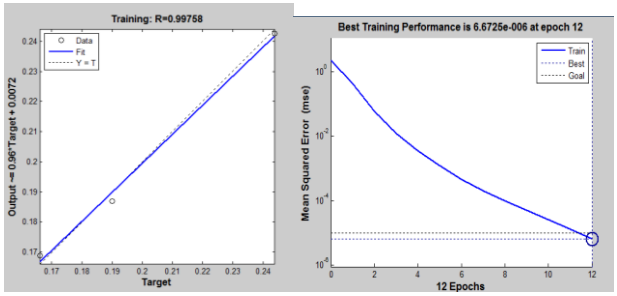
In order to improve the forecast performance, the above two situations were combined. So in this mode, ten colours of the past three years were considered to predict the fourth colour trend.

(1) Different learning rate

In this case, *Nsize* =8, train function='traingdx', learn function='learngdm'.

TABLE 7 Multiple factors forecast of the hue yellow (η =0.05)

Value \ Year	2010	2011	2012
Actual value	0.2440	0.190	0.1660
Forecast value	0.2427	0.1868	0.1688
Error	0.0013	0.0032	-0.0028

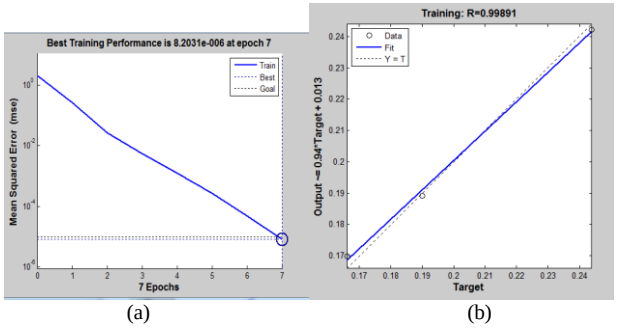


(a) (b)

FIGURE 6 (a) Performance plot; (b) Regression plot

TABLE 8 Multiple factors forecast of the hue yellow (η =0.1)

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2435	0.1886	0.1623
Error	0.0005	0.0014	0.0037



(a) (b)

FIGURE 7 (a) Performance plot; (b) Regression plot

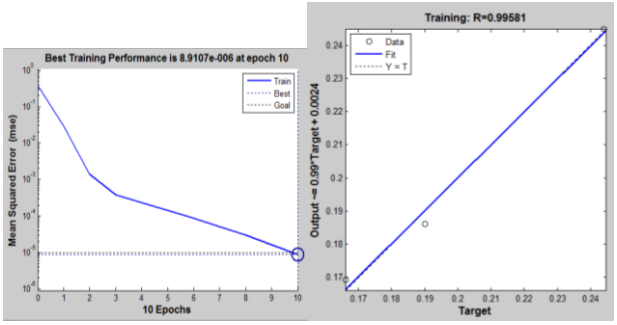
The experimental results of different learning rates are shown in Table 7, Table 8 and Figure 6, Figure 7. Bigger learning rates may make the network weight change too much each time, or even lead to weights jump without convergence during the training process; on the other hand, smaller learning rates lead to learning time too long and can't guarantee convergence to a minimum. In this example, η =0.1 has better results.

TABLE 9 Multiple factors forecast of the hue yellow (train function='traingdx', learning function='learngd')

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2448	0.1861	0.1693
Error	-0.0008	0.0039	-0.0033

(2) Different training function and learning function

In this experiment, η =0.1, *Nsize* =8.

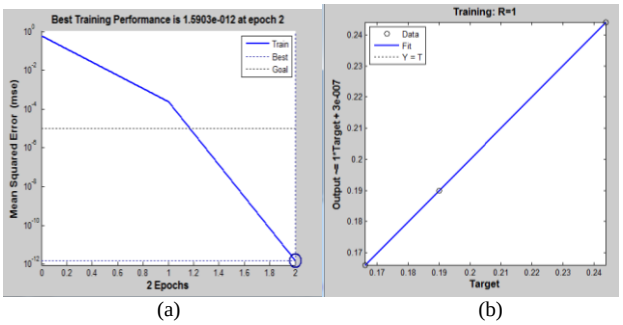


(a) (b)

FIGURE 8 (a) Performance plot; (b) Regression plot

TABLE 10 Multiple factors forecast of the hue yellow (training function='trainlm', learning function='learngdm')

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2440	0.1900	0.1660
Error	0	0	0



(a) (b)

FIGURE 9 (a) Performance plot; (b) Regression plot

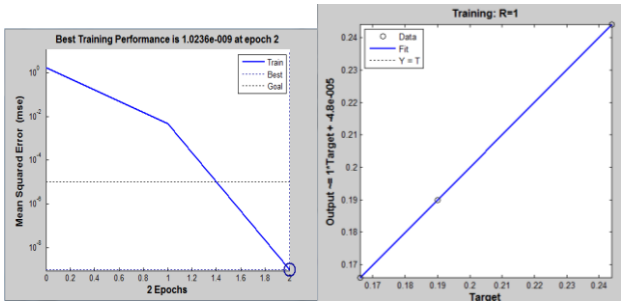
Form the results in Table 9, Table 10 and Figure 8, Figure 9, samples were perfectly fit and the error was zero. TRAINLM training function uses Levenberg – Marquardt algorithm and has the fastest convergence speed, but requires more storage space. Learngdm is a Gradient descent function with momentum back propagation and considers the learning experience.

(3) Different neurons in hidden layer

η =0.1, training function='trainlm', learning function= 'learngdm'. *Nsize* has different value.

TABLE 11 Multiple factors forecast of the hue yellow (*Nsize* =7)

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2440	0.1900	0.1660
Error	0	0	0

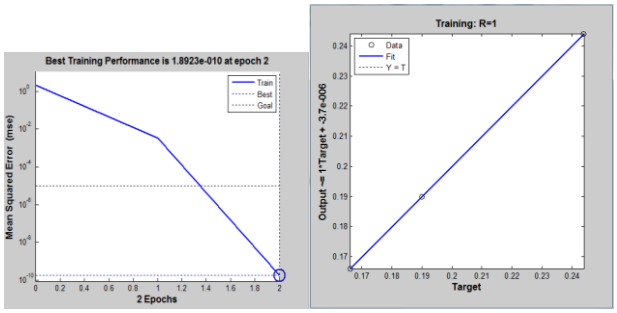


(a) (b)

FIGURE 10 (a) Performance plot; (b) Regression plot (*Nsize* =7)

TABLE 12 Multiple factors forecast of the hue yellow (*Nsize* =6)

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2440	0.1900	0.1660
Error	0	0	0

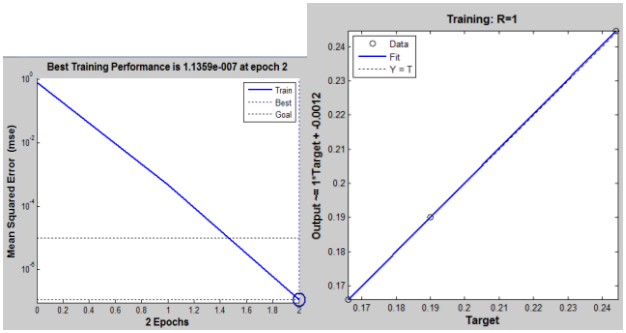


(a) (b)

FIGURE 11 (a) Performance plot; (b) Regression plot (*Nsize* =6)

TABLE 13 Multiple factors forecast of the hue yellow (*Nsize* =2)

Value \ Year	2010	2011	2012
Actual value	0.2440	0.1900	0.1660
Forecast value	0.2440	0.1900	0.1660
Error	0	0	0



(a) (b)

FIGURE 12 (a) Performance plot; (b) Regression plot (*Nsize* =2)

The above results under different hidden layers are given in Table 11, Table 12, Table 13 and Figure 10, Figure 11, Figure 12. The results told that the number of hidden layer neurons has less effect to forecast performance. The main reason is that less size of input and output of samples in this example and less neuron can give better results.

4 Conclusions

The above results have demonstrated that the BPNN algorithm can forecast the fashion colour very close. When selecting a different training and learning functions, and other parameters, it can adjust the forecasting performance. In this example, the appropriate samples and network parameters, can achieve zero error prediction and it confirmed the superiority of the neural network in fashion colour forecasting. In the same time, some parameters have little influence on forecasting performance. Especially, multi factors model of the colour data of past three years has considered much information and done better work.

Abstract

To study the genders impact on identification, this paper analysis the electroencephalograph (EEG) of eight male subjects and seven female subjects. In order to reduce the noise signal interference, the high pass and low pass were used to cut extra frequencies, and in order to prominent the feature signal, the power spectrum method was used to convent the time domain signal to frequency domain, and then fisher distance was used to extraction the feature. All EEG signal was acquired by neurescan, and the EEG signal was evoked by VEP method used subjects photo. The experiment was divided into three models: all subjects were the same sex, added some opposite sex, added some stranger. The analysis results show, to model 1, the correct recognition rate for male subjects, average is 88.50, and this for female, average is 92.51%; the false recognition rate for male subjects, average is 30.84%, and this for female, average is 27.67%,this result indicates VEP can be used as identification tool, the results of model 2 and model 3 show weather opposite sex or stranger should affect the correct recognition rate, but to male subject, the opposite sex effect is greater than stranger, to female, the result were reversed. The results also show noise photo affected female lower than male.

Keywords: Genders Impact, EEG, gender, Fisher Distance

1 Introduction

EEG brain of external things to make a biological reaction process to produce electricity, and when received outside special stimulation, the brain will produce features with this stimulation, the use of this nature, by brain researchers electrical signals to the brain as a bridge launched a variety of studies, such as the use of EEG studies BCI system control peripheral devices, the use of EEG studies of various diseases, the use of EEG to study various psychological phenomena, etc.. With the development of a variety of camouflage technology, the traditional identification technology increasingly difficult to do today's information security applications, looking for new biometric technology becomes increasingly important.

EEG advantages due to its difficult to counterfeit, and therefore the use of EEG as an identification tool for many a research investigator in the study of electrical signals in the brain, evoked potentials, especially the visual evoked potential cut is easy to implement because of the stability characteristics which is widely used in the identification same study, the researchers also used a lot of evoked potentials identification study, more successful in these studies. Paranjape et al Acquisition subjects wide open, EP signal is generated when the eyes closed, use AR model parameters as recognizable features [1]. In a recent research results, Riera et al chose the two electrodes, collecting subjects wide open, EP eyes closed when the signal is analyzed using autoregressive, Fourier transform, mutual information, etc. multi- feature fusion achieved 87.5% to 98.1% recognition rate[2]. When there is a specific visual stimulus will produce visual evoked potential (Visual Evoked Potential, VEP), which is a good entry point, Singhal et al use VEP peak there are individual differences in characteristics, setting relevant peak potential matching algorithm identifying subjects also achieved good results[3]. In study Biel, etc., then the design of the subjects viewed a picture, the choice of the three electrodes, using VEP as a signal source analysis, implementation verification using multivariate statistical methods. Palaniappan use the definition of an automatic identification method using Davies-Bouldin index information to select the largest electrode, the black and white pictures of common objects as visual stimuli, using a neural network classification [4, 5]. Touyama et al study is unfolding from the perspective of ERP[6], they take advantage of the characteristics of the P300, P300 evoked that will only appear when the target stimulus, the experiment they let 9 photos randomly, participants selected targets stimulation, selected different subjects of different target stimulus, they choose a password that is [7]. Wardzinski et al while the use of linear and nonlinear methods for EEG signal analysis, the model parameters as features, and based on Mahalanobis distance classifier, the recognition rate of 88% [8, 9]. Poulos et al uses of wave EEG signals were identified, using the AR model for feature extraction, the final recognition rate between 72 -84%[10,11,12,13].

Based on existing research, we use visual evoked potential as a tool for identity recognition research, the first of the collected EEG filtering, select a specific wavelength as the signal source, and then on the EEG power spectrum estimation, calculation different band EEG power spectrum, and finally the use of distance between the characteristics of different subjects for feature selection, feature matching validated by the final

* ***Corresponding author*** e-mail: 418623577@qq.com

results achieved recognition rate 80%-96%[14,15], the results show that the use of visual evoked potentials can be very good for identity recognition research.

2 Visual evoked potentials and experimental models

Visual evoked potential (Visual Evoked Potential, EVP) is occipital cortex electrical response to visual stimuli occurred District, on behalf of the retina receive stimulation through visual pathway conduction to the occipital cortex caused by potential changes. Visual evoked potential (VEP) in respect of its stimulation divided into non graphical stimulus (flash stimulation) and graphic stimuli into two categories, the current use of the latter in particular Othello plate grid, grating pattern image. Their black and white compositions at a rate conversion constitute a valid alternative stimulation induced electrical activity called pattern reversal visual evoked potentials (PRVEP). With visual stimulation in the occipital scalp recorded VEP main representative of the central field of vision visual impulses 6 ° ~ 12 °, and by the lateral geniculate body projected onto the occipital pole electrical activity from the state after the split rear and pillow . Today, visual evoked potentials, is the most successful application of visual evoked potentials for detection of retinal ganglion cells and optic nerve diseases such as central as the passage of optic neuritis, multiple sclerosis, cancer and other oppressed optic neuropathy disease ; graphics VEP can be used for an objective determination of visual acuity. In the visual evoked potential studies often use ERP component analysis, the main object of study for the N75, P100, N145 and other ingredients.

As used herein, the basis of the different subjects of the experiment is to familiarize yourself with the different responses favorite pictures and other pictures reactions, resulting in different brain wave signal is mainly based on, for example, a photo of yourself and a photo of a different reaction to the others collected in accordance with the visual EEG evoked potentials data . Experiments in Jiangxi Institute of Technology Institute of Information Technology BCI laboratory, Jiangxi University of Science subjects in school, subjects were placed in a quiet shielded room, sitting on soft chairs without armrests experiment during the experiment, subjects in accordance with the test requirements, looking at the computer screen in front of the related operations, 15 experimenters were divided into three groups of five people, the experimenter experimental models include the following three modes : experimental background for the next gay familiar experiments have become familiar with the background to participate in sex case experiments and experimental background in the case of a stranger to participate in the experiment. Under each group mode, the experimenter was asked to do attention be collected under their own photos EEG circumstances and concerns of others cases, each experiment, the picture display 750ms, then the interval 1s.

EEG acquisition is the use of lead Neuroscan amplifier 40 through scan4.3 software for acquiring, using the right of way of the mastoid reference electrode as the reference electrode, the use of 1000Hz sampling rate, the use of 200Hz low-pass band collection, 0.05Hz 50Hz high- pass and notch.

3 Method

3.1 FILTER

Intermediate signals received useful signal selection process is called filtering, "received signal" corresponds to the observed random process, the "useful signal" corresponds to the random process is estimated. E.g., aircraft tracking radar, the measured position data of the aircraft, the other containing the measurement errors and random noise, how to use them to estimate as accurately as possible the position of the aircraft at each moment, velocity, acceleration, and to predict future aircraft position, is a filtering and prediction problems. Such problems in electronics, aerospace science, control engineering and other scientific and technical sectors are abounding.

Filtering is carried out in accordance with, or just on some sampling points can be divided into a continuous-time filter and a discrete-time filtering on the entire time. The former set time parameters T will be desirable half real axle $[0,\infty)$ or the real axis; latter T desirable non-negative integers {0, 1, 2, 3…} or integers {…,-2,-1, 0, 1, 2…}.

Set $X=\{X,t\in T,t\in T\}$ is limited, that is to say:

$$C(H_j\mid r)=\sum_{i=1}^{M-1}C_{ji}P(H_i\mid r), \tag{1}$$

where X is a process to be estimated, it can not be directly observed; Y is the observed process, which contains some information of X.

Use $y^t=\{y_s:s\in T,s\le t\}$ to represents the observed data with the time t until the whole. If you can find a function f(x) about a variable in y making it reach the minimum mean square error of $E\mid X_t-f(y)^t\mid$, $X_t-f(y)^t$ is said to the optimal filtering $X_{t.}$

In order to facilitate the application and narrative, sometimes also above definition to classify more detail. Let τ t is a real number or integer determined, and the process is considered to be estimated as

$$(X_{\tau+t},t\in T),X_{\tau+t}=\tilde{E}(X_{\tau+t}\mid y). \tag{2}$$

Or

$$\tilde{E}(X_{\tau+t}\mid y^t),\tilde{X}_{t+\tau|t}=X_{t+\tau}-\tilde{X}_{t+\tau|t},D_{t+\tau|t}. \tag{3}$$
$$=E(X_{t+\tau}\mid y^t)$$

According to τ = 0, τ> 0, τ <0, are called optimal filtering, (τ-step) prediction or extrapolation, (τ step)

smoothing or interpolation. $\tilde{X}_{t+\tau|t}$, $D_{t+\tau|t}$ corresponding to each error and the mean square error, and collectively these problems for the filter problem.

According to brain wave frequency characteristics, this paper 1Hz high pass and 55Hz low-pass method of combining the signal source is filtered, collected EEG first by 1Hz high-pass filter to reduce direct impact, and then conduct a 55Hz low-pass filter, so You can select 1-55hz useful EEG.

3.2 POWER SPECTRUM CALCULATION

The original EEG is a signal domain, the features are hidden between the various noise data, through the original EEG feature extraction speed and accuracy will be affected, in order to improve the speed of analysis and analysis accuracy, can be converted to the original EEG power spectrum, the frequency analysis.

A simple way to estimate the power spectrum of the stochastic process is a direct request sampling DFT, and then takes the results of the square of the amplitude. Such a method is called period gram

A length L of the signal $x_L[n]$ is estimated period gram PSD as follow

$$\tilde{P}_{xx}(f)=\frac{|X_L(f)|^2}{f_s L}, \tag{4}$$

where $X_L(f)$ is defined using the FFT matlab inside without normalization coefficients, so dividing L.

$$X_L(f)=\sum_{n=0}^{L-1}x_L[n]e^{-2\pi jfn/fs}. \tag{5}$$

The actual calculation of $X_L(f)$ may be performed using FFT, and only on a limited frequency. Applications in practice are most period gram PSD estimation to calculate the N-point:

$$\tilde{P}_{xx}(f)=\frac{|X_L(f)|^2}{f_s L}, f_k=\frac{kf_s}{N}, k=1,2,3...,N-1$$

$$X_L(f_k)=\sum_{n=0}^{L-1}x_L[n]e^{-2\pi jfn/N}. \tag{6}$$

3.3 FEATURE EXTRACTION METHODS

EEG feature extraction in order to extract useful brain signals, thereby to classify the feature extraction method to identify subjects used herein are described below:

Step1. Common average: In this paper, we use Hjort derivation to reduce interference from the neighbouring electrode, The Hjort derivation C_i^H is calculated as

$$C_i^H=c_i-\frac{1}{4}\sum_{j\in S_i}sc_j, \tag{7}$$

where ci is the reading of the centre electrode sc_j, with i=1…30 and j is the set of indices corresponding to the eight electrodes surrounding electrode c_i.

Step2. Filter: EEG signal acquisition band from 0.05Hz to 200Hz, in order to extract features, we filter EEG signal band from 0.05Hz to 50Hz.

Step3. AR conversion: time-domain EEG data disorganized EEG in order to better highlight the characteristics of EEG signal, we use AR model to convert the time domain signals into frequency domain, and extract the feature from the frequency domain signals.

Step4. Calculate add of Fisher' distance: Calculated the Fisher distance between two classes. Fisher distance $F_{i,j}$ is calculated as

$$F_{i,j}=\frac{(\mu_i-\mu_j)^2}{\sigma_i^2+\sigma_j^2}, \tag{8}$$

where $F_{i,j}$ is Fisher' distance between the subject I and the subject j. μ and σ are the mean and the standard deviation of the feature they correspond to.

The add of Fisher' distance F_i is calculated as

$$F_i=\sum_{j\neq i1}F_{i,j}. \tag{9}$$

Step5. Sort the Fisher's distance adds: The Fisher distance was often used to denote differences between classes in classification research. The bigger the fisher distance was the more notable the difference was. So we sort the Fisher's distance on descending order.

Step6. Feature extraction: Through analysis the five subjects Fisher's distance, we select three thousand as feature range, all feature are selected from this range.

Step7. Get the classifier: Use BP neural network to calculate the feature then can get these five subjects classifier. To the test sample of these subjects, if the result is in credibility, that is to say, this sample is right

In this paper, the correct recognition rate, error recognition rate, false recognition rate and credibility used to analysis the results, the following were defined them:

1. Correct recognition rate: the correct recognition rate is defined as the rate of correct recognizes the iden-

tity of subjects through use subjects' classification to test their own samples.

2. Error recognition rate: the error recognition rate is defined as the rate of incorrect recognizes the identity of subjects through use subjects' classification to test their own samples.

3. False recognition rate: the false recognition rate is defined as the rate of recognize the identity of subjects is himself through use subjects' classification to test others samples.

4. Credibility. The credibility is defined as acceptable error range (in this paper, the credibility is [-0.02 0.02]).

4 Results and discussion

In this paper, experiments using three modes: all same group subject is same gender and familiar, some subject in group is different gender, some subjects in group is stranger. Participation has sex with strangers during the experiment, namely to study the impact of the opposite sex and strangers on the classification accuracy, each of which is divided into a group of five people to experiment, three groups were collected from 15 individuals of brain waves, which 8 males, 7 females, each subject collected EEG data 183 trial, excluding invalid trial, each subject was eventually carried out using 156 trial identification calculations, this paper is divided into these 156 trial characteristics extraction collection and validation collection, which features a collection of 50 extraction trial, the validation set 106 trial.

After the same background, the same group of subjects were EEG analysis, the feature set of the first to use the method described earlier for data conversion, data conversion After feature extraction, feature subjects extracted using the same data conversion method for EEG data conversion, and then select the appropriate feature set, classification calculated by feature matching, feature extraction for a set T, and a test set tc, electrical test matches z formula can be expressed in the brain as follows:

$$z = (\sum_{i=1}^{n} | x_i - y_i |) / n, x_i \in T, y_i \in TC, \quad (10)$$

where n is the number of features.
Classification accuracy of the eight male subjects show as following.

As described in Figure 1, the x axis indicates that the three experimental model, 1 is all same group subject is same gender and familiar, 2 is some subject in group is different gender, 3 is some subjects in group is stranger. The Y axis indicates that the value of correct recognition rates, and corresponding to the histogram of each model is eight male subjects.

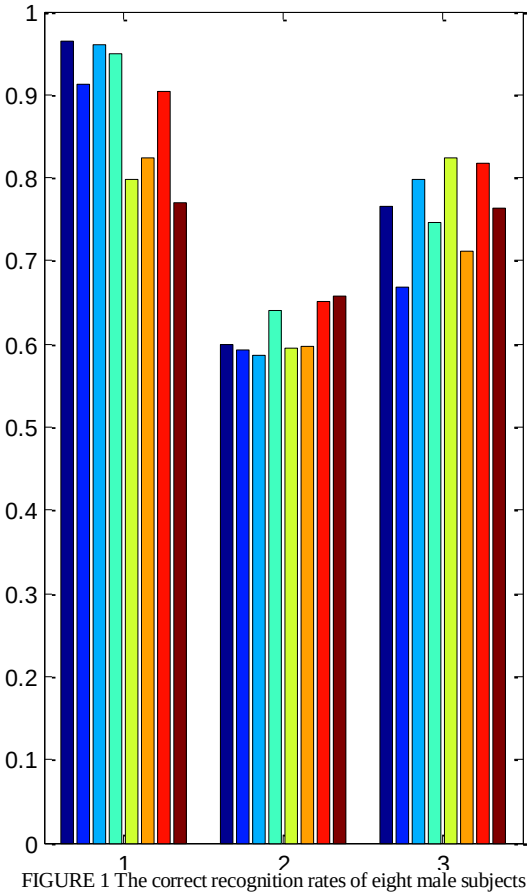

FIGURE 1 The correct recognition rates of eight male subjects

As figure 1 shows, when input the test samples, the correct recognition rate of model 1 are 96.33%, 91.18%, 96.03%, 94.96%, 79.71%, 82.41%, 90.04%, 77.05%. The correct recognition rate of model 2 are 59.89%, 59.20%, 58.70%, 63.96%, 59.52%, 59.79%, 65.21%, 65.59%. The correct recognition rate of model 3 are 76.53%, 66.85%, 79.85%, 74.71%, 82.30%, 71.22%, 81.64%, 76.37%. As correct recognition rate result shows, if the same group subject all is male, the lowest result is 77.05%, and the highest result is 96.33%, that is to say, use EEG signal as tool of identification can recognize them, if test in model 2, the lowest result is 58.70%, the highest result is 65.59%, compare to model 1, the correct recognition rate is decreased, if test in model 3, the lower result is 66.85%, the highest result is 82.30%, compare to model 1, the correct recognition rate is decreased too.

Figure 2 show the eight male subjects false recognition rates.

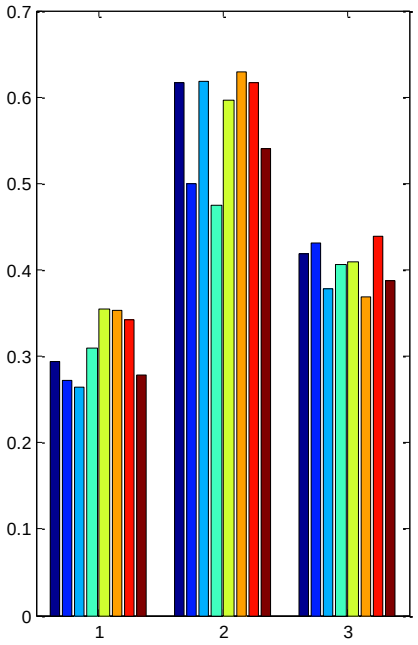

FIGURE 2 The false recognition rates of eight male subjects

As described in Figure 2, the x axis indicates same as Figure 1; y axis indicates that the value of false recognition rates of eight male subjects.

As figure 2 shows, when input the test samples, the false recognition rate of model 1 are 29.31%, 27.20%, 26.45%, 30.98%, 35.48%, 35.36%,34.17%, 27.75%. The false recognition rate of model 2 are 61.66%, 49.90%, 61.89%, 41.49%, 59.65%, 62.87%, 61.73%, 54.06%. The false recognition rate of model 3 are 41.79%, 43.13%, 37.86%, 40.56%, 40.95%, 36.91%, 43.86%, 38.67%.

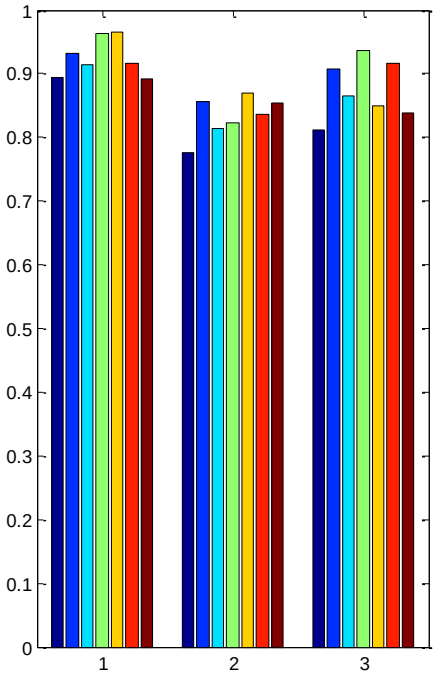

FIGURE 3 The correct recognition rates of seven female subjects

The x axis indicates same as Figure 1; y axis indicates that the value of correct recognition rates of seven female subjects.

As figure 3 shows, when input the test samples, the correct recognition rate of model 1 are 89.46%, 93.20%, 91.32%, 96.24%, 96.46%, 91.69%, 89.21%. The correct recognition rate of model 2 are 77.66%, 85.70%, 81.31%, 82.31%, 86.68%, 83.63%, 85.38%,. The correct recognition rate of model 3 are 81.11%, 90.78%, 86.43%, 93.69%, 84.96%, 91.74%, 83.92%,. As correct recognition rate result shows, if the same group subject all is male, the lowest result is 89.21%, and the highest result is 96.46%, that is to say, use EEG signal as tool of identification can recognize them, if test in model 2, the lowest result is 77.66%, the highest result is 86.88%, compare to model 1, the correct recognition rate is decreased, if test in model 3, the lower result is 81.11%, the highest result is 93.69%, compare to model 1, the correct recognition rate is decreased too.

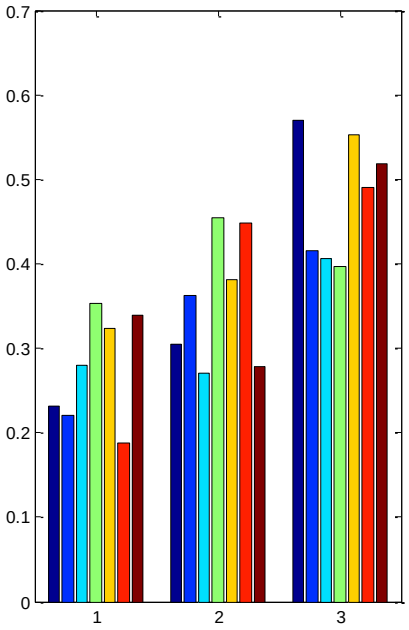

FIGURE 4 The false recognition rates of seven female subjects

As described in Figure 4, the x axis indicates same as Figure 1; y axis indicates that the value of false recognition rates of seven female subjects.

As figure 4 shows, when input the test samples, the false recognition rate of model 1 are 23.22%, 22.04%, 27.99%, 35.32%, 32.42%, 18.73%, 33.95%,. The false recognition rate of model 2 are 30.48%, 36.23%, 27.08%, 45.44%, 38.15%, 44.87%, 27.76%. The false recognition rate of model 3 are 56.91%, 41.50%, 40.65%,39.63%, 55.31%, 49.00%, 51.80%,.

Experimental results show that the time when the subject of the same sex, male subjects being able to confirm the correct recognition rate their average of 88.50%, and the average of female correct recognition is

92.51%, the test sample is added when the others after EEG sample misidentification rate male subjects with an average of 30.84%, the error recognition rate of female subjects with an average of 27.67%, the experimental data show that in their own photo as a reference, the female subjects than recognition rate is generally higher than male subjects male subjects, while female subjects to others EEG signals recognized as its own recognition rate is also lower than male subjects, VEP feature shows the subjects picture familiarity observed, the average correct recognition rate and error recognition rate results showed photos of female subjects for their degree of concern than male subjects, the correct identification rate data also show the use of visual evoked potentials can be used as identity identification tool.

In order to study the change of identification rate, this paper introduced opposite sex and strangers photo as noise. in the same experimental model and methods of analysis, compared to model 1, table 1 show the correct recognition rate of eight male change of add opposite sex and strangers experimental model. the classification accuracy decreased average: 0.2702, wherein the maximum change is 0.3733, min changes is 0.1146, when the stranger cases, the average correct classification rate dropped 0.1232, the biggest change is 0.2433, the smallest change is 0.0259.

TABLE 1. Male affect recognition rate

number	correct recognition rate of mode 1	model2 change	model 3 change
1	0.9633	0.3644	0.1980
2	0.9118	0.3198	0.2433
3	0.9603	0.3733	0.1618
4	0.9496	0.3100	0.2020
5	0.7971	0.2019	-0.0259
6	0.8241	0.2262	0.1119
7	0.9034	0.2513	0.0870
8	0.7705	0.1146	0.0068

The result of Table 1 show that male subject easer affected by opposite sex than stranger.

The same experiment for female, we can get the result table 2.

TABLE 2 Female affect recognition rate

number	correct recognition rate of mode 1	model2 change	model 3 change
1	0.8946	0.1180	0.0835
2	0.9320	0.0750	0.0242
3	0.9132	0.1001	0.0489
4	0.9624	0.1393	0.0255
5	0.9646	0.0958	0.1150
6	0.9169	0.0806	-0.0005
7	0.8921	0.0383	0.0529

As table 2 shows, to the seven female subjects, if add opposite sex subject, the correct recognition rates would decrease, the average rate dropped 0.0924, the biggest change is 0.1393 and the smallest change is 0.0383.
The result of Table 2 show that the opposite sex and strange also affected the female subjects focus.

Compare table 1 and table 2 results, gender impact on the experiment as show in Figure 5, to opposite sex, this effect is more than female, and to strange, this effect also male more than female, this VEP result show that female is focus on their own photo more than male, so the correct recognition rate effect to noise photo is smaller than male. Whether male or female, the correct recognition rate show use this way to identification is effective.

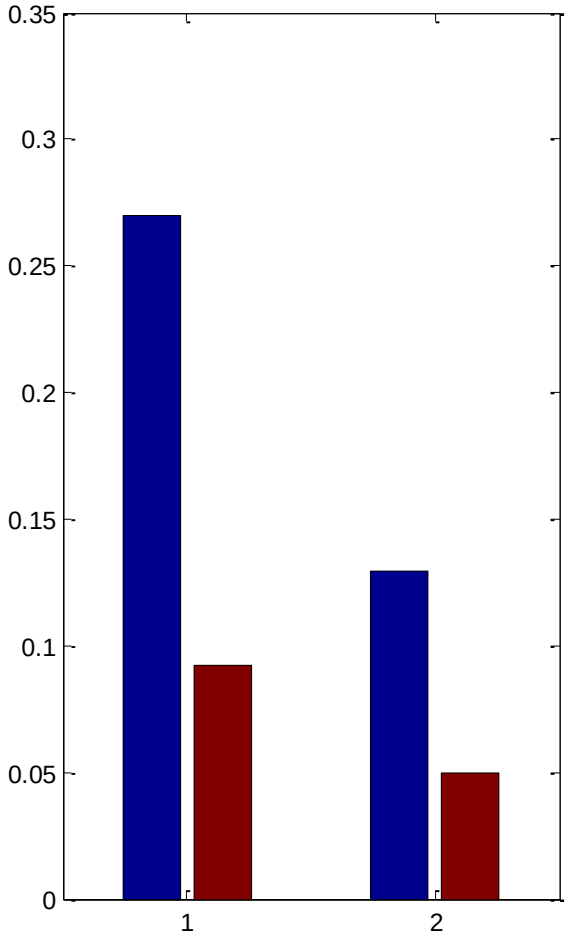

FIGURE 5 Gender impact on correct recognition rate

The correct recognition rate is affected by noise photo; weather false recognition rate would effect by noise too?

Table 3 and table 4 is male and female result of this effect.

TABLE 3 Male affect false recognition rate

number	false recognition rate of mode 1	model2 change	model 3 change
1	0.2931	-0.3235	-0.1248
2	0.2720	-0.2270	-0.1593
3	0.2645	-0.3544	-0.1141
4	0.3098	-0.1651	-0.0958
5	0.3548	-0.2417	-0.0547
6	0.3536	-0.2751	-0.0155
7	0.3417	-0.2756	-0.0969
8	0.2775	-0.2631	-0.1092

TABLE 4 Female affect false recognition rate

number	false recognition rate of mode 1	model2 change	model 3 change
1	0.2322	-0.0727	-0.3369
2	0.2204	-0.1420	-0.0194
3	0.2799	-0.0091	-0.1266
4	0.3532	-0.1011	-0.0430
5	0.3242	-0.0573	-0.2289
6	0.1873	-0.2613	-0.3027
7	0.3395	-0.0619	-0.1785

As show in Table 1 and Table 2, under model 2, that is to say if a opposite sex subject be added, the false recognition rate, to male subject will ascend, the average number is raise 0.2657, and under model, the false recognition rate is also ascend, this number average raise 0.0963, this result show, to male subject, the opposite sex is more attractive than stranger. The same analyses method to female, under this two models, the false recognition rate are all ascend, to model 1,this number raise 0.0805, and to model 2,this number raise 0.2016, that is to say, to female subjects, the stranger is more attractive than opposite sex, this result can describe in Figure 6.

To the study of VEP, if uses the method of overlap some trial data, the gender impact is not big, but to the study of identification, weather this impact is no big too? Through the eight male subjects and seven female subjects research results show that the noise of opposite sex and strangers subjects will be affected, but the impact of female subjects than male subjects suffered by little affected.

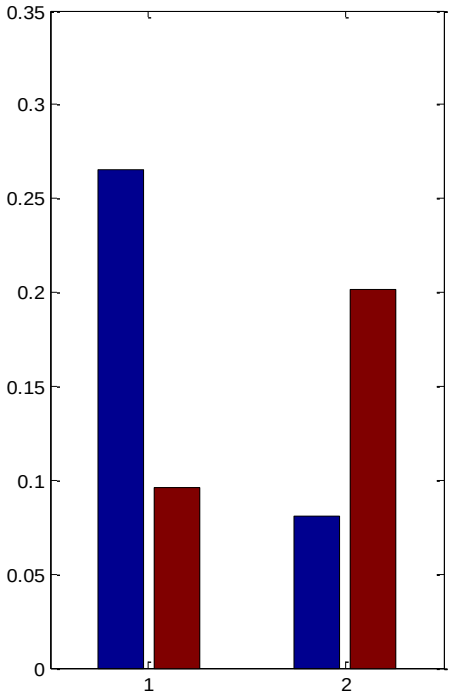

FIGURE6. Gender impact on false recognition rate

Abstract

Fuzzy comprehensive evaluation refers to a comprehensive assessment method based on fuzzy mathematics through quantifying the factors difficult to quantify with obscure boundaries and using the principle of fuzzy relation synthetic. Fuzzy comprehensive evaluation can comprehensively evaluate the object system involving fuzzy factors and is widely applied in the fields of economy and society. This paper takes new public service theory as the research perspective; designs evaluation index system which can comprehensively reflect sport development level of urban community applies fuzzy comprehensive evaluation to evaluate sport development level of urban community in Hunan province and provides the evaluation process. The evaluation results show leadership organization and team construction of the urban community fail to develop to certain level and that the health index of community residents is slightly low. This paper presents suggestions to improve this situation.

Keywords: Fuzzy Mathematics, Fuzzy Comprehensive Evaluation, Evaluation Index System, Urban Community, Sport Service

1 Introduction

Fuzzy comprehensive evaluation (FCE) was first put forward by an American L.A. Sade in 1965 [1]. It is a method to describe fuzzy mathematics written in Fuzzy Sets. This method declared the birth of fuzzy mathematics. Since then, fuzzy phenomena have entered the field of human scientific research [2]. FCE is an important aspect of fuzzy mathematics applied in natural science field and social science field. Evaluation objects of comprehensive evaluation problem are decided by factors in multiple aspects, so it is required to evaluate every factor [3]. With regard to evaluation of sport development level of urban community, the influencing factors are very complex and fuzzy. Thus, fuzzy means is used to deal with fuzzy problems, which will make the evaluation results truer and more rational [4].

Community sport as the main base for national fitness and an important constituent part of community building is highly valued by the government [5]. However, it is found in practice real sport service system of urban community has not been established currently [6]. Various mass physical fitness organizations, grass-root fitness clubs, fitness stations and grass-root sport associations as well as the network formed on this basis are not perfect [7]. The development is unstable and disorderly [8]. How to make the input in community sport more scientific and rational, to make community sport resources utilized more fully and effectively, to make organizational measure of community sport more beneficial and to make community sport produce greater social benefits requires scientific evaluation of community sport resources [9].

One thing often needs multiple indexes to depict its nature and characteristics. Besides, the people's evaluations for one thing are not simply good or bad, but they adopt fuzzy language to evaluate it with different degrees [10]. Since the relation of evaluation levels are fuzzy without absolutely explicit dividing line, so the evaluation is fuzzy [11]. Obviously, for this fuzzy evaluation problem, classical evaluation method is not rational. But the application of fuzzy mathematics for comprehensive judgment will gain better practical effects. So, this paper utilizes FCE method to evaluate community sport development level of a city on the basis of analysing the factors influencing community sport development level.

2 Public service level index system of community sport

With the advancement in networking and multimedia technologies enables the distribution and sharing of multimedia content widely [12]. In the meantime, piracy becomes increasingly rampant as the customers can easily duplicate and redistribute the received multimedia content to a large audience [13].

The hierarchy, regional nature, overall comprehensiveness and trend of public service of community sport decide public service level index system of community sport has the following characteristics [14]:

(1) Universality of evaluation content. There are many factors influencing public services of community sport, including two aspects: "hardware" and "software". Since the contents involved are many, index system design,

[*] ***Corresponding author*** e-mail: zhengmei1111@yeah.net

standard formulation and method selection should follow the principle of combining subjectivity and objectivity, nature determination and quantification as well as self-evaluation and expert evaluation.

TABLE 1 Opinions of community residents on national fitness paths and equipment

	Able to exercise	Interesting	Good shape	Useless	Danger
n	115	27	28	20	10
%	57.5	13.5	14.0	10.0	5.0

(2) Regional correlation. Public service level of community sport is also restricted by social economic development level of the community. Construction environment of index system should start from practical situations and realistic demand, ensure combination of scientificalness and practical applicability and meanwhile consider the imbalance of regional development. So, different things should not be treated as the same simply.

TABLE 2 Construction situations of fitness centers of 6 cities

	City A	City B	City C	City D	City E	City F
Fitness centers	10	8	7	10	17	4
Fitness sites	55	40	61	54	66	18
Communities	51	65	45	66	96	6
Proportion (fitness centers)	1.7	1.0	1.8	1.3	1.2	5.0

(3) Objective consistency. Consistency contains the maiming at two levels. At the first level, the objective to establish evaluation index system should be consistent with the demands of community members. The establishment of system index is to better serve community residents for physical fitness. So, the system should be able to reflect the common desire of the community residents and be oriented to their demands. At the second level, evaluation objective and construction objective should be consistent.

Overall structure of public service indexes of community sport refers to the core problem of index system design. During construction of this system, all indexes of public services of community sport should form an organic whole and coordinate mutually. There are many factors influencing public service of community sport. These factors involve various aspects. The influences of some indexes are very small and can be neglected. There are many evaluation indexes for sport development level of urban community, including qualitative index, quantitative index, macroscopic index and microcosmic index. In comprehensive evaluation, corresponding indexes are often selected from these for permutation and combination.

3 FCE of sport development level of urban community

FCE can comprehensively evaluate the object system involving fuzzy factors and is widely applied in economic and social fields [15]. FCE has strong subjectivity in evaluation and cannot solve the problem of repeated evaluation information caused by evaluation indexes. In addition, there is no systematic method to confirm membership function [16]. Especially when faced with a complex system, since there are many factors in need of consideration; it is very difficult to confirm weight allocation of each factor when FCE is applied. Meanwhile, FCE applies normalization handling method. After weight allocation is confirmed, it is still necessary to comprehensively evaluate Sade operator for the index. Thus, the results cannot meet the due value. This paper based on the above considerations optimizes FCE and adopts multi-level FCE for multi-level processing of weight allocation. They are classified into several levels according to factors or indexes. Firstly, low-level factors are comprehensively evaluated; the evaluation results are used for higher-level comprehensive evaluation. Single factor evaluation of each level is multi-factor comprehensive hiragana at lower-level. So, the evaluation is carried out from low level to high level one by one. Moreover, to consider from different perspectives, we can first classify the personnel participating in judging. In line with the steps of FCE, fuzzy statistics matrix of each type of judging personnel on the evaluation object is provided to calculate the judging results of each type of judging personnel on the evaluation object. The influences of the judges with different perspectives are considered through "quadric weighting". The steps for construction of multilevel FCE model are shown in Fig.1:

(1) To confirm multilevel factor set according to original data of the evaluation object. The factor set includes all indexes used to evaluate the object. The factor set is expressed through collective concept. The matrix form of the collection is as follows:

$$U=(U_1,U_2,\cdots,U_n)=\begin{pmatrix}(u_{11},u_{12},\cdots,u_{1m})\\ \vdots \\ (u_{n1},u_{n2},\cdots,u_{nm})\end{pmatrix}=\begin{pmatrix}\begin{pmatrix}(u_{111},u_{112},\cdots,u_{11i})\\ \vdots \\ (u_{1m1},u_{1m2},\cdots,u_{1mi})\end{pmatrix}\\ (\vdots)\\ \begin{pmatrix}(u_{n11},u_{n12},\cdots,u_{n1i})\\ \vdots \\ (u_{nm1},u_{nm2},\cdots,u_{nmi})\end{pmatrix}\end{pmatrix}, \quad (1)$$

where, U is factor set; n is the number of the first-level factors; each first-level indexes can be divided into $U_i=(u_{i1},u_{i2},\cdots,u_{im})$ second-level sub-indexes; m is the number of second-level indexes. By parity of reasoning, all lower-level I can be reasoned out.

(2) To catty out weight assignment for each index in the above index sets and the weight sets gained are as follows:

$$W=(W_1,W_2,\cdots,W_n)=\begin{pmatrix}(w_{11},w_{12},\cdots,w_{1m})\\ (w_{21},w_{22},\cdots,w_{2m})\\ \vdots \\ (w_{n1},w_{n2},\cdots,w_{nm})\end{pmatrix}=\begin{pmatrix}\begin{pmatrix}(w_{111},w_{112},\cdots,w_{11i})\\ \vdots \\ (w_{1m1},w_{1m2},\cdots,w_{1mi})\end{pmatrix}\\ (\vdots)\\ \begin{pmatrix}(w_{n11},w_{n12},\cdots,w_{n1i})\\ \vdots \\ (w_{nm1},w_{nm2},\cdots,w_{nmi})\end{pmatrix}\end{pmatrix}, \quad (2)$$

where, $W=(W_1,W_2,\cdots,W_n)$ is the weight of the first-level index $U=(U_1,U_2,\cdots,U_n)$; $W=(w_{i1},w_{i2},\cdots,w_{im})$ is the weight of second-level index $U_i=(u_{i1},u_{i2},\cdots,u_{im})$ relative to the first-level index $U=(U_1,U_2,\cdots,U_n)$.

(3) To conduct level evaluation for all indexes. Usually, $V=(v_1,v_2,\cdots,v_k)$ is expressed as the evaluation level of each index, where k is the number of evaluation level. In FCE, each level evaluation is classified into five levels {very good, good, general, bad, very bad}, and it is expressed in figure is $V=\{5,4,3,2,1\}$.

(4) After the above work is finished, confirm fuzzy mapping relationship between evaluation index and evaluation set in the index sets. The fuzzy mapping matrix is as follows:

$$W_j^{carbon}=(\alpha_1+\alpha_2+\alpha_3)\sigma\gamma_j q_j^s=M\gamma_j q_j^s \quad (3)$$

where, n is the number of the first-level indexes; R_i is fuzzy mapping if i indexes in the first-level indexes ($i=1,2,3,\cdots,n$); k_i is the number of the last-level indexes corresponding to every first-level indexes; r_{ij} means membership degree of last indexes to evaluation set V.

(5) Finally, implement matrix operations for matrix fuzzy relation and weight set $B=RW$. Then, fuzzy evaluation results are gained.

FCE is a very effective multi-factor decision-making method to comprehensively evaluate the things influenced by multiple factors. Evaluation of public services of community sport often involves multiple factors or indexes. At this moment, it is required to evaluate the thing according to multiple factors, instead of single factor. This paper establishes FCE model for public services of community sport through referring to pertinent literatures.

4 Application example

This paper takes urban community in Hunan province for example and conducts empirical analysis of urban community in Hunan province. In accordance with characteristics of urban community in Hunan province, software and hardware conditions of existing sport, an evaluation system including three second-level indexes (infrastructure and service, resident participation degree and sport benefit) and 11 third-level indexes under the basic principle of SERVQUAL. The indexes are shown in Table 3.

TABLE 3 Evaluation index system

Level 1 index	Level 2 index	Level 3 index
Sport service level of urban community	Infrastructure and service	Management rules
		Sport service team
		Sport field
		Sport funds
	Resident participation degree	Form of sport activities
		Resident participation time
		Sport consumption expenditure
		Large fitness activity
		Participation in superior sport activity team
	Sport benefit	Physical fitness measurement index
		Results of athletic contest

Confirm the weight of each index, evaluation level and membership degree through analytic hierarchy process, as shown in Table 4.

TABLE 4 Evaluation index weight of urban community sport

Second-level		Third-level		Evaluation index and membership degree				
Index	*Weight*	*Index*	*Weight*	*V1*	*V2*	*V3*	*V4*	*V5*
U1	0.35	U11	0.25	0.1	0.25	0.3	0.2	0.15
		U12	0.3	0.2	0.2	0.1	0.3	0.2
		U13	0.25	0.3	0.2	0.4	0.1	0
		U14	0.2	0	0.3	0.2	0	0.5
U2	0.35	U21	0.3	0.4	0	0.1	0.3	0.2
		U22	0.2	0.2	0.4	0.1	0.1	0.2
		U23	0.25	0	0.4	0.2	0.3	0.1
		U24	0.25	0.3	0.2	0.2	0.2	0.1
U3	0.3	U31	0.3	0.3	0.1	0.1	0.3	0.2
		U32	0.4	0.2	0.2	0.4	0.1	0.1
		U33	0.3	0.1	0.1	0.3	0.3	0.2

The result matrix of each step is gained according to the process of FCE as follows:

1) Index weight at each level

$$W=(W_1,W_2,\cdots,W_n)=(0.35,0.35,0.3)=\begin{pmatrix}(w_{11},w_{12},w_{13},w_{14})\\(w_{21},w_{22},w_{23},w_{24})\\(w_{31},w_{32},w_{33})\end{pmatrix}=\begin{pmatrix}(0.25,0.3,0.25,0.2)\\(0.3,0.2,0.25,0.25)\\(0.3,0.4,0.3)\end{pmatrix}$$

2) Membership degree and evaluation matrix of the third-level index

$$R_1=\begin{bmatrix}0.1&0.25&0.3&0.2&0.15\\0.2&0.2&0.1&0.3&0.2\\0.3&0.2&0.4&0.1&0\\0&0.3&0.2&0&0.5\end{bmatrix}$$

$$R_2=\begin{bmatrix}0.4&0&0.1&0.3&0.2\\0.2&0.4&0.1&0.1&0.2\\0&0.4&0.2&0.3&0.1\\0.3&0.2&0.2&0.2&0.1\end{bmatrix},$$

$$R_3 = \begin{bmatrix} 0.3 & 0.1 & 0.1 & 0.3 & 0.2 \\ 0.2 & 0.2 & 0.4 & 0.1 & 0.1 \\ 0.1 & 0.1 & 0.3 & 0.3 & 0.2 \end{bmatrix}$$

3) Comprehensive evaluation

$$R = \begin{bmatrix} B_1 \\ B_2 \\ B_3 \end{bmatrix} = \begin{bmatrix} W_1 R_1 \\ W_2 R_2 \\ W_2 R_2 \end{bmatrix} = \begin{bmatrix} 0.16 & 0.23 & 0.25 & 0.17 & 0.20 \\ 0.24 & 0.23 & 0.15 & 0.24 & 0.15 \\ 0.20 & 0.14 & 0.28 & 0.22 & 0.16 \end{bmatrix}$$

$$B = WR = (0.20\ 0.20\ 0.23\ 0.21\ 0.17)$$

Carry out five-level FCE of the above results and gain the valuation result of community sport development level as follows:

$$BV = (0.20\ 0.20\ 0.23\ 0.21\ 0.17)\begin{pmatrix} 5 \\ 4 \\ 3 \\ 2 \\ 1 \end{pmatrix} = 3.05$$

The sport development of this urban community is 3.05, above general and below good. This analysis indicates sport development of urban community in Hunan province has large development space. This is mainly because the infrastructure and service level remain improving; resident participation awareness remains improving; resident health is at a low level. Thus, the community sport development needs urgent enhancement. The sport input and education should be highly valued by leadership organization of the community.

5 Conclusions and suggestions

5.1 CONCLUSIONS

This paper designs evaluation index system which can comprehensively reflect community sport service level, applies FCE to evaluate sport development level of an urban community and provides the evaluation process.

Evaluation system for sport service level of urban community contains 3 second-level indexes and 11 third-level indexes.

This paper adopts FCE to construct FCE mathematical model for public services of community sport and implements empirical research by taking urban community in Hunan province as example. The results show community sport development level of Hunan province is above average and remains further improving.

5.2 SUGGESTIONS

To establish and perfect public service performance evaluation system for community sport as soon as possible according to the requirement for community sport service construction put forward by modern social and economic development by taking evaluation as the means and improvement of public services of community sport as the objective;

In order to enhance service-oriented government construction. The government should position the role accurately in public services of community sport, specify the responsibility and improve service level.

To regard service as the common goal, standardize and perfect public service system of community sport, construct community sport public service convenient for people, favourable to people and friendly to people based on all residents and improve health level and life quality of residents through diversified public sport services.

Abstract

Recommendation systems have been recognized as an effective approach to heavy information load. In recommendation systems, trust/reputation has attracted increasing attention because it helps to improve the precision of recommendation and the robustness of systems to shilling attacks. Recommendation system oriented trust models, mostly rating-based, used to build the reputation and trustiness among users. They are often evaluated in terms of how accurately they help to predict user ratings and how robustly they resist shilling attacks. However, those evaluation techniques disregard the trust values themselves: how accurately they calculate the trust values themselves is not measured. To solve the problem, in this work, we propose an approach to measure the trust values based on electronic word-of-mouth (eWoM) theory. The eWoM believes a user is reliability if he is of good public praise. In our approach, firstly, according to eWoM, the reliability value of a user can be judged by other users' votes - whether the user's ratings or feedbacks are positive or negative. Secondly, the trust values of users can be calculated by a trust model. Finally, we compare trust values and reliability values. As a case study, we propose a simple rating-based trust model and then evaluate the trust model based on the proposed evaluation approach and Amazon dataset.

Keywords: Recommendation Systems, Evaluation Approach, Trust Model

1 Introduction

Trust has been a spot in recommendation systems, because combining trust and recommendation systems can improve the accuracy and stability of recommendations and improve the user's experience [1]. Trust models have been used to recommend movies, songs, products in e-commercial websites, and friends in social networks.

Trust models, usually rating-based in recommendation systems, are often evaluated according to how accurately they help to predict these ratings [1, 2], or by measuring the stability of rating prediction and hit ratio [3, 8]. However, the set of evaluation techniques disregard the trust values themselves: how accurately they calculate the trust values themselves is not measured. To solve the problem, we proposed an evaluation approach to measure trust models according to eWoM theory [4, 5]. The approach can evaluate the accuracy of a trust model by users' assessment. Applied this evaluation approach, the well-performed trust model can be applied to other recommendation systems without user's assessment. For example, there is a trust model m1, according to the evaluation approach and datasets with user assessments (e.g. the datasets driving from Amazon.com), we can evaluate m1. If m1 is good enough, then it can be used to other recommendation systems without user assessments information, such as Movielens and Netflix.

In this work, we first provide an overview of trust model, evaluation approaches and their limitations (Section 2) to explain why a novel evaluation approach may be important in recommendation systems. We proposed a eWoM-based approach to evaluate trust models (Section 3): by proposing a eWoM-based algorithm for reliability values of users, and then comparing those reliability values and trust model based trust values. We finally to illuminate the evaluation approach using a case study (Section 4), comparing the trust values calculated by a trust model to the public reliability values on datasets deriving from Amazon. We draw conclusion in Section 5.

2 Related works and associated problems

With the advancement in networking and multimedia technologies enables the distribution and sharing of multimedia content widely. In the meantime, piracy becomes increasingly rampant as the customers can easily duplicate and redistribute the received multimedia content to a large audience.

Trust/reputation is what is generally said or believed about a person's or thing's character or standing [6, 7].

[*] ***Corresponding author*** e-mail: skycat1980@hotmail.com

Giorgos and Zacharia [8] proposed Sporas model based on eBay and consider the trustworthiness of the graded counterpart to mitigate influences of malicious behaviours; and then they propose a novel collaborative reputation mechanism for electronic marketplaces [9]. Guo, Jiang, and Cai [10] modified Sporas into E-Sporas by adding the factors of volume and number of trades to make Sporas better in C2C. Wang, Zhang, and Chen [11] proposed a cloud-based reputation reporting mechanism to solve the fake and joint cheat recommendations of malicious customers. Li, Liang, and Zhang [12] gave a systematic study on trustworthiness and reputation management model in e-commerce. Wu, Li, and Kuo [13] proposed several metrics for online auctions to evaluate the trust values of participants. Abdel-Hafez, Xu, and Tjondronegoro [14] provided a product reputation model for recommendation based on opinion mining techniques.

In recommendation systems, Golbeck et al. looked specifically at trust between people who have no directly links to another and proposed TidalTrust [15] mechanism to infer trust in continuous trust networks. Paolo Avesani et al proposed a time-efficient trust metric named Moletrust [16] and applied it in Moleskiing application to compute the trustworthiness of users. Levien et al. [17] investigated the role of trust metrics in attack-resistant public key certification. Kuter et al. described SUNNY [2], a new trust inference algorithm using a probabilistic sampling technique to estimate confidence. Cai-Nicolas Ziegler et al. provide a novel trust metric Appleseed [18] for local group trust of semantic web issues. Massa and Avesani [19, 20] proposed approaches to estimate all trust weights of users by propagate trust over a trust network. Verbiest et al. [21] proposed a new approach to calculate trust and distrust by introduce path length incorporating aggregation strategies. Victor et al. proposed bilattice-based aggregation approaches for gradual trust and distrust [22] and then incorporated the gradual trust and distrust in recommender systems [23].

Large numbers of literatures concern about trust and reputation recently. However, they are mainly proposed for constructing better recommendations, such as decreasing the accuracy (e.g. MAE, RMSE) of rating prediction, improving precision and recall of recommendations [9, 10, 14], and improving robustness [8, 11, 13] (especially stability ability under shilling attacks) and users' satisfactions [8-14]. However, the set of evaluation techniques disregard the trust values themselves: how accurately they calculate the trust values themselves is not measured. Thus, we propose a new evaluation approach to solve the problem.

3 An EWoM-based evaluation approach

Traditionally, WoM is to pass information from person to person by oral communication. When WoM is mediated through electronic means, the eWoM refers to any statement consumers share via the Internet about a product, service, brand, or company [4]. The eWoM proves to have more effectiveness in leading purchasing decisions, as the wide scale of online broadcasting and weak correlations between online customers and marketers [5]. The enormous impact of eWoM on consumer behaviour and product success thus attracts many researchers.

The steps for the evaluation approach are show as Figure 1. We can get reliability values from eWoM-based algorithm (subsections 3.1 and 3.2) and then compare those reliability values to trust values based on trust models (subsection 3.3).

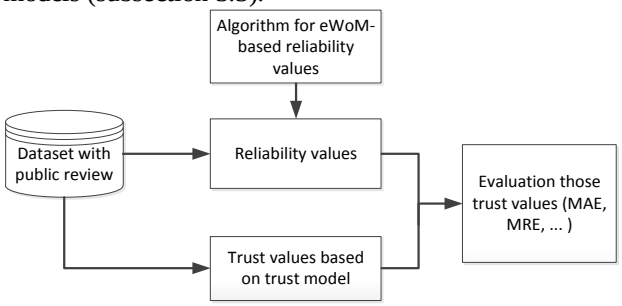

FIGURE 1 The steps for the evaluation approach

3.1 EWOM-BASED RELIABILITY VALUES

As known to us all that, people can rate their consumed product after each transaction. However, the reliability [7] of those consumers and their ratings is still a problem. Inspired by the effectiveness of eWoM, an empirically convincing evaluation approach under mass attitude is proposed to assess reputation of customer with their ratings.

Firstly, we collect support ϕ_j of the whole ratings from a customer u_j; at the same time, compute the weight φ_j of u_j's ratings over the whole system. Then the reliability value of u_j's from public views can be simply denoted as Equation (1).

$$Reli_j = \alpha f_j + \beta j_j, \tag{1}$$

where the weights of ϕ_j and φ_j are α and β, $\alpha + \beta = 1$; $\phi_j = \sum_{0 \le i \le k} h_{i,j} / v_{i,j}$, where $h_{i,j}$ is the helpful votes from u_j to item i, $v_{i,j}$ is the corresponding total votes; $\varphi_j = k_j / R$, $k_j = |r(u_j)|$, k_j is the number of u_j's all ratings; R is the number of all ratings in the dataset.

The weights α and β can be set to suitable values by experiments. We will illuminate how to find the suitable values in Section 3.2.

3.2 SET THE WEIGHTS USING AMAZON DATASET

The dataset is Amazon product co-purchasing network metadata* collected in summer 2006. The dataset contains 548,552 different items (Books, music CDs, DVDs, and VHS video tapes). Each item contains reviews from customers, including ratings, the number of helpful votes for ratings, and total number of votes.

* http://snap.stanford.edu/data/amazon-meta.html

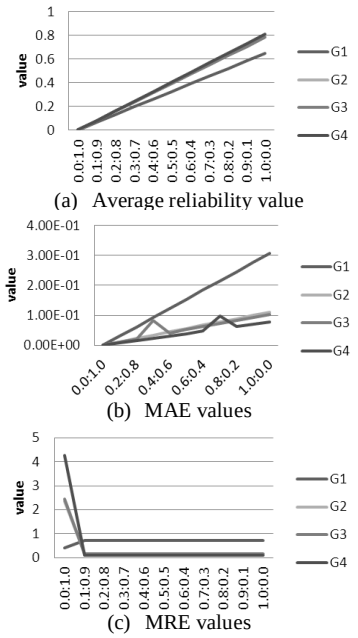
To get suitable values of the weights, we divided the datasets to four subsets G1, G2, G3, and G4 according to the number of all ratings of a user k (k>0, k>5, k>10, k>20). We calculated the average reliability value avg_R_{ci}, mean absolute error (MAE) MAE_{ci}, and mean relative error (MRE) MRE_{ci} (see Equations 2, 3, and 4), using ten combinations of α and β, C = (0.0, 1.0; 0.1, 0.9; 0.2, 0.8; 0.3, 0.7; 0.4, 0.6; 0.5, 0.5; 0.6, 0.4; 0.7, 0.3; 0.8, 0.2; 0.9, 0.1; 1.0, 0.0), marked by c_1, c_2, ..., and c_n.

$$avg\_Reli_{c_i} = \sum_{i=1}^{n} \left| Reli_{u_i}(c_i) \right| \tag{2}$$

$$MAE_{c_i} = \frac{\sum_{i=1}^{n} \left| Reli_{u_i}(c_i) - R_{u_i} / all\_avg\_I * avg\_Reli_{c_i} \right|}{n} \tag{3}$$

$$MRE_{c_i} = \frac{\sum_{i=1}^{n} \left(\left| Reli_{u_i}(c_i) - R_{u_i} / all\_avg\_I * avg\_Reli(c_i) \right| / Reli_{u_i} \right)}{n}, \tag{4}$$

where n means the total number of users in group; $Reli_{ui}(c_i)$ can be calculated by Equation (1); Ru_i is a set of u_j's all ratings; all_ave_I is the average of all items average rating scores.



(a) Average reliability value

(b) MAE values

(c) MRE values

FIGURE 2 Four groups of average E, absolute error, and relative error

The avg_Reli_{ci} results are shown as Figure 2 (a). It is simply that 4 curves grow linear with the value of α increase, though β decreases. Actually, k / all_num is normally too small to have nearly no impacts on the results.

From sampling ratings from Amazon dataset, the value of all_avg_I is 4.18, thus we could get the absolute and relative error values according to Equations (3) and (4) respectively, and then have the corresponding curves as Figure 2 (b) and (c) denotes.

In Figure 2 (b), all groups' absolute errors are very small even though the proportion of α and β are different, which seem to remind us that proportion of α and β takes no effect. In Figure 2 (c), we can find a phenomenon that there are 4 outlier points where the value of (α, β) is (0.0, 1.0). The phenomenon gives us a further authentication that the first part of the equation (1) plays an important role in computing the value of $Reli_{ui}$ in another direction. Another obvious phenomenon in (c) is that all curves rise and fall slightly around certain numbers, which look like 4 straight lines no matter what happens to the value of (α, β) later. From the above two figures, we could make sure that any proportion of α and β can work except α equals 0.0. Thus, in the next experiments, we keep (α, β) is (0.8, 0.2).

3.3 EVALUATION APPROACH

To evaluate a trust model, we calculate *wMAE* (weighted MAE) and *wMRE* (weighted MRE) for the trust model based trust values and eWoM-based reliability values (See Equations (5) and (6)).

$$wMAE = \sum_{j=1}^{n} (T_j * \overline{Reli} / \overline{T} - Reli_j) / n \ , \tag{5}$$

$$wMRE = \sum_{i=1}^{n} ((T_j * \overline{Reli} / \overline{T} - Reli_j) / Reli_j) / n \cdot \tag{6}$$

In the Equations,

$$\overline{T} = \sum_{j=1}^{n} T_j / n \ , \tag{7}$$

$$\overline{Reli} = \sum_{j=1}^{n} Reli_j / n \ \cdot \tag{8}$$

T_j is the trust value for user j. $\overline{T}$ is the average value of T_j. $Reli_j$ is the reliability value for user j.

4 Promoting the proposed evaluation approach

To illuminate the steps for applying the evaluation approach, we will use a simple trust model first as an example, then evaluate the model using the proposed approach.

4.1 A SIMPLE TRUST MODEL – AS A CASE STUDY

Here we have a simple but effective trust model for customer according to a basic truth, that is, each rating has a potential bias since each rating is affected by users' sentimental factor. Thus we should use correct function (5) to objectify the biased rating r_{ij}.

$$r_{ij}^{'} = r_{ij} * \frac{\bar{r}}{\bar{r}_i}, \tag{9}$$

where $\bar{r}$ is the average rating of the whole system, while $\bar{r}_i$ is the average rating of item i. The objective part of r_{ij} is $r_{ij}^{'}$.

After the correction, we could modify the existed trust value of u_j iteratively (See Equation 10).

$$T_j = \frac{T_j^{'} * k + r_{ij}^{'}}{k+1}, \tag{10}$$

where $T_j^{'}$ is the previous trust value before u_j rated item *i*.

4.2 THE COMPARISON AND ANALYSIS

We derived two random selected groups from Amazon dataset to validate the tendency: the consistency - how the average trust values and average reliability values looked like. Experimental results are shown in Figure 3.

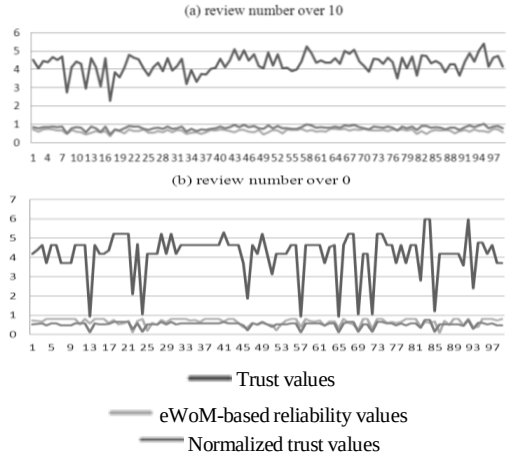


FIGURE 3 Reputation trends in review number (a) over 10, (b) over 0, with initial trust values, the normalized trust values from equation and reliability values from equation (1) with α=0.8 and β=0.2

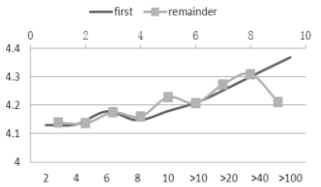
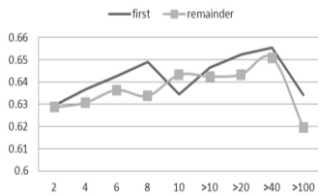
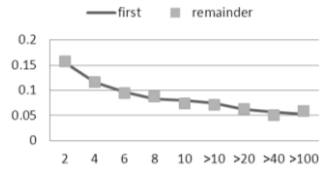
We then derived from selected sample data with 40000 items. We divided the data to two groups according to the number of users' total reviews *k*. One group was the *first* 20000 sample items, and the other one was the *remaining* 20000 sample items. We firstly grouped 9 classes to perform experiments where k=2, k=4, k=6, k=8, k=10, k>10, k>20, k>40, and k>100 respectively, and then calculated the average trust values (*T*), average reliability values (*ave_Reli*), *wMAE*, and *wMRE* according to Equation (5) - (8). The results are shown in Figure 4.



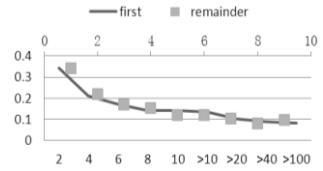
(a) Average trust values



(b) Average reliability values



(c) Weighted *MAE*



(d) Weighted *MRE*

FIGURE 4 The comparisons of two sets between (a) Average trust values (*T*), (b) average reliability values (*ave_Reli*), (c) *wMAE*, (d) *wMRE*

From Figure 4 (a) and 4 (b), each two lines have small fluctuations respectively, but still can fit to others to some extent, which confirms that both of the two samples can reflect the overall dataset. From Figure 4 (c) and 4 (d), we can see that both two sets' curves of *wMAE* and *wMRE* firstly decrease quickly before k = 8 or so, then slowly and have signs of tending towards stability after k = 8.

The largest *wMAE* in the first group is 0.156 at the first point, and falls down to 0.1 at the fifth point, and preserves stable around 0.08 after 8. It is almost the same trend to the second group's curve.

Therefore, we can conclude that, most *wMAE* is smaller than 0.1, and larger value of k means lower absolutely error. Similarly, we can analyse that the range of relative error is 0.0 - 0.2, and larger k means lower relative error.

5 Conclusions and future work

In this paper, we have analysed up-to-date trust/reputation models especially in recommendation systems. We have introduced evaluation approaches of the models and their problem: disregard the accuracy of trust values themselves. To solve the problem, we have proposed an evaluation approach based on WoM theory and given a case study and experiments on Amazon dataset to illuminate how to apply and analyse the proposed evaluation approach.

We have just used a trust model to show how to apply the proposed approach in the paper. We will try to apply the evaluation approach to more trust models and further analyse and improve the approach.

Abstract

The security of stadium is one of the problems increasingly concerned by people. Among various security problems, the fire risk of stadium is the most important. By using principal component analysis (PCA) and combining the influencing factors of risk prediction of stadium, several influencing factors of the fire risk of stadium are evaluated and analysed, then the uppermost principal component factors are selected, the inconspicuous components are eliminated, the influence of relevant factors on the fire risk prediction of stadium is analysed, and the correlation of various indicators with fire risks of stadium is understood to find the potential best security management prediction system, for the purpose of taking pertinent prediction measures of fire accident risks to overcome the unfavourable factors in the security management, and ensure the safe and normal operation of stadium as well as the personal and property security of sporters.

Keywords: Principal Component Analysis, Stadium, Fire Risk, Prediction

1 Introduction

The principal component analysis (PCA) is a kind of statistical analysis method that converts multiple original variables into several comprehensive indicators [1]. From the mathematical perspective, it is a dimension reduction technology [2]. Its general idea is: a research object is often a multi-element complex system. Too many variables will certainly increase the difficulty and complexity of problem analysis [3]. It is a way to simplify the problem by using the correlation between original variables; replacing more original variables with less new variables and making the fewer variables preserve the information reflected by more original variables as more as possible.

The security management of large stadium is an important issue [4]. As a large public place, the large stadium is an indispensable part of people's spiritual entertainment, characterized by highly populated people and big liquidity, so it often causes significant casualty and property loss in case of any fire, thus bringing great negative impacts [5]. Therefore, the fire accident in the safety management is the most serious. In recent years, the stadiums in China have suffered more than 200 fires, with a death of more than 1000 people, which fully reveals the serious problem in the security management of stadium [6]. The academic circles and manager pay more and more attention to seek the way of reducing fire risks by analysing the influencing factors of the fire risk prediction of stadium. To better ensure the security of stadium, it is required to strengthen the research on the reasonability and scientific of the fire risk prediction of stadium [7]. In order to analyze the influencing factors of the fire risk prediction of stadium, it is required to conduct research and analysis from different theories, thus introducing the application of PCA in the fire risk prediction of stadium [8]. PCA converts many indicator factors into several important comprehensive indicators through the thought of dimension reduction. In practical problems, the primary and secondary cannot be mastered because of the complicated and changing conditions as well as more influencing factors, so it is hoped that there are less variable indicators in the quantitative analysis and more information can be got from these indicators [9]. This can be met by analytic hierarchy process (AHP) as it can explains the most original variables with less indicator variables, converts the indicators with high correlation into independent indicator variables, without any correlation and also can well explain most variables [10].

PCA is one of the important methods of analysing problems in the academic circles at present, which can select according to the correlation degree of influencing factors to reveal the intrinsic connection and difference of objective things. By studying the relevant factors that influence the fire risk of stadium, the application of PCA in the fire risk prediction of stadium can be explored, which is of great realistic significance in the fire risk management and security system of stadium.

2 Overview of PCA

2.1 BASIC IDEA OF PCA

The basic idea of PCA is to recombine, divide and convert more original P indicators X1, X2, …, XP with correlation into a set of less representative indicators, without any correlation. Finally, the fewer indicators without any correlation are used to replace more original indicators.

Suppose that F1 means the principal component indicator formed by the first linear combination of original variables, that is, $F_1 = a_{11}X_1 + a_{21}X_2 + ... + a_{p1}X_p$, it is known by mathematical knowledge that the information got from each principal component can be measured by its variance. The larger the variance Var(F1) is, the more the information contained in F1 will be. Generally, it is hoped that the principal component F1 contains the largest information, so F1 selected from the linear combination should be the one with the largest variance in the linear combinations of X1, X2, …, XP, so F1 is the first principal component. If the first principal component fails to represent the information of original p indicators, the second principal component indicator F2 can be selected. To effectively reflect the original information, the existing information of F1 will not occur in F2, that is, F2 and F1 should be independent and uncorrelated. In the mathematical language, Cov(F1, F2)=0, so F2 is one with the largest variance in the linear combinations of X1, X2, …, XP without any correlation with F1, and F2 is called the second principal component. F1, F2, ……, Fm got by this analogy are the first, second,..., m principal component of original variable indicators X1, X2……XP.

$$\begin{cases} F_1 = a_{11}X_1 + a_{12}X_2 + ... + a_{1p}X_p \\ F_2 = a_{21}X_1 + a_{22}X_2 + ... + a_{2p}X_p \\ \quad ..... \\ F_m = a_{m1}X_1 + a_{m2}X_2 + ... + a_{mp}X_p \end{cases} \quad (1)$$

It is known from the above analysis that:

(1) Fi and Fj are uncorrelated, that is, Cov(Fi, Fj) = 0 and Var(Fi)=ai'Σai, in which Σ is the covariance matrix of X.

(2) F1 is of the largest variance in the linear combinations of X1, X2, …, Xp (the coefficient meets the above requirements), that is, Fm is of the largest variance in the linear combinations of X1, X2, …, Xp, without any correlation with F1, F2, ……, Fm-1.

F1, F2, …, Fm (m≤p) are the new variable indicators, that is, the first, second, ..., m principal component of original variable indicators.

2.2 MAIN FEATURE OF PCA

When PCA is used to analyse the research problems, there are two main characteristics:

(1) Obtain the equation of each principal component Fi (i = 1, 2,..., m) relative to the original variable Xj (j = 1, 2,..., p), namely, coefficient a_{ij} (i = 1, 2,..., m; j = 1, 2,..., p). By using the mathematical knowledge, it is proved that the variance of principal component is the characteristic root of original variable covariance matrix, so the front m larger characteristic roots represent the front m larger principal component variances; the corresponding eigenvectors of front m characteristic roots λi of original variable covariance matrix (to ensure the largest variance of principal component in turn) is the coefficient of corresponding principal component Fi expression ai. To limit, the coefficient of ai adopts the corresponding unit eigenvector of λi.

(2) Calculate the principal component load, which reflects the correlation degree of principal component Fi and original variable Xj:

$$P(Z_k, x_i) = \sqrt{\lambda_k}\, a_{ki} (i, = 1, 2, \cdots, p; k = 1, 2, \cdots, m).$$

2.3 CALULATION STEPS OF PCA

2.3.1 Obtain the covariance matrix

The original variable covariance matrix of sample is Σ=(sij)p×p, where

$$s_{ij} = \frac{1}{n-1}\sum_{k=1}^{n}(x_{ki} - \overline{x}_i)(x_{kj} - \overline{x}_j) \quad I, j = 1, 2, \ldots, p\,. \quad (2)$$

2.3.2 Obtain the characteristic value λ_i of covariance matrix and corresponding eigenvector a_i under orthogonally conditions

The front m larger characteristic values of matrix, λ1≥λ2≥…λm>0 are the corresponding variances of front m principal components, the corresponding unit eigenvector a_i of λ_i is the coefficient of principal component Fi relative to the original variable, so the principal component Fi of i original variable is:

$$F_i = X \quad (3)$$

The variance contribution of principal component generally represents the reflection information, the greater the contribution is, the more the information will be. α_i is:

$$\alpha_i = \lambda_i / \sum_{i=1}^{m}\lambda_i \quad (4)$$

2.3.3 Choose the principal component

The most principal component among various indicators, that is, m in F1, F2,……,Fm should be confirmed by calculating the accumulated variance distribution.

$$G(m) = \sum_{i=1}^{m}\lambda_i / \sum_{k=1}^{p}\lambda_k \quad . \quad (5)$$

Generally, when the accumulated variance distribution is more than 85%, the information of original variable can be better reflected and m is the number of principal components selected finally.

2.2.4 Confirm the principal component load

The principal component load presents the correlation between principal component Fi and original variable Xj and the load lij (i=1, 2, ..., m; j=1, 2, ..., p) of original variable Xj (j=1, 2, ..., p) on the principal component Fi ((i=1, 2, ..., m) is as follows:

$$l(Z_i, X_j) = \sqrt{\lambda_i} a_{ij} (i = 1, 2, \cdots, m; j = 1, 2, \cdots, p) . \quad (6)$$

Then, SPSS software can be used for calculation and analysis and the "component matrix" obtained is the principal component load matrix.

2.2.5 Calculate the score of principal component

Based on the calculation of principal component, the score of principal component is calculated:

$$F_i = a_{1i} X_1 + a_{2i} X_2 + ... + a_{pi} X_p \quad i = 1, 2, \ldots, m \quad (7)$$

However, in the actual problem, each indicator has different dimensional effects, so it is required to eliminate the influence of dimension on it before calculating the score. Generally, the dimensional influence of data is eliminated through the standardization treatment of original data, that is, the data conversion is transformed as follows:

$$x_{ij}^* = \frac{x_{ij} - \overline{x}_j}{s_j} \qquad i = 1, 2, ..., n; \ j = 1, 2, ..., p \quad (8)$$

According to the mathematical expression and relevant mathematic principle, on one hand, after standardized transformation, the variable covariance matrix can express its relevant coefficient matrix; on the other hand, the standardized covariance is the relevant coefficient of original variable, so it is concluded that after the standardized treatment of original variable, the relevant coefficient matrix is of no change.

All in all, the corresponding characteristic value λi of the relevant coefficient matrix of original indicator is the variance contribution of principal component and the variance distribution is $\alpha_i = \lambda_i / \sum_{i=1}^{p} \lambda_i$. The larger α_i is, the stronger the ability of corresponding principal component to reflect the comprehensive information. The principal component can be selected according to λi. The combination coefficient (load of original variable on the principal component) a_i of each principal component is the corresponding unit eigenvector of characteristic value λi.

3 Comprehensive application of PCA in fire risk warning of stadium

In the research on fire accident of stadium, the evaluation and assessment of influencing factors of fire risk warning are an essential part in our daily warning. With the social development, the evaluation system and method for fire risk warning become diversified, however, most of which are limited to the investigation and analysis phase and rarely conducts further analysis and verification from the theoretical perspective. According to the above situation, the fire risk system of PCA is established and the subjective analysis is integrated with the scientific component of mathematical model to realize the change from qualitative analysis accurate quantitative analysis.

3.1 INDICATOR SELECTION OF STADIUM

The influencing factors of fire risk of stadium from 1990-2013 are calculated by using PCA and the main indicators are selected. According to the actual situation of stadium, 9 main indicators are selected finally as follows:

TABLE 1 Indicator of fire rusk prediction model of stadium

Indicator	Meaning
X1	Electric fire
X2	Poor internal fire security inspection
X3	Fail to build the stadium according to the fire design
X4	Incomplete patrol
X5	Poor automatic fire warning system
X6	Poor fire acceptance of stadium
X7	Poorly implemented fire security and regulations of stadium
X8	Insufficient fire extinguisher or failure of fire extinguisher
X9	Fail to take actions immediately

3.2 SPECIFIC STEPS OF PCA IN FIRE RISK

According to the above elaboration, to eliminate the dimensional influence, the covariance matrix is calculated after standardization of variable, that is, the relevant coefficient matrix of original variable is calculated directly, so the calculation steps of PCA in fire risk of stadium are as follows:

(1) Calculate the relevant coefficient matrix;
(2) Obtain the characteristic value λ_i and corresponding orthogonal unit eigenvector a_i of relevant coefficient matrix;
(3) Calculate the weight of each component;
(4) Choose the principal component.

3.3 APPLICATION EXAMPLE OF PCA IN FIRE RISK

In the research on fire risk prediction of stadium, 9 main indicators among various risk influencing factors are selected to discuss the application of PCA.

According to the specific steps of PCA, the relevant coefficient matrix is obtained after standardizing the

original indicator data and then SPSS software is used to calculate the relevant coefficient matrix and characteristic value of 9 evaluation indicators to confirm the main factor number of evaluation. The number of principal component is confirmed according to the accumulated variance contribution of characteristic value.

After eliminating the dimensional influence of original data of fire risk influencing factors of stadium, the standardized data is obtained (see table 2). The relevant matrix coefficient is shown in table 3.

The characteristic root, contribution and accumulated contribution of relevant coefficient matrix are obtained through further calculation.

It is known from the characteristic equation $|R-\lambda I_9|=0$ that 9 indicators are non-negative characteristic roots, that is, $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \ldots \geq \lambda_9 \geq 0$, where λ1=7.7719, λ2=0.756, λ3=0.3796, λ4=0.077 and λ5=0.0155. The results are shown in table 4.

According to the characteristic root of matrix λi (i=1, 2, 3, ····, 9), the eigenvector is further obtained as shown in table 5.

9 new components are obtained by using PCA. It can be seen from table 3 that the characteristic root λ4, λ7, λ8, λ9 =0 and the corresponding contribution and accumulated contribution are also 0, indicating that some indicators among original indicators are of great correlation and 5 variable indicators can completely represent the information reflected by 9 original indicators. so 5 indicators are selected as the principal components and other 4 are eliminated. Next, by calculating the weight of original 9 indicators in reflecting the influencing factors of fire risk of stadium, the indicator with the largest weight is obtained and the principal component is confirmed.

$$\xi_1 = 0.2978\times 7.7719 + 0.1622\times 0.756 + 0.104\times 0.3796 + 0.5274\times 0.077 - 0.7079\times 0.0155 + 0.056\times 0 + 0.03\times 3 - 0.2352\times 0 - 0.0708\times 0 = 2.4987.$$

By this analogy, the weight of X2,X3,X4,…,X9 in the comprehensive information can be obtained, that is, ξ2=2.1468, ξ3=2.2602, ξ4=2.3766, ξ5=2.7844, ξ6=2.604, ξ7=2.8274, ξ8=2.5632, ξ9=2.1178.

The weight in a descending order is X7, X6, X5, X8, X1, X4, X3, X2, X9. Therefore, 4 corresponding indicators with the minimum weight to be eliminated are X4, X3, X2, X9.

Through the above calculation and analysis, the main influencing indicators that influences the fire risk prediction of stadium are screened, which are poorly implemented fire security rules and regulations of stadium X7, poor fire acceptance of stadium X6, poor automatic fire warning system X5, insufficient fire extinguisher or failure of fire extinguisher X8 and electric fire X1. These indicators considers the critical influencing indicator factors of fire risk prediction of stadium and are also greatly concerned by the relevant staff of enterprise upon management because they play a decisive influence role in the fire risk prediction of stadium, thus providing important and reliable direction for the security management decision of stadium. If the indicator that influences the risk prediction of stadium is uncertain and complex, the PCA can be used to screen the main indicators and eliminate the relevant indicators in the comprehensive evaluation. This method is of good value in the fire risk prediction of stadium and great theoretical and realistic significance in the security management of stadium.

4 Conclusions

PCA, with simple principles, is simple and convenient in the practical application. Although the computation task is large in case of a large amount of data, with the popularization and application of computer, supported by computer program and relevant software, the results can be obtained accurately and rapidly. PCA is a widely used among various analysis methods, which chooses the most principal component from the multiple indicators (variables) and multiple observation data of sample and quantitatively confirms the relevant influence between sample and indicators. In studying the fire risk prediction of stadium, it is allowed to analyze the influencing factors by using the mathematics and computer tool as well as PCA and choose the primary and secondary component to make relevant management personnel directly know the correlation between indicators in the fire risk of stadium and find the potential best security management prediction system, for the purpose of taking pertinent prediction measures of fire accident risks to overcome the unfavourable factors in the security management and ensure the safe and normal operation of stadium as well as the personal and property security of sporters. In addition, in the analysis and applica-

tion, the actual situation is combined. PCA in this paper provides some new ideas for other analysis method, which increases the theoretical research basis of PCA and provides some references to the further research, with theoretical and realistic significance.

Received 1 June 2014, www.cmnt.lv

Abstract

In basketball arena project construction, the project safety is an important topic. Aimed at the current situation of basketball arena project construction, the risk factors in the project construction are evaluated from the aspect of factor analysis method and the data in the process are processed according to relevant theory of factor analysis method and by virtue of SAPP software, so as to verify the scientific reasonableness of the method. In addition, in the process of evaluation, the subjectivity is linked with the objectivity in combination with the reality to provide main basis for the safety risk problems in the basketball arena project construction, which is beneficial for the safety management in the project construction. The application of factor analysis method in the basketball arena project construction can provide some new thoughts for other analysis methods, so as to enhance the theoretical research basis for the factor analysis method.

Keywords: Factor analysis method, Basketball arena, Project construction risk, Evaluation

1 Introduction

The concept of factor analysis originated from the intelligent test statistical analysis experiment of Karl Pearson and Charles Spearmen etc. [1]. In recent decades, with the rapid development of computer network, factor analysis method has been widely applied in various fields, so as to further enrich the theory and method of factor analysis [2]. Factor analysis method is a model analysis method to find out the relevant public factors, which is to construct several public factors with clear significance on the basis of main components, and to analyze and explain the original variables based on these public factors, so as to get the relation with the original variables [3].

With the continuous deepening of the reform and opening up, more and more basketball arenas are required, and the project construction of basketball arena has also welcomed infinite vitality, developing at an unprecedented scale and speed [4]. However, in recent years, the project construction has become "the disaster area of corruption", with a lot of risk safety crisis, mainly reflected in the following two aspects: first in the risk management of project construction, the construction unit selects staff with low quality and skill level, the machinery and equipment are operated unreasonably and there is an improper management for the material purchase and quality; second, the supervisors do not strengthen supervision to the project, with cheating on workmanship and materials [5-6]. Therefore, the researching and analysis on the risk problems in the basketball arena project construction and effectively finding out a risk control approach have been increasingly emphasized by the academic circle and political circle [7]. In order to construct the project construction better, it is required to strength the research on the risk evaluation problem of basketball arena project construction [8]. In order to comprehensively evaluate the basketball arena project construction, we research and discuss from different theories, so as to introduce the application of factor analysis method in the risk evaluation of basketball arena project construction [9].

Factor analysis method is a multi-variable statistical analysis method of including a lot of variables with complicated relations into several comprehensive factors by starting from the research on the dependence of internal correlation [10]. Its key is to detect and classify the correlation between variables and finally use a public factor to express the original variable, and it is widely used for limited unforeseeable invisible variables to explain the correlation between the original variables [11]. Factor analysis method is one of the important methods in the academic circle to analyse a lot of problems. In this research, the factor analysis method is used to comprehensively evaluate the risk problems of basketball arena project construction, so as to further discuss the application of factor analysis method.

2 Overview of factor analysis method

The main purpose of factor analysis method is to use a few factors to describe more indicators and analyze the correlation among these factors, and include several variables with close relation into the same category, each category of variable is one of the factors (because it is not the specific variable, and cannot be observed), and use a few factor to reflect most of the information of the things evaluated.

* ***Corresponding author*** e-mail: huronghui@yeah.net

Using this research method, we can analyze and solve a lot of problems better conveniently.

2.1 BASIC MODEL OF FACTOR ANALYSIS METHOD

The basic model of factor analysis method is described as follows:

(1) $X=(X_1, X_2, \ldots, X_P)$, in which X is an observable random vector, with mean factor $E(X)=0$, covariance matrix $Cov(X)=\sum$, and the covariance matrix $\sum$ is equal to relevant matrix R (the variable should be standardized to achieve equality of the two).

(2) $F=(F_1, F_2, \ldots F_m)$, in which $F(m<p)$ is an unobservable vector, with mean factor $E(F)=0$, covariance matrix $Cov(F)=I$, and at this moment, each component is mutually independent.

(3) $e=(e_1, e_2, \ldots, e_p)$, in which e and F are mutually independent, and $E(e)=0$, e is the covariance matrix $\sum$, which is a diagonal matrix, and at this moment, each component e is also mutually independent, so the matrix can be expressed as:

$$
\begin{aligned}
X_1 &= A_{11}F_1 + A_{12}F_2 + \ldots + A_{1m}F_m + e_1 \\
X_2 &= A_{21}F_1 + A_{22}F_2 + \ldots + A_{2m}F_m + e_2 \\
&\ldots \\
X_P &= A_{p1}F_1 + A_{p2}F_2 + \ldots + A_{pm}F_m + e_p
\end{aligned}
$$

It is called factor analysis model, this model is aimed at the variable for calculation, and each factor is mutually orthogonal, so it is also called R-type orthogonal factor model.

Its model matrix form is $x=A_F+e$

Where, X, A, F, e are the known correlatives.

Here,

(1) m is unequal to p;

(2) $Cov(F, 0)=0$, i.e. F is unrelated to e;

(3) $D(F)=I_m$, i.e. $F_1, F_2, \ldots, F_m$ are unrelated and their variance is 1;

The quadratic sum of each element of column $j(j=1, 2, \ldots, m)$ of the factor load matrix A is recorded as g_{j2}, called the variance of the public factor F_j to X. g_{j2} is the sum of variance provided by the j_{th} public factor F_j to each component $X_i(i=1, 2, \ldots, p)$ of X, which is an important factor to weigh the public factor. The more g_{j2} is, the more contribution of the public factor F_j to X will be, or the larger influence on X will be. If we calculate all $g_{j2}(j=1, 2, \ldots, m)$ of the factor load matrix A, and sort them in order of size, finally we can get the most influential public factor based on this.

2.2 BASIC CALCULATION STEP OF FACTOR ANALYSIS METHOD

During research and analysis on the factor analysis method, the main problem faced is to reasonably construct the factor variable and name and interpret the factor variable, and the general steps are:

(1) Input the raw data, detects their reasonable correlation, calculate the sample covariance and carry out standardized processing;

(2) Calculate the sample correlation coefficient matrix R;

(3) Calculate the characteristic root $\lambda_i(\lambda_1, \lambda_2, \lambda_3 \cdots \succ 0)$ of correlation coefficient matrix, and the characteristic vector.

(4) Determine the number of public factor, and calculate its communality variance;

(5) Rotate the load matrix, so as to better explain the public factor;

(6) Have a special explanation on the public factor;

(5) Calculate the final score with the variance contribution rate weight of each factor.

3 Application of factor analysis method in risk evaluation of basketball arena project construction

In the research on the fire accident in gymnasium, evaluation and assessment on the warn of fire disaster risk is an inseparable link in our daily warning. With the development of society, the assessment systems and methods for the fire risk warning have been diversified increasingly, but most of them are limited to the investtigation and analysis stage, and there is seldom further analysis and affirmation from theory. According to the above situation, we establish the fire risk system of main component analysis method and add the scientific component of mathematical model to the subjective analysis, so as to realize the transformation from qualitative analysis to the accurate quantitative analysis.

3.1 SELECTION OF RISK EVALUATION INDICATORS IN BASKETBALL ARENA PROJECT CONSTRUCTION

The factor analysis method is applied to consider the comprehensive factors in the project construction in recent 10 years, from the initial construction to the later completion of the basketball arena, including many risks, 10 specific risk manifestation indicators are selected as the raw data, see Table 1;

TABLE 1 Risk manifestation indicators

Raw data indicator	
X_1	Personnel physical quality risk
X_2	Personnel professional skill risk
X_3	Personnel knowledge and common sense risk
X_4	Mechanical technology risk
X_5	Project design risk
X_6	Material technology risk
X_7	Project supervision risk
X_8	Artificial environment risk
X_9	Natural condition risk
X_{10}	Geographical condition risk

3.2 PROCESS ANALYSIS IN RISK EVALUATION OF BASKETBALL ARENA PROJECT CONSTRUCTION

With the popularization of computer and its use in various aspects, in the process SAPP data analysis software can be used for the factor analysis method.

(1) Analyse whether the selection of evaluation indicator in basketball arena project construction is appropriate for the factor analysis. Bartlett's test of sphericity and KMO detection are used for detection and SPSS software is used for the calculation to obtain the raw data correlation examination, as shown in Table 2.

TABLE 2 KMO detection result

Bartlett and KMO detection		
Sufficient sampling through KMO weighing		0.708
Bartlett's test of sphericity	About Chi-square	253.875
	Degree of freedom	120
	Examination value of difference significance	0.000

KMO detection value ranges from 0 to 1, the more KMO value indicates that there are more communities among variables and it is more appropriate for factor analysis. Generally, when the detection value is more than 0.5, factor analysis is appropriate, whole not appropriate when less than 0.5. The result in Table 1 sows that the KMO value is 0.708, Bartlett examination value is 0.00, less than 1%, indicating that the evaluation indicator is appropriate for the factor analysis, but there is a correlation among the variables.

(2) Carry out standardization processing to the primitive matrix, the standardization expression formula is $Zi = \frac{Xj - \bar{X}j}{Sj}$ in which X_j is the j_{th} risk evaluation indicator of the i_{th} basketball arena, S_j is the mean value and sample covariance of X_j, so as to calculate the relevant coefficient matrix of the standardization data and get the characteristic value.

TABLE 3 Factor variance contribution rate

8	0.722	4.511	79.846			
9	0.669	4.182	84.028			
10	0.624	3.9	87.928			

TABLE 4 Rotated factor load matrix

	Component				
	1	*2*	*3*	*4*	*5*
X_1	0.709	0.14	0.039	0.092	-0.073
X_2	0.697	0.11	-0.308	0.166	-0.091
X_3	0.826	0.149	0.04	0.054	0.071
X_4	0.102	-0.454	-0.147	0.089	0.213
X_5	0.395	0.602	-0.278	-0.31	0.031
X_6	-0.2	0.694	0.09	-0.018	0.099
X_7	0.048	0.168	-0.782	-0.148	0.196
X_8	0.125	-0.191	0.14	0.974	0.083
X_9	0.183	0.151	-0.043	-0.849	0.053
X10	0.026	0.6	0.118	0.068	0.706

Generally, according to the calculation of variance contribution rate and the accumulative variance contribution rate, the total variance contribution rate should be above 80%.

(3) Rotate and determine the factors. Imagine F_1, F_2, …, F_m are m factors, the first n factors with accumulative variance contribution rate above 80% are obtained, and these n factors can represent all information volume. The actual significance of these n factors cannot be determined clearly, so they are often rotated to obtain the significant actual meaning.

TABLE 6 Factor scoring coefficient matrix

	Component				
	1	*2*	*3*	*4*	*5*
X1	-0.098	0.495	-0.073	0.092	-0.081
X2	0.187	-0.011	-0.178	0.2	-0.12
X3	-0.002	0.104	-0.128	0.69	0.058
X4	0.205	-0.137	-0.049	0.11	0.121
X5	0.189	-0.095	-0.071	-0.192	-0.025
X6	-0.025	0.002	0.473	-0.143	0.082
X7	-0.081	0.086	-0.053	-0.095	0.627
X8	0.038	-0.158	0.066	0.202	0.539
X9	-0.014	0.099	-0.224	-0.21	0.031
X10	-0.063	0.301	0.279	-0.157	0.064

The factor matrix is rotated with orthogonal rotation method, the results obtained show that the first factor has a large load in X_1, X_2 and X_3, i.e. the influential factors represent these aspects; the second one has a relatively large load in X_4, X_5 and X_6; the third one has a large load in X_7, the fourth one has a large load in X_8 and X_9, the fourth factor has a large load in X_8 and X_9 and the fifth one has a relatively large load in X_{10}. The first factor represents the staff, the second one the influence of project construction machinery, facilities and materials, the third one the influence of construction site, the fourth factor the influence of environmental conditions, and the fifth factor the influence of geology selected for the project construction, so it is concluded that the variables represented by the factors are as shown in Table 5 below, consistent with the actual condition.

TABLE 5 Factor structure

Factor	Raw data	Variable
F_1	X_1	Staff physical condition: disease, emotion, attitude
	X_2	Staff skills: Proficiency, mastering degree of professional knowledge
	X_3	Staff knowledge: special and hazardous work, equipment safety, electrical power, open fire operation site, construction technology, protective goods, mastering and defect of protection technology.
F_2	X_4	Machinery: obsolete or problematic machinery,
	X_5	overloading operation, mixed operation of
	X_6	personnel and machinery. Facilities: setup, overloading operation Materials: transmission method, ordering degree of stacking, use of nonconforming materials, storage of special materials, use of members, accessories and factor prefabricated members.
F_3	X_7	Site: size of working face, whether work platform or not, arrangement of construction site, whether protective facilities or not, overhead operation or deep foundation pit operation, clearing of construction site.
F_4	X_8	Condition: special environment (oxygen deficit,
	X_9	toxic gas, smoke, noise, vibration), on-site lighting and obstacle influencing vision etc. Climate: severe natural environment
F_5	X_{10}	Geology: stratum, water quality, construction

(4) Calculate comprehensive score: carry out linear combination with raw indicator data, so as to get the weight of covariance contribution rate of each factor, the comprehensive evaluation of the linear combination of factor indicator is expressed as:

$F = \omega_1 F_1 + \omega_2 F_2 + \omega_3 F_3 + \cdots + \omega_m F_m$, in which ω_m represents the covariance contribution weight of the rotated factor.

The score of each factor can be calculated according to the formula $F = \omega_1 F_1 + \omega_2 F_2 + \omega_3 F_3 + \cdots + \omega_m F_m$.

$$\begin{cases} F_1 = -0.098X_1 + 0.187X_2 - 0.002X_3 + \cdots - 0.063X_{10} \\ F_2 = 0.495X_1 - 0.011X_2 + 0.104X_3 + \cdots + 0.301X_{10} \\ F_3 = -0.073X_1 - 0.178X_2 - 0.128X_3 + \cdots + 0.279X_{10} \\ F_4 = 0.092X_1 + 0.200X_2 - 0.690X_3 + \cdots - 0.157X_{10} \\ F_5 = -0.081X_1 - 0.120X_2 - 0.058X_3 + \cdots + 0.064X_{10} \end{cases}$$

Then SPSS is used to calculate the function scoring result based on the above matrix formula, and the scores of the 5 factors are converted into new variables, then the covariance contribution rate weight of each factor is calculated, and finally it is concluded that the comprehensive situation of the risk evaluation of project ball arena project construction is:

$$F = 0.179F_l + 0.230F_2 + 0.187F_3 + 0.078F_4 + O.067F_5 .$$

3.3 RESULT ANALYSIS OF RISK EVALUATION OF BASKETBALL ARENA PROJECT CONSTRUCTION

The comprehensive score of each factor can be obtained according to the covariance contribution rate of the rotated factor, so as to analyze the influence of the factors on the risk evaluation of basketball area project construction according to the score. The result shows that the second factor has the highest score, with coefficient 0.230, followed by the third factor 0.180, and then successively the first one 0.179, the fourth one 0.078 and the fifth one 0.067. As the second factor represents the machinery (obsolete or problematic machinery, overloading operation, mixed operation of personnel and machinery), facilities (setup, overloading operation) and materials (transmission method, ordering degree of stacking, use of nonconforming materials, storage of special materials, use of members, accessories and factory prefabricated units), which are the skeleton of basketball arena construction in actual application and play a vital important role for the project safety; the third factor site (size of working face, weather work platform or not, arrangement of construction site, whether protective facilities or not, overhead operation or deep foundation pit operation and clearing of construction site) also directly concerns the safety in project construction, while the objective factors such as geology and environmental condition have a small risk influence on the project construction.

Therefore, in the basketball area project construction, first, strictly control the quality and operation of machinery, equipment and raw materials, when supervising the project, relevant departments must detect the project strictly according to the national regulations and systems; second, the project construction personnel should have professional technical level and basic occupational moral

quality, prevent cheating in craftsmanship and materials and illegal operation. Finally, in the basketball area project construction, it is also required to pay attention to the selection of geological condition, and select the high-quality geographical environment as far as possible.

4 Conclusions

The factor analysis method has a simple principle, with relatively complicated calculation process. With the wide application of computer, using SAPP to process and analyze the step calculation process greatly reduces the work amount of data calculation and improves the accuracy, so factor analysis method had been gradually applied in various fields. It is possible to objectively analyze the safety of basketball arena project construction, discover the potential risks timely and overcome the adverse factors unfavorable for the project construction by using factor analysis method to comprehensively evaluate the basketball arena project construction risks, carrying standardization processing to the raw data and rotating the factor to get the comprehensive score of each factor, so as to promote the normal, healthy and continuous development of the basketball arena project construction. Besides, this evaluation and analysis method is to used data for statistical processing via computer, the influences of subjective factors are overcome in the process of evaluation and the result obtained is more objective, conforming to the actual project construction condition more. The application of factor analysis method researched in this paper in the risk evaluation of basketball arena project construction provides some new thoughts for other analysis methods in a certain extent, increasing the theoretical research basis for the factor analysis method and providing some reference values for the further research.

Short-term traffic flow forecast of highway network based on chaos time series method

Hao Zhang*

Department industrial engineering, Tsinghua University, Beijing, China, 100084

Received 1 August 2014, www.cmnt.lv

Abstract

With the construction of the highway network and the growing traffic flows, demand for real-time control and guiding service have become increasingly prominent. As for short-term forecast of highway network, it is not only the basis and foundation of the real-time control and guiding service for traffic flows, and the precise forecast result will have a magnificent impact on improving the traffic capacity and service levels. This paper builds a short-term traffic flows forecast model for highway network based on chaotic time series analysis and prediction theory. The forecast of the traffic flows in given areas can be calculated. Results show that this model is feasible and has a high accuracy.

Keywords: highway network, traffic flow, chaos theory, time series, prediction

1 Introduction

With the increasing completed highway network and traffic flow, the demand for real time control and guidance services of highway traffic flow becomes increasingly prominent. Short-term traffic flow forecast of highway network not only is the foundation and basis of real time control and guidance services of highway traffic flow, and the accuracy of prediction results is important to improve traffic capacity and level of service of highway network.

According to the traffic flow prediction for different purposes, the focus and requirements of the prediction are also different. On the one hand, for long-term traffic flow forecasting, the demand for prediction accuracy is not high. On the other hand, in order to make network traffic control scheme, especially to make traffic control and guidance service, the prediction period is greatly reduced. Known for short-term traffic flow forecast, it requires high precision. At present, short-term traffic flow forecast mainly serves for real-time control and guidance services for city traffic so it requires high real-time control. The maximum period of traffic control is 2.5-3min generally and traffic guidance is 5min. Thus, the period of short-term traffic flow forecast of city traffic is generally no more than 15min. However, with the development of highway network in China, traffic congestion is increasingly frequent and serious in the local highway. Therefore, the demand for real time control and guidance services of highway traffic flow is increasingly urgent. Due to the difference between the highway traffic flow characteristics and city road network, it is necessary to study short-term traffic flow forecast of regional highway network.

2 Choosing short-term traffic flow forecast method of highway network

Traffic flow forecast is to speculate the future traffic flow according to the present traffic flow data, namely to make real-time prediction of traffic flow for the next time $t+\Delta T$ and subsequent several times at the moment t. Usually, the traffic flow within 15min is called the short-term traffic flow, so to predict the traffic flow between t and $t+\Delta t$ which does not exceed 15min is short-term traffic flow forecast.

There are many prediction methods for short-term traffic flow forecast [1-3,5,7], but generally can be divided into two categories: one is based on traditional statistics methods, such as regression prediction, time series prediction, Kalman Filtering model and so on; the other category is the forecast method based on neural network, fuzzy mathematics and nonlinear theory, which does not pursue mathematical derivation strictly and clear physical meaning of the object but pay more attention to the fitting effect of the real traffic flow phenomena. Among the above prediction methods, historical mean method and regression method use least square estimation to compute parameters, which is a simple calculation but the uncertainty and nonlinear of the traffic flow are difficult to reflect and the influence of random factors are difficult to overcome; neural network forecasting method, including BP network, fuzzy neural network and the high order neural network trains parameters complicatedly and needs long computing time; Kalman Filtering method and nonlinear time series method are characterized as high real-time and accuracy. Due to the complex feature of highway traffic flow whose change process is nonlinear and uncertain, and it is difficult to find a mathematical model to reflect the traffic flow characteristics in practice, this paper adopts second category of forecasting methods,

* ***Corresponding author's*** e-mail: statistics.zhang@gmail.com

namely short-term traffic flow forecast of highway network based on chaos theory.

To predict short-term traffic flow of highway network based on chaos theory, it is primarily to distinguish whether the road network traffic flow system is a chaotic system. If it is a chaotic system, there can be short-term prediction, but not for long-term forecast; secondly, to determine the embedding dimension and time delay parameters and to find out the last known points in phase space, we need to use phase space reconstruction technique to make phase space reconstruction for traffic flow time series data; then we find out several adjacent points in the phase space and determine the predictive value of fitting function and separation in a known point as the center.

At present, there are many achievements of chaos theory to predict short-term traffic flow in domestic and foreign application [4,6,13,18], but most of these studies are used for traffic flow forecasting on a section in the city road network, while there needs further research for multiple sectional short-term traffic flow forecasting methods and models for highway network. The following will discuss the use of multidimensional chaotic time sequence to construct multiple sectional short-term traffic flow forecast model of highway network.

3 Short-term traffic flow forecast model of highway network based on chaos theory

3.1 BUILDING MULTIDIMENSIONAL CHAOTIC TIME SERIES PREDICTION MODEL

First, construction of multidimensional time series matrix.

Assumption (1): choosing traffic flow statistical data of M sections, corresponding M time series is obtained. X_i, i = l, 2, …, M.

Assumption (2): the length of each traffic flow time series sample is N. Thus, a multidimensional time series matrix as follows:

$$\begin{bmatrix} x_{1,1} & x_{1,2} & \cdots & x_{1,N} \\ x_{2,1} & x_{2,1} & \cdots & x_{2,N} \\ \vdots & \vdots & \cdots & \vdots \\ x_{N,1} & x_{N,1} & \cdots & x_{N,N} \end{bmatrix}. \tag{1}$$

Second, identification of chaotic time series. To make chaotic time series analysis of the traffic flow time series X_i respectively above, and select time delay σ_i and embedding dimension d_i to make phase space reconstruction, calculating Lyapunov index of each time series. If the index is greater than zero, it indicates that the time series is a chaotic time series, where the related theory and the method of chaotic time series can be used for analysis and modeling.

Third, reconstruction of multidimensional phase space. Based on the chaotic time series, according to multidimensional phase space reconstruction method proposed by Liangyue Caoetal (1998), the reconstruction of phase space is obtained:

$$\begin{aligned} V_n = (&x_{1,n}, x_{1,n-r_1}, ..., x_{1,n-(d_1-1)r_1}, \\ &x_{2,n}, x_{2,n-r_2}, ..., x_{1,n-(d_1-1)r_2}, \\ &..., \\ &x_{M,n}, x_{M,n-r_m}, ..., x_{M,n-(d_1-1)r_m}), \end{aligned} \tag{2}$$

$$n = \max_{1 \le i \le M}(d_i - 1)\tau_i + 1, \ldots, N, \tag{3}$$

Forth, construction of prediction model. According to the embedding theorem, there is a smooth mapping function in a D dimensional space like $F\left(d = \sum_{i=1}^{M} d_i\right)$: $R^{\mathrm{d}} \to R^{\mathrm{d}}$, If d or di is sufficiently large to make $V_{\mathrm{n+1}} = F(V_{\mathrm{n}})$, then the model can be described as:

$$V_{1,n+1} = F_1(V_{\mathrm{n}}), V_{2,n+1} = F_2(V_{\mathrm{n}}), \ldots, V_{M,n+1} = F_M(V_{\mathrm{n}}). \tag{4}$$

After establishing the prediction model, there comes out a phase space after reconstruction of multi-dimensional chaotic time series. According to the embedding theorems of chaos theory, there is a smooth mapping function F which can reflect the law of phase space, and the smooth mapping function F can establish a dynamic mathematical model to fit it to predict the motion trace of phase space, which can get the forecasting results of highway network traffic flow. After finishing the reconstruction of phase space through multidimensional time series, we adopt prediction methods like global method, local method and maximum Lyapunov exponent to establish the mathematical model to approximate the mapping function F. In this paper, we use the weighted zero order local forecasting method to make calculation, using V_n as the center point to predict V_{n+1}.

3.2 STEPS OF WEIGHTED ZERO ORDER LOCAL PREDICTION CALCULATION

Steps of weighted zero order local prediction calculation are as following based on reconstruction of phase space:

First, calculating K adjacent points $V_{n,j}^{\min}$, which is the minimum Euclidean distance with V_n in the phase space after reconstruction, the distance of each point are respectively R_j, j = l, 2, …, K, and let $R_{\min}$ be the minimum value. Thus, each adjacent point's weight can be defined as:

$$P_j = e^{-l(R_j - R_{\min})} / \sum_{j=1}^{K} e^{-l(R_j - R_{\min})}. \tag{5}$$

Secondly, V_{n+1} is calculated according to the following equation:

$$V_{n+1} = \sum_{j=1}^{K} P_j V_{n,j}^{\min} \ . \tag{6}$$

Lastly, according to:

$$\begin{aligned} V_{n+1} = (&x_{1,n+1}, x_{1,n+1-r_1}, \cdots, x_{1,n+1-(d_1-1)r_1}, \\ &x_{2,n+1}, x_{2,n+1-r_2}, \cdots, x_{1,n+1-(d_1-1)r_2}, \\ &\cdots, \\ &x_{M,n+1}, x_{M,n+1-r_m}, \cdots, x_{M,n+1-(d_1-1)r_m}), \end{aligned} \tag{7}$$

The V_{n+1} can be isolated from the final traffic flow prediction results as:

$$\left(x_{1,n+1}, x_{2,n+1}, ..., x_{M,n+1}\right). \tag{8}$$

There are two parts of the parameters in the above model. One part is the time σ_i and embedding dimension d_i of phase space reconstruction. The other part is the neighbor number K and the calculation of adjacent weight parameter l in the weighted zero order local forecasting method. In the theory of chaotic time series analysis, there are many ways to determine the time delay σ_i and embedding dimension d_i, such as the auto-correlation method, mutual information method and C-C method. Methods to determine the embedding dimension are G-P algorithm, the false neighbor method C -C method and Cao method. This paper use C-C method to determine the time delay and embedded dimension. The parameters K represents the number of neighboring points. Too few adjacent points leads to low prediction accuracy, while too many neighbor points is unnecessary because it may make the computational complexity increase and affect the prediction effect; the parameter l represents the weights of adjacent points, its weight is determined according to the proximity to the center point of the Euclidean distance in the forecast. In certain Euclidean distance, less l means greater proportion. In this paper use the particle swarm optimization algorithm to select the parameters of K and l, because the particle swarm algorithm is simple and effective and the solving process is easier.

4 Empirical studies

4.1 SOURCES OF DATA

In order to test the model and the method, the traffic flow data comes from Jinggangao Highway, Hurong Highway, Huyu Highway and Yinfu Highway Yuenan Station in the Hubei highway network from 00:00 in September 15 to 23:59 in September 15th, 2013. Through the correlation data pre-processing and completed analysis, the traffic flow of Section 1, Section 2,… Section 6 are sources of data. The flow curves are shown in Figure 1 to 3 (Section 1 for example). The time interval Δ_t is respectively 5 min, 10min and 15min. Then the prediction results and the measured results are compared based on established model, parameters optimization and prediction.

4.2 STEPS OF THE EMPIRICAL STUDIES

Firstly, to make pre-treatment of the selected section traffic flow data and make correlation analysis with the completed data.

Secondly, calculating the time delay embedding dimension and Lyapunov index of each time series using the C-C method shown in Table 1. The lyapnuvo index is positive shown in Table 1, which suggests that the 6 time series are all chaotic time series so we can use the chaos theory to analyze and predict.

TABLE 1 Result of parameters calculated under 6 time series and three intervals

5min	Section 1	Section 2	Section 3	Section 4	Section 5	Section 6
Time delay	1	1	2	2	1	2

Embedding dimension	1.75	2	3	3	5	3
Lyapnuvo	0.379	0.381	0.31	0.4836	0.4541	0.3756

4.3 COMPUTATIONAL PREDICTION AND ERROR

According to the time delay and embedding dimension, using the multi section model of chaotic prediction and the use of particle swarm optimization algorithm of K and optimization of l parameters, the calculation results of traffic flow of each cross section. The prediction results see Figures 1-3 (in Section 1 as an example), the solid

part is the prediction of traffic flow, the dashed part for the measured traffic flow, a unit for every 5 minutes, every 10 minutes and a bus every 15 minutes.

At different time intervals, each section of traffic flow forecast value and the actual value of average error, see Table 2.

TABLE 2 Different time intervals of the cross-section traffic predicted and actual values of average error table

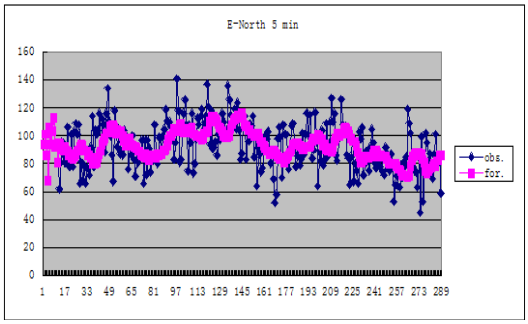

FIGURE 4 Under section 3 in 5min-interval actual and predicted traffic volume comparison chart

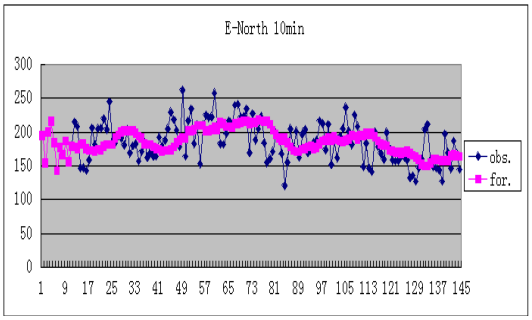

FIGURE 5 Under section 3 in 10 min-interval actual and predicted traffic volume comparison chart

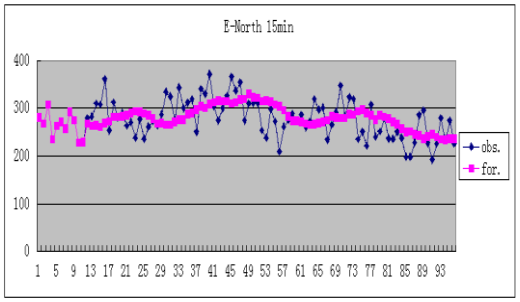

FIGURE 6 Under section 3 in 15 min-interval actual and predicted traffic volume comparison chart

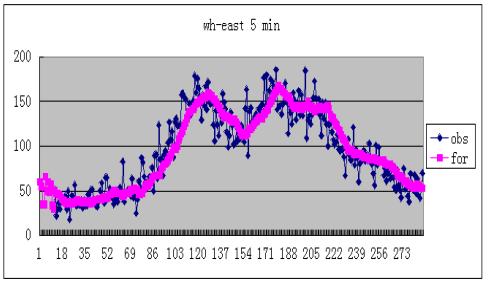

FIGURE 7 Under section 4 in 5min-interval actual and predicted traffic volume comparison chart

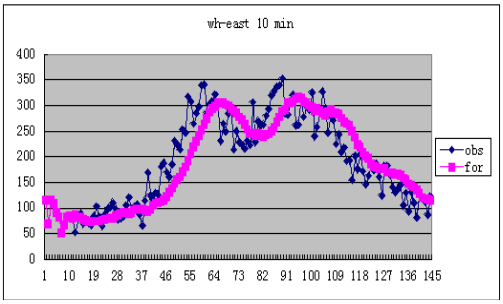

FIGURE 8 Under section 4 in 10 min-interval actual and predicted traffic volume comparison chart

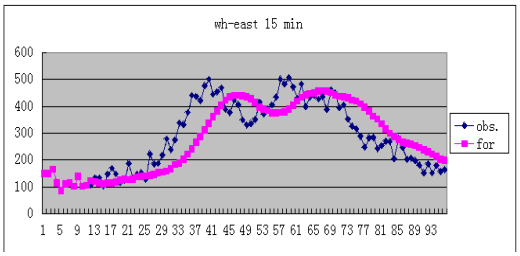

FIGURE 9 Under section 4 in 15 min-interval actual and predicted traffic volume comparison chart

5 Conclusions

Compared the actual and predicted values of traffic flow in section 1 and section3, it shows that the average prediction error tends to decrease with the increasing time intervals. Meanwhile, compared with chaotic time series prediction values in a separate and single section, the prediction accuracy of multiple-sections forecasting method is higher than single-section forecasting methods. Overall, the multiple-sections traffic flow forecasting method in road network based on multi-dimensional chaotic time series prediction is feasible, and the predictive effect is better than of the single-section chaotic time series prediction method. On the contrary to the short-term traffic flow forecasting in urban road network, see Figure 7, Figure 8 and Figure 9 in Section4 located at the intersection of the urban road network and the highway network, if the time intervals relatively increase in short-term traffic flow prediction of highway network, its predictive effect would be better.

Optimization of industrial structure configuration based on fruit fly optimization algorithm

Sujiao Liu*

School of Philosophy and Public Administration, Henan University, Kaifeng, Henan, 475000, China

Received 1October 2014, www.cmnt.lv

Abstract

Establishing the mathematical optimization model of Shangqiu's agricultural structure from three aspects - economy, ecology and society, the agricultural industry structure in Shangqiu is regarded as the research object, utilizing fruit fly optimization algorithm to solve the mathematical model. Simulation results show that fruit fly optimization algorithm can solve the optimal solution for Shangqiu's agricultural industry structure to achieve the maximum benefits, thus providing the decision-making basis for adjustment and development of Shangqiu's agricultural structure.

Keywords: fruit fly optimization algorithm, industrial structure, optimization model, population size, iterations

1 Introduction

Shangqiu has a large population, little land, fragile ecological environment, farmers with low cultural quality, poor economy and improper industry positioning which lead to the unfavorable development of poverty reduction in the region. There are a large proportion of absolute poor population in Shangqiu, and backward is still the reality of this region. Based on 2012-2020 poverty reduction program of Henan Province, Shangqiu, for example, will build mathematical model for the agricultural structure in the region from aspects of economy, ecology and society, utilize fruit fly optimization algorithm for multi-objective optimization solution and achieve the optimal allocation in Shangqiu's agricultural structure, thereby providing decision-making basis for the development of agricultural industry structure in Shangqiu area [1-7].

2 Fruit fly optimization algorithm

2.1 OVERVIEW OF FRUIT FLY OPTIMIZATION ALGORITHM

Fruit fly optimization algorithm is a new group intelligence algorithm proposed by Pan Chao [8] in 2011. Fruit flies can detect food source on the air through their olfactory and visual superiority, and after detecting the food, they use acute vision to locate food and companions, and fly toward the food. The method is to deduce a new way to realize global optimization based on the foraging behavior of Fruit flies. Fruit fly optimization process is shown in Figure 1.

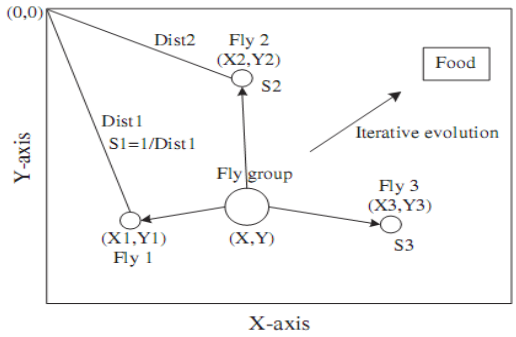

FIGURE 1 Optimization roadmap of fruit fly group

2.2 STEPS OF FRUIT FLY OPTIMIZATION ALGORITHM

Fruit fly optimization algorithms can be divided into seven steps as follows.

1) In Figure 1, the position initialization result of fruit fly group is $Init\ X\_axis$ and $Init\ Y\_axis$.

2) After setting the search direction RV_x and RV_y, random search distance of single fruit fly can be obtained by the following Equation:

$$Yi = Init\ Y\_axis + RV_y . \quad (1)$$

3) The distance from the origin to the current position of fruit fly is estimated a $Xi = Init\ X\_axis + RV_x$ a $Disti$, and the smell concentration is estimated according to Equation (2), which is equal to the reciprocal of the distance.

* ***Corresponding author's*** e-mail: kfliusujiao@126.com

$$Disti = \sqrt{Xi^2 + Yi^2}$$
$$Si = 1/Disti \quad (2)$$

4) The result of Equation (2) is substituted into Equation (3), the determination function of smell concentration, thus calculating the smell concentration value corresponding to the current position of individual fly.

$$Smelli = Function(Si) . \quad (3)$$

5) Best smell concentration of fruit fly group can be obtained by the following Equation

$$[bestSmell\ bestIndex] = \max(Smelli) . \quad (4)$$

6) Best smell concentration of fly group and the corresponding *x* and *y* coordinates are retained, and the fly group flies toward the food source through visual positioning.

$$Smellbest = bestSmell$$
$$X\_axis = X(bestIndex) \quad (5)$$
$$Y\_axis = Y(bestIndex)$$

7) Steps from 2) to 5) are repeated, and the smell concentration is judged. If a better smell concentration is obtained, go to Step 6); otherwise, iterative optimization will be executed.

3 Modeling

3.1 BOUNDARY DETERMINATION

The agricultural industry structure in Shangqiu is selected as the study object with 2012 as the planning year, and the study mainly focuses on the relationship between agriculture, forestry, animal husbandry and fishery, thus conducting the simultaneous layout optimization on the internal structure of crop farming and animal husbandry and achieving coordinated and sustainable development of different industries. Due to complex industrial structure in the region, different industries cannot be studied through a careful division, so a lot of data in the model are replaced by the average values [9,10].

3.2 DECISION VARIABLES

The planting area of selected major crops and cash crops in Shangqiu is X_{1j} (Ten thousand hm2), where rice X_{11}, wheat X_{12}, corn X_{13}, soybeans X_{14}, millet X_{15}, sorghum X_{16}, potato X_{11}, oil plant X_{18}, beet X_{19}, flax X_{110}, tobacco X_{111}, vegetable X_{112}, melon and fruit X_{113}, forage grass X_{114} and forage crop X_{115}. Forage grass and forage crop are regarded as a study entirety. In animal husbandry, the decision variable X_{2j} includes five variables: beef X_{21}, dairy cattle X_{22}, pig X_{23}, sheep X_{24} and poultry X_{25}. Forestry and aquaculture industry are regarded as a study entirety, where woodland area is X_3 (Ten thousand hm2) and the total aquaculture area is X_4 (Ten thousand hm2).

3.3 OBJECTIVE FUNCTION

Objective function $E(x)$ indicates the sum net income of various industries. And in crop farming, net income is the product of net output per unit area and total acreages; the expression of net income in animal husbandry can be obtained through the method of best square approximation [11-13]. The relationship between net income and feeding amount can be expressed by the linear weighted sum of logarithmic function $y = a\ln(1+bx)$ and logistic curve $y = \frac{a^*}{1+b^*e^{-cx}}$, where x indicates the feeding amount, and y indicates the net income; net incomes of forestry and aquaculture farming are similar to that of crop farming, which can be approximated as a linear function. Therefore, the objective function can be expressed as follows.

$$\begin{aligned}\max\ E(x) &= 5547.8X_{11} + 1505X_{12} + 1622X_{13} + 2359X_{14} + 1287.2X_{15} + \\ &1248.4X_{16} + 1197.7X_{17} + 1220X_{18} + 1116.3X_{19} + 4078.8X_{110} + 3173.7X_{111} + \\ &8464.8X_{112} + 18176X_{113} + 2665X_{114} + 1472X_{115} + \frac{442850}{1+65.4e^{-0.0121X_{21}}} \times 0.63 + \\ &572404\ln(1+0.0017X_{21}) \times 0.37 + \frac{588940}{1+162.2e^{-0.077X_{22}}} \times 0.61 + 6829556\ln(1+0.0006X_{22}) \times 0.39 \\ &+ \frac{269450}{1+78.9e^{-0.0049X_{23}}} \times 0.89 + 3601713\ln(1+0.0002X_{23}) \times 0.11 + \frac{82100}{1+19.6e^{-0.0071X_{24}}} \times 0.81 + 99598\ln(1+0.0007X_{24}) \times 0.19 \\ &+ \frac{473800}{1+17.6e^{-0.0004X_{25}}} \times 0.92 + 1564320\ln(1+0.000019X_{25}) \times 0.08 + 67X_3 + 4152X_4\end{aligned} \quad . (6)$$

Due to the fundamental status of soil in agricultural production, soil nutrient and moisture have direct impact on crop growth, animal husbandry development and the expansion of aquaculture area, so the content of organic

matter in soil is regarded as an important decision variable. In this research, the difference $\delta(x)$ between the current content and balance content of organic matter in the soil is an important indicator of soil fertility, while influencing factors including the status of soil, water conservation and vegetation cover are regarded as constraints. The organic matter content in the soil is predicted and evaluated through Jenny mathematical model, wherein the topsoil depth is 0.2mm [14-16].

$$\min\ \delta(x)=0.04-\frac{1}{0.0564\times 225\times(\sum_{j=1}^{15}X_{1j}+X_3)}([0.6\times(2.25(X_{21}+X_{22})+1.5X_{23}+0.52X_{24}+0.015X_{25})+3908.8\times 0.108\times 0.5]\times 0.512+[0.3\times(9X_{11}+4.19X_{12}+11.14X_{13}+2.36X_{14}+3.08X_{15}+8.24X_{16})+2.175X_{11}+0.838X_{12}+0.502X_{13}+0.41X_{14}+0.533X_{15}+0.412X_{16}]\times 0.203)\times(1-e^{-0.0564\times 6})-0.0317e^{-0.0564\times 6} \quad (7)$$

$$\min\ D_\delta(x)=([3200-0.9\times(7.5X_{11}+2.99X_{12}+5.57X_{13}+2.05X_{15}+4.12X_{16})+650-0.9\times 2.05X_{14}]+1800-30.38X_{112})\times 0.72+[450-(0.198X_{21}+0.089X_{23}+0.015X_{24}+0.0019X_{25})+1250-3.8X_{22}+160-0.0044X_{25}+75-0.98X_4]\times 0.28 \quad (8)$$

3.4 CONSTRAINTS

1) Natural resource constraints. The constraint of total available land area:

$$\sum_{j=1}^{15}X_{1j}+X_3+X_4\le 3758.7. \quad (9)$$

The constraint of arable land resource:

$$\sum_{j=1}^{15}X_{1j}\le 1180. \quad (10)$$

2) Acreage constraint. Aquaculture area constraint:

$$X_4\ge 40. \quad (11)$$

Economic crop acreage constraint:

$$\sum_{j=1}^{13}X_{1j}\ge 220. \quad (12)$$

Forage crop acreage constraint:

$$X_{114}+X_{115}\ge 30. \quad (13)$$

3) Ecological constraint. Constraint of organic fertilizer amount: the total amount of required fertilizer for various crops and waste fertilizer should not exceed the amount of provided fertilizer.

$$4.875X_{11}+2.792X_{12}+4.137X_{13}+1.822X_{14}+1.936X_{15}+2.725X_{16}+1.439X_{17}+3.12\sum_{j=1}^{15}X_{1j}+8.274X_{112}+2.17X_{113}+1.19X_3\le 2.25(X_{21}+X_{22})+1.5X_{23}+0.52X_{24}+0.015X_{25}+3908.8\times 0.108+9X_{11}+4.19X_{12}+11.14X_{13}+2.26X_{14}+3.08X_{15}+8.24X_{16}+2.175X_{11}+0.838X_{12}+0.502X_{13}+0.41X_{14}+0.533X_{15}+0.412X_{16}. \quad (14)$$

Green coverage constraint:

$$X_3\ge 0.42\times 4546. \quad (15)$$

4) Demand constraint. Grain output constraint:

$$7.50X_{11}+2.99X_{12}+5.57X_{13}+2.05X_{14}+2.05X_{15}+4.12X_{16}\ge 300036. \quad (16)$$

Meat output constraint:

$$0.198X_{21}+0.089X_{23}+0.015X_{24}+0.0063X_{25}\ge 400. \quad (17)$$

Vegetable output constraint:

$$30.38X_{112}\ge 1200. \quad (18)$$

Constraint of required roughage for the development of animal husbandry:

$$(9X_{11}+4.19X_{12}+11.14X_{13}+2.26X_{14}+3.08X_{15}+8.24X_{16})\times 0.23+4.12X_{114}+600\times 1.41\ge 1.51X_{21}+3.42X_{22}+0.054X_{24}. \quad (19)$$

Constraint of concentrated feed demand:

$$(0.128X_{21}+1.065X_{22}+0.19X_{23}+0.022X_{24}+0.015X_{25}+0.432X_4)\times 0.5\le 0.1\times(7.50X_{11}+2.99X_{12}+2.05X_{14}+2.05X_{15}+4.12X_{16}+3.19X_{17})+0.4\times 5.57X_{13}+4.54X_{115}. \quad (20)$$

Minimum quantity of dairy cattle:

$$X_{22}\ge 260. \quad (21)$$

Non-negative constraint of decision variables:

$$X_{ij}\ge 0\ \ (i=1,2,3,4). \quad (22)$$

4 Solutions for these problems

MATLAB software is utilized as research platform for solving the simulation model of agricultural structure in Shangqiu, China, with the results shown in Table 1, Figure 2, Figure 3 and Figure 4.

5 Conclusions

In this research, based on the coordinating research in three aspects – economy, ecology and society, multi-objective optimization model of agricultural industry structure in Shangqiu is established, and fruit fly optimization algorithm is utilized for solving the multi-objective optimization model, thus optimizing the objective functions in different degrees; meanwhile, multi-index evaluation is carried out on the optimization results, which greatly enhances and improves the coordinated and sustainable development of Shangqiu's agricultural industry structure through fruit fly optimization algorithm.

Researches on industrial structure allocation through fruit fly optimization algorithm have important theoretical and practical significance on agricultural structure adjustment and allocation in Shangqiu, China. And some competitive industries can be developed based on the optimization results, such as increasing the acreage of rice and soybean; economic and forage crops should be mainly developed on the basis of ensuring food security; livestock and dairy products, returning rate of organic fertilizer and soil fertility should be enhanced; besides, local government needs to vigorously develop green food and explore potentials in agricultural industry.

Investigation of the strategic alignment in public sector organisations using knowledge based strategy

Shuwen Ma*

Hangzhou College of Commerce, Zhejiang Gongshang University, 310012, Hangzhou, China

Received 1 May 2014, www.cmnt.lv

Abstract

Ageing workforce is one of the critical challenges a public sector organisation is facing and will face more terribly. The cost of knowledge loss can have huge impact on the bottom line of business. A major issue facing Public Sector Organisations (PSOs) in recent times has been the increasing pressure to demonstrate value from investments in Information Technology (IT). One omnipresent but often overlooked solution is Strategic Alignment (SA) between corporate business objectives and IT initiatives as achieving SA remains one of the more enduring challenges for organisations. Moreover, deriving value from IT investments through SA requires both IT and business executives to foster synergies between their respective areas, which contributes to increased organisational performance. Conversely, business-IT misalignment may eventually lead to failure in achieving business goals. Shared Domain Knowledge (SDK) is a key factor within the social dimension of SA and is concerned with the level of knowledge business and IT have of each other's to each other's missions, objectives, and plans. This paper presents findings from a study which investigated the influence of SDK on SA within organisations in the Australian public sector. The developed research model examined SDK between business and IT professionals as a factor that would potentially influence SA. The findings suggest that increased levels of SDK between professionals from the business and IT domains leads to more efficient SA in PSOs.

Keywords: shared domain knowledge, strategic alignment, public sector, organisational performance

1 Introduction

Ageing workforce is one of the critical challenges a public sector organisation is facing and will face more terribly. The speculation of the mass retirement of the baby boomers generation will leave an organisation with a big challenge of retaining knowledge of experience employees, storing this knowledge and transferring knowledge to the new or existing employees in understandable manner. The cost of knowledge loss can have huge impact on the bottom line of business. A major issue facing public sector organisations (PSOs) is the increasing pressure to demonstrate the value for business from Information Technology (IT) investment which has been more often than not intangible. In order to reap the full benefits of IT, decision-makers are encouraged to integrate IT missions, objectives, and plans into various aspects of business functions within the organisation [1]. In an attempt to boost operational efficiency, organisations have been making continuous efforts to take advantage of IT investments to improve business performance and customer service [2]. Improving the communications, shared domain knowledge, relationship between business and IT executives have been proposed to meet the challenges of value realisation and obtaining maximum benefit from IT investments [3].

A strategic alignment (SA) between business and IT has been long sought by public and private sector organisations for many years [4]. Not only it is hard to achieve, but this type of alignment is also hard to maintain [5]. SA refers to the "congruence between an organisation's business and IS/IT strategies" [6] and is found to have a direct impact on firm performance because of its role as a mediator between IT investments and business objectives [7]. Not only that, but SA is also found to positively influence the effectiveness of IT and contributes to maximising business profits [8]. On the other hand, failure to leverage existing IT investments (i.e., not simply just investing more in IT) is expected to get in the way of organisations performance and viability [9].

Some of the issues that obstruct achieving the social dimension revolve around shared domain knowledge (SDK) between the business and IT domains [10] as SDK is major contributor to the successful creation and execution of strategic plans [11,12]. Consequently, IT managers need to have knowledge about business goals and objectives prior to developing IT strategic plans. For example, it has been observed that CIO's with good business knowledge enjoy greater participation in top management decision-ma king [13], whereas the lack of such knowledge hinders the organisation's ability to employ IT strategically and thus stands in the way of SA [14]. Business executives also need to be aware of IT initiatives so that they are able to objectively make investment decisions, which enables a more realistic expectations of the organisation's IT capabilities [14]. Therefore, exploring effective ways for achieving and sustaining SA in PSOs through SDK remains a challenge requiring more research to address what is still conside-

* ***Corresponding author's*** e-mail: 1622913173@qq.com

red a major concern for executives [15]. While many relevant factors are important in achieving high levels of SA, the focus of the study reported here is solely on understanding the influence of shared domain knowledge on strategic alignment.

2 Related works

Given the emphasis in today's environment on customer focus, stake holder interests, public sector organisational performance and other methods of assessment are employed to address issues in the new public management and prevailing managerialism in measurement of public sector organisations around the world. Therefore, many public sector organisations have been encouraged to implement benchmarking as one way of satisfying the government's requirement that public organisations provide best value services. SA between business and IT is usually described in terms of strategy (i.e., business strategy, IT strategy). In literature, business strategy is considered the driver of an organisation through a set of actions and decision -ma king relating to long-term direction and the scope of activities, addressing changes in the environment to gain advantage over competitors, and building on resources to meet stakeholders' expectations [16,17]. Within the same context, IT strategy often refers to the identification of innovative solutions that provide a competitive edge for businesses and optimise the return of investments [18]. A well-crafted IT strategy is expected to be based on a clear business strategy, and covers technology, information systems, and governance [19].

There are a number of different definitions of SA that describe how business and IT should be integrated, coherent and in sync. SA is defined as "the continuous process, involving management and design subprocesses, of consciously and coherently inter relating all components of the business-IT relationship in order to contribute to the organisation's performance over time." [20] It is no longer considered as an end-state, but rather a continuous and dynamic process that evolves into a relationship between IT and business functions and requires to be actively maintained [21,22]. Further, SA is not an isolated management action as "…no single activity will enable a firm to attain and sustain alignment." [23], but rather a "…continuous and dynamic synchronization of the capabilities inherent in the information infrastructure and the demands of strategy" [24]. SA can be seen as "… applying IT in an appropriate and timely way, in harmony with business strategies, goals and needs…" [25]. In a public sector context, SA is expressed as "the degree to which the IT goals support the strategic goals of a public agency, and to which administration and IT stakeholders are committed to support these goals." [26]

The motivation for SA emerged from a focus on strategic business planning and long-term IT decision-ma king. SA is a major concern for business executives and is ranked among the most important issues faced by IT managers [27]. The most proclaimed advantage in which SA can be beneficial to organisations is the capability to achieve a more focused and strategic use of IT resources leading to improved business and organisational performance [28]. Financial benefits are no longer the only factor used to measure the value added by IT investments. Instead, business executives are now considering non-financial benefits (e.g., the ability to react to new possibilities) as an indication of sound IT investments [29]. Although, the importance of SA has been widely recognised and well documented, many organisations today are still misaligned and this has led to undesirable outcomes including dissatisfied stakeholders, cancelled or failed projects, amplified costs of IT, and systems that do not meet the needs of the business [30]. Thus, the effect of misalignment between business and IT is expected to lead to degraded business performance [31].

A wide range of factors/dimensions that influence SA exist in literature, such as structural, strategic/intellectual, social, and cultural. Although more attention is given to the strategic/intellectual and structural dimensions, SA is also contingent on many of the social and cultural aspects of an organisation [32]. The social dimension is defined as "the state in which business and IT executives within an organisational unit understand and are committed to the business and IT mission, objectives and plans" [33]. The main social dimension factors that have the potential to influence SA are: connections between business and IT planning, communication between business and IT executives, previous imp le mentation of IT plans/projects, Shared Domain Knowledge (SDK), and external influences [11].

SDK is defined as "the knowledge that the IT manager possesses about the business process, the knowledge that the business manager possesses about the potential opportunities to apply IT to improve business process, and the common understanding between the IT and the line manager regarding how IT can be used to improve business process performance." [34] Consequently, two dimensions of SDK have been identified, namely: IT managers' knowledge of business and business executives' knowledge of IT [12].

SDK improves communication [35], increases innovation [36], and enhances IT performance and the use of IT resources [11]. The business and IT executives' knowledge of IT and business strategy results in developing a shared perception and vision [37], and achieves better linkages between objectives and actions [11]. In contrast, business managers' lack of IT knowledge hinders SA [38].

Emerging from the literature thus far, previous research focused on SA as an outcome of integration between business and IT [39], while others have concentrated on the relationship between SA and IT performance [40], or between SDK and IT performance [41]. However, an empirical investigation of the relationship between SDK and SA in PSOs has not been conducted. This paper endeavours to address this limitation by

investigating the influence of SDK on SA within the Australian public sector.

3 The proposed method

Presents, from a systemic perspective, an examination and discussion of performance measurement, performance indicators and associated improvement initiatives, as typically applied in public sector organisations. Such mechanisms are usually implemented as a causal loop which is established between perceived performance and resulting actions, thereby constituting a form of feedback control. Within this context a two dimensional matrix model is postulated in which the independent dimensions are the source of control and the nature of the resultant control action. As PSOs are large consumers of information technology [42], this paper aims at exploring the potential influence of SDK on SA within these organisations. The research methodology, which is exploratory in nature, draws on a survey of business and IT/IS professionals. This paper utilised key informants from the Australian public sector to provide information about PSOs' level of IT and business knowledge, and SA levels. Officers with at least 3-5 years of experience in IT or business and public administration were chosen as key informants. The selection of experienced officers reduces the number of informants required as they tend to be a more reliable source of information; however, this approach provides the potential for common method bias [43]. In addition, this paper endeavoured to control other external and IT characteristic factors which may influence SDK or SA by collecting data from organisations within the same environment/industry. As well as choosing a sample from organisations where IT was regarded of high strategic value, as measured by IT budget and the appointment of a dedicated CIO or senior IT executive.

3.1 RESEARCH MODEL

The model presented below illustrates the conceptual hypotheses and hierarchical relationships of three constructs examined in this paper (i.e., Business objectives knowledge, IT processes knowledge, and SA). The theoretical model depicts the relationships that this paper aims to investigate (i.e., SDK association with SA). The lines connecting constructs symbolise the hypotheses that will be statistically tested. Each of the constructs correlated to items on the data collection instrument (i.e., questionnaire). The model has been designed to examine two hypotheses; business objectives knowledge correlates with the SA (H1), IT processes knowledge correlates with the SA (H2).

3.2 HYPOTHESIS DEVELOPMENT

The available literature contains definitions and measurable indicators (or variables) of the constructs but the operation allocation of these indicators was not specific to the SDK-SA relationship examined in this paper. Rather than adopt these broader indicators, this study used field-driven measures based on existing theory. In total, 22 items were used to measure three constructs. The measurable indicators of each research construct are discussed below.

The first construct, business objectives knowledge, was conceptualised as the aggregate of two variables: experience in public administration (V1) and familiarity with business objectives within the surveyed organisation (V2). Both variables were perceived as important to the ability to participate in strategic decisions within PSOs. A prerequisite of 3-5 years of experience was established for the first variable (V1), whereas the second variable (V2) was assessed on a five point Likert-type scale. The second construct, IT processes knowledge, was operationalised using two variables: experience in IT governance (V3) and familiarity with IT processes within the surveyed organisation (V4). Potentially, both of these variables would lead to identifying opportunities for utilising IT to support business goals. A prerequisite of 3-5 years of experience in IT governance was established for the first variable (V3), whereas the second variable (V4) was assessed on a five point Likert-type scale. As two variables (i.e., V1 and V3) were established prior to data collection and therefore did not require measuring, only two variables (i.e., V2 and V4) were measured using the data collecting instrument to indicate the level of business objectives and IT processes knowledge of each respondent. The third construct, strategic alignment, has been frequently measured using financial and perceptual indicators in previous research (e.g., Kearns and Sabherwal [12]; Reich and Benbasat [35]; and Winkler [26]). Perceptual indicators were selected for this study through utilising high-level processes from the COBIT 5 frame work due to its worldwide application (e.g., private and public industries, governments, accounting and audit firms) as a reliable source for assessing IT governance and business/IT alignment [44]. The latest version, COBIT 5, divides the governance of IT into five domains: Evaluate, Direct and Monitor (EDM) ; Align, Plan and Organise (APO); Build, Acquire and Implement (BAI); Deliver, Service and Support (DSS); and Monitor, Evaluate and Assess (MEA), which are broken into 37 high-level processes [45]. As a result, and judging by the nature of each of the COBIT 5 domains, the EDM (V5-V9) and APO (V10-V22) do ma ins were used as measurable indicators of strategic alignment.

3.3 DATA SETS

Data were drawn from a cross-sectional field study from the public sector population. A pilot test of the questionnaire was administered to five thought leaders from the Queensland public sector with at least ten years experience in the field. Based on their feedback, no further amendments were required to the developed instrument. The survey included participants drawn from

three different representative groups to limit any sample frame bias. Moreover, to reduce the possibility of single-source bias that might result from exaggeration or self-pro motion and to encourage participation, the respondents were assured that the results would be completely anonymous and that they would receive a summary of the study findings.

From a total of 112 invitations, 56 usable responses were available which provided an unadjusted response rate of 50%. Analysis of nonresponse bias was performed by comparing early and late responses [46]. Early respondents are those who respond to the initial email, while late respondents are those who respond only after a reminder is sent. T-tests of the mean differences for each of the constructs and number of respondents failed to demonstrate any significant differences ($p<0.05$, two-tailed), suggesting that nonresponse bias was not an issue in this study.

4 Experiments

Specific statistical approaches were used to assess the model and establish the results. The primary method of assessing the correlation between the knowledge areas was Spearman's Rank Correlation Coefficient. The tables below (see Tables 1-2) detail some descriptive statistics that characterise the data collected. Analysis of descriptive statistics was undertaken to search for possible affects or bias resulting from certain patterns in the sample data. The results of the descriptive statistics for constructs are displayed in Table 2 and show no sign of misrepresentation as all responses seem to follow an approximately normal distribution (i.e. all data-points fall within two standard deviations).

TABLE 1 Role distribution

Role	Count
Executive/Manager	26
Junior/Operational	30
Total	56

TABLE 2 Descriptive statistics

Construct	Total	Average	StdDev
Business objective knowledge	222	4	0.94
IT Processes knowledge	216	4	0.92
Strategic alignment	177	5	1.3

For internal consistency analyses of the Likert-type scales, Cronbach's Alpha reliability coefficient was used as it relates to the measurement of the internal consistency and homogeneity of items in a scale [47]. The results were significant for all items in the questionnaire at Cronbach's alpha >0.7. Construct validity was measured using the Kaiser Meyer Olkin (KMO) and Barlett tests. The KMO test assesses the adequacy of the sample magnitude for factor analysis, while the Barlett test is used to determine whether the data come from multivariate and normal distribution. The KMO's value ranges between 0 to 1 and is expected to be over 0.60 while 0.80-0.90 is considered a very good range [48]. For this study, the KMO value was 0.89 indicating sampling adequacy, and the Bartlett's test result was significant at 1256.7 ($P<0.05$). Other forms of data validation (i.e., confirmatory factor analysis) for convergent and divergent validity could not be performed on such low sample size as the minimum sample recommended for conducting such analysis should be at least 100 [49]. Descriptive statistics for variables (V5–V22) is expressed.

Variable correlation was conducted using the Spearman's rank correlation coefficient, which is a non-parametric correlation suited for small sample sizes where a normal distribution is difficult to be assumed [48]. The Spearman's Rank Correlations values vary from -1 to 1, where a high positive value denotes a stronger relationship between the variables and vice versa. Based on the p-value no null hypotheses can be rejected, therefore no results are significant. Hypothesis one has moderately a stronger positive correlation based on the Spearman's rank ($R=0.21$) whereas hypothesis two has a weaker positive correlation ($R=0.19$).

Despite the low significance of results an attempt will be made to draw implications of the relationship between SDK and SA from the Spearman's rank correlation. The results indicate that the relationship between SDK and SA is not as clearly defined as previous research indicated. Although the initial expectation was that there is a strong direct relation between SDK and SA in PSOs, the results suggest that the level of SA may depend on other factors as well, perhaps more than SDK. For instance, knowledge of IT Governance was found to improve the perceived level of SA.

Looking back at the theoretical frame work, results of the construct measurements (i.e., business objectives knowledge, IT processes knowledge, and SA) suggest that mutual understanding between the business and IT domains may create imp roved SA as both correlations of SDK (i.e., business objectives knowledge and IT processes knowledge) were relatively positive.

Based on the number of items where the average score was greater than the mean score, we note that participants with senior roles placed higher emphasis on stakeholder management, while operational areas (e.g., security) were perceived less important. Similarly, participants with junior roles perceived risk management as more important than benefits delivery and managing innovation. This supports the assumption that junior roles have a great understanding of the use of IT processes and risk management in PSOs while executives have a better understanding of enabling business objectives to meet stakeholders' needs.

FIGURE 1 SDK and SA breakdown based on role

Furthermore, the business objectives knowledge rating for senior and executive participants was higher than their rating of IT processes knowledge as illustrated in Figure 1. In contrast, IT processes knowledge rating for junior participants was higher than their rating of business objectives knowledge.

Moreover, IT knowledgeable business executives and business savvy operational/IT staff are expected to optimise SA in PSOs. Presumably, regular communication is intended to bridge this identified knowledge gap between executives and operational staff. The results also demonstrated that the rating of SDK has a positive relation with the rating of SA. For instance, the SDK rating for junior staff was higher than the one for executives, and as a result, the SA rating for junior staff was also higher. Thus, staff at all levels should invest in identifying capabilities for business and IT to interconnect, which consequently improves SDK and SA. Academics on the other hand are urged to extend the understanding of SDK by testing the individual constructs identified in this paper using a larger sample sizes to refine the exploratory results; explore the applicability of results on non-public sector organisations; and explore alternative measurable indicators/variables for SA and SDK.

5 Conclusions

This research contributes to an overall conceptual understanding of SDK as a factor fo r build ing organisational and Information Systems performance. SDK is concerned with reaching a state by which IT managers grow into business savvies and business executives develop IT governance/processes knowledge. As PSOs are forced to operate in an environment where demands grow and resources are reduced, improving business-IT synergies through SDK becomes critical. Based on the results, it appears as though, achieving high levels of SDK within PSOs result in optimising SA between business – IT. Consequently, in order to improve SA, IT and business staff at different levels should have adequate knowledge about business objectives and IT processes. In order to create an environment for SDK to develop, actions such as physically moving IT staff into business units, planning shared workshops and brainstorming sessions, and sending IT staff on regular visits to frontline offices may be required. Other methods may include rotating business managers through IT roles to reinforce the message that IT is an integral part of the business. In line with previous research [e.g.,50] external factors (e.g., IT processes/governance) have less effect on SA than internal factors (e.g., business objectives/governance). Thus, a possible direction for this research stream is to evaluate if SDK is only necessary for internal evaluations. Research points to the conclusion that SA is contingent on the existence of SDK between the business and IT domains. Improving SDK within PSOs like any other core competency takes time to develop, therefore; IT managers and business executives need a clear roadmap to build and maintain these capabilities.

This study suggests several implications for future research. First, this paper supports the critical role of SA in deriving value from IT investments and highlights the mediating role of SDK in PSOs. Future research could examine if SDK indirectly improves other aspects of IT. Second, future studies could include a more comprehensive conceptualisation and operationalisation of SA that better reflects its multi-dimensional nature. It is suggested that further research investigate whether the results are reproduced using other methods and in other contexts and industries. Moreover, it is important to study other factors (e.g., changing political environments) that might facilitate or inhibit SDK and subsequently influence SA.

Received 1 May 2014, www.cmnt.lv

Abstract

The feature and various index properties of E-commerce website are considered as a whole by applying the expert grading method, with the construction of the multi-index hierarchical structure of an E-commerce website competitiveness index evaluation and the establishment of an E-commerce website competiveness index evaluation index system. The competiveness level of the website is quantified after calculating the competiveness index of the E-commerce website. On this basis, this work adopted Radial Basis Function (RBF) neural network algorithm to perform evaluation research on the competiveness index of E-commerce website. Aiming at the problems exist in the evaluation research, this work tried to use Fruit Fly Optimization Algorithm (FOA) to perform improvement on the RBF neural network algorithm. Through the simulation and comparison of practical examples, FOA-RBF algorithm is obviously better than RBF neural network algorithm when the E-commerce website competiveness index is calculated and evaluated, thus the validity and reliability of calculating method presented in this work are verified.

Keywords: e-commerce, neural network, radial basis function, fruit fly optimization algorithm, expert grading method

1 Introduction

In recent years E-commerce has obtained fast development, and competition is also becoming increasingly fierce. For E-commerce website, its own competitive power is sufficiently evaluated and understood, which is favourable to strengthen website construction and improve the quality of the website; the premise for enterprises to improve competiveness level and obtain competitive advantage; a problem [1] which needs to be solved urgently.

2 Evaluation research on the competitiveness index of E-commerce website

2.1 TYPES OF E-COMMERCE WEBSITE

The E-commerce website can be divided into different types [2] by different classification methods.

1) Classified according to commercial purpose and business function

- Basic commerce website.

For the basic commerce website, the company publicity and customer service are performed by means of basic measures in network media and E-commerce. This kind of website is appropriate for small enterprises with weak power of professionals and in need of E-commerce service. Its characteristics are cheap price of website construction, and high performance cost ratio.

- Publicity commerce website.

Website can be served as the important window of enterprises' public relationship, which is used to publicize the latest news and the business condition of the enterprises. This kind of website is mainly served for some listed companies at home and abroad, on the official websites of which the columns of company news and introduction of the investors are established, becoming the official channel for enterprises to publish news and source rule. The publicity commerce website is appropriate for all kinds of enterprises, especially for the foreign trade enterprises.

- Customer-oriented service website.

This kind of website can provide the inquiry of the after-sale service and the dynamic service status, satisfying the customer demands at a higher level.

- Complete E-commerce operation website.

Complete E-commerce operation website refers to various aspects of E-commerce, such as the distribution management, online shopping and online recruitment. This kind of website can be more clearly described as a set of business management system software.

2) Classified according to the principal part of constructing a website

- Industry E-commerce website.

Industry E-commerce website means a large-scale E-commerce website constructed with the industry organization as the principal part, providing a platform of information distribution, commodity order and customer communication for enterprises and departments in the Industry to perform E-commerce.

- Enterprise E-commerce.

Enterprise E-commerce means that the website is constructed with the enterprises as the principal part to implement E-commerce activities, and can be further divided

* ***Corresponding author's*** e-mail: sjzlugang@126.com

into variously different types of websites according to the leading products of enterprises and the different services provided.

- Government E-commerce website.

Government E-commerce website means the website is constructed with the government body as the principal part to implement E-commerce activities.

- Service organization E-commerce website.

Service organization E-commerce website means the website is constructed with the service organization as the principal part to implement E-commerce activities.

3) Classified according to the responsibilities of the website owners

- Production commerce website.
- Circulation commerce website.

4) Classified according to E-commerce model.

- B2B commerce website.
- B2C commerce website.
- C2C commerce website.
- G2C commerce website.

2.2 COMPETIVENESS INDEX OF E-COMMERCE WEBSITE

Whatever kinds of E-commerce websites, the dominant factors affecting its operation effects and competitive power, are basically the same. The overall level of the E-commerce website is decided by the combined effect of these factors, producing great influence on the function realization of the website and making the E-commerce website present different competitive power. Therefore, the competiveness index of E-commerce website is proposed to measure E-commerce website in competition, reflecting the level of the website in design operation [3].

Aiming at the development status and characteristics of E-commerce website, this work performed research on the competiveness index of E-commerce website according to the principles of comprehensiveness, scientific, operability, industry representativeness and taking content as the core. On basis of performing in-depth investigation and research on the currently famous E-commerce websites as well as learning the research achievements of other scholars and some organizations [4], the more optimized algorithm is used to simulate and calculate the competiveness index of an E-commerce website.

2.3 INDEX SYSTEM OF E-COMMERCE WEBSITE COMPETIVENESS INDEX MEASUREMENT

Through relatively specific literature research, the evaluation index system of E-commerce website competiveness index is established by adopting comprehensive evaluation method during the process of performing measurement on E-commerce website competiveness index. Twenty representative secondary indexes are finally selected as the evaluation object after performing investtigation analysis and literature learning on lots of E-commerce websites. The finally-designed index system includes the first class index and the secondary index, therein to, the first class index includes five indexes - website content, user service, usability, website technology and website function, and the five first class indexes are subdivided on this basis to constitute the secondary evaluation index [5].

3 RBF neural network algorithm

3.1 CONCEPT OF RBF NEURAL NETWORK ALGORITHM

Artificial neural network is applied successfully in many fields by means of its unique information processing capacity. It not only possesses powerful nonlinear mapping capacity, but also obtains the characteristics of self-adaption, self-learning and fault tolerance, clustering and learning from lots of historical data so as to find the change law of some behaviour. Radial basis function (RBF) is a kind of fresh and valid forward feedback neural network [6], with the property of the best approximation and global optimum. Meanwhile, the training method is quickly and easily to be implemented, and there is no problem of local optimum. These advantages make RBF network broadly applied in nonlinear time series prediction. In 1985 Powell presented the Radial-Basis Function (RBF) method of multivariate interpolation [7]. In 1988 Broomhead and Lowe firstly applied RBF to neural website design, constituting the RBF neural network [8].

3.2 COMPOSITION OF RBF NEURAL NETWORK

The most basic composition of RBF neural network includes three layers – input layer, hidden layer (middle layer) and output layer. Therein to, the input layer is composed of some source points (perception units), which connect the network with the external environment, with the transmit function of data information and no transformation on the input information; the kernel function (or action function) of the hidden layer neuron is adopted as the RBF, which performs nonlinear transformation between the input information and the space of the hidden layer, and the higher dimensionality is usually obtained; the output layer is linear provides response for the activation pattern of the input layer.

Setting the neurons of the hidden layer and the output layer as M and Q, respectively, the input pattern is noted as X, and $X=[x_1,x_2,\cdots,x_R]^T$; the output pattern is noted as Y, and $Y=[y_1,y_2,\cdots,y_Q]^T$. The RBF in this work is Gauss function, so the output of the hidden unit is [9]:

$$z_j=\exp\left(-\left\|\frac{X-C_j}{\sigma_j}\right\|^2\right),\ j=1,2,\cdots,M\ , \tag{1}$$

where z_j is the output value of the j neuron in hidden layer; C_j is the center of the j neuron of the hidden layer, composed by the j neuron of the hidden layer corresponding to the center component of all neurons in the input layer, and $C_j = \left[c_{j1}, c_{j2}, \cdots, c_{jR}\right]^T$; σ_j is the width of the j neuron of the hidden layer, corresponding to C_j; $\|\bullet\|$ is Euclid Norm.

The in-out relational expression of the neurons in output layer is:

$$y_k = \sum_{j=1}^{M} w_{kj} z_j \qquad k = 1, 2, \cdots, Q, \tag{2}$$

where y_k is the output value of the j neuron of the output layer; w_{kj} is the weight between the k neuron of the output layer and the j neuron of the hidden layer.

The parameter of the RBF neuron network hereby mainly means the center, width of the network and the adjust weight [10].

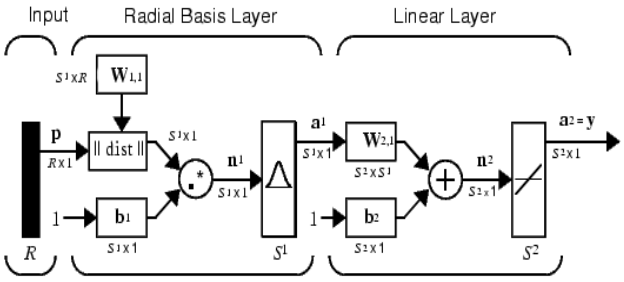

FIGURE 1 RBF neuron network structure

4 Competitiveness index evaluation of E-commerce website based on RBF neuron network algorithm

4.1 ANALYTIC HIERARCHY PROCESS

Analytic Hierarchy Process (AHP) is a kind of hierarchical and structuralized decision analysis method of qualitative and quantitative combination, proposed by American operational research expert T.L.Saaty in 1970s [11]. This method is the most representative comprehensive evaluation method where the factor aggregation is hierarchical, the hierarchical structure model composed, and then the analysis performed by layers according to the interrelationship between factors on the basis of the nature of problems and the component elements of the goal decomposition problems; the weight of various factors is established according to the comparison between factors, appropriate for the decision problems with multiple targets and attribution. It's concise and effective, with extensive practicability.

4.2 DETERMINATION OF RBF NEURAL NETWORK INPUT AND OUTPUT

The method of RBF neural network is adopted to perform measurement and evaluation on the competitiveness index of E-commerce website, and the determination of target output is critical for RBF neural network. Because RBF neural network belongs to supervised learning, a group of expected output data is required as the reference for learning. Therefore, various indexes of E-commerce website competitiveness index should be scored if the target output would be determined.

Expert grading method is a common method, analytic hierarchy process is applied in this work to calculate the weight of various indexes by means of expert grading method, and then the evaluation index system of E-commerce website competitiveness index is used to perform measurement and evaluation on the E-commerce website competitiveness index, evaluating the quality and competitiveness level of E-commerce website [12].

The method of combining expert interview with questionnaire survey is adopted in expert grading method, which can effectively guarantee the objectivity and validity of the obtained data.

The marking rules are as follows: the 20 secondary indexes in the evaluation index system of E-commerce service website are served as the RBF neural network input to perform evaluation on the website (Table 1). The index of each website is scored by experts, and then the quantitative analysis is performed on the results to quantize each evaluation index [13].

TABLE 1 Score list of website evaluation index system

The first class index	The secondary index	Better (score)	Medium (score)	Worse (score)	Scoring methods
A1 Website content	B1 Timeliness	6	4	2	Monitoring method
	B2 Accuracy	6	4	2	Investigation method
	B3 Professional	5	3	1	Investigation method
	B4 Authority	5	3	1	Investigation method
A2 User service	B5 Personalized service	6	4	2	Investigation method
	B6 Protection of user privacy	5	3	1	Investigation method
	B7 Credit monitoring of transaction norm	4	2	0	Investigation method

	B8 Expert technical support	4	2	0	Investigation method
	B9 Website customer service	5	3	1	Investigation method
	B10 User interaction	4	2	0	Investigation method
A3 Usability	B11 Site map	5	3	1	Investigation method
	B12 Website design	5	3	1	Investigation method
	B13 Classification of website information	5	3	1	Investigation method
A4 Web technology	B14 Search function	5	3	1	Investigation method
	B15 Validity of links	5	3	1	Test method
	B16 Browser compatibility	5	3	1	Test method
	B17Website security	5	3	1	Test method
A5 Website operation	B18 Website traffic	5	3	1	Monitoring method
	B19 Quantity of the linked	5	3	1	Monitoring method
	B20 User number of the website	5	3	1	Monitoring method
	Total	100	60	20	

4.3 APPLICATION OF ANALYTIC HIERARCHY PROCESS IN INDEX SYSTEM

What we should urgently solve and determine is that the "contribution degree"---weight of various secondary indexes in the website competitiveness evaluation after the evaluated first class index and various secondary indexes are determined. The analytical hierarch process can be adopted to perform index weight evaluation on the first class index and secondary index in order to determine the weight. And the specific operation steps are that the user survey and data analysis should be firstly performed, the judgment matrix of different levels of indexes are established after the indexes at the same layer are compared pairwise (the comparison of importance degree and non-importance degree), the weight of various indexes and their characteristic root can be obtained after calculation by means of AHP method, the consistency test should be performed on the above results, and the satisfying consistency can be recognized until CR<0.10. The judgment matrix at each layer of index is established in this work according to the steps of analytic hierarchy process, the relative weight value of each layer index could be obtainned by calculation, and then the weight of various indexes of E-commerce website competitiveness evaluation index are obtained by consistency test, thus a complete evaluation index system [14] which is appropriate for E-commerce website competitiveness is finally constructed.

4.4 DETERMINATION STEPS OF EVALUATION INDEX SYSTEM WEIGHT

4.4.1 Establishment of judgment matrix

Generally speaking, users express different attention on the characteristics at various aspects of the website, someone pay more attention to the content elements of the website, and someone place extra emphasis on the obtained service and feelings. For this purpose, the result of expert grading is applied to establish the judgment matrix. The specific operation are as follows: aiming at each index (including the first class index and secondary index), five importance grades are established, which respectively are the most important, very important, important, more important and generally important. The score for the most important is $K_1 = 5$, followed by $K_2 = 4$, $K_2 = 4$, $K_4 = 2$ and $K_4 = 2$. Thus the calculation Equation of the importance score for each index is [15]:

$$M = \sum_{n=1}^{5} P_n g K_n ,$$

where P_1, P_2, P_3, P_4 and P_5 respectively represent the ratio in the overall number of people, aiming at each index and the people who choose different importance grades.

4.4.2 The judgment matrix is determined by scores

Calculation steps are as follows:

1) Calculating the product of the elements in each row of judgment matrix, the Equation is:

$$L_i = \prod_{j=1}^{n} a_{ij} \qquad (i = 1, 2, ..., n)$$

2) Calculating L_i to the N[th] root value in each row, the j is:

$$K_i = \sqrt[n]{L_i} .$$

3) The vector $K = (K_1, K_2, K_3, K_4, K_5)^T$ is performed by normalization processing, $w = K_i \Big/ \sum_{\wedge j=1}^{n} K_j$ (w is the index weight at each level).

Accordingly, the weight of each secondary index in the affiliated level can be calculated. Table 2 shows the calculation result.

TABLE2 Weight of secondary index in the affiliated level

Secondary index	*w*	Secondary index	*w*	Secondary index	*w*
B1	0.4	B8	0.107	B15	0.177
B2	0.4	B9	0.055	B16	0.315
B3	0.2	B10	0.328	B17	0.061
B4	0.247	B11	0.150	B18	0.168
B5	0.113	B12	0.068	B19	0.397
B6	0.247	B13	0.454	B20	0.051
B7	0.231	B14	0.447	-	-

The website with higher scores indicates that the comprehensive quality of the website is better. It's divided into 5 grades which are excellent, good, better, worse and very bad. The score explanation at each grade refers to Table 3.

TABLE 3 Score explanation of website evaluation grades

Grade	Score
Excellent	0.9score and above
Good	0. 75-0. 89 score
Better	0. 65-0. 74 score
Worse	0. 55-0. 64 score
Very bad	0.54score and below

4.5 RBF NEURAL NETWORK ALGORITHM ADOPTED TO CALCULATE THE COMPETITIVENESS INDEX OF E-COMMERCE WEBSITE

The order of adopting RBF neural network to perform evaluation on the website is: firstly, the data of evaluation index system of E-commerce competitiveness index which have been established serve as the input sample, and a RBF neural network model is established to performing training on internet; secondly, test is performed on the established evaluation network model according to the results of training and learning; finally, conclusion and analysis should be performed on the results of website learning and training. From March to June in 2013, the competitiveness index of 100 designated E-commerce websites is scored by means of expert grading method, and the uniform treatment is performed on the obtained data. The front 70 groups of data are used to test, and test is performed on the rear 30 groups of data. The parameter of the RBF neural network is set as: the error goal=0.0001, spread=1, the maximum quantity of the neurons at the hidden layer is mn=20, and the displayed frequency in the training process df=1. The training results are shown in Figure 1:

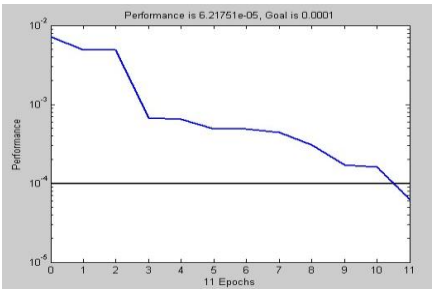

FIGURE 1 Training process figure of RBF neural network

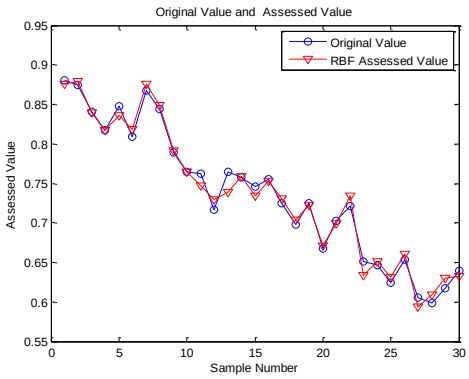

FIGURE 2 Comparison figure of the RBF predicted result and the original value

It can be found that the E-commerce evaluation result of applying RBF neural network is better, and the evaluated absolute error figure and relative error figure are shown in Figure 3 and Figure 4, respectively.

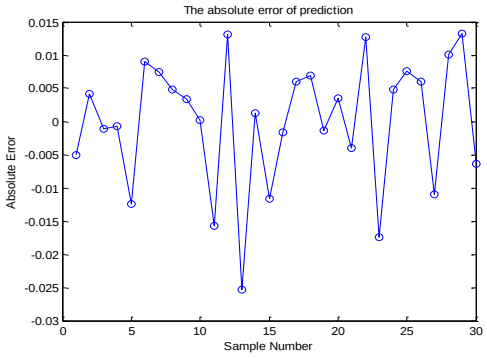

FIGURE 3 Absolute error figure predicted by RBF

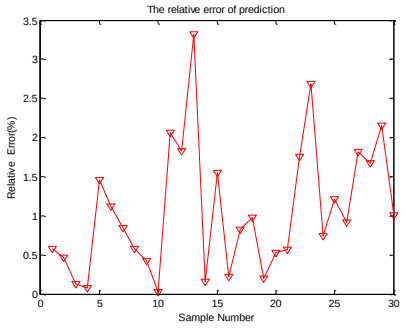

FIGURE 4 Relative error figure predicted by RBF

Figure 4 shows the average value of relative error in E-commerce website evaluation is at 2.5% by adopting

RBF neural network, with the better effect; but the problems of long time evaluation and excessive error in some evaluation points exist

5 Fruit fly algorithm optimization RBF neural network model

5.1 BRIEF INTRODUCTION OF FRUIT FLY OPTIMIZATION ALGORITHM

Fruit Fly Optimization Algorithm (FOA) was a kind of brand new evolutionary computation method presented by Taiwan young teacher Pan Wenchao [5-8] in 2011. Because the fruit fly is superior in the sense of smell and sight, which is shown in Figure 5. Fruit fly searches the food source in air; its keen sense of sight is used to find food and the position where its companions gather after finding food, and finally fly to the position. Therefore, this method considers that fruit fly searches food, it firstly searches the approximate position of the food by smell and then confirms the correct position of the food by sight. This method is a new method of seeking global optimization based on the foraging behavior of fruit fly.

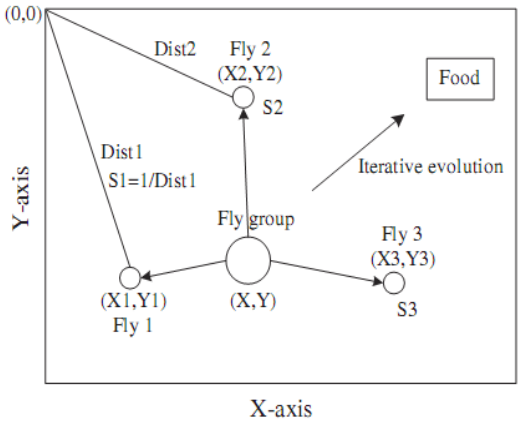

FIGURE 5 Iteration food search figure of fruit fly group

5.2 STEPS OF FRUIT FLY OPTIMIZATION ALGORITHM

The fruit fly optimization algorithm can be divided into seven steps as follows [9]:

1) Figure 5 shows the initialization of the fruit fly group position, and the result of initialization is Init X_axis; Init Y_axis;

2) When the search direction RV_x and RV_x is set, random search distance of the individual fruit fly can be obtained by the following formula:

$$\begin{aligned} Xi &= Init\ X\_axis + RV_x \\ Yi &= Init\ Y\_axis + RV_y \end{aligned} . \tag{3}$$

3) Because the position of the food is unknown, therefore the distance Disti between the current position of individual fruit fly and the original point needs to be evaluated. The decision value Si of taste and consistency can be calculated after that, the decision value of taste and consistency equals to the reciprocal of the distance.

$$\begin{aligned} Disti &= \sqrt{Xi^2 + Yi^2} \\ Si &= 1/Disti \end{aligned} . \tag{4}$$

4) Taste and consistency decision value is substituted into taste consistency to judge the function and calculate the taste consistency of the individual fly's current position.

$$Smelli = Function(Si) . \tag{5}$$

5) The best taste consistency in fruit fly group can be obtained by the following formula:

$$[bestSmell\ bestIndex] = \max(Smelli) .$$

6) Preserve the best taste consistency value of fruit fly group and its corresponding x-coordinate and y-coordinate, then the fruit fly group performs positioning on the food source by means of personal sight, and fly to the position of the food source after that.

$$\begin{aligned} Smellbest &= bestSmell \\ X\_axis &= X(bestIndex) . \\ Y\_axis &= Y(bestIndex) \end{aligned}$$

7) Entering iterative optimization, repeat the iteration steps 2-5, and meanwhile judge if the taste consistency is better than the previous iterative taste and consistency; if it's established, the step 6 shall be performed.

5.3 MODEL OF FRUIT FLY ALGORITHM RBF NEURAL NETWORK

This work uses MATLAB neural network tool box RBF neural network function to establish improved RBF neural evaluation model [16] of fruit fly optimization algorithm. The spreading parameter Spread of RBF neural network is mainly optimized, the bigger the Spread is, the more smooth the function matching is. But the excessive Spread means to require lots of neurons to adapt to the rapid change of function. If the Spread is undersize, which means more neurons are required to be fit to the slow change of the function, thus the website performance is worse.

In the past different Spread values are tried to determine the optimum value during the design process of RBF, thus lots of time will be spent, and meanwhile the best of the determined Spread value can't be guaranteed.

FOA algorithm in this work is adopted to search the optimum value within the whole situation, the predicted error sum of squares and served as the taste judgment function to determine the optimum RBF spreading parameter Spread. The specific steps of algorithm are as follows:

1) Confirming the number of individuals and the maximum iteration times in the group, and meanwhile the initial position of the fruit fly can be generated randomly;
2) Endowing the random flight direction and distance section [-1 1] for fruit fly individual to search food.
3) Estimating the distance between the original point, calculating the taste and consistency judge value, which is the spreading parameter Spread, if the spreading parameter Spread <0.01, thus the Spread=1.
4) Taking Spread into the RBF to perform network training and simulation, the function shall be judged by the predicted error squares and as the taste, the taste and consistency of the fruit fly position can be obtained, which is the error sum of squares.
5) The optimum taste and consistency in the fruit fly group, which means, the fruit fly with the lowest taste consistency make the error sum of squares the lowest.
6) Preserving the optimum spread parameter Spread and its corresponding x-coordinate and y-coordinate, meanwhile the fruit fly group performs positioning on food source by means of own sight, and then fly to the position where the food source exists.
7) Entering the iterative optimization, repeating iterative steps 2-5, meanwhile judging if the taste consistency is better than the previous iterative taste consistency; if it's successful, the step 6 will be performed.

6 E-commerce website competitiveness index is calculated based on the fruit fly optimization RBF neural network algorithm

Set the parameter of fruit fly optimization algorithm, the number of iterations is 100, the population size is 30. MATLAB is applied to solve by programming, and the solved result are as follows:

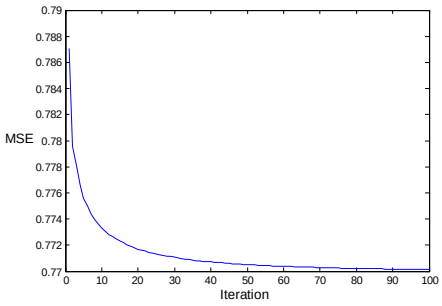

FIGURE 6 The square error convergence map of fruit fly optimization algorithm RBF

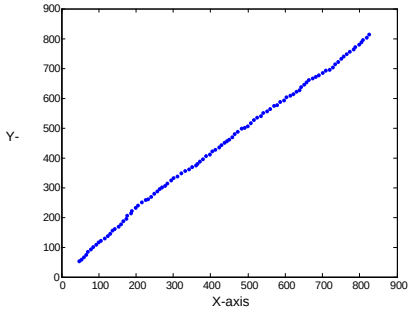

FIGURE 7 Optimization path of fruit fly algorithm

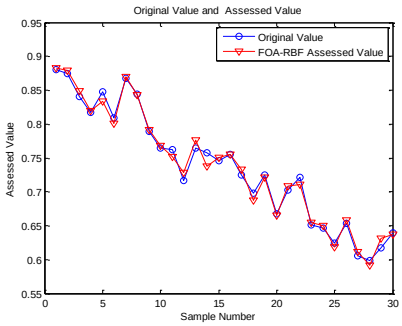

FIGURE 8 Comparison figure of FOA-RBF predicted result and the original value

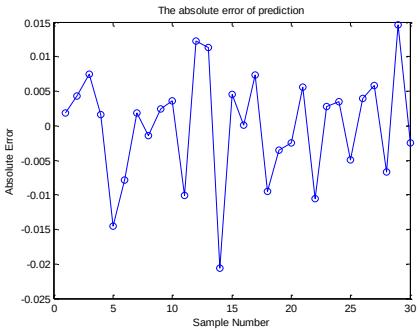

FIGURE 9 FOA-RBF predicted absolute error figure

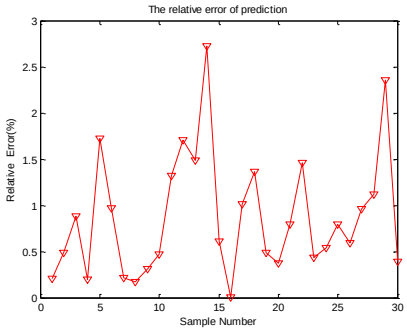

FIGURE 10 FOA-RBF predicted relative error figure

The simulated result of FOA-RBF algorithm shows that the prediction accuracy of FOA-RBF algorithm is higher than the RBF neural network algorithm, and the expected absolute error and relative error are shown in Figure 9 and Figure 10. The optimizing rate of convergence is faster in FOA-RBF algorithm, with good convergence. The characte-

ristic of convergence is shown in Figure 6, and the optimazing path of fruit fly in 2-D space in Figure 7.

7 Conclusions

The expert grading method is used to construct a multi-index hierarchical structure of E-commerce website competitiveness evaluation, with the establishment of an E-commerce website competitiveness evaluation index system, and thus quantizing the competitive level of the website. After that, RBF neural network algorithm is used to perform evaluation research on E-commerce website, aiming at the problems exist in evaluation research, fruit fly optimization algorithm is applied to perform improvement on RBF neural network algorithm. It can be seen by means of simulated comparison of the practical examples, FOA-RBF algorithm is obviously better than RBF neural network algorithm on evaluating the accuracy and processing time of E-commerce website, thus the validity and reliability of the algorithm in this work are verified, and this method can be promoted to other fields so as to easily solve other similar problems.

Web search engine based trend analysis of electronic commerce market

Zihui Yang*

School of Traffic & Transportation Engineering, Central South University, Changsha Normal University, China

Received 1 May 2014, www.cmnt.lv

Abstract

Google Trends offer weekly free information about internet searches. Users can see and download search volume patterns for the search term and the information is available by the category and by the location of those making the search. Also, Google provides "Hot searches" and "Top charts" including top and rising searches that include the search term. All these information is up to date as it provides weekly figures for a period up to and including the current week. In here, the proposed methods present a predictive model for Electronic Commerce market using the searched data in Google search engine (Google Trend data). Through the predictive model for the market and analysis of the Google Trend data, the proposed methods can get an efficient and meaningful result for the Electronic Commerce market, also we can enforce the marketing on highly ranked countries and cities. Those are very useful information for the Electronic Commerce manufacturers.

Keywords: electronic commerce, search engine, trend analysis

1 Introduction

Electronic commerce, commonly known as E-commerce, is trading in products or services using computer networks, such as the Internet. Electronic commerce draws on technologies such as mobile commerce, electronic funds transfer, supply chain management, Internet marketing, online transaction processing, electronic data interchange (EDI), inventory management systems, and automated data collection systems. Modern electronic commerce typically uses the World Wide Web for at least one part of the transaction's life cycle, although it may also use other technologies such as e-mail, mobile devices, social media, and telephones.

Electronic commerce is generally considered to be the sales aspect of e-business. It also consists of the exchange of data to facilitate the financing and payment aspects of business transactions. This is an effective and efficient way of communicating within an organization and one of the most effective and useful ways of conducting business. It is a market entry strategy where the company may or may not have a physical presence. There are already a range of studies about how the data can be used to monitor economic trends because Google data is extremely up to date. Those are called as nowcasting [2]. We can predict a near future based on Google Trends data. Google Trends coupled with an explanation of its potential pitfalls and other caveats, and then we compare patterns of search data from Google Trends with the real statistics from the local information, providing a justification for the possible utility of Google Trends.

In Google Trends, the data are measures of the likelihood of searches, which indicates the likelihood of a random user searching for a particular term from a certain location at a certain time. Repeated queries from a single user over a short period of time are filtered out, so that the level of interest isn't impacted. Also, data are displayed on a scale of 0 to 100 after normalization, hence if a term was most searched for in the first week of the month, the annual chart of such searches would have a peak of 100 in that week and all other weeks would be displayed as proportions of the volumes of searches for the peak week. The "Search Volume Index" is displayed graphically on screen but the underlying data can be downloaded as a CSV file. The series started from the beginning of 2004 and are provided on a weekly basis. Results for combinations of search terms can be generated, and the values obtained are scaled and normalized figures.

Government data are often released with a lag of months or more, which is a delay in assessing the current economic conditions. The term frequency of online search engine like Google provides a highly accurate and up to date but simple way to predict the future business. We can uncover sales trends before government publish the data by recognizing consumers' interests through their online behaviours analysis. As the search engine becomes pervasive, more shoppers are using the Web to collect the information about the product to purchase and narrow down the number of selections, especially for expensive products. There are many examples to show the correlation between search and actual data. For example, Google flu trend showed strong correlation between the search and real flu patient data [7].

With the help of cloud computing [16-19], internet of things [20-23], and Big Data [24-26] Advances in search engine technology, big data analytics technologies, etc.

* ***Corresponding author's*** e-mail: 12498303@qq.com

provide remarkable detailed information of human behaviours. With these technologies, we now can take advantage of (almost) real-time data.

Nowadays, companies have already made predictions, such as consumer preferences, supplies and demands for goods as well as the number of inventory level and turnover rate. A lot of companies such as Amazon, Coca-Cola, and Volvo are making a decision about their business strategies and to achieve tremendous profits from the market.

2 Related works

In the United States some electronic commerce activities are regulated by the Federal Trade Commission (FTC). These activities include the use of commercial e-mails, online advertising and consumer privacy. The CAN-SPAM Act of 2003 establishes national standards for direct marketing over e-mail. The Federal Trade Commission Act regulates all forms of advertising, including online advertising, and states that advertising must be truthful and non-deceptive. Using its authority under Section 5 of the FTC Act, which prohibits unfair or deceptive practices, the FTC has brought a number of cases to enforce the promises in corporate privacy statements, including promises about the security of consumers' personal information. As result, any corporate privacy policy related to e-commerce activity may be subject to enforcement by the FTC.

The Ryan Haight Online Pharmacy Consumer Protection Act of 2008, which came into law in 2008, amends the Controlled Substances Act to address online pharmacies.

Internationally there is the International Consumer Protection and Enforcement Network (ICPEN), which was formed in 1991 from an informal network of government customer fair trade organisations. The purpose was stated as being to find ways of co-operating on tackling consumer problems connected with cross-border transactions in both goods and services, and to help ensure exchanges of information among the participants for mutual benefit and understanding. From this came Econsumer.gov, an ICPEN initiative since April 2001. It is a portal to report complaints about online and related transactions with foreign companies.

There is also Asia Pacific Economic Cooperation (APEC) was established in 1989 with the vision of achieving stability, security and prosperity for the region through free and open trade and investment. APEC has an Electronic Commerce Steering Group as well as working on common privacy regulations throughout the APEC region.

In Australia Trade is covered under Australian Treasury Guidelines for electronic commerce, and the Australian Competition and Consumer Commission regulates and offers advice on how to deal with businesses online, and offers specific advice on what happens if things go wrong. Also Australian government e-commerce website provides information on e-commerce in Australia.

In the United Kingdom the FSA (Financial Services Authority) is the competent authority for most aspects of the Payment Services Directive (PSD). The UK implemented the PSD through the Payment Services Regulations 2009 (PSRs), which came into effect on 1 November 2009. The PSR affects firms providing payment services and their customers. These firms include banks, non-bank credit card issuers and non-bank merchant acquirers, e-money issuers, etc. The PSRs created a new class of regulated firms known as payment institutions (PIs), who are subject to prudential requirements. Article 87 of the PSD requires the European Commission to report on the implementation and impact of the PSD by 1 November 2012.

Moe et al. showed that online behaviours can be used to show consumers' interest and predict purchase outcomes [10]. Ginsberg et al. accurately estimated the current level of weekly influenza activity in each region of the United States. There were highly correlation between the relative frequency of certain queries and the percentage of physician visits in which a patient presents with influenza-like symptoms. Through their work, we could detect influenza epidemics in areas with a large population of web search users using search queries [7]. Hand et al. investigated and showed that forecasts of cinema admissions based on seasonal patterns in the data could be improved using Google Trend data [9]. Lui et al. tested predictive power against the US congressional elections (2008 and 2010). Based on their investigation, Google Trend data was not a good predictor in this case and they explained why this may be the case [10]. Choi et al. Showed how Google Trend data may help predict initial claims for unemployment benefits in the United States. And they found that Google Trend data played a key role to improve forecasting accuracy [4,5]. Wu et al. predicted housing prices and sales with Google Trend data and found that housing search index is strongly predictive of the future housing market sales and prices. Also, they suggested how those data can be used in other markets [15]. Contreras et al. provided a method to predict next-day electricity prices based on the ARIMA methodology. They showed the result of Spain and California market [6]. With the ability to collect search queries over time, Google trends data is useful to capture the decision makers' intention. Google trends data provides unprecedented opportunities to make predictions in electronics markets. Google search frequencies can be used as a reliable predictor for the underlying electronics market trends both in the present and in the near future, which is called "nowcast" using very simple regression model [2].

3 Google trends

In 2010 the United Kingdom had the biggest e-commerce market in the world when measured by the amount spent per capita. The Czech Republic is the European country where ecommerce delivers the biggest contribution to the enterprises´ total revenue. Almost a quarter (24%) of the country's total turnover is generated via the online channel.

Among emerging economies, China's e-commerce presence continues to expand every year. With 384 million

internet users, China's online shopping sales rose to $36.6 billion in 2009 and one of the reasons behind the huge growth has been the improved trust level for shoppers. The Chinese retailers have been able to help consumers feel more comfortable shopping online. China's cross-border e-commerce is also growing rapidly. E-commerce transactions between China and other countries increased 32% to 2.3 trillion yuan ($375.8 billion) in 2012 and accounted for 9.6% of China's total international trade.

Google is dominant in the search engine field. People from all around the world are using Google because Google's search algorithm is superior. Google is processing more than 60% of all the online queries in the world. [10] I got the data from Google Trends, which analyse web searches to compute how many searches have been done for the terms you input, and provide weekly and monthly reports on query statistics. Online queries submitted to the Google search engine since 2004 are captured and categorized them into several predefined categories. Definitely, queries not within the predefined categories are also captured systematically.

A search index from Google Trends doesn't provide the absolute number of counts of queries. Instead, it is calculated as the search volume for each query in a given geographical location divided by the total number of queries, so the index is always from 0 to 100. Google Trends data is easy to access and up to date.

I don't use a predefined category in Google Trends. I checked with tv, smart tv, led tv, hdtv and 3d tv at the Google search engine. As you can see in Figure 1, many people are still searching by just typing 'tv' than smart tv, led tv, hdtv or 3d tv. Google flu estimate showed that Google Trend data have the potential to predict people's interest over time and I believe that the volume of Google search queries can be used to predict future economic indicators.

4 Google flu trends

Google provides weekly influenza activity estimates for the world based on aggregated Google search data. Not every person who searched for "flu is actually sick, but some pattern can be found. Through the comparison between Google's query counts and the number of people actually have flu symptoms, we can find a close relationship [7].

As you can see, there is a positive relationship between Google flue trends estimate and the data of US centres for disease control. In here, we are going to compare TV data from Google search engine. Actually, we compared TV, Smart TV, HDTV, LED TV and 3D TV. As you can see in Figure 1, Search for just 'TV' is dominant. All other terms including Smart tv, HDTV, LED tv and 3D tv are 0 or 1 as a normalized value in most of the period. As you can see in Figure 2, Samsung tv is ranked #1 in from around 2009 to now. LG and Sony are competing for the 2nd place. As you can see in Figure 2, the search of each tv manufacturer has some seasonality, so it showed the local peak in end of each year. It means that end of the year is usually a shopping season.

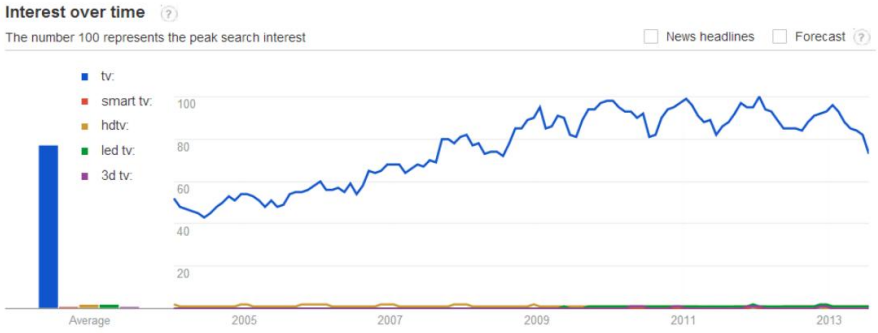

FIGURE 1 Comparison of TV related search terms in Google search engine

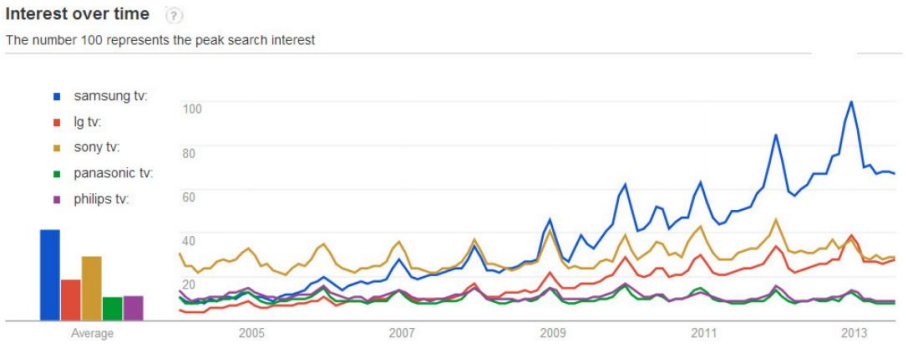

FIGURE 2 Comparison of 5 TV manufacturers in Google search engine

5 Predictive model of TV time series data

I used ARIMA (Auto Regressive Integrated Moving Average) [6] as a statistical model and the model was implemented in R. Exponential smoothing is useful for making forecasts and make no assumptions about the correlations between successive values of the time series data.

ARIMA models include an explicit statistical model for the irregular component of a time series data and it allows for non-zero autocorrelations in the irregular component. ARIMA models are defined for stationary time series. Hence, your time series data is a non-stationary, first you have to difference a time series data to obtain a stationary time series. Typically, the ARIMA model can be written as ARIMA (p,d,q), where p is the number of autoregressive terms, d is the order of differencing and q is the number of moving average terms. For example, ARIMA (1,1,0) is a first-order AR model with one order of differencing. In most cases, the best model turns out a model that uses either only AR terms or only MA terms.

Economists have theorized that e-commerce ought to lead to intensified price competition, as it increases consumers' ability to gather information about products and prices. Research by four economists at the University of Chicago has found that the growth of online shopping has also affected industry structure in two areas that have seen significant growth in e-commerce, bookshops and travel agencies. Generally, larger firms are able to use economies of scale and offer lower prices. The lone exception to this pattern has been the very smallest category of bookseller, shops with between one and four employees, which appear to have withstood the trend.

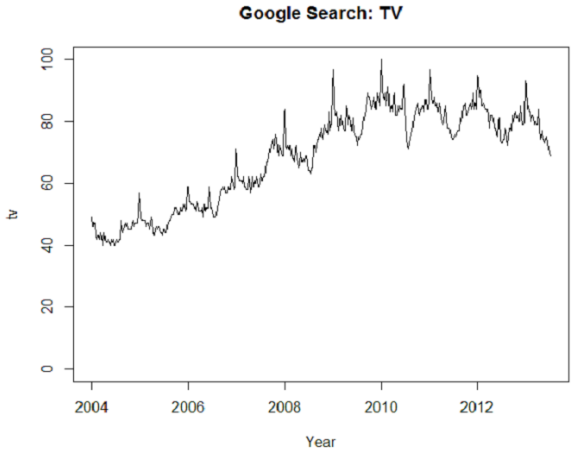

FIGURE 3 TV search result in Google search engine

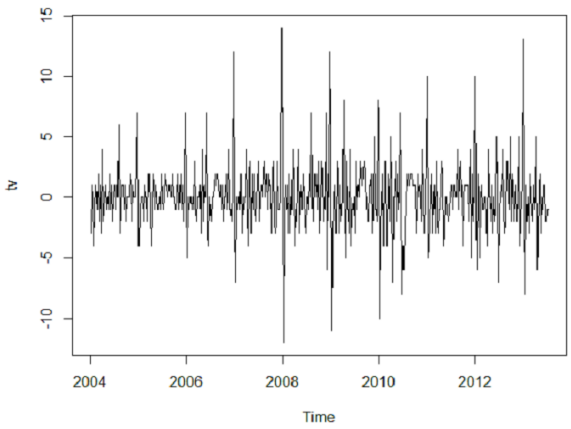

FIGURE 4 Time series data of first difference

The mean forecast error is 0.048. The time series forecast errors have a positive mean rather than a zero mean. Figure 5 showed the results of the prediction model using an ARIMA model. Blue line represents the nowcast using the prediction model. Red line represents the result with 5% significance level.

Individual or business involved in e-commerce whether buyers or sellers rely on Internet-based technology in order to accomplish their transactions. E-commerce is recognized for its ability to allow business to communicate and to form transaction anytime and anyplace. Whether an individual is in the US or overseas, business can be conducted through the internet. The power of e-commerce allows geophysical barriers to disappear, making all consumers and businesses on earth potential customers and suppliers. E-bay is a good example of e-commerce business individuals and businesses are able to post their items and sell them around the Globe.

6 Experiment and results

In case of 'tv' search on Google search engine, local maxima are always January of each year, so January 2013, January 2012, January 2011 was local maxima. Local maxima are August 2012, June 2011, July 2010, and July 2009. Hence, we can see that the search data of 'tv' is seasonal, which is increased on January of each year and decreased on summer (June, July or August) of each year. I depicted the volume of Google search engine for 'tv'. As you can see, the graph is not stationary time series, so I can difference the time series once and plot the difference series in Figure 3. As you can see in Figure 3, the search result for 'tv in Google search engine is somewhat seasonal and not stationary. As you can see in Figure 4, the differenced time series looks stationary in mean.

Based on ACF and PACF, MA(1) model is appropriate for the data. In case of ACF, the value at lag 2 exceeded the significance bounds. In case of PACF, the values at lag 2, 11, 14 and 17 exceeded the significance bounds.

Pakistan, France and Romania are top 3 'tv' search countries on Google search engine. Figure 6 showed the term 'tv' search result based on city. Istanbul, Paris and Ankara are top 3 'tv' search cities on Google search engine. According to the Google Trends data, the search for 'tv' is hot in Pakistan, France, Romania, Turkey (Country) and Istanbul, Paris, Ankara and Warsaw (City),

so manufacturers have to intensify the marketing in these countries and cities right now to increase the revenue. I think that the searched data in Google search engine have a positive relationship with real sales like the Google Flu Trends data. Also, as seen on prediction model in Figure 5, market for 'tv' might be increased smoothly.

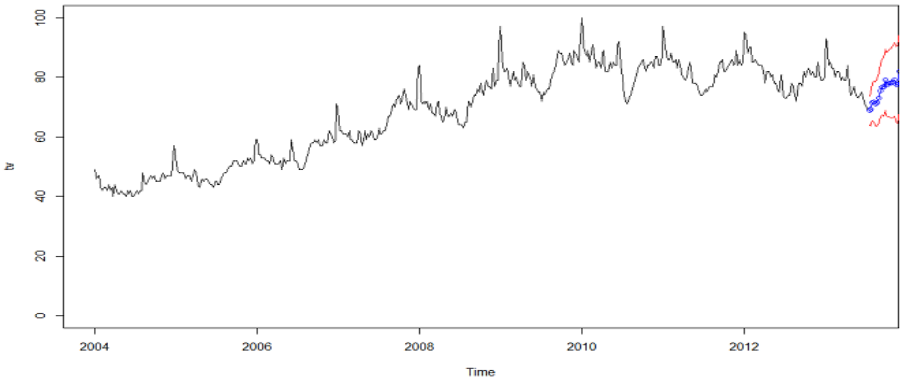

FIGURE 5 Prediction model of Google Trends data

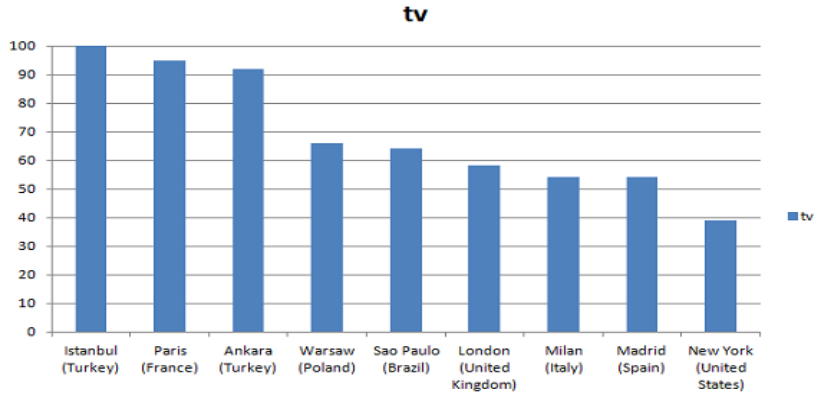

FIGURE 6 Search Results based on the City

I also investigated the 'tv' related terms such as smart tv, hdtv, led tv and 3d tv. For smart tv, Pakistan, Turkey and Ghana are top 3 in search frequency. For hdtv, United States, South Korea and Germany are top 3. For led tv, India, Brazil and Hungary are top 3. For 3d tv, Brazil, United Kingdom and Hungary are top 3. All these results are based on current Google search, so if some issues or policy changes of each country happen, it can be changed quickly. For example, recently BBC announced that they have no more plan for 3D format after the trial period ends, so it would affect the search result in UK sooner or later. However, compared with the 'tv', search result of other terms was so trivial.

7 Conclusions

In this paper I reviewed the TV search data through Google search engine and predicted the TV market based on the searched data and ARIMA model. Also, I could estimate the target market based on the frequencies of the search on the Google search engine. By intensifying the marketing in the regions which showed a high search frequency, the sales of the item (TV) might be increased. The search result of Google Trend will be different as time goes by because the search of people will be different based on various factors.

I've found that we can predict the near future of the market of home electronics (e.g., TV) using Google Trends data. Google Trends data reveals up to date trend of the people.

It might be applied to other products (e.g., Refrigerator, Cell phone, etc.) or areas (e.g., Home sales, diseases, etc.) Through the analysis of the Google Trend data, we can see that people from which country and from which city like the keyword which we've searched in the Google search engine. We can find useful trend or information by watching the Google search trend. For example, it can predict daily price moves in the Dow Jones industrial average. We already saw Google flu trend data, which correlated with the real flu data. Like this, we will see more useful correlation result in the near future.

Received 0 October 2014, www.cmnt.lv

Abstract

Although the importance of tourist destination image as a tool to enhance tourist loyalty is commonly acknowledged, prior research on the relationship between tourist destination image and tourist loyalty is not in-depth. Drawing on place attachment theory, a model depicting the relationship among tourist destination image, place attachment and tourist loyalty is constructed. Using the sample of 337 inbound tourists from Japanese and Korean and the structural equation modeling method, the empirical results reveal that: 1) Landscape image, merchandise image and facility image have positive effects on affective image. Landscape image and merchandise image significantly and directly affect place attachment while partially mediating the effect of affective image. Service image has a direct effect on place attachment. Facility image has an indirect effect on place attachment. Facility image significantly and directly affects tourist loyalty while partially mediating the effect of place attachment. 2) Affective image has a direct effect on place attachment and it is an antecedent of tourist loyalty while completely mediating the effect of place attachment.

Keywords: tourist destination image, cognitive image, affective image, place attachment, tourist loyalty

1 Introduction

Since more than 40 years ago, tourist destination image has grown into one of the most pervasive areas in tourism studies [1,2]. Previous researches have sought to emphasize the crucial part it plays in tourism production and consumption [3,4]. Indeed, tourist destination image is understood to play an important role in destination positioning [5], destination branding [6], and tourist decision [7,8]. Therefore, the construction and maintenance of effective tourist destination images has been a major focus of the marketing [9]. In other words, tourist destination image plays an important role in enhancing tourist loyalty. Regardless of significant progress achieved, few studies examine the role of place attachment in the relationship between tourist destination image and tourist loyalty. Due to the importance of place attachment in revealing tourist loyalty [10,11], there is an imperative need to examine the relationship among tourist destination image, place attachment and tourist loyalty.

With the fast development of tourism industry in China, the number of inbound tourists has increased sharply. It is worth mentioning that Japan and Korea have been the main focus of China's inbound tourism marketing in recent years. Hangzhou is famous for a beautiful international tourist destination. Despite all this, Hangzhou's tourist destinations have long suffered a critical problem. An important of manifestation of the problem reveals low revisit to a particular place. Hence, it is urgent that destination marketing organizations find the effective solutions for cultivating positive tourist destination images without compromising the viability of natural and cultural resources. Based on the above consideration, in order to solve this problem, the main purpose of this article is to contribute to this study of tourist destination image, by examining the relationship among tourist destination image, place attachment and tourist loyalty.

2 Literature review and hypothesis development

2.1 DEFINITION OF RELATED CONCEPTS

Tourist destination image studies have proliferated as a major focus of tourism research over the past four decades [12]. Tourist destination image is defined as the sum of the beliefs and impressions that an individual has of a tourist destination [13]. Phelps (1986) defines tourist destination image as an individual's overall perception of a tourist destination [14]. Fakeye & Crompton (1991) defines tourist destination image as an individual's mental representation of knowledge and overall perception of a particular tourist destination [15]. It is referred to the sum of perceptual beliefs and impressions based on information processed from a number of sources over time [16]. It is viewed as an individual's mental representation of knowledge and global impressions about a tourist destination [7]. So most related academic scholars commonly agree that it could be conceptualized from a psychological perspective.

Regardless of this dispute, it is commonly accepted that tourist destination image as a multidimensional concept. Prior researchers describe tourist destination image could

* ***Corresponding author's*** e-mail: qiuhongliang1127@163.com

be divided into several sub-constructs from the cognitive image perspective [5,17]. With the deepening of tourist destination image studies, it is widely understood that tourist destination image could be divided into two separate dimensions of cognitive image and affective image [18-25]. Therefore, tourist destination image could be conceptualized as the sum of perceptual beliefs and affective feeling that a tourist has about a tourist destination, which could be divided into cognitive image and affective image. In order to explore what constitutes the multi factors of tourist destination cognitive image, this article uses the focus group discussion to ascertain it. Four experts are chosen to conduct this survey. It is widely accepted that tourist destination cognitive image of landscape image, merchandise image, facility image, service image and entertainment image. On the basis of the previous studies and the focus group discussion, tourist destination cognitive image could be divided into landscape image, merchandise image, facility image, service image and entertainment image. Therefore, the following hypothesis is developed.

Tourist destination image can be divided into landscape image, merchandise image, facility image, service image, entertainment image and affective image (H1).

It is commonly acknowledged that the notion of place attachment is traceable to attachment theory [26]. Precisely, the concept of place attachment originates from interpersonal attachment theory, which is first reported by Bowlby (1979) [27]. It's further developed by several scholars [28,29]. Hence, attachment originally is defined as the emotional and psychological bonds of interpersonal relationships. Interpersonal attachment theory is found extendable beyond interpersonal relationship context to person-to-object context [30,31]. For tourism marketing, place attachment is capable of bonding the tourist emotionally and psychologically with the tourist destination [32].

Williams et al. (1992) defines place attachment as the emotional bond between an individual and a place [33]. Guiliani & Feldman (1993) defines place attachment as the bonding between individuals and places [34]. Mazumdar (2005) describes place attachment as the emotional bond between individuals and places [35]. Regardless of this dispute, it is widely acknowledged that place attachment is described as a multidimensional notion. It is commonly understood that place attachment could be divided into two separate dimensions of place dependence and place identity [33, 36-38]. Therefore, place attachment is viewed as a bond with a particular tourist destination, which could be divided into place dependence and place identity. Place dependence is viewed as tourists' functional attachment to a specific destination [33]. Place identity refers to a far-reaching connection between a place and an individual's personal identity [39].

2.2 RELATIONSHIP AMONG TOURIST DESTINATION IMAGE, PLACE ATTACHMENT AND TOURIST LOYALTY

Prior academic researchers have examined the relationship among tourist destination image, place attachment, tourist loyalty [40]. However, few studies examine the role of tourist destination image factors in the relationship. At the same time, the relationship between cognitive image and affective image is tested by most scholars. That is, cognitive image is an antecedent variable of affective image. So there is an imperative need to examine the effect of each factor of tourist destination image of place attachment and tourist loyalty. Taking account into the preceding discussion, the following hypotheses are developed.

Landscape image, merchandise image, facility image, service image and entertainment image relate positively to affective image respectively (H2a-H2e).

Landscape image, merchandise image, facility image, service image and entertainment image relate positively to place attachment respectively (H3a-H3e).

Landscape image, merchandise image, facility image, service image and entertainment image relate positively to tourist loyalty respectively (H4a-H4e).

Affective image relate positively to place attachment (H5).

Affective image relate positively to tourist loyalty (H6).

Place attachment relate positively to tourist loyalty (H7).

2.3 THE HYPOTHETICAL MODEL

Taking account into the preceding discussion, the six-factor of tourist destination image measurement model (M1) is proposed, which consists of landscape image, merchandise image, facility image, service image and entertainment image and affective image. Moreover, the model depicting the relationship among tourist destination image, place attachment and tourist loyalty (M2) is constructed, which is presented in Figure 1.

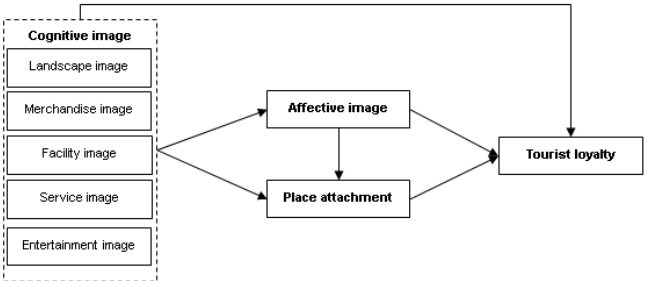

FIGURE 1 Research theory model

3 Methods

3.1 MEASURES

Measurements of the variables in this article are drawn from the prior literature and the focus group discussion. These constructs in this article are measured with multiple items. Each factor of tourist destination image is measured with 19 items by a combination of previous studies and focus group discussions. Landscape image is measured with four items (e.g., "I think Hangzhou is a beautiful international tourist destination"). Merchandise image is measured with three items (e.g., "I think Hangzhou has unique local specialties and souvenirs"). Facility image is measured with three items (e.g., "As an international tourist destination, I think internal traffic of Hangzhou is convenient"). Service image is measured with three items (e.g., "I think Hangzhou has a high service quality of catering"). Entertainment image is measured with two items (e.g., "I think leisure activities of Hangzhou are rich and colourful"). Affective image is measured with four items (e.g., "As an international tourist destination, I think visiting Hangzhou is excited"). Place attachment with four items is adapted from Williams et al. (1992) [33]. Tourist loyalty with 2 items is modified from Bao & Hu (2008) [41].

3.2 PARTICIPANT AND PROCEDURE

The sample is collected in Hangzhou tourist destination which locates at Zhejiang province. Facing the visiting inbound tourists from Japan and Korea, the 400 questionnaires are distributed. This study obtained 337 completed valid questionnaires, for an effective response rate of 84.25%. The socio-demographic and tourist profiles of the respondents are summarized as follows. Briefly, 55.2% are female and 44.8% are male; 34.5% are 25-34 years old and 25.9% are 35-44 years old; 80.7% have a university education and 15.3% have a high school education; 66.3% are repeated visit and 33.7% are first visit.

4 Tables

4.1 DIMENSIONALITY OF TOURIST DESTINATION IMAGE

Exploratory factor analysis is carried out using the principle component method with VARIMAX rotation to examine the dimensionality of tourist destination image [42]. As recommended by Hair et al. (2010), factor loadings greater than 0.50 and eigenvalues greater than 1.0 indicate significance [43]. For the tourist destination image scale, none items do not meet the criteria, and thus none items are eliminated from further analyses, yielding a six-factor model with 19 items (See Table 1). The factor solution accounts for approximately 68.704% of the total variance extracted. Therefore, all initial indicators of tourist destination image are preserved for reliability and validity testing, which is shown in Table 1.

TABLE 1 Exploratory factor analysis, reliability and validity

Variable	Eigenvalues	Item coding	Factor loadings(EFA)	Cronbach α	Factor loadings (CFA)	C.R.	AVE
Landscape image	1.931	A1 A2 A3 A4	0.778 0.752 0.795 0.649	0.777	0.714 0.696 0.748 0.586	9.262 9.135 9.478 -	0.556

Overall fit : $\chi 2$/df=2.183 RMR=0.029 RMSEA=0.059 GFI=0.913 TLI=0.912 NFI=0.878							

Reliability and validity testing

Table 1 indicates that the Cronbach's α of all factors of tourist destination image reach 0.7, satisfying the specified standard of internal consistency [44]. So tourist destination image scale is considered acceptable as a good indication of reliability. In addition, as recommended by Song et al. (2014), each construct's Average variance extracted (AVE) above 0.5 is treated as indications

of convergent validity [45]. The AVE for the scale ranges from 0.526 to 0.657, indicating an acceptable level of convergent validity. According to the criteria by Lee et al. (2012), if the average variance value extracted for each construct is greater than the squared correlation coefficient for corresponding inter-constructs, the scale is considered acceptable as a good indication of discriminant validity [46]. Based on the above criteria, the scale of tourist destination image has acceptable levels of discriminant validity (see Table 2). Moreover, according to the criteria by Hung & Petrick (2012), the overall fit measures indicate that tourist destination image scale is a good representation of the structures underlying the observed data [47]. Therefore, H1 generally receive support from the empirical findings.

TABLE 2 Discriminant validity analysis

Variable	1	2	3	4	5	6
1.Landscape image	(0.746)					
2.Merchandise image	0.337	(0.750)				
3.Facility image	0.553	0.380	(0.725)			
4.Service image	0.553	0.369	0.471	(0.771)		
5.Entertainment image	0.268	0.275	0.341	0.482	(0.782)	
6.Affective image	0.467	0.562	0.532	0.364	0.289	(0.811)

4.3 STRUCTURAL MODEL AND HYPOTHESES TESTING

According to the criteria by Hung & Petrick (2012), the overall fit measures indicate that M2 has acceptable levels of overall fit (see Table 3). On this basis, this study builds CM2 through eliminating no significant relationship on M2. In Table 3, CM2 is more reasonable for examining the relationship among each factor of tourist destination image, place attachment and tourist loyalty. In the light of the output results of CM2, this study sorts out the relevant information, this is shown in Table 4. According to the output results of CM2, this study draws the final relationship figure (see Figure 2).

TABLE 3 M2 /CM2 fit index

Category	X^2/DF	RMR	RMSEA	GFI	IFI	CFI	TLI	NFI
M2	2.159	0.029	0.059	0.887	0.913	0.911	0.892	0.849
CM2	2.035	0.027	0.056	0.898	0.927	0.926	0.913	0.866

TABLE 4 Test results of CM2

Hypothesis	Estimate	C.R.	P-value	Result
Landscape image→ affective image	0.154	2.087	0.037	Supported
Merchandise image→ affective image	0.398	5.522	***	Supported
Facility image→ affective image	0.309	3.790	***	Supported
Landscape image→ place attachment	0.434	5.963	***	Supported
Merchandise image→ place attachment	0.176	2.497	0.013	Supported
Service image→ place attachment	0.173	2.984	0.003	Supported
Affective image→ place attachment	0.350	4.954	***	Supported
Facility image→ tourist loyalty	0.245	2.731	0.006	Supported
Place attachment→ tourist loyalty	0.846	7.511	***	Supported

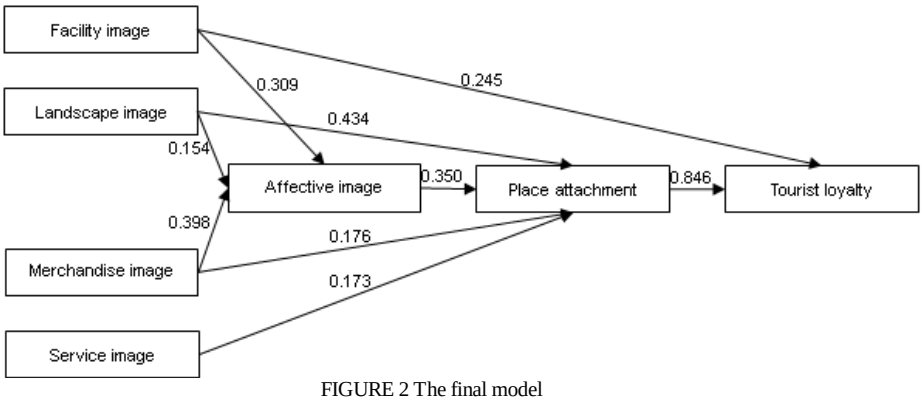

FIGURE 2 The final model

In the light of the relationship described by Figure 2, this study figures up direct effects and indirect effects (see Table 5). Table 5 indicates that:

1) Among the factors of tourist destination cognitive image, merchandise image is the important antecedent variable of affective image.
2) Merchandise image is the important antecedent variable of place attachment.
3) Facility image is the important antecedent variable of tourist loyalty.

TABLE 5 Influential effects

Path	Standardized estimate		
	Direct effects	Indirect effects	Indirect effects
landscape image→ affective image	0.154	0	0.154
Merchandise image → affective image	0.398	0	0.398
facility image → affective image	0.309	0	0.309
landscape image→ place attachment	0	0.054	0.054
Merchandise image → place attachment	0.176	0.139	0.315
facility image → place attachment	0	0.108	0.108
service image → place attachment	0.173	0	0.173
landscape image→ tourist loyalty	0	0.046	0.046
Merchandise image → tourist loyalty	0	0.266	0.266
facility image → tourist loyalty	0.245	0.091	0.336
service image → tourist loyalty	0	0.146	0.146

5 Discussion and conclusion

This article examines the relationship among each factor of tourist destination image, place attachment and tourist loyalty. The results of the structural relationship analysis reveal that:

1) Landscape image, merchandise image and facility image have positive effects on affective image.
2) Landscape image and merchandise image significantly and directly affect place attachment while partially mediating the effect of affective image.
3) Service image has a direct effect on place attachment.
4) Facility image has an indirect effect on place attachment.
5) Facility image significantly and directly affects tourist loyalty while partially mediating the effect of place attachment. Therefore, each factor of cognitive image has different effects on the relationship among affective image, place attachment and tourist loyalty, indicating that each factor of cognitive image should be treated differently.

Another finding of this article is that Affective image has a direct effect on place attachment. Not only that, but affective image is an antecedent variable of tourist loyalty while completely mediating the effect of place attachment. In other words, affective image and place attachment are two important antecedent variables of tourist loyalty. These results reveal that:

1) It is imperative to foster affective image in order to improve place attachment.

2) It is urgent that international tourist destination management should cultivate place attachment in order to enhance tourist loyalty.

Deployment algorithm based on dynamic multi-populations particle swarm optimization for wireless sensor networks

Lei Hong*

School of Information Technology, Jinling Institute of Technology, Nanjing 211169, China

Received 1 March 2014, www.cmnt.lv

Abstract

Aiming at improving coverage rate and reducing coverage holes of wireless sensor networks, this paper proposes a deployment algorithm based on dynamic multi-populations particle swarm optimization. K-Means clustering algorithm is employed to divide the network into several sub-populations dynamically, which could weaken particles on the pursuit of local optima, realize the improvement of basic PSO (Particle Swarm Optimization) algorithm, and solve the "premature" problem of basic PSO algorithm effectively. In addition, it also accelerates the convergence of the algorithm. Simulation results show that this deployment algorithm can improve the network coverage rate effectively. Comparing with the conventional particle swarm optimization algorithm, its coverage rate is increased by 3.66%.

Keywords: deployment, particle swarm optimization, *k*-means, wireless sensor networks

1 Introduction

Wireless sensor network is constituted in ways of self-organization and multi-hop by large volumes of sensor nodes with communication and computation capability. Nodes in the network are able to collaboratively perceive, collect, process, and transmit the information of perceived objects within the coverage area of the network, as well as to report the information to users [1,2]. Wireless sensor network has great potential application value in military, transportation, medical care, and environment monitoring [3,4]. Node deployment is a key issue in wireless sensor network, which reflects the quality of awareness service provided by the network.

Currently, there are mainly two ways to deploy nodes for wireless sensor network: deterministic deployment and random deployment [5]. Deterministic deployment refers to the approach that, when the status of wireless sensor network is relatively fixed, or the size of deployment area is determined, network topology structure may be determined according to pre-set node position, or sensor node density in key areas may be increased. However, in practical natural environment, the environment of monitored area may be quite severe, or the network status is not determined in advance. As for this, random deployment may be adopted. However, this deployment method may easily lead to dead zones. Under certain deployment density, it may be hard to reach the required coverage rate. Hereby, how to reduce dead zones and to improve network coverage rate is an important problem urgently needing to be solved by wireless sensor network.

Based on parallel optimization and fast convergence of fish swarm algorithm, Literature [6] proposed WSNs coverage optimization strategy based on fish swarm algorithm. Literature [7] put forward a mobile sensor deployment algorithm based on virtual force. The algorithm integrates the concepts of field potential and disc packet. Yet, VFA didn't solve the problem of "dead zone". Literature [8] proposed a sensor node deployment algorithm based on virtual rhombic grid. The algorithm integrates deterministic deployment and self-organizing deployment into a unified platform. Particle Swarm Optimization (PSO) [9] is an intelligent optimization algorithm firstly proposed by Professor Kennedy and Eberhard from the US. Its ideology derived from artificial life and evolutionary computation theory, which was mainly inspired by birds flock's behaviour of looking for food. Literature [10] and Literature [11] presented a wireless sensor network deployment optimization method based on particle sward optimization algorithm. Although particle sward optimization algorithm is proved with the ability to optimize wireless sensor network deployment, in spatial searching, standard particle sward optimization algorithm is easy to take on "precocity" phenomenon, which limits the searching range of particle. In allusion to the problem of regional optimization that may be resulted by precocity of PSO algorithm, Literature [12] introduced the concept of disturbance factor into the basic particle sward optimization algorithm, and also applied disturbance factor in mixed wireless sensor networks. In Literature [13], Lin, et al. put forward multi-populations PSO algorithm, which was able to improve the optimazation performance of particles. It's running efficiency and precision was both superior to mono-population PSO algorithm. However, the literature divided sub-population by randomly selecting particles in populations. Such sub-population division strategy was blind to some extent.

* ***Corresponding author's*** e-mail: honglei@jit.edu.cn

With respect to the above issues, the paper puts forward a wireless sensor network node deployment optimization strategy based on dynamic multi-populations particle sward optimization (DMPSO) algorithm. In the optimization process, *k*-means clustering algorithm is introduced to divide the population into several sub-populations, so that optimization may be performed independently on these sub-populations. On the other hand, in order to enhance the information exchange between sub-populations, sub-populations are dynamically re-grouped, so as to reduce parties' pursuit for regional optimal point, and to effectively avoid particle "precocity" in basic PSO algorithm. This improves the coverage rate of network.

The rest part of this paper is organized as follows: in Section 2, we propose the deployment model for wireless sensor networks. In Section 3, we propose the DMPSO algorithm. In Section 4, we simulate the DMPSO optimazation scheme by using computer software and evaluate its performance. Finally, in Section 5, we reach the main conclusions.

2 Deployment model

2.1 PARTICLE SWARM OPTIMIZATION MODEL

Standard particle sward optimization algorithm [14] takes individuals as particles without weight and volume in *N*-dimensional space, which flies at a certain velocity in the searching space. The flying velocity is dynamically adjusted according to individual and population flying experience.

Assuming that $X_i=(X_{i1}, X_{i2}, \ldots, X_{iN})$ is present position of Particle *i*; $V_i=(V_{i1}, V_{i2}, \ldots, V_{iN})$ is present flying velocity of Particle *i*; $P_i=(P_{i1}, P_{i2}, \ldots, P_{iN})$ is the best position experienced by Particle *i*, i.e. the position experienced by Particle *i* with the best adaptive value, which is denoted as P_{best}, also referred to as individual best position. Assuming $f(x)$ as minimized fitness function, so that the best position of Particle *i* may be determined by the below equation:

$$P_i(t+1)=\begin{cases} P_i(t) & f(X_i(t+1)) \geq f(P_i(t)) \\ X_i(t+1) & f(X_i(t+1)) < f(P_i(t)) \end{cases}. \quad (1)$$

Assuming the number of particles in the population is *s*, and the best position experienced by all particles in the population as P_g, also referred to as global best position g_{best}, so that:

$$P_g(t) \in \{P_0(t), P_1(t), \ldots, P_s(t)\} \mid f(P_g(t)) = \min\{f(P_0(t)), f(P_1(t)), \ldots, f(P_s(t))\}. \quad (2)$$

For the *t*-th iteration, motion of Particle *i* in *d*-dimensional space ($1 \leq d \leq D$) follows the below Equation:

$$v_{id}(t+1)=\omega \cdot v_{id}(t)+c_1 \cdot rand() \cdot (P_i - x_{id}(t)) \quad c_2 \cdot rand() \cdot (P_g - x_{id}(t)), \quad (3)$$

$$x_{id}(t+1)=x_{id}(t)+v_{id}(t+1), \quad (4)$$

where, ω is inertia coefficient, which endows particles with the tendency to expand the searching space, so as to search new areas; c_1 and c_2 are acceleration constant; rand() refers to the random values within [0,1].

2.2 OPTIMIZATION MODEL FOR DMPSO

Particle swarm optimization algorithm based on dynamic multi-populations (DMPSO) is an improved multi-populations PSO algorithm. Basic ideology of DMPSO: In the algorithm, population is divided into several sub-populations by *k*-means clustering algorithm, so that sub-populations may be optimized independently. Meanwhile, after several generations of iteration, sub-populations are then re-divided to form new sub-populations, so as to enhance information exchange between sub-populations.

Assuming that there are m particles in Population *M*, the m particles are then divided into *K* sub-populations, which may be described as $M=(M_1, M_2, \ldots, M_k)$. Each sub-population may also be represented as $M_i=(X_1, X_2 \ldots X_p)$, ($i=1, 2 \ldots K$; $0 \leq p \leq m$), and elements in sub-populations stand for individual particles, and the total number of particles in all sub-populations is *m*. For each Particle *i* in sub-populations, X_i is employed to indicate its position $X_i=(X_{i1}^1, X_{i1}^2, X_{i2}^1, X_{i2}^2, \ldots, X_{iN}^1, X_{iN}^2)$, where elements in it separately refer to horizontal coordinate and vertical coordinate of sensor nodes in the particle. The flying velocity of Particle *i* is described as $V_i=(V_{i1}^1, V_{i1}^2, V_{i2}^1, V_{i2}^2, \ldots, V_{iN}^1, V_{iN}^2)$, where elements in it the component velocity of sensor nodes in the particle along X axis and Y axis. Clustering center is taken as the best position passed by all particles in each sub-population, represented by P_{lg}, also referred to as Lg_{best}. P_{lg} is used to replace population global best position P_g in Equation (1). After the improvement, velocity evolution formula of Particle *i* in *d*-dimensional space ($1 \leq d \leq D$) is shown below:

$$v_{id}(t+1)=\omega \cdot v_{id}(t)+c_1 \cdot rand() \cdot (P_i - x_{id}(t)) \quad c_2 \cdot rand() \cdot (P_{lg} - x_{id}(t)). \quad (5)$$

In each sub-population, particles often perform searching with clustering center as the best position of the sub-population. If clustering center of the sub-population is coincidentally located at the position of regional optimal solution, the sub-population may take on "precocity" convergence. Here, after *R* generations' iteration, all particles in population will be considered as a whole, and will be divided into new sub-generations by *k*-means clustering algorithm. Dynamic re-combination of sub-population is designed to improve information exchange between sub-populations, so as to avoid "precocity" of particles.

Moreover, *k*-means clustering algorithm is adopted to partition the data of all node coordinates into *K* areas, i.e. the number of sub-populations. The number of sub-populations determines social information sharing degree between particles in each sub-population. If parties are lack

of social information sharing, network coverage may be significantly reduced.

In order to enhance global searching performance of particles in searching process, inertia coefficient factor in velocity evolution Equation (5) will be appropriately adjusted:

$$\omega(\mathrm{t}) = 0.9 - \frac{t}{\max Iterations} \cdot 0.5, \tag{6}$$

where, t refers to present iteration generation of particle, and maxIterations stands for the maximum iteration generation in the algorithm. It may be seen from Equation (6) that ω reduces linearly with the iteration generation increases. As for this, the algorithm is endowed with strong global searching ability in the beginning and strong regionnal searching ability in later phase.

3 DMPSO deployment algorithms

In the paper, random deployment method is employed. In the beginning when nodes are scattered into the monitoring area, dead zones may be easily caused in the network. As for this, secondary deployment shall be performed in allusion to such "problematic" area. In order to simplify the network model, assuming that Monitoring Area A is a two-dimensional plane, while N sensor nodes with the same parameters are scattered in the area. The perception radius of each node is denoted as R_s, and communication radius as R_C. In order to keep the connectivity of network, communication radius is set no less than two times of the perception radius [15], i.e. $R_c \geq 2R_s$. Sensor node set is denoted as $S=\{S_1, S_2, \ldots, S_N\}$, where, $S_i = \{x_i, y_i, R_s\}$, $i \in (1, 2, \ldots, N)$. The coverage model of each node may be considered as a circle with coordinates of the node as the center, and R_s as the radius.

Digitally discretizing Monitoring Area A as $\mathrm{m} \times \mathrm{n}$ pixels, with coordinates of pixels as (x,y), and the distance between sensor node $\mathrm{S_i}$ and a certain pixel p shall be:

$$d(\mathrm{S}_i,\mathrm{p}) = \sqrt{(x_i - x)^2 + (y_i - y)^2}. \tag{7}$$

Here, node Boolean coverage model, i.e. 0-1 coverage model, is employed. Assuming the event of a certain pixel's being covered by sensor nodes in the monitoring area as $\mathrm{t_i}$, if the event is true, $p(\mathrm{t_i})=1$; or else $p(\mathrm{t_i})=0$. Being described in Equation:

$$p(\mathrm{t}_i) = \begin{cases} 1, & d(S_i, p) \leq R_s \\ 0, & d(S_i, p) > R_s \end{cases}. \tag{8}$$

Monitoring Area A is a $\mathrm{m} \times \mathrm{n}$ rectangle, which is divided into $\mathrm{m} \times \mathrm{n}$ pixels of equal size, with area as 1. The discrete precision is 1. For pixel (x,y), as long as there is 1 node in Node Set S covers the pixel, the pixel shall be considered being covered by Node Set S. Otherwise, the pixel (x,y) shall be considered uncovered. Denoting the rate of pixel (x,y)'s being covered by Node Set S as p(x,y,S), so that:

$$p(\mathrm{x},\mathrm{y},\mathrm{S}) = \mathrm{p}(\bigcup_{i=1}^{N} t_i) = 1 - \prod_{i=1}^{N} (1 - \mathrm{p}(\mathrm{t}_i)). \tag{9}$$

As for this, the total area covered by Sensor Node Set S is just the union set of all pixels covered by all nodes in the node set, denoted as S_{area}, then:

$$S_{area} = \int_0^m \int_0^n p(\mathrm{x},\mathrm{y},\mathrm{S})\,\mathrm{dxdy}. \tag{10}$$

The optimization goal of wireless sensor network node deployment is to maximum the coverage rate of the network. Here, coverage rate refers to the specific value between coverage area of Node Set S and the total area of the monitoring area, i.e.:

$$\sigma = \frac{S_{area}}{\mathrm{m} \times n}. \tag{11}$$

Denoting the fitness function as follows:

$$f(\mathrm{X}) = \max \sigma = \max(\frac{S_{area}}{m \times n}). \tag{12}$$

When f(X) obtains it maximum value, node position information is the best deployment position of node in wireless sensor network.

Each particle in monitoring area represents one sensor node deployment method. When Equation (9) is taken as the fitness function, node deployment optimization algorithm based on DMPSO is shown as Algorithm 1:

ALGORITHM 1: DMPSO algorithm

Algorithm: DMPSO

a) Initializing m particles, i.e. randomly generating Position X_i and Velocity V_i of each particle;
b) Dividing the population into K sub-populations with k-means clustering algorithm;
c) Updating the velocity and position of each particle in each sub-population with Formula (2)~(4);
d) Calculating the coverage rate of each particle according to fitness function;
e) Comparing the coverage rate of particle with its best position P_{best}; if the result is better, re-setting P_{best};
f) Comparing the coverage rate of each particle in each sub-population with the best position of the sub-population Lg_{best}; if the result is better, re-setting Lg_{best};
g) Judging if R iteration generations have been reach; if so, returning to b); or else, executing h);
h) If the pre-set maximum iteration generation or satisfactory coverage rate has been reached, stopping the process; optimal individual position X_i of the population shall be taken as the result; or else, returning to c) and repeating the steps.

4 Experiments and result analysis

4.1 COVERAGE AND UNIFORMITY

Generally, coverage can be considered as the measure of quality of service of a sensor network. Gage invented the concept of coverage in the research of multi-robot systems [16]. We define it as the ratio between sum of the coverage area of all the nodes and the area of the entire target region,

shown in Equation (13). The definition of sum of the coverage area is taken from the concept of union in the Set Theory, thus the coverage is usually less than or equal to 1.

$$Coverage = \frac{\bigcup_{i=1,\ldots,N} A_i}{A}. \quad (13)$$

The uniformity of coverage is a well-defined standard to measure the service life of a network. Article [17] describes the concept as the standard deviation of distance between nodes. Smaller standard deviation means better coverage uniformity of the network, as shown in Equation (14).

$$\begin{cases} U_i = \left[\frac{1}{n}\sum_{j=1}^{n}(d_{i,j} - \bar{d})^2\right]^{\frac{1}{2}}, \\ U = \frac{1}{N}\sum_{i=1}^{N} U_i \end{cases} \quad (14)$$

where in Equation (14), U is the Uniformity, N is the total number of nodes, U_i is the standard deviation of distance between the i-th node and its adjacent nodes, n is the number of neighbors of the ith node, $d_{i,j}$ is the distance between i-th and j-th nodes, $\bar{d}$ is the mean of internal distances between the ith node and its neighbors. So far, we have discussed the relation between communication and coverage. Article [16] has proved that when the communication range of node is twice or larger than the sensing range, coverage will contain pure connections. In practical deployment, we only have to consider the coverage so as to ensure the connection. At the moment, coverage contains connection problems.

4.2 SIMULATION

Assuming that the monitoring area of wireless sensor network is a 50m×50m square, perception radius of each sensor node R_s=5m, and communication radius R_c=2R_s=10m. 35 nodes are randomly deployed in the monitoring area. As particles are diversified, when the number of particles is larger, distribution of nodes may be relatively even. However, with the number of particles increases, the calculation duration may increase exponenttially, largely reducing the calculation speed. Taking into consideration the above factors, the number of particles in the population is assumed to be 30. The flying velocity of particles is limited within -3-3m/s, parameter $c1$=0.9, $c2$=0.9, maximum iteration generation I=500.

The number of sub-populations divided with k-means clustering algorithm may eventually affect the coverage rate of the monitoring area. 50 experiments are conducted under situations with K=2 to 30. On this basis, the average value is figured out, leading to the experimental data shown in Figure 1.

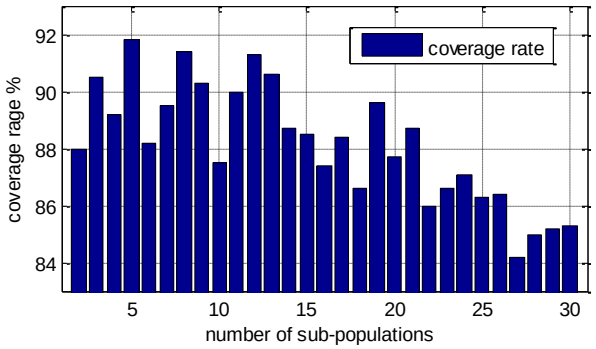

FIGURE 1 Coverage vs. various sub-populations

It can be seen from Figure 1 that, when the number of sub-populations is less than half of the population scale, the coverage rate is generally higher than that when the number of sub-populations is more than half of the population scale. As for this, the number of sub-populations is controlled within 3-8, and the effect would be better. The reason is that, when the number of sub-populations is relatively less, a certain amount of particles for each subpopulation could be guaranteed. In essence, PSO algorithm is a sort of swarm intelligence algorithm. The velocity of particle is co-determined by its flying experience and companions' flying experience. Population diversifycation of each sub-population shall be guaranteed, so that particles in each sub-population may be able to interact and to exchange information. On the contrary, when the number of divided sub-populations is larger, there might be fewer particles for each sub-population. As for this, particles may be lack of social information sharing, and the probability of reaching optimal solution would be lower. According to the experiment, when the population is divided into 5 sub-populations, wireless sensor network deployment optimization effect is the best, and the coverage rate at the moment is 91.89%.

In order to test the effectiveness of DMPSO algorithm, simulation experiment based on two models is performed. In other words, standard PSO algorithm and improved DMPSO algorithm are separately applied to optimize node deployment for wireless sensor network. Figure 2a shows the initial status of node random deployment; Figure 2b is wireless sensor network deployment result based on the optimized PSO algorithm; Figure 3c is wireless sensor network deployment result based on the improved DMPSO algorithm.

In the Figure 2, solid black dots indicate the position of sensor nodes, while circles refer to the perception range of nodes. After 500 times' iteration, the coverage rate of wireless sensor network deployed with standard PSO algorithm is 88.23%; the coverage rate of wireless sensor network deployed with DMPSO algorithm is 91.89%. Thus, it can be seen that, the coverage rate of the improved algorithm is increased by 3.66%, reaching the effect of deployment optimization. Shown by Figure 2, node distribution in (c) is more even than that in (b), so that the rate of "dead zone" and repeat coverage is relatively lower. DMPSO algorithm divides particles into

several sub-populations via clustering. On this basis, particles in each sub-population will be able to adjust the flying direction according to their respective flying experience and the "global optimum" of their sub-population. When the frequency of worst fitness of a certain particle reaches the pre-set value, the particle will consequently be regarded as being unfit for present searching environment, which needs to be optimized. As for this, the particle will be removed from regional optimal value for optimal solution. In this way, particles may be able to get rid of regional optimal value, to expand the searching range, and to effectively solve the problem of "precocity".

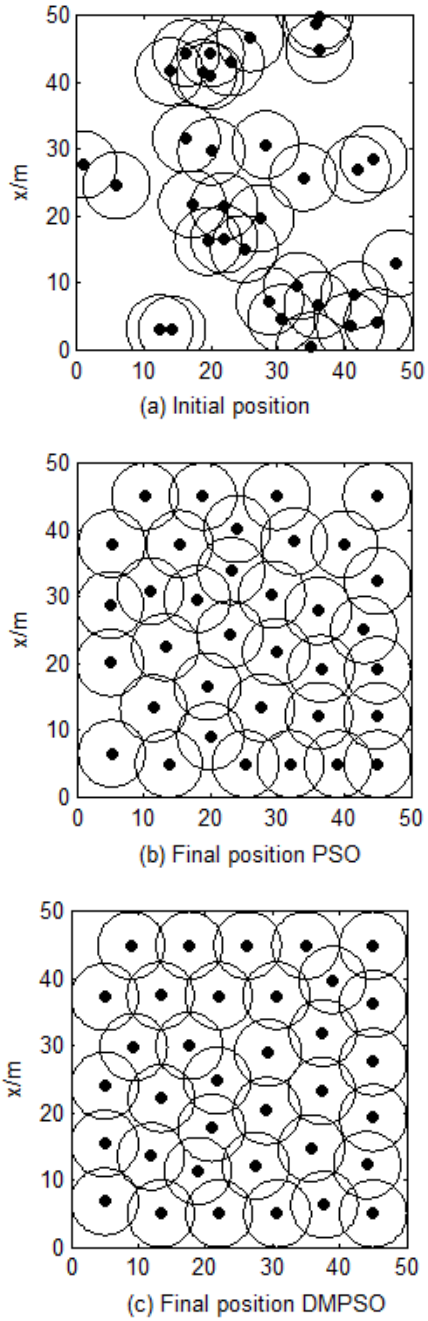

FIGURE 2 Deployment of sensor nodes

Figure 3 shows coverage and uniformity changing curve of DMPSO algorithm. According to the figure, the initial coverage rate of network is approximately 35%. After 500 iterations, the coverage rate is significantly improved. Seeing from the growth slope of the curve, in the first 100 generations of iteration, the slope of curve is relatively higher, and the coverage rate increases sharply. After 150 iterations, the slope reduces obviously, and the coverage rate grows gently, eventually being stabilized to a constant. The reason for this is that, under the influence of inertia coefficient, the algorithm is easy to converge to a global best position in the early stage. With the number of iteration increases, particles begin to oscillate around the best position, so that the result obtained tends to be stabilized to the best result 91.89%. Compared with the initial coverage rate, the coverage rate at the moment is improved by approximately 55%. Thus, it may be seen that, the algorithm shows more obvious effect in improving network coverage rate.

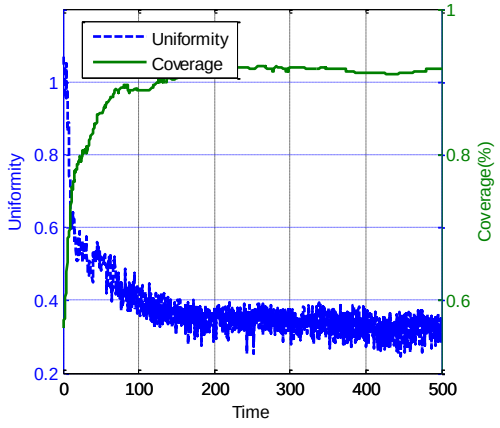

FIGURE 3 Coverage and Uniformity of DMPSO

Figure 4 shows the coverage rate of standard PSO algorithm and DMPSO algorithm. According to Figure 4, the number of iteration of standard PSO algorithm when reaching convergence is around 350, and for DMPSO algorithm, the number is around 300. The convergence speed of the improved algorithm is improved by approximately 14%.

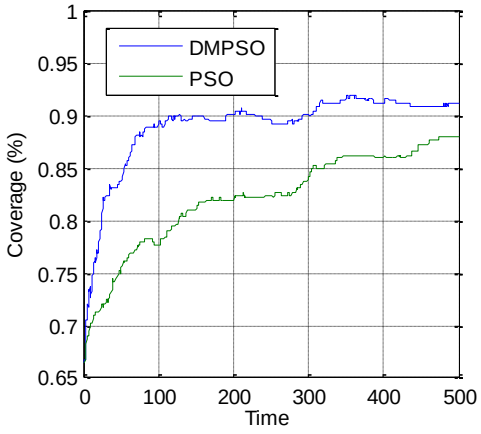

FIGURE 4 Comparison of PSO and DMPSO coverage

Thus, it may be seen that, in wireless sensor network deployment optimization, DMPSO algorithm has better convergence performance than that of PSO algorithm.

In order to further test the feasibility of DMPSO algorithm, common genetic algorithm, and bee colony algorithm are employed to compare with DMPSO algorithm proposed in this paper. The number of iteration of all the three algorithms is 500. Table 1 shows simulation result comparison of the 3 algorithms after 50 times of statistics.

TABLE 1 Comparison of various algorithms

Algorithm	Coverage %	Iteration
Genetic Algorithm	80.3	485
Bee Colony Algorithm	85.2	426
DMPSO	91.89	308

Shown by Table 1, compared with genetic algorithm and bee colony algorithm, DMPSO algorithm improves network coverage rate separately by 11.59% and 6.65%. Moreover, DMPSO algorithm reaches the best solution within less generation. As for this, it is feasible to apply DMPSO algorithm to optimize wireless sensor network node deployment.

4 Conclusions

In this paper k-means clustering method is introduced to propose a particle swarm model for dynamically dividing sub-populations. The algorithm effectively solves the "precocity" problem of standard PSO algorithm. Moreover, the simulation result also shows that, the proposed DMPSO algorithm is able to optimize the deployment of WSN node, and to improve the network coverage. How to reduce the repeat coverage of node, so as to further improve network coverage rate is a key problem to be further studied in future.

Abstract

The paper proposed a mathematical modelling of financial contagion dynamics that is tightly linked to systematic risk of industrial complex network. And the paper provides a practical method to assess fragility of industrial complex network in the context of financial contagion. To examine its function, an experimental analysis based on real data set of a Chinese textile industrial network is conducted. The experimental analysis shows that the method proposed in the paper is effective ad reliable, and is capable to assess fragility of industrial complex network in the context of financial contagion.

Keywords: financial contagion, fragility, industrial complex network, assessment method

1 Introduction

Industrial complex network, such as Industrial clusters, are complex network of lots of interconnected companies in a specific industry. These companies are bonded together with highly complicated business, technological and financial relationships. In this way, these industrial systems are essentially complex networks. And these industrial complex networks play significant roles in the process of regional development in European countries, Asian countries and other areas. In rural area of emerging countries, many township economies are essentially mixtures of several industrial clusters that are typical industrial complex networks. The performance of these industrial clusters is crucial for economic development and social stability of these developing areas.

However, these industrial complex networks are readily destructed by market fluctuation and economic crisis because their interior complex network imposed risk interdependency on each individual organization. "Robust yet fragile" is a characteristic of complex network. Idiosyncratic risk of bankruptcy of an important company in the network would be likely to trigger systematic risk by inter-company financial contagion in context of interdependent industrial network. Domino-style bankruptcy in such interdependent business cycle occurs more frequently in recent years, and receives concerns of policy-makers. The argument that inter-company financial contagion is a critical step leading to systematic crisis [1] is supported by empirical evidences and case studies in recent literatures. With financial contagion and systematic risk are widely talk about in literatures, fragility of industrial complex network in the context of financial contagion became an important topic. Recent work on physical networks, such as internet and power grid, has addressed the resilience of these networks to idiosyncratic risk. Scientific works in complex network-related field has provides ideas about how to measure fragility of physical complex network. And recent financial literatures offer in-depth insights about financial contagion [2-7]. Though similar topics are discussed by scholars from disciplines, more efforts are needed to shed some light on financial contagion and its impact on fragility of industrial complex network. In previous works, the author proposed a framework for testing stability of regional industrial cluster considering inter-company financial contagion [9], and developed a network model for inter-company financial contagion [10]. In the paper, the author tries further to propose a new method for evaluating fragility of industrial complex network in the context of financial contagion.

The paper is organized as follows. The paper discusses contagious effect of idiosyncratic risk in the complex network of an industrial network in the second section. Then the paper introduces a new method for measuring fragility of industrial complex network in third section. In fourth section, the paper would illustrate an experimental analysis in the background of a Chinese industrial cluster. Its fragility would be discussed in details in this section, along with validation of this new measuring method.

2 Modelling financial contagion dynamics

In this section, the paper derives a basic mathematical framework for modelling dynamic process of financial contagion triggered by bankruptcy of one or several companies in context of industrial complex network. The paper considers mechanisms of risk interdependence and trend reinforcement in an inter-company network in the model. The paper describes an industrial complex network as a graph (donated by $G=(N,R)$), in which a set of N companies are connected with others via financial contacts.

* ***Corresponding author's*** e-mail: jamesbewood@126.com

The network is also associated with an adjacency matrix $M=\left[M_{ij}\right]$, where $M_{ij}=0$ means there is not financial contract from company *i* to company *j*, and $M_{ij}=1$ represents there is some kind of financial contract from company *i* to company *j*, i.e. company *i* invested some money or lend some money to company *j*. And the out-degree of company *i* in this network, k_i represents the number of counterparties to which company *i* is exposed. And a weight matrix $H=\left[H_{ij}\right]$ is introduced. In which, the weight H_{ij} represents the exposure of *i* to *j* relative to its portfolio of all exposures. So, the matrix H is defined as a row-stochastic matrix, and subjects to $\sum_j H_{ij}=1$. Denote M_{ij} must equal to 1, if H_{ij} is more than zero.

According to literatures about financial contagion, the dynamic law of financial contagion process can be modelled as the two mechanisms of interdependence and trend reinforcement (or financial accelerator). The paper employs stochastic differential equation (SDE) to include mechanisms of interdependence and trend reinforcement in our framework, and to investigate their interplay in the contagious process. Denote a financial robustness indicator β_i for each node *i*, to measure its distance from actual default or to indicate its state of liability reputation. If $\beta_i=0$, the node *i* has been on the situation of default or bankruptcy. A drift term that depends on the past realizations is introduced in the SDE for representing the mechanism of financial accelerator. The paper restricts the dependence at time t on the past only to $t'=t-T$. This is, β_i at t time is dependent on the realization of β_i at time $t'=t-T$. So, the paper models the law of motion of robustness by the following time-delayed SDE.

$$d\beta_i=L\left(\beta(t),\beta(t')\right)dt+\sigma d\varepsilon_i, \tag{1}$$

where $L\left(\beta(t),\beta(t')\right)$ is not more than 0, σ is the variance of idiosyncratic shocks that hit company *i*, and $d\varepsilon_i$ denotes the Wiener stochastic process.

Then, the expected fist passage time T_f is $T_f\sim 1/\sigma^2$, if financial accelerator is absent ($L\equiv 0$). While, the negative drift would make the expected fist passage time shorter, i.e. $T_f\left(L\prec 0\right)\prec T_f\left(L=0\right)$. In this way, financial accelerator would increase the probability of default or bankruptcy. And the paper restricts interdependence in the context of complex network. Denote C_{ij} as the asset related to company *j* and held by company, such as a liability of company *j* to company *i*. Then the value of asset C_{ij} depends on financial robustness of company *j*, i.e. its ability to meet the obligation to company *i*. To be more specific, the paper assumes the value of asset C_{ij} is proportional to the financial robustness of β_i, i.e. $C_{ij}=C_{ij}^0\times\beta_j$, where C_{ij}^0 is nominal value of the asset. Then the total assets of company *i* at a time *t* is determined based on the estimate of financial robustness of its counterparties at time $t-1$.

$$C_i(t)=\sum_j C_{ij}(t-1)=C_i^0\sum_j H_{ij}\beta_j(t-1), \tag{2}$$

where C_{ij}^0 is the nominal value of investments or obligations invested or lent by company *i*, H_{ij} is fraction of investments or obligations of company *i* that is related to company *j*. Thus, H_{ij} is a reasonable proxy of relative impact on total asset of company *i* due to a change in financial robustness of company *j*. In this way, the interdependence mechanism is modelled in the context of a network of financial contacts.

The paper assumes financial robustness is linearly dependent on its counterparties in absence of bankruptcies:

$$\beta_i(t)=\sum_j H_{ij}\left(\beta_j(t-1)+\sigma\varepsilon_i(t-1)\right). \tag{3}$$

And assume financial robustness is subject to independently and identically normal distribution. If company *i* is hit by idiosyncratic shock, its own loss is only proportionally to the term H_{ij} due to this shock hit. Other loss would be shared among its counterparties. And company *i* also would be proportionally affected by the shocks hitting its counterparties. Then, the change of financial robustness is express by following equation:

$$\beta_i(t)-\beta_i(t-1)=\sum_j H_{ij}\left(\beta_j(t-1)-\beta_i(t-1)\right)+\sigma\sum_j H_{ij}\varepsilon_j(t-1). \tag{4}$$

Passing to the limit of continuous time and introducing Equation (1) into Equation (4) to capture the financial accelerator, then:

$$d\beta_i=\left[\sum_j H_{ij}\beta_j(t)-\beta_i(t)+L\left(\beta(t),\beta(t')\right)\right]dt+\sigma\sum_j H_{ij}d\varepsilon_j, \tag{5}$$

where $d\varepsilon_j$ is an independent Wiener stochastic process. Since $d\varepsilon_j$ is independent, its linear combination is still a Wiener stochastic process. So, denoted as $d\tau_i=\sum_j H_{ij}d\varepsilon_j$, Equation (5) could rewrite as following:

$$d\beta_i=\left[\sum_j H_{ij}\beta_j(t)-\beta_i(t)+L\left(\beta(t),\beta(t')\right)\right]dt+\sigma d\tau_i. \tag{6}$$

A company goes bankrupt when its robustness falls below a given threshold. If the bottom threshold is hit then the robustness value is initiated to Zero. Also, for the sake of simplicity, the paper assumes the robustness cannot exceed an upper barrier at $\beta_i=1$. Then the dynamics of financial contagion process in the context of industrial complex network can be captured by the theoretical model.

3 Assessing fragility of industrial complex network

To simulate financial contagion process as described in the above theoretical model, the paper formulated a simulation procedure as illustrated in Figure 1. The simulation procedure is realized in MATLAB circumstance, operated with the help of software MATLAB 2010(a). Please see Appendix A for details of the simulation procedure.

Recent literatures of scale-free and small-world complex network research have deepened understanding of vulnerability of real-world networks [10,11]. In these researches, fragility of a complex network is generally evaluated by damage of the complex network after removing some most important nodes. To measure fragility of an industrial complex network, the paper simulates a deliberate attack at initial stage, pick up a number of top systematically-weighted nodes as bankrupts, and removes these nodes simultaneously from the network at initial stage. Then a contagion process triggered by this deliberate attack is simulated according to above mentioned procedure. Top 1, top 2 and top 3 systematically weighted nodes are respectively removed in specific simulation circumstances. For simplicity, systemically importance is evaluated by node degree. And the fragility of industrial complex network in such a deliberate attack is measured by the ratio of nodes going bankrupt and total node number.

$$F_T = B/N \,, \tag{7}$$

where F denotes fragility of industrial cluster, T represents simulation circumstance in which top 1, top 2 or top 3 systematically-weighted important nodes are removed by risk shock. B is the number of companys in the industrial complex network that go bankrupt after the ending of contagion process. N is the total number of companys at initial stage.

4 Experimental analysis

4.1 EXPERIMENTAL DATA

To examine the effectiveness of the method for assessing fragility of industrial complex network, this section evaluates fragility of an industrial complex network in Huzhou City of P.R. China. Huzhou city is located in the centre of Yangtze River Delta Economic Area. The city is composed of 6 districts with a total area of 5817 square Kilometres and a population of 2.54 million.

In its history, the city is known for its silk products and other textile products. A network dataset of Huzhou textile industrial cluster is employed in the experimental analysis. And visualization of the industrial complex network is illustrated in Figure 1.

All 27 nodes represent 27 textile companies in the city, which is interconnected with financial bonds. In here, financial bonds include share-holding relationship, debtor-creditor relationship and mutually credit guarantee. Financial information is collected from annual financial reports of these 27 companies, and their capacity to resist risk impact and financial robustness are evaluated based on their asset data and financial indicators.

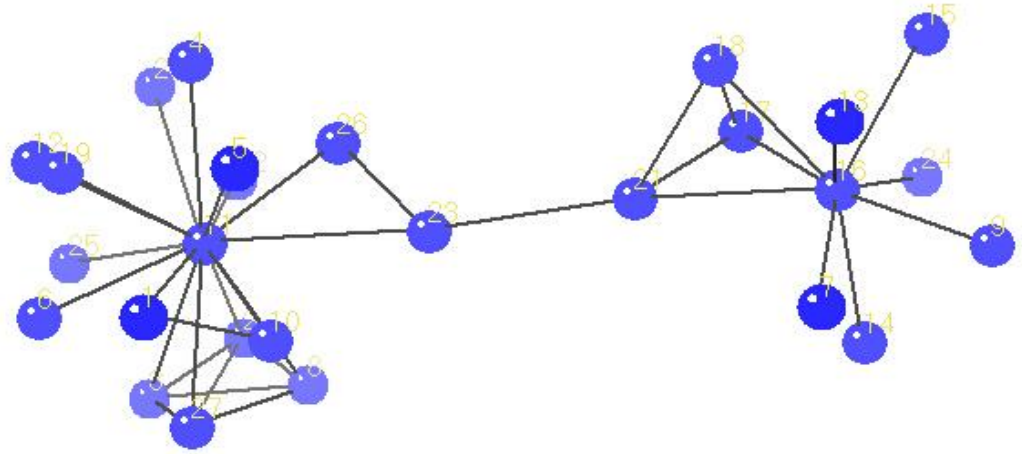

FIGURE 1 Visualization of the industrial complex network in Huzhou City

The strengths of financial bonds are calculated based on their financial releases about investments, liabilities and credit guarantees. The structure characteristics of the network of financial bonds are analyzed by UCINET 6.0, please see Table 1 for details.

TABLE 1 Network characteristics of the industrial complex network in Huzhou city

Network Characteristics	Value
Network centralization	55.08%
Network scale	27 (nodes)
Financial Bonds	73 (ties)
Average Degree	2.71
Network Density	0.1054
Clustering Coefficient	0.370

In the network, node code# 11 and node code# 9 is listed as systematically important nodes. Their share of degree is respectively 21.6% and 12.2% (see Appendix A). And there are many nodes are connected with the two nodes. If the two nodes are removed, these nodes will be disconnected.

4.2 RESULTS

In the experimental analysis, financial contagion process is simulated in a given experimental environment that is similar to real conditions in the Huzhou textile industrial cluster. Contagion effects trigged by each nodes are calculated (Table 2).

In the experimental analysis, the companies that are infected in the contagious process and finally go to bankrupt in the process are counted as infected number. These infected companies that have direct financial contact with the impacted node that is knock out by risk shock at initial stage are listed as number of directly infected. And in the experimental analysis, the industrial complex network is fragile, because 62.96% of nodes in the industrial cluster will go bankrupt in the contagion process if the node code # 11 is removed by risk shock. Furthermore, the whole industrial cluster will be crashed down if only the two nodes (code #11 and 16) are removed by risk shocks. In other aspect, the network is also robust because any other individual bankruptcy, excluding the two nodes (code #11 and 16), will not cause significant impact. Their *F* values are lower than 20%. Only deliberately risk attacks to node code #11 and 16 would cause serious financial panics leading to collapse of the whole network (Table 3).

TABLE 2 Simulation results of contagion process triggered by single bankruptcy

impacted node #	Infected number	Directly infected	Indirectly infected	*F* value	impacted node #	Infected number	Directly infected	Indirectly infected	*F* value

5 Conclusions

The paper has proposed a methodology to evaluate fragility of industrial cluster in the context of financial contagion. The evaluation is based on calculation of contagious effects triggered by bankruptcy of one or several companies and simulation of the contagion process. Huzhou textile industrial cluster is analyzed using the methodology proposed by the paper. The paper concludes that the industrial cluster is fragile, because deliberate attacks targeting only two specific companies will lead to collapse of the whole industrial cluster in the contagion process. And this experimental result supports existing evidence about risk evaluation of similar industrial clusters [6,11,12]. So, the methodology proposed in the paper is an effective way to evaluate fragility of industrial cluster in the context of financial contagion.

TABLE 3 Fragility assessments of deliberate attacks

Deliberate Attacks	Infected nodes (Bankruptcy)	F value Fragility Assessment
Top 1	16 nodes +1 nodes	62.96%
Top 2	25 nodes+2 nodes	100%
Top3	24 nodes+3nodes	100%

In the experimental analysis, all nodes are given an initial financial robustness value ($\beta_i(0)=1$ for all nodes). The financial robustness will be changed rapidly in the dynamic process of financial contagion. The simulation shows that 25 nodes out of total 27 nodes will not trigger substantial financial contagion. This is, the bankruptcy of these companies is not likely to cause financial panics in the industrial complex network, and lead to systematic risk.

In additional tests, the author found that in more severe circumstance, which means more average lower financial robustness, these nodes is still less likely to cause systematic risk. While, the two systematically important nodes (code No.11 and 16) is still more likely to cause large-scale financial contagion and lead to systematic risk. So, in the case of the experimental analysis, network structure is more important factor in determining the fragility of an industrial complex network. This argument is supported by many evidences in related literatures. In the experimental analysis, the paper ranks systematic importance of nodes according its position, especially its centrality degree. The experimental result shows this method is effective. And the logic underlying the

method is also connected with above argument, and supported by literatures.

In the experimental analysis, direct contagion is major effect in the contagion process. Only 3 nodes are cause indirect contagion. However, the author thinks indirect contagion is restricted by its star-centred structure in the experimental analysis. The trend reinforcement effect or financial accelerator plays important role in the contagion dynamics simulated in the experimental analysis. Indirect effects should not be undervalued.

Abstract

Maersk Line has recently introduced a daily service in Asia-Europe route. This new service will bring in a revolutionary impact on the current fixed schedule shipping service in China. There are different views from China market on such daily service since the daily Asia-Europe service route calls mainly China's ports. Through the study of the 'daily Maersk' from 5 perspectives, namely shipping market demand, the required basic port infrastructure, relevant Government policies and regulations, operational aspects and low carbon emission, it is possible to reveal a kind of 'collaborative relations' in the China fixed schedule shipping market. The analysis adopts a qualitative approach via a questionnaire survey of selected experts. With the support of a theoretical mathematical model, it is possible to quantify the collaborative relations in different development phases in China. The study concludes that there are 3 broad phases of the development of collaborative relations and the current daily service emerges in the 'new development era' phase. It is because there are sufficient freight and adequate port infrastructure. The daily service outperforms the general industry practice under the "Rotterdam Rules" on carrier's responsibility and liability and injects contemporary logistics management concepts in the industry. Moreover, it is in the same pace of current China's requirements on energy saving and carbon emission reduction targets.

Keywords: 'Maersk', collaboration, collaborative relations, Asia-Europe

1 Introduction

Maersk Line has introduced a new 'daily Maersk' service for the Asia-Europe route starting in Shanghai [1] from November 2011. The daily service borrows the idea of fixed schedule service from air transport service. It allows shippers to have a better control on their delivery schedules. However, there are some concerns about the provision of daily service within the China shipping industry. The port conditions and level of shipping service have not developed evenly in China to support seamless freight flow for foreign trade. Can the Maersk's daily service in China survive in the short and long run? Through the study of the collaborative relations, the feasibility of providing daily service will be assessed by looking into 5 perspectives, namely shipping market demand, calling port infrastructure, Government policies and regulations, shipping operational factors and carbon emission. A mathematical model has been established to assist in the analysis of different phases of collaborative relations development in China. Finally it is possible to conclude that there are general 3 broad phases in the development of collaborative relations in China shipping industry. The introduction of the 'daily Maersk' is subsumed in the third phase and it should be able to survive. Some enhancements for such daily service will be identified and recommended at the end of this study.

2 Concerns about daily service

This daily service involves the 4 calling ports in Asia with three ports in China (Ningbo, Shanghai, Yantian) and one in Malaysia (Tanjung Pelepas) whereas the European ports at Philip Ke Situo (UK), Rotterdam (Netherlands), and Bremen (Germany). For shipment with Maersk Line scheduled service, it is expected to be on-time but the current 50% on-time is common in the China shipping market. The poor service level forces the shippers to adjust their production schedule as well as its supply chain. The daily service changes the operation of the shipping industry and the shippers' inventory planning. It creates a new standard and marks a milestone. Shippers can now benefit from better inventory control and bank finance. At the moment of writing, the booking of the daily service is getting momentum and growing gradually.

However, the concerns are merger of the 'big' players in order to share their resources to strike against this new challenge. For the small and medium shipping companies, they would easily go broke due to high cost of running daily service and possible demurrage. Subsequently, a new wave of merger and takeover could eliminate some existing players but Maersk Line will secure its monopolistic position in the China shipping industry. On the other hand,

[*] ***Corresponding author's e-mail:*** 552186316@qq.com

the Chinese shipping industry is still developing and the level of ancillary service and conditions may not be able to match with Maersk Line's expectation. Can the Maersk's daily survive in the short and long run? The development of Chinese ports and the supporting service could be a critical factor.

3 Influential factors

3.1 SHIPPING MARKET DEMAND IN CHINA

Would there be sufficient volume of freight to support the development of the Maersk's daily service? The financial tsunami in 2008 had significant impact on Sino-Europe trade. However, after 3 years of recovery in world economy, the trade volume has rebounded and exceeded the level in 2008. According to the 2008 and 2010 China Customs statistics [3] and the internal data analysis (FOXPRO program) of the China Waterborne Transport Research Institute, the container trade between China and the Europe are summarised as follows:

1. In 2010, the trading level reached the value of US$573.1 billion with the export value of US$355.2 billion and import value US$217.9. When comparing with the 2008 level, the 2010 level increased by 12.2%, 3.6% and 29.6% respectively.
2. The demand for container trade is about a total of 11 million TEUs and export from China to Europe with 8.3 million TEUs and 3.2 million TEUs vice versa. It is a huge imbalance of trade. The major sources of TEUs for the Sino-Europe route are coming from 7 provinces in China (Guangdong, Zhejiang, Jiangsu, Shandong, Fujian, Shanghai and Hebei) counting towards 87% of the total (see Table 1 below).
3. In the Asia-Europe route, Maersk will put in 70 ships in the "daily Maersk' service. The capacity is around 8,500 TEUs to 15,000 TEUs. It carries about 57,000 TEUs per week or about 3 million TEUs per year. According to the above Table 1, the annual demand for container transportation will be about 7.7 million TEUs from China to Europe. The Maersk is sharing about 40 percent of Sino-Europe trade so there should be sufficient freight for 'daily Maersk'. Maersk is taking a strategic move in the vulnerable shipping market (after the financial tsunami) in order to scramble for more market share. Other Chinese shipping companies need not be panic and it is just to make sure that their service level could be improved and reliable, rather than simply competing on price in the sea freight.

TABLE 1 Sources of freight (TEUs) in Sino-Europe container trade

4. The unit value of the container trade between China and Europe after financial tsunami has increased as China has undergone structural change in the industry although the container trade volume is decreased (-12.8%) from year 2008 of 225.2TEU / billion U.S. dollars down to year 2010 of 199.6TEU / billion U.S. dollars shown in Table 2. Comparing the year 2010 and 2008, Guangdong, Jiangsu, Zhejiang and Shanghai (municipal) forerun in the adjustment of industrial structure. As long as the world economy is not fluctuated significantly, the demand for container transportation between China and Europe is increasing.

3.2 BASIC INFRASTRUCTURE

3.2.1 Shanghai Port

Shanghai Port refers to container terminals located in Yangshan, Waigaoqiao, and Wusong involving a total of 46 container berths, 155 container quay cranes and 463 gantry cranes, and the yard area of 6.34 million m2. All these container terminals are included as the Shanghai Port integrated by sea and land shuttle service and 'daily Maersk' uses Yangshan Container Terminal (Table 3).

TABLE 3 Yangshan container terminal

	Mingdong	Shengdong	Guandong	Total

3.2.2 Ningbo Port

Ningbo Port refers to Beilun, Chuanshan and Daxie container terminals with total 14 berths and quay length of 4,733 meters. The basic infrastructure for these container terminals are summarised in Table 4.

TABLE 4 Ningbo Port

Container terminal	Berth capacity	Quay length	Berth	Water depth
	(10,000 tonnes)	(m)	(no.)	(m)
Beilun	5~10	2138	7	13.5~15
Chuanshan	10	1785	5	17
Daxie	10	810	2	17.5

Source: website of Ningbo Port at www.nbport.com.cn [5]

3.2.3 Shenzhen Port

Shenzhen Port refers to Shekou, Chiwan and Yantian container terminals with total 44 container berths and a capacity of 18.91 million TEUs.

3.3 GOVERNMENT POLICY AND REGULATIONS

Maersk Line has been keen to maintain close relationship with China Customs to ensure the smooth operation. China Customs is also willing to support Maersk Line via Daxie's Customs which has set up an innovative high-tech regulatory model. The monitoring process is through online data exchange between the Customs and Maersk. Provided that the information is correct, the rebate for the export tax is fast tracked and customs clearance is greatly improved. This is one of the reasons that Maersk Line strategically positions its daily Maersk service in Ningbo Port.

A major possible obstacle in hindering 'daily Maersk' service is the collaboration with different local governments along their voyage when ship replacement is needed. On the other hand, the international regulation "Rotterdam Rules" may have impact on China shipping industry as China has not signed in yet. This does not affect Maersk Line as they have already fixed the demurrage of US$100 per container for delay of first 3 days and US$300 per container for the fourth days or more.

3.4 OPERATIONAL ASPECTS

The ocean container transportation has significantly changed the pattern of world trade. In the past decades, the development of China shipping industry has however no major breakthrough. The unreliable shipment has been a common criticism in the China shipping industry and only 50 percent arriving on time. Every year, China has about a total of 11 million TEUs 'in' and 'out' from/to Europe excluding the transfer of the empty container which adds up to around 15 million TEUs. Maersk Line has offered a fixed schedule daily service in the China shipping market with fixed demurrage. The daily service does not just relieve the pressure of the shippers' inventory control but also enhances the competitiveness of the manufacturing companies in China. This service will change the weakest link in the supply chain into a powerful link. The recent observation is about 95% on-time which projects an average saving between US$200 to US$400 per container.

3.5 ENERGY SAVING AND REDUCTION OF CARBON EMISSION

The trend to change the economic development structure so as to achieve resources saving and carbon emission reduction has been stated in the national policy level since the '11th Five-Year Plan'. The energy consumption in the operation unit of the ship transportation and port throughput fell by 7% and 4% respectively and achieved the related reduction target in energy-saving and carbon emission. In the '12th Five-Year Plan' i.e. the period up to 2015, the proposed energy consumption for the unit of the ship transportation and port throughput to be decreased by 15% and 8% respectively compared to 2005, carbon dioxide emissions would be decreased by 16% and 10% respectively [6].

'Daily Maersk' service is at 13% carbon dioxide emissions lower than the industry average per container with its newly investment in the twenty '3E' class ships to run on the Asia-North Europe route would become the world's most energy-efficient route.

4 Phases of Collaborative Relations

'Collaboration' concept in this study refers to the balancing various needs in the shipping industry via positive and constructive relations. It is a dynamic, interactive and complicated process in order to materialize collaborative relations. The 5 perspectives elaborated in the previous sections would be quantified in a mathematical model below to differentiate the development of collaboration in the China shipping industry at different stage if any. The collaborative relation is therefore quantified through a theoretical mathematical model as follows [7]:

$$F_k = A_k C_k^k \left(X_1,\ X_2,\ \ldots,\ X_i\right) + b, \tag{1}$$

where F_k is the collaborative relations 'k' phase. Collaborative relations phase F_k is directly proportional to the collaborative degree A, which increases as the F_k increases:

$$\begin{cases} F_1 = A_1 C_1 (X_1,\ X_2,\ \ldots, X_i) + b \\ F_2 = F_1 + A_2 C_2^2 (X_1,\ X_2,\ \ldots, X_i) \\ F_3 = F_2 + A_3 C_3^3 (X_1,\ X_2,\ \ldots, X_i) \\ F_4 = F_3 + A_4 C_4^4 (X_1,\ X_2,\ \ldots, X_i) \end{cases}, \tag{2}$$

If $F_1 \leqq F_k < F_2$: the collaborative relations are under an incubation stage;

If $F_2 \leqq F_k < F_3$: collaborative relations in the developing phase;

If $F_3 \leqq F_k < F_4$: collaborative relations in a new era stage where a new business environment emerges:

1) 'A' represents the degree of collaboration subject to factors X_1, X_2, …, X_i (see section 3 above) i.e. different phases when 'A' has developed into different state, then the collaborative relations has evolved into a new environment and new collaborative relation phase; and the value of A_1, A_2, …, A_k can be obtained through a "power function" method:

$$d_i = e^{-e^{\frac{x_i - s}{s-n}}}.$$

When x_i reaches the threshold between the uncoordinated and basic coordination, the A_2 is: d_2=0.3679. When x_i reaches the critical value between the coordination and basic coordination, the A_3 is: d_3=0.6922. So the boundary value of A, that is 0, 0.3679, 0.6922 and 1 respectively, assessments using the Equation (2), calculating the boundary value of F_k when A_i at various degree (A_1=0, A_2=0.3679, A_3=0.6922, A_4=1), 'C' value is 1; and boundary value with no randomness, 'b' = '0' with 'i' factors, therefore:

$$\begin{cases} F_1 = 0 \\ F_2 = F_1 + 0.3679(4i) = 1.4716i \\ F_3 = 1.4716i + 0.6922(8i) = 7.0092i \\ F_4 = 7.0092i + 10i = 17.0092i \end{cases}.$$

2) 'C' represents the degree of collaboration in different phase;

3) 'B' represents the random impact factor; this is to cancel out the random effect of Xi. It can be resolved by curve fitting and i and n are natural number. In order to limit the calibration in this study, the values of C_1, C_2, …, C_k are assumed to be '1' for equal weighting of importance.

5 Expert Assessment on Collaborative Relations

5.1 EXPERTS AND QUESTIONNAIRE

A questionnaire survey to assess the rating of the 5 selected factors was issued to the experts from China Waterborne Transport Research Institute (WTI), China Ocean Shipping Company (COSCO), Tianjin Port (TJ), Shanghai Customs (S Customs), China Maritime Safety Administration (China MSA), Shanghai Maritime University (SMU). The rating provided by the experts were separated in 3 periods within the last 20 years: years 1990~2000 (S1), 2001~2005 (S2), and 2006~2010 (S3); And the feedbacks were summarized in Table 5 below:

TABLE 5 Rating of Experts on the 3 Collaborative Relations

Experts	X_1			X_2			X_3			X_4			X_5		
	S_1	S_2	S_3	S_1	S_2	S_3	S_1	S_2	S_3	S_1	S_2	S_1	S_2	S_1	S_2
WTI	2	4	9	1	5	10	0	5	8	0	5	0	5	0	5
COSCO	1	5	8	1	5	8	1	6	8	1	4	1	4	1	4
TJ	2	4	8	1	4	8	2	5	8	1	6	1	6	1	6
S Customs	3	5	10	1	4	9	1	4	8	0	5	0	5	0	5
China MSA	3	5	9	1	4	9	0	4	8	0	4	0	4	0	4
SMU	1	4	8	1	4	9	1	5	8	0	3	0	3	0	3

In Table 5, the experts rated the 5 factors including market demand, basic infrastructure, Government policies and regulation, corporate operational aspect and reduction in carbon emission in the range of '0' to '10' where '10' the highest rating and '0' the lowest relations. In this study, there are 5 factors so i=5, therefore:

$$\begin{aligned} F_1 &= 0 \\ F_2 &= 1.4716 \cdot 5 = 7.358 \\ F_3 &= 7.0092 \cdot 5 = 35.046 \\ F_4 &= 17.0092 \cdot 5 = 85.046 \end{aligned}.$$

The theoretical value of the collaborative relations is calculated by averaging the total expert rating in a period for each factor (Table 6).

$$S_{tvi} = \frac{1}{n}\sum_{k=1}^{n}\frac{\overline{s_{tvki}}}{n}. \quad (3)$$

S_1 period: *WTI* (X_1, X_2, X_3, X_4, X_5)=(2, 1, 0, 0, 0), $S_{tv1} = X_1 + X_2 + X_3 + X_4 + X_5 = 3$, and so on as in Equation (3): S_{tv1} = theoretical value = (3+4+6+5+4+3)/6=4.2

TABLE 6 Theoretical Value of Collaborative Relations at each period

Experts	S_{tvi}		
	S_{tv1}	S_{tv2}	S_{tv3}
WTI	3.0	24.0	43.0
COSCO	4.0	26.0	40.0
TJ	6.0	23.0	40.0
S Customs	5.0	24.0	44.0
China MSA	4.0	22.0	41.0
SMU	3.0	20.0	41.0
Theoretical value	4.2	23.2	41.5

5.2 THREE PHASES OF COLLABORATIVE RELATIONS

1. In 1990~2000, S_{tv1}=4.2, $F_1 < S_{tv1} < F_2$, the collaborative relations is under an incubation stage. It is the beginning of the container transport market and just receiving attention. The market demand is not strong whereas the container transport infrastructure was poor. The Government policies and regulations did not provide support and there was little effective operation concept. The requirement was basically 'shipped' service since China was in the economic development stage and had little attention on energy saving and environmental protection. It is therefore the expert assessment were in the lowest range '0' for all factors X_1, X_2, …, X_i.
2. In 2001~2005, S_{tv2}=23.2, $F_2 < S_{tv2} < F_3$ collaborative relations in the developing phase together with the rapid development in China's economy and foreign trade (import and export), and the improvement in container transport security, the popularity of using container transport was gaining momentum. Subsequently container transport facilities and infrastructures as well as the Government policies and regulation were gradually matching with the development of container transportation. Furthermore, the introduction of contemporary logistics concepts, national concerns in energy saving and environmental protecttion etc, has put container transport under the spot light. The shippers required more and requested 'shipped well' service. In this phase, the experts rated the factors, X_1, X_2, …, X_i around the mid way 5 points. In this stage, the shipping companies began with strategic alliances to share the capacity among themselves and offer new services in order to reduce the risk. Therefore, this is the developing stage.
3. In 2006~2010, S_{tv3}=41.5, $F_3 < S_{tv3} < F_4$, collaborative relations in a new development era phase where a new business environment emerges. Under this phase, the industrial structure has been adjusted and the economy has recovered from the financial turmoil. There is growing demand in container transport in the foreign trade so the port facilities have also been improved accordingly in particular the improvement in the efficiency of the Customs so as to support the foreign trade. The "Rotterdam rules" gradually attracted the worldwide attention even the shippers require not only "shipped" but "shipped well" so as to achieve environmental benefits. The International Maritime Organization (IMO) adopted the MARPOL 73/78 Convention, marking the official commencement of the low-carbon era. It is therefore the experts rated the factors X_1, X_2, …, Xi for 8 points and more in most cases.

6 Conclusions and Suggestions

6.1 CONCLUSIONS

The three phases of collaborative relations were identified through a mathematical model. It highlighted that the 'Daily Maserk' would definitely bring in a breakthrough in the China fixed schedule shipping service. It is certainly a new standard of service for the shipping industry and raises the level of service to record high. According to the analysis of the collaborative relations, it is concluded that Maersk has launched the 'daily Maersk' service in China's third phase of collaborative relations (new development era phase) so:

1) It has sufficient freight from China calling ports.
2) It has some calling ports with adequate port infrastructure.
3) It can outperform China's requirement in the carrier's responsibility and liability ("Rotterdam Rules").
4) It can inject contemporary logistics concepts into the China ship management practice.
5) It can keep up with the same pace of China's energy saving and reduction of carbon emission.

6.2 SUGGESTIONS

The study reveals that the demand for Sino-Europe route is 11.5 million TEUs in 2010 in which 8.3 million TEUs from China to Europe and 3.2 million vice versa. This serious imbalance generates five million empty containers to be reshuffled. The Maersk operation management should pay attention to this imbalance.

'Daily Maersk' can handle about 3 million TEUs in the Asia-Europe route each year. There is a strong demand on road distribution which may bring in a heavy traffic pressure on the calling ports and creating pollution problem therein. Although a carbon emission of "Daily Maersk" service at its sea link is low, there are more carbon emissions in the upstream of the road transportation chain. Would it be beneficial to use more river fee-

der service? On the other hand, it is recommended that 'daily Maersk' service could be extended to the Taicang Port and Nanjing Port so as to reduce urban traffic and exhaust pollution in Shanghai, as well as to provide shippers in Jiangsu Province with direct service.

Abstract

Capital, the guarantee for normal operation of an enterprise, is crucial to production. Therefore, optimizing the capital structure has been an important task in the development of enterprises. Combining with VAR model, this paper selects 7 factors, which are profitability, operation ability, the current debt servicing ability, development ability, tax, strategic position and the assets structure, so as to make an exploratory study on the capital structure of Chinese real estate industry, based on the data from June 2002 to December 2012. The study shows that the Liquid ratio and the gross profit are of great effects on the capital structure of a listed company.

Keywords: capital structure, listed company, the real estate, impulse responses

1 Introduction

Capital structure refers to the composition and relationship of capital. Research on the capital structure of the real estate industry mainly concentrates in the issue of financing and capital structure. Gau and Wang (1990) found that the liability of real estate Company, which has a positive effect on investment cost, has a negative effect on the expected cost of non-debt tax shield, market interest rates and financial crisis. Chen and Xia (2006) studied on the financing behaviour and financing options of the real estate company. They found that asset-liability ratio, which has a positive effect on firm size, has a negative effect on operation ability and ownership concentration. In addition, asset-liability ratio does not have a significant relationship with the profitability, solvency, and non-debt tax shields.

2 Data processing

Existing studies on influencing factors of capital structure contain the industry ones. However, there is not a confirmative relationship between capital structure and industry. Many scholars have found that capital structure has significant industry difference (Scott, 1972; Scott and Martin, 1975; Bradley, Jarrel and Kim, 1984; Liu, 2003; He, 2005; Tan, 2005). However, some studies have quite contrary conclusions (Hong and Shen, 2000). This study makes an analysis on the influencing factors in Chinese listed Company of real estate industry only.

2.1 THE SELECTED VARIABLES

We design dependent variable and independent variable as follow:

1) The dependent variable.

We adopt asset-liability ratio (total liability/ total assets), equity ratio (total liability/ Owners' Equity) and $\frac{\text{current liabilities}}{\text{total assets}}$ to measure company's capital structure.

2) The independent variable.

This paper has selected 7 factors, which is profitability, operation ability, the current debt servicing ability, development ability, tax, strategic position and the assets structure (Feng, Wu and Liu, 2000; Xiao and Wu, 2002; Zhou and Xu, 2012), shown as Table 2.1.

TABLE 2.1 Indicators and illustration

Influencing factor	Index	Simbol	Illustration
Profitability	Gross profit	XSMLL	Profit from operation/ Operating income
Operation ability	Turnover rate of return on common stockholders' equity	GDSYZZL	Revenue / Net assets
The current debt servicing ability	Liquid ratio	LDB	Current Assets / Current liability
Development ability	The growth rate of net profit	JLRZZL	(Current net profit –The net profit for last period)/ The net profit for last period
Tax	The actual tax rate	SJSL	The actual expense of tax /Total profit before tax
Strategic position	Enterprise size	QYGM	ln(Revenue)
The assets structure	The percentage from fixed assets to the total assets	GDZCB	Fixed assets at the end of the period /Total assets at the end of the period

2.2. DATA SCREENING OF THE SAMPLE

According to <the classification guide of listed Company>, which is issued by the National Commission in April 2001, this paper selects the whole data of Shanghai and Shenzhen listed Company of the real estate industry, dating from June 2002 to December 2012. This paper excludes ST companies and incomplete ones, getting 42 companies. After standardization, we make descriptive statistics of variables shown as Table 2.2:

TABLE 2.2 Descriptive statistics

Variable	Mean	Standard error	Median	Minimum	Maximum
XSMLL	0.038252588	0.228387053	0.145544823	-0.514002733	0.214036792
GDSYZZL	0.589755935	0.255617372	0.56523868	0.278723053	1.042955974
LDB	2.152296439	0.255165836	2.152734428	1.785741754	2.7967487

(Date from: annual report of SSE and SZSE listed companies)

3 Processing and analysis of data

Making a second order autoregressive analysis from every influencing factors to asset-liability ratio, equity ratio and, we can obtain a VAR estimation result, shown as Table 3.1.

TABLE 3.1The fitting coefficients of VAR regression

	Modified coefficient of determination of the asset-liability ratio	Modified coefficient of determination of the equity ratio	Modified coefficient of determination of $\frac{\text{current liabilities}}{\text{total assets}}$
XSMLL	0.832302	0.512510	0.390131
GDSYZZL	0.923190	0.910093	0.904657
LDB	0.187130	0.313559	0.235956
JLRZZL	0.834355	0.125683	-0.087677
QYGM	0.846181	0.923855	0.935781
GDZCB	0.845998	0.859906	0.874597

It can be seen from Table 3.1 that, the fitting to capital structure from liquid ratio and the growth rate of net profit is low, while other influencing factors have a significant fitting result.

3.1 ANALYSIS OF IMPULSE RESPONSES

Based on VAR estimation, we can make a static simulate shown as Figure 3.1:

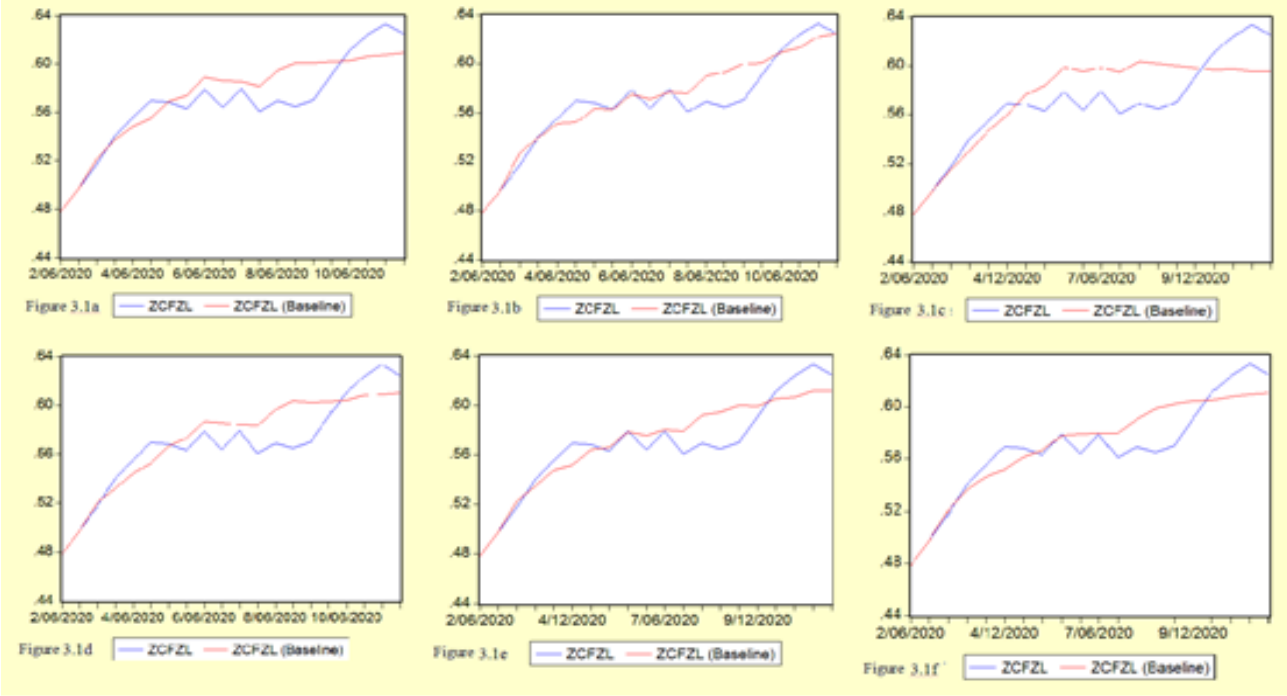

FIGURE 3.1 Static simulation from every influencing factor to asset-liability ratio

It can be seen from Figure 3.1 that, the simulation result is fine. Based on VAR model, we make an analysis of impulse response function of every factor. After giving a unit of residual shock to each factor, we could get an impulse response result shown as Figure 3.2. The horizontal axis represents the period of impulse response, while the vertical axis represents a unit of response to a residual shock. The solid line, which represents the function of impulse response, is on behalf of the response for every factor to a shock of asset-liability ratio residual.

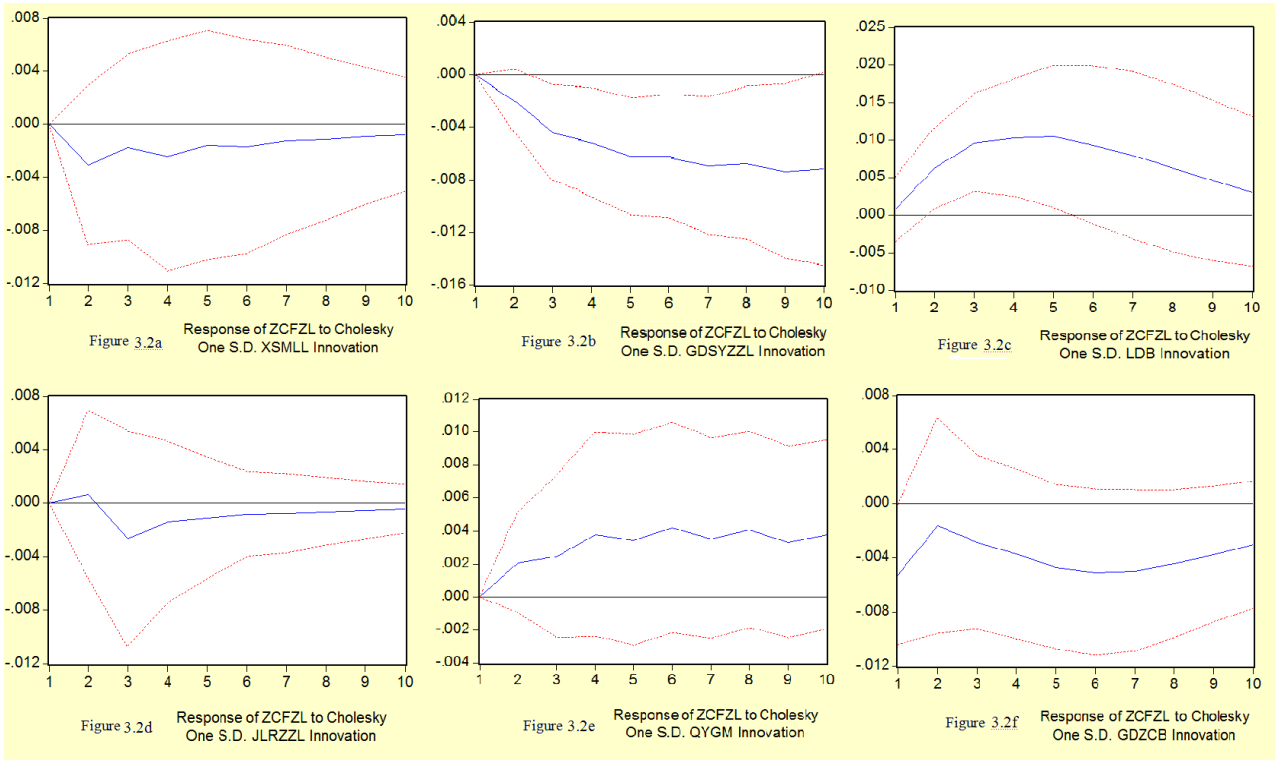

FIGURE 3.2 Impulse responses analysis from the influencing factors to asset-liability ratio

When it gives a residential shock to gross profit or the growth rate of net profit, asset-liability ratio will soon achieve convergence. Meanwhile, the shock from turn-over rate of return on common stockholders' equity, liquid ratio, enterprise size, and the percentage from fixed assets to the total assets to asset-liability ratio will not achieve convergence in the short period. We could see that in Figure 3.2.

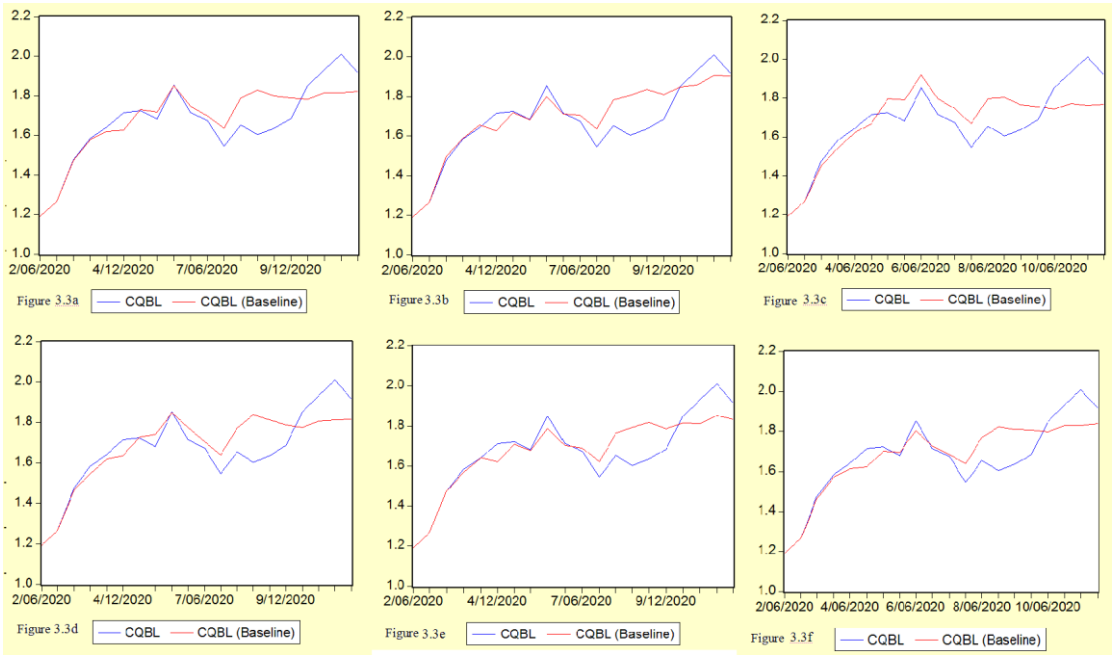

FIGURE 3.3 Static simulation from every factor to the equity ratio

In VAR simulation, every factor fits well to the equity ratio.

When it gives a residential shock to gross profit, the growth rate of net profit, or the percentage from fixed assets to total assets, the equity ratio will soon achieve convergence in current period. Meanwhile, other factors cannot achieve convergence in short period. We could see that phenomenon in Figure 3.4 as follow:

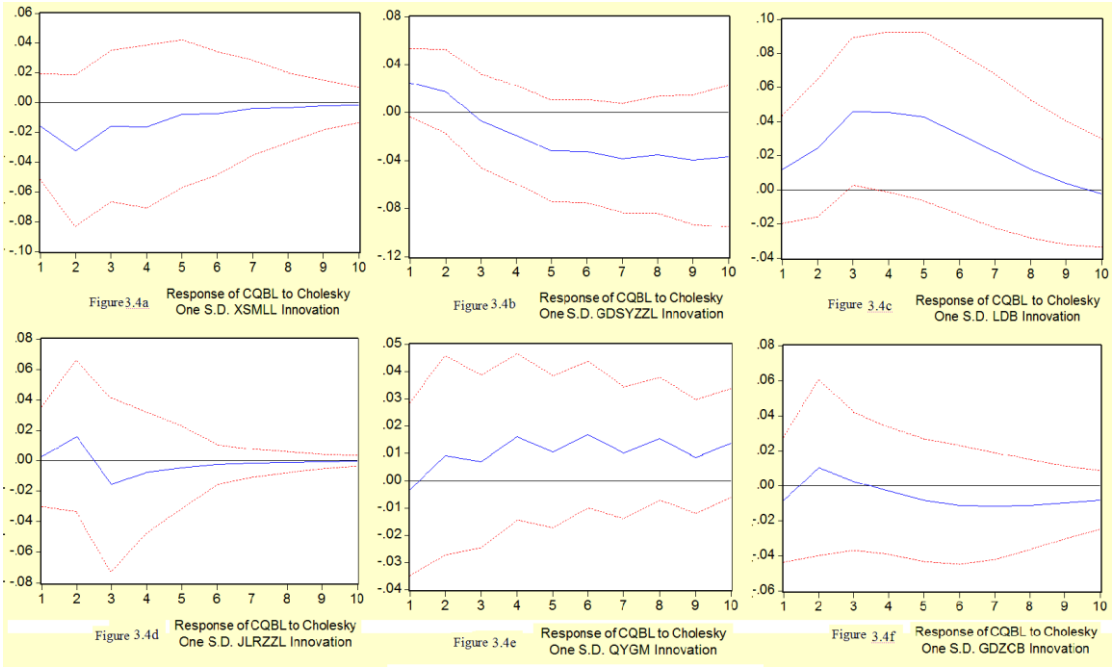

FIGURE 3.4 Impulse responses analysis from the influencing factors to equity ratio

After the VAR analysis from each influencing factor to $\frac{\text{current liabilities}}{\text{total assets}}$, we can make a static simulation. We find that every factor fits good, shown as Figure 3.5:

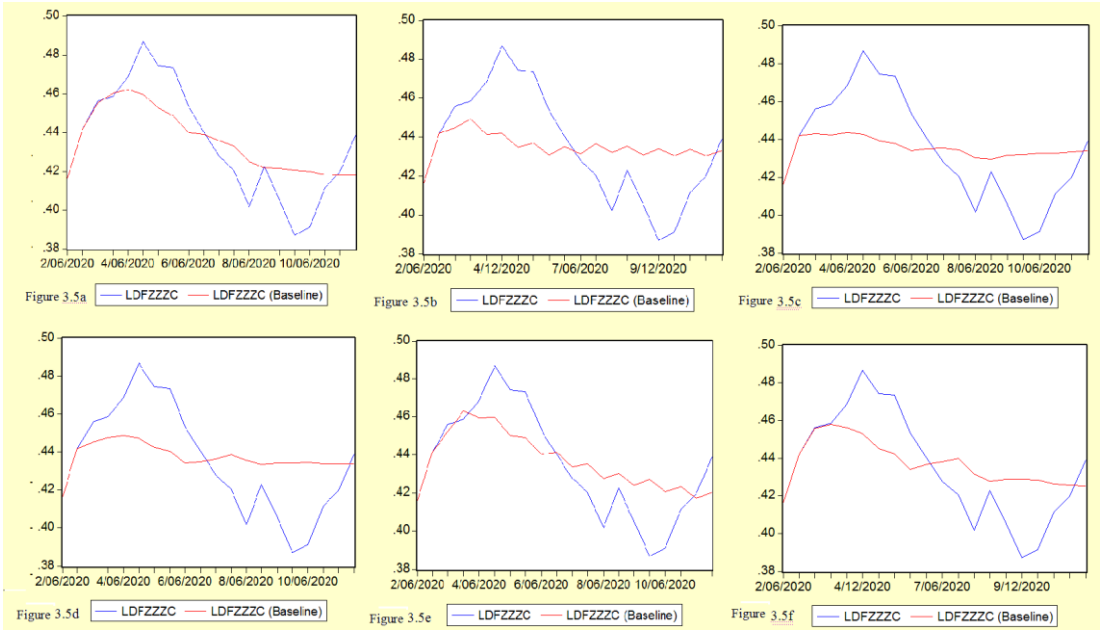

FIGURE 3.5 Static simulation from every factor to $\frac{\text{current liabilities}}{\text{total assets}}$

We make an analysis of impulse responses for every influencing factor to $\frac{\text{current liabilities}}{\text{total assets}}$, shown as Figure 3.6:

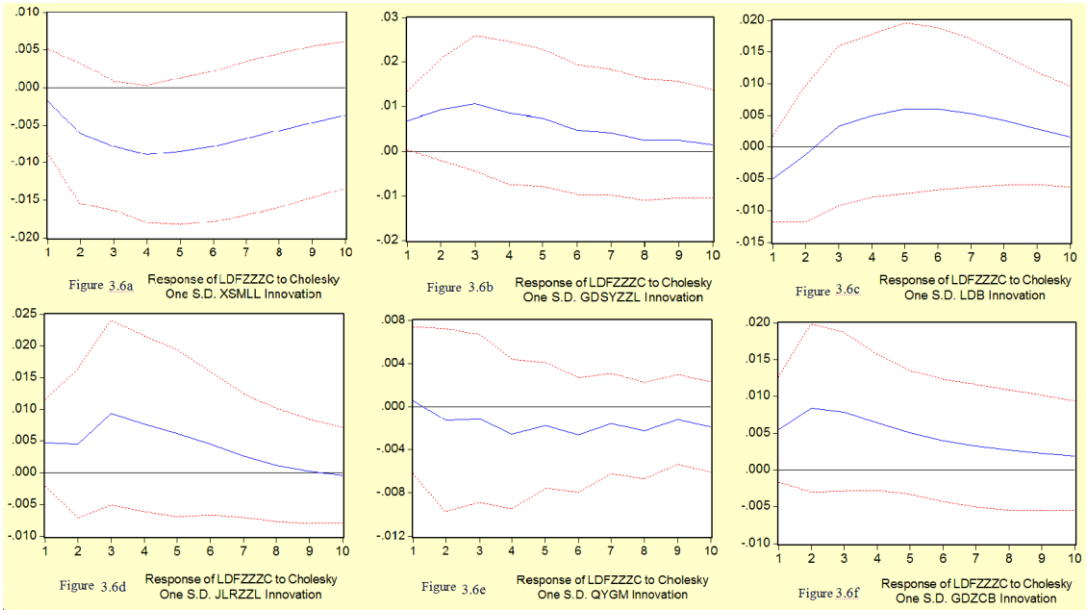

FIGURE 3.6 Impulse responses analysis from the influencing factors to $\frac{\text{current liabilities}}{\text{total assets}}$

When it gives a shock to influencing factors, $\frac{\text{current liabilities}}{\text{total assets}}$ will not achieve convergence in a short period, shown as Figure 3.6.

Therefore, we can see from the analysis of impulse responses that turnover rate of return on common stockholders 'equity, enterprise size, and the percentage

from fixed assets to the total assets could impact capital structure largely, while gross profit can just impact capital structure in a short time.

3.2 VARIANCE DECOMPOSITION

We decompose variance, shown as in Table 3.2 as follow:

TABLE 3.2 the results of variance decomposition

Responsing variable	periods	Impulsing variable

It can be seen from Figure 3.2 that, the liquid ratio and turnover rate of return on common stockholders' equity have a larger impact on the equity ratio and the asset-liability ratio, while is largely impacted by gross profit.

4 Conclusions and suggestions

4.1 THE CONCLUSIONS OF EMPIRICAL ANALYSIS

Through VAR analysis of influencing factors and measure variables of capital structure, we find that, gross profit and the turnover rate of return on common stockholders' equity impact capital structure most.

Therefore, in the short period, when it comes to the real estate company, we should be mainly concern about profitability and operation ability. In the long term, we should take more attention to the stability of operation ability.

4.2 SUGGESTIONS

The influencing factors of capital structure can reflect the preferences of the company's financing choice. According to the research, we take some advice as follow:

1) Focus on the profitability of the company

How profitable a company's operation is a crucial target. In the corporative governance, we should pay attention to how to maintain it profitable. A company, which is in a profitable operation condition, can not only provides funds to it, but also maintain its capital structure stable in a short period.

2) The company should ensure the stability of operation ability

To ensure the funds fluid is an important guarantee for the sustainable operation of a company. Enough turnover rate of return on common stockholders' equity can not only makes the funds fluid, but also maintain shareholders rights, so as to maintain the stability of capital structure. Therefore, a certain level of turnover rate of

return on common stockholders' equity is a protection for a long term operation.

Hence, whether from the point of profitability or the stability of capital structure, an enterprise shall keep the earning capacity and the operation capacity in balance.

Abstract

Performance measurement of knowledge management is a decision-making analysis project that involves multiple complex factors, levels and fuzzy uncertain information. On the basis of analysis of influence factors of knowledge management performance measurement, the study established an evaluation index system of enterprise knowledge management performance. Meanwhile, by combining grey relational analysis method and Euclidean distance measurement, a performance measurement model of knowledge measurement was established. Via standardization of different types of evaluation indexes of knowledge management performance, Euclidean distances of standardized evaluation indexes of knowledge management performance and the grey relational coefficients based on Euclidean distances were established respectively. Then the weighted grey correlations of evaluation indexes of knowledge management performance were obtained. In this way, evaluation analysis of enterprise knowledge management performance was realized. Finally, the model and algorithm was tested with a case study. The result proves that the method of combining grey relational analysis and Euclidean distance is efficient and has its application value in performance evaluation of knowledge management.

Keywords: knowledge management, performance measurement, Grey relational analysis, euclidean distance, model

1 Introduction

In the era of knowledge economy, knowledge has become key resource in economic growth, social development and enterprise development. Efficient knowledge management is important for an enterprise to acquire and maintain advantages in competition. Thus, knowledge management is increasingly important in enterprise management. As a key section in knowledge management, performance evaluation of knowledge management can evaluate the level and capacity of enterprise knowledge management performance in an effective, accurate and objective way. It is beneficial to the enterprise to control its knowledge management and development changes and can help with the evaluation of enterprise development. What's more, enterprise can find problems in knowledge management in the process of performance measurement of knowledge management and make plans to deal with these problems, which is an important way for the enterprise to evaluate its capacity of knowledge management [1-3]. Thus, finding the key influence factors in the improvement of performance and taking effective measures on time are of theoretical importance and engineering application value. Knowledge management combines multiple disciplines and methods. Enterprise managers improve the overall organizing efficiency of enterprise system, Reaction capacity of enterprise business operation, enterprise marketing competitiveness, innovation capacity in production, enterprise capital appreciation, etc. Thus, the performance measurement of enterprise knowledge management usually concentrates on these issues. By far, there have been some studies direct on this problem and have gained corresponding achievements [4-8]. However, different scholars and specialists have different perspectives in performance measurement of knowledge management. Thus, there are no unified evaluation indexes of knowledge management performance and elements in knowledge management cannot be reflected. Besides, some methods of performance measurement of knowledge management are not operable and performable enough. In a word, the current methods of performance measurement of knowledge management have some limitations. Thus, this study, based on existing studies and researches, tentatively puts forward a performance measurement model of knowledge management based on grey relational analysis [8-11]. Via a case study, the feasibility and operability of the model were tested.

2 The evaluation index system of performance measurement of enterprise knowledge management

2.1 PRINCIPLE OF THE CHOICE OF EVALUATION INDEXES OF PERFORMANCE MEASUREMENT OF KNOWLEDGE MANAGEMENT

There are complex dynamic factors of multiple levels and perspectives that influence the result of performance measurement of knowledge management, which make the design principle of choosing of the evaluation indexes of knowledge management performance in the evaluation index system of enterprise knowledge management performance. Whether the evaluation indexes of knowledge

* ***Corresponding author's*** e-mail: 125721815@qq.com

management performance is valid or not concerns the reliability and validity of the whole evaluation index system of knowledge management performance. There is no unified design principle in choosing evaluation indexes of knowledge management performance in the field of designation of evaluation system of knowledge management performance, and different scholars and specialists have different perspectives in principles to follow in the designation of evaluation indexes of knowledge management performance. The author of this paper deems that the choice of evaluation indexes of knowledge management performance should guarantee the objecttiveness, accurateness and effectiveness of the performance measurement result of knowledge management, and the performance measurement of knowledge management should be conducted from multiple perspectives and levels. Thus, in the establishment of evaluation indexes of knowledge management performance, the following principles should be followed:

1) Scientific: in choosing evaluation indexes of knowledge management performance, elements in enterprise knowledge management and the rationality of the overall structure of evaluation indexes should be considered in the first place. The indexes should analyse the condition of enterprise knowledge management from a scientific perspective. Thus, the reliability and representativeness of chosen evaluation indexes can be guaranteed.
2) Comprehensiveness: the evaluation index system of enterprise knowledge management should comprehensively reflect the overall condition of enterprise knowledge management system. It should be able to analyse the condition of knowledge management from different perspectives. Thus, the choice of evaluation indexes of knowledge management performance should consider factors in multiple aspects.
3) Integral: the evaluation index system of enterprise knowledge management is a complex decision-making system. Thus, the choice of evaluation index of knowledge management performance should keep the integral and internal relations among each element and avoid imperfect and omission of index element.
4) Objectiveness: the choice of evaluation indexes of knowledge management performance should avoid the influence of subjective factors to the greatest extent. Each evaluation index should be able to reflect the actual condition of enterprise knowledge management.
5) Consistency: different evaluation indexes of knowledge management performance should apply consistent standard in assignment.
6) Hierarchy: the levels of evaluation index system of knowledge management performance and the membership between each two levels should be clear.
7) Operability: the evaluation indexes of knowledge management performance should be operable enough so as to conduct quantitative or qualitative measurement.

2.2 ESTABLISHMENT OF EVALUATION INDEX SYSTEM OF ENTERPRISE KNOWLEDGE MANAGEMENT PERFORMANCE

Based on the above-mentioned design principles, an evaluation index system of knowledge management performance was established in this paper, as presented in Table 1. The evaluation index system contains five 1st level indexes, namely the capacity of information management, the marketing capacity, the level of knowledge stock, the maturity of learning organization and the transfer ability of knowledge using.

Table1 The evaluation index system of knowledge management performance

Objective level	1st level index	2nd level index
Evaluation index system of knowledge management performance U	The capacity of information management U_1	Information level of the enterprise u_{11} Information communication level among employees u_{12} Information communication level among departments u_{13} Information communication level between the enterprise and the customers u_{14} Information support level of cooperation in production u_{15}
	The marketing capacity U_2	Customer satisfaction u_{21} Customer profitability u_{22} Market retention rate u_{23} Market share u_{24} Quick reaction capacity in marketing u_{25}
	The level of knowledge stock U_3	The ratio of technical personnel u_{31} The holding quantity of technological achievements u_{32} The conservation rate of technical personnel u_{33} The average level of education of technical personnel u_{34}
	The maturity of learning organization U_4	The learning competence in external communication u_{41} The learning competence in internal training u_{42} The improvement level of incentive mechanism u_{43} The ability of the knowledge managers u_{44}
	The transfer ability of knowledge using U_5	The knowledge acquisition capacity u_{51} The knowledge innovation capacity u_{52} The knowledge transformation capacity u_{53} The knowledge learning capacity u_{54}

3 Performance measurement model of knowledge management based on grey relational analysis

3.1 THE SET OF EVALUATION PLANS AND THE SET OF EVALUATION INDEXES

Assume that there are *m* enterprises that conduct evaluation and analysis of knowledge management performance. Thus, the set of evaluation plans will be formed as $C=\{C_1,C_2,...,C_n\}$. In the set, C_i is the evaluation plan of knowledge management performance of one of those different enterprises? Meanwhile, based on the structure and content of Table 1, the set evaluation indexes of knowledge management performance *U* with multiple levels can be determined. In this model $U=\{U_1,U_2,U_3,U_4,U_5\}$ and $\underset{i\neq j}{\forall}(U_i\cap U_j)=O,1\le i,j\le 5$. In the set $U_1=\{u_{11},u_{12},u_{13},u_{14},u_{15}\}$, $U_2=\{u_{21},u_{22},u_{23},u_{24},u_{25}\}$, $U_3=\{u_{31},u_{32},u_{33},u_{34}\}$, $U_4=\{u_{41},u_{42},u_{43},u_{44}\}$, $U_5=\{u_{51},u_{52},u_{53},u_{54}\}$.

3.2 STANDARDIZATION OF EVALUATION INDEXES

According to the content of evaluation indexes of knowledge management performance, different evaluation indexes can have different types of value of information. On the one hand, some values of evaluation indexes are accurate, while those of others are fuzzy and uncertain. On the other hand, some evaluation indexes have positive effect for the level of enterprise knowledge management performance and are positive evaluation indexes, and some have negative effect for the level of enterprise knowledge management performance and are negative evaluation indexes. Thus, in order to conduct effectively the performance measurement of knowledge management, different types of evaluation indexes need to be unified and standardized.

In order to keep the generality of statement, assume that the value of enterprise *i* on performance evaluation index *j* is $V_{ij}=[v_{ij}^{\min},v_{ij}^{\max}]$, $v_{ij}^{\min}<v_{ij}^{\max}$.

If the evaluation index is a positive evaluation index, its standardized value $\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]$ of enterprise *i* on performance evaluation index *j* is:

$$\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]=\left[\frac{v_{ij}^{-\min}-\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{\max\limits_{1\le i\le m}(v_{ij}^{-\max})-\min\limits_{1\le i\le m}(v_{ij}^{-\min})},\frac{v_{ij}^{-\max}-\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{\max\limits_{1\le i\le m}(a_{ij})-\min\limits_{1\le i\le m}(a_{ij})}\right]. \quad (1)$$

If the evaluation index *j* is a negative evaluation index, its standardized value $\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]$ of enterprise *i* on performance evaluation index *j* is:

$$\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]=\left[\frac{\max(v_{ij}^{-\max})-v_{ij}^{-\min}}{\max\limits_{1\le i\le m}(v_{ij}^{-\max})-\min\limits_{1\le i\le m}(v_{ij}^{-\min})},\frac{\max(v_{ij}^{-\max})-v_{ij}^{-\max}}{\max\limits_{1\le i\le m}(a_{ij})-\min\limits_{1\le i\le m}(a_{ij})}\right]. \quad (2)$$

If the evaluation index *j* is a moderate evaluation index, its standardized value $\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]$ of enterprise *i* on performance evaluation index *j* is:

$$\bar{V}_{ij}=\left[v_{ij}^{-\min},v_{ij}^{-\max}\right]=\left[\frac{\frac{\max(v_{ij}^{-\max})+\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{2}-v_{ij}^{-\min}}{\frac{\max\limits_{1\le i\le m}(v_{ij}^{-\max})-\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{2}},\frac{\frac{\max(v_{ij}^{-\max})+\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{2}-v_{ij}^{-\max}}{\frac{\max\limits_{1\le i\le m}(v_{ij}^{-\max})-\min\limits_{1\le i\le m}(v_{ij}^{-\min})}{2}}\right]. \quad (3)$$

It can be observed that those standardized evaluation indexes of knowledge management performance all satisfy $0\le v_{ij}^{-\min}\le 1$, $0\le v_{ij}^{-\max}\le 1$. Then the differentiation among those evaluation indexes is removed and measure standard of all the evaluation indexes is unified, which is beneficial to the accuracy of performance measurement of knowledge management.

3.3 THE GREY RELATIONAL DEGREE OF PERFORMANCE MEASUREMENT OF ENTERPRISE KNOWLEDGE MANAGEMENT

Grey relational analysis is a decision-making analysis method that analyzes and determines the degree of influence between two systems by analyzing the reference sequence and comparing the proximity of the geometrical shape of sequences to judge the proximity of changing tendency based on the analysis of the geometrical proximity of the data sequence of the system. It measures the relational degree between systems or between factors based on the grey relational degree, and describes the relative changes of factors in the development of the system. In the development process of the system, if the consistency of change trends of two factors is high, the grey relational degree between the two factors is high; otherwise the grey relational degree between the two factors is low. The grey relational analysis analyzes the development trend of the system, so it does not require strictly the sample size and typical regulations of distribution. Thus, it can be widely applied. However, when grey relational analysis is conducted to fuzzy and uncertain values of evaluation indexes, the classical grey

relational analysis method needs to be improved. Thus, this study introduces Euclidean distance in analysis.

Assume that all the evaluation indexes of knowledge management performances have been standardized, and the standardized indexes are all positive indexes. Thus, the optimal evaluation index sequence V^* of the set of evaluation indexes of knowledge management performance can be established as:

$$V^* = \left(\bar{V}_1^*, \bar{V}_2^*, ..., \bar{V}_n^*\right) = \left(\left[v_1^{-\min*}, v_1^{-\max*}\right], \left[v_2^{-\min*}, v_2^{-\max*}\right], ..., \left[v_n^{-\min*}, v_n^{-\max*}\right]\right). \quad (4)$$

In the sequence:

$$\bar{V}_j^* = [\max_{1\le i\le m}(v_{ij}^{-\min}), \max_{1\le i\le m}(v_{ij}^{-\max})]. \quad (5)$$

Thus, the Euclidean distance $D_{ij}(\bar{V}_{ij} \to \bar{V}_j^*)$ of the enterprise i on the evaluation index of knowledge management performance j and the ideal optimal sequence of evaluation indexes V^* is:

$$D_{ij}\left(\bar{V}_{ij} \to \bar{V}_j^*\right) = \frac{\left[\left|v_{ij}^{-\min} - \max_{1\le i\le m}\left(v_{ij}^{-\min}\right)\right|^2 + \left|v_{ij}^{-\max} - \max_{1\le i\le m}\left(v_{ij}^{-\max}\right)\right|^2\right]^{\frac{1}{2}}}{\sqrt{2}}. \quad (6)$$

According to the relative theories of grey relational analysis method, the relational coefficient ξ_{ij} of enterprise i on the evaluation index of knowledge management performance j and the ideal optimal evaluation index sequence V^* is:

$$\xi_{ij} = \frac{\min\limits_{1\le i\le m}\min\limits_{1\le i\le n} D_{ij}(\bar{V}_{ij} \to \bar{V}_j^*) + \rho \max\limits_{1\le i\le m}\max\limits_{1\le i\le n} D_{ij}(\bar{V}_{ij} \to \bar{V}_j^*)}{D_{ij}(\bar{V}_{ij} \to \bar{V}_j^*) + \rho \max\limits_{1\le i\le m}\max\limits_{1\le i\le n} D_{ij}(\bar{V}_{ij} \to \bar{V}_j^*)}, \quad (7)$$

where $i = 1, 2, ..., m$; $j = 1, 2, ..., n$; ρ is the resolution ratio and $\rho \in (0,1)$. Generally, $\rho = 0.5$.

Considering the weights w_{ij}^2 of different 2nd level evaluation indexes are different, the weighted grey relational degree φ_i^2 of enterprise i on the 2nd level evaluation index on knowledge management performance is:

$$\varphi_i^2 = \sum_{j=1}^{n^2}(w_{ij}^2 \xi_{ij}). \quad (8)$$

Combining the weights w_{ij}^1 of the 1st level of evaluation indexes, the weighted grey relational degree ψ_i of enterprise i on the evaluation index set of knowledge management performance is:

$$\psi_i = \sum_{j=1}^{n^1}(w_{ij}^1 \varphi_i^2). \quad (9)$$

Thus, according to the principle of selecting the closest in the analysis of grey relational analysis with multiple attributes based on grey relational degree of comprehensive weight, if:

$$\psi_i = \max\{\psi_1, \psi_2, \cdots, \psi_m\}. \quad (10)$$

The level of knowledge management performance of the enterprise i is the closest to the level of knowledge management performance correspondent to the ideal optimal evaluation index sequence.

3.4 REALIZATION OF THE MODEL AND ALGORITHM OF PERFORMANCE MEASUREMENT OF KNOWLEDGE MANAGEMENT BASED ON GREY RELATIONAL ANALYSIS METHOD

Based on what mentioned above, the algorithm implementation of performance measurement model of knowledge management based on grey relational analysis method can be described as below:

Step 1: Determine the basic principles in choosing evaluation indexes of enterprise knowledge management performance directing at the complex dynamic influence factors of multiple levels and aspects in the process of enterprise knowledge management.

Step 2: Establish the evaluation index system of knowledge management performance under the guidance of principles of choosing evaluation indexes, and form evaluation plan and evaluation index set of knowledge management performance based on this evaluation index system.

Step 3: Determine the types of evaluation indexes in the above-mentioned evaluation index set, and obtain the values of evaluation indexes of knowledge management performance plans of different enterprises.

Step 4: Standardize positive indexes, negative indexes and moderate indexes respectively according to Equations (1)-(3) and unify the measure standard of each type of evaluation indexes.

Step 5: Construct the optimal evaluation index sequence of evaluation index set of knowledge management performance with Equations (4) and (5).

Step 6: Obtain the Euclidean distance between the plan of knowledge management performance and the ideal optimal evaluation index sequence with Equation (6).

Step 7: Obtain the grey relational coefficient between the plan of knowledge management performance and the ideal optimal evaluation index sequence with Equation (7).

Step 8: consider the weights of different levels of evaluation indexes of knowledge management performance and obtain the comprehensive weighted grey relational degree with Equations (8) and (9).

Step 9: According to the value of comprehensive weighted grey relational degree obtains the optimal plan of knowledge management performance with Equation (10).

4 Verification of the model and the algorithm

This paper set the evaluation and analysis of knowledge management performance of three enterprises in the economic and technological development zone of the new city zone of a provincial capital as the object for the case study, in order to prove the algorithm feasible and practicable. The set of analysis object of performance measurement of knowledge management is $C=\{C_1,C_2,C_3\}$. C_1, C_2 and C_3 respectively stand for the three enterprises. The weight values were obtained from specialists in domain design with comprehensive understanding of the mechanism of the three enterprises. They combined the investigation and analysis of the relative materials of the three enterprises, their own knowledge, experience and personal preference and analysed the weights of the 1st level indexes and the 2nd level indexes of the above-mentioned evaluation index system of knowledge management performance with comprehensive judgment approach. The corresponding weighted values are presented in Table 2. Meanwhile, via investigation, statistics and analysis, the information of the knowledge management performance of the three enterprises was obtained, as also presented in Table 2.

If a table is too long to fit onto one page, the table number and headings should be repeated on the next page before the table is continued.

Alternatively, the table can be spread over two consecutive pages (first on even-numbered, then on odd-numbered page).

For a wide table you can use 1-column section (Table 1), for a small standard table 2-column section is used (Table 2).

Table 2 Information of evaluation index of knowledge management performance

1st level index	Weight	2nd level index	Weight	Information of evaluation index		
				Enterprise 1	Enterprise 2	Enterprise 3
The capacity of information management U_1	0.21	Information level of the enterprise u_{11}	0.21	0.83–0.85	0.80–0.83	0.67–0.70
		Information communication level among employees u_{12}	0.19	0.68–0.73	0.75–0.80	0.78–0.83
		Information communication level among departments u_{13}	0.22	0.75–0.78	0.75–0.80	0.75–0.78
		Information communication level between the enterprise and the customers u_{14}	0.18	0.80–0.85	0.75–0.80	0.75–0.80
		Information support level of cooperation in production u_{15}	0.20	0.76–0.80	0.70–0.74	0.67–0.70
The marketing capacity U_2	0.15	Customer satisfaction u_{21}	0.18	0.80–0.85	0.60–0.65	0.80–0.85
		Customer profitability u_{22}	0.17	1.35	2.32	0.98
		Market retention rate u_{23}	0.20	85–90	80–85	85–90
		Market share u_{24}	0.25	0.016–0.018	0.013–0.015	0.012–0.015
		Quick reaction capacity in marketing u_{25}	0.20	0.60–0.70	0.75–0.85	0.65–0.75
The level of knowledge stock U_3	0.19	The ratio of technical personnel u_{31}	0.20	0.73	0.58	0.69
		The holding quantity of technological achievements u_{32}	0.30	15	22	18
		The conservation rate of technical personnel u_{33}	0.28	0.75–0.80	0.85–0.90	0.75–0.80
		The average level of education of technical personnel u_{34}	0.22	1.34	1.50	2.01
The maturity of learning organization U_4	0.22	The learning competence in external communication u_{41}	0.25	2.50–2.80	1.60–1.80	2.00–2.20
		The learning competence in internal training u_{42}	0.25	20.00–25.00	12.00–14.00	16.00–18.00
		The improvement level of incentive mechanism u_{43}	0.26	0.77–0.80	0.68–0.75	0.54–0.60
		The ability of the knowledge managers u_{44}	0.24	0.80–0.85	0.75–0.80	0.70–0.75
The transfer ability of knowledge using U_5	0.23	The knowledge acquisition capacity u_{51}	0.30	90–95	80–85	85–90
		The knowledge innovation capacity u_{52}	0.25	80–85	85–90	85–90
		The knowledge transformation capacity u_{53}	0.25	80–85	70–75	80–85
		The knowledge learning capacity u_{54}	0.20	70–75	80–85	80–85

Based on the type of evaluation indexes, applying the method of standardization of evaluation index in the paper, the standardized information of different evaluation indexes can be obtained. The values are presented in Table 3.

Table 3 The standardized value of evaluation indexes of knowledge management performance

2nd level index	Information of evaluation index		
	Enterprise 1	**Enterprise 2**	**Enterprise 3**
Information level of the enterprise u_{11}	0.976–1.000	0.941–0.976	0.788–0.824
Information communication level among employees u_{12}	0.819–0.880	0.904–0.964	0.940–1.000
Information communication level among departments u_{13}	0.938–0.975	0. 938–1.000	0.938–0.975
Information communication level between the enterprise and the customers u_{14}	0.941–1.000	0.882–0. 941	0.882–0.941
Information support level of cooperation in production u_{15}	0.950–1.000	0.875–0.925	0.838–0.875
Customer satisfaction u_{21}	0.941–1.000	0.706–0.765	0.941–1.000
Customer profitability u_{22}	0.582	1.000	0.422
Market retention rate u_{23}	0.944–1.000	0.889–0.944	0.944–1.000
Market share u_{24}	0.889–1.000	0.722–0.833	0.667–0.833
Quick reaction capacity in marketing u_{25}	0.706–0.824	0.882–1.000	0.765–0.882
The ratio of technical personnel u_{31}	1.000	0.795	0.945
The holding quantity of technological achievements u_{32}	0.682	1.000	0.818
The conservation rate of technical personnel u_{33}	0.833–0.889	0.944–1.000	0.833–0.889
The average level of education of technical personnel u_{34}	0.667	0.746	1.000
The learning competence in external communication u_{41}	0.893–1.000	0.571–0.643	0.714–0.786
The learning competence in internal training u_{42}	0.800–1.000	0.480–0.560	0.640–0.720
The improvement level of incentive mechanism u_{43}	0.963–1.000	0.850–0.938	0.675–0.750
The ability of the knowledge managers u_{44}	0.941–1.000	0.882–0.941	0.823–0.882
The knowledge acquisition capacity u_{51}	0.947–1.000	0.842–0.895	0.895–0.947
The knowledge innovation capacity u_{52}	0.889–0.944	0.944–1.000	0.944–1.000
The knowledge transformation capacity u_{53}	0.941–1.000	0.824–0.882	0.941–1.000
The knowledge learning capacity u_{54}	0.824–0.882	0.941–1.000	0.941–1.000

By applying the calculation formula of Euclidean distance in the paper, the matrix of Euclidean distance of performance measurement of knowledge management can be obtained:

$$\mathbf{D}=\begin{bmatrix}0.000 & 0.030 & 0.182\\ 0.170 & 0.051 & 0.000\\ 0.018 & 0.000 & 0.018\\ 0.000 & 0.059 & 0.059\\ 0.000 & 0.075 & 0.119\\ 0.000 & 0.235 & 0.000\\ 0.418 & 0.000 & 0.578\\ 0.000 & 0.056 & 0.000\\ 0.000 & 0.167 & 0.279\\ 0.176 & 0.000 & 0.166\\ 0.000 & 0.205 & 0.055\\ 0.318 & 0.000 & 0.182\\ 0.111 & 0.000 & 0.111\\ 0.333 & 0.254 & 0.000\\ 0.000 & 0.340 & 0.197\\ 0.000 & 0.385 & 0.228\\ 0.000 & 0.091 & 0.230\\ 0.000 & 0.059 & 0.118\\ 0.000 & 0.105 & 0.053\\ 0.056 & 0.000 & 0.000\\ 0.000 & 0.118 & 0.000\\ 0.118 & 0.000 & 0.000\end{bmatrix}_{22x3}$$

The matrix of grey relational coefficient of 2nd level indexes of performance measurement of knowledge management can be obtained based on the matrix of Euclidean distance:

$$\mathbf{H}=\begin{bmatrix}1.000 & 0.906 & 0.614\\ 0.630 & 0.850 & 1.000\\ 0.941 & 1.000 & 0.941\\ 1.000 & 0.830 & 0.830\\ 1.000 & 0.794 & 0.708\\ 1.000 & 0.552 & 1.000\\ 0.409 & 1.000 & 0.333\\ 1.000 & 0.838 & 1.000\\ 1.000 & 0.634 & 0.509\\ 0.622 & 1.000 & 0.635\\ 1.000 & 0.637 & 0.840\\ 0.476 & 1.000 & 0.614\\ 0.723 & 1.000 & 0.723\\ 0.465 & 0.532 & 1.000\\ 1.000 & 0.459 & 0.595\\ 1.000 & 0.429 & 0.559\\ 1.000 & 0.761 & 0.557\\ 1.000 & 0.830 & 0.710\\ 1.000 & 0.734 & 0.845\\ 0.838 & 1.000 & 1.000\\ 1.000 & 0.710 & 1.000\\ 0.710 & 1.000 & 1.000\end{bmatrix}_{22x3}$$

The sequence of comprehensive weighted grey relational degree can be obtained via considering comprehensively the weight of 1st level evaluation indexes and 2nd level evaluation indexes. According to the principle of selecting the closest of the comprehensive weight grey relational degree, the knowledge management performance of Enterprise 1 is the optimal in the three, which consists with the actual condition.

5 Conclusion

Directing at the problems in the process of performance measurement of knowledge management, this paper puts forward a performance measurement model of knowledge management based on grey relational analysis. By establishing evaluation index system of knowledge management performance, standardization of different types of evaluation indexes is realized and an improved grey relational coefficient calculation model of evaluation indexes of knowledge management performance based on Euclidean distance is put forward. Thus, the weighted grey relational degree of performance measurement of knowledge management can be obtained, and evaluation and analysis of the knowledge management performance can be realized. Then by a case study, this model proves feasible and practicable, and can provide decision basis to the guidance of knowledge management development, which can help to improve the level of knowledge management and strengthen the competitiveness of the enterprise. What's more, it can also verify the regulations in studies of knowledge management and find new problems in knowledge management of enterprise, which is beneficial to the development of the discipline of enterprise knowledge management.

Abstract

Based on the external financing analysis framework under asymmetric information, this paper analyzes the influence of corporate growth on liquid assets value and financing decision. Both of the theory and numerical calculations show that liquid assets value would increase with the increasing in corporate growth. For the reinvestment decision in the case of higher reinvestment demand, if the price of liquidity assets is higher than value, it is optimal not to reinvest; if the price is lower than value, it is optimal to reinvest; if the price is equal to value, there is no difference found in reinvesting or not.

Keywords: liquidity shocks, liquid assets value, corporate growth, financing decision

1 Introduction

Shortage of liquidity has been considered to be the main reason of financial crisis sweeping global. As an important part of the companies' operation process, holding of liquidity asset may influence its operating performance, and directly impact on its management, investment and financing activities. Why do companies hold large pools of liquidity? What will holding liquidity do for the companies' value? How to determine the value of liquidity assets? What factors will affect the value of liquid assets? Such problems have been hot issues of the academic research.

As far as factors affecting the value of liquid assets is concerned. Harford (1999) proves that mergers and acquisitions will damage the companies' cash value by studying the relationship between policy of mergers and acquisitions and value of holding liquid assets. Faulkender and Wang (2006) et al. consider that the marginal value of holding liquid assets increases with the increasing in financing constraints. Denis and Sibilkov (2007) deem that holding liquid assets can help the enterprise get projects with higher yields, and so the enterprise with higher financing constraints may own higher value of holding liquid assets. Pinkowitz and Williamson (2007), Kalcheva and Lins (2007) make a comparative study for multinational corporations and find that, compared to countries with poor shareholders' protection, investors contain higher liquidity assets valuation in those with better protection. Tong (2009) believes the enterprise's diversification can increase agency cost and reduce the value of liquid assets. Drobetz et al. (2010) think the entrepreneur's moral hazard could reduce the value of liquid assets on account of asymmetric information.

In point of research on the growth and value of liquidity assets, Myers and Majluf (1984) believe that, compared with the enterprise with lower growth, the enterprise with higher growth may own higher cost of underinvestment and more serious problem of asymmetric information, so the cash value is relatively higher held by the enterprise with higher growth. Mikkelson and Partch (2003) find that companies holding more liquidity assets usually own more investment, more research and development expenses and bigger expansion of asset scale. Saddour (2006) deems the companies' market value is positively correlated with holding level of liquid assets, and compared with the enterprise with lower growth; this kind of positive correlation is more significant for the enterprise with higher growth. Through the empirical analysis, Pinkowitz and Williamson (2007) think that for the company in high-speed growth stage, its market value of holding liquidity assets would be higher.

Based on the external financing analysis framework under asymmetric information built by Tirole (2006), this article investigates the influence of corporate growth on liquidity assets value, and then makes a deep exploration on the entrepreneur's optimal financing decision in the condition of certain liquidity asset price. Basis of the study is that the enterprise can not meet his reinvestment demand by create enough internal liquidity relying on its future earnings.

2 Assumptions

The basic assumptions will be given in the following: three periods: $t=0$ represents ex enter period; $t=1$ represents intermediate period; $t=2$ represents ex post period.

Participants: an entrepreneur and investors.

At date $t=0$, the entrepreneur has "assets" A and a project requiring variable investment $I \in [0,\infty)$. To imp-

[*]***Corresponding author's*** e-mail: wuyi0871@126.com

lement the project the entrepreneur must borrow $I-A$ from investors.

If the project can get financing, the company meets a reinvestment opportunity requiring an amount ρI at date $t=1$, where ρ means the reinvestment amount required by one unit of initial investment for reinvesting. ρ is unknown at date $t=1$ and subjects to the following two-point distribution:

per unit of reinvestment	ρ_H	ρ_L
probability	$1-\lambda$	λ

Average reinvestment demand for per unit of initial investment is:

$$\bar{\rho} \equiv (1-\lambda)\rho_L + \lambda\rho_H .$$

Whether the enterprise reinvests or not, the company can continue to operate.

At date $t=2$, the project either succeeds, that is, yields verifiable income RI, or fails, that is, yields no income, where R is the yield of initial investment in the case of success?

The probability of success would be influenced by the effort degree of the entrepreneur and reinvestment opportunities.

At date $t=1$, if the company does not reinvest, the probability of success would be p; on the contrary, if the company reinvest, the probability of success would be $p+\tau$. Where $\tau>0$ indicates the size of growth opportunities. The bigger τ, the greater growth opportunities.

p is affected by the effort degree of the entrepreneur, but it is unobservable. Behaving yields probability $p=p_H$ of success and no private benefit to the entrepreneur, and misbehaving results in probability $p=p_L<p_H$ of success and private benefit $BI>0$. Let $\Delta p=p_H-p_L$.

Per unit investment has positive NPV if the entrepreneur behaves at date $t=2$, but negative NPV even if one includes the entrepreneur's private benefit, if he does not. In other words, the initial contract need to motivate the entrepreneur to behave at date $t=2$.

Reinvestment is also optimal for the society, even if the company requires reinvesting $\rho_H I$ for growth opportunities. That is:

$$(p_H+\tau)RI-\rho_H I-I>p_H RI-I \Rightarrow \tau R>\rho_H . \quad (1)$$

At date $t=1$, the entrepreneur can raise internal liquidity $\tau(R-B/\Delta p)I$ when facing reinvestment demand. Let:

$$\rho_L I<\tau(R-B/\Delta p)I<\rho_H I . \quad (2)$$

This means that, when faced with reinvestment needs $\rho_L I$, the enterprise could meet his reinvestment needs through internal liquidity; otherwise, when faced with reinvestment needs $\rho_H I$, he could not meet his reinvestment needs through internal liquidity.

There exist in the economy liquid assets. That is, 1 unit invested at $t=0$ delivers a return of 1 unit at $t=1$.

The price of liquid assets is q at $t=0$, where $q\geq 1$.

In order to ensure the threshold of liquidity assets price is not less than 1, let:

$$\rho_H+\tau'[(1-\lambda)(\rho_H-\rho_L)-1]\leq 0, \quad (3)$$

where $\tau'=\tau/p_H$. In fact, τ' reflects the increasing proportion of the success probability due to growth opportunities, in the case of behaving; and it could be used to measure the marginal productivity of growth opportunities.

In order to ensure the investment scale of equilibrium is positive, let:

$$1+(1-\lambda)\rho_L-\rho_0-(1-\lambda)\tau'\rho_0>0, \quad (4)$$

where $\rho_0=p_H(R-B/\Delta p)I$ denotes the expected pledge able income per unit of investment at $t=2$ without reinvestment.

Both the entrepreneur and investors are risk neutral.

Both the entrepreneur and investors have not time preference; the riskless rate is taken to be 0.

Investors behave competitively in the sense that the loan, if any, makes zero profit.

The entrepreneur has bargaining power, and he puts forward a financing contract for investors "either accept or reject", he is also protected by limited liability.

The timing could be summarized in Figure 1.

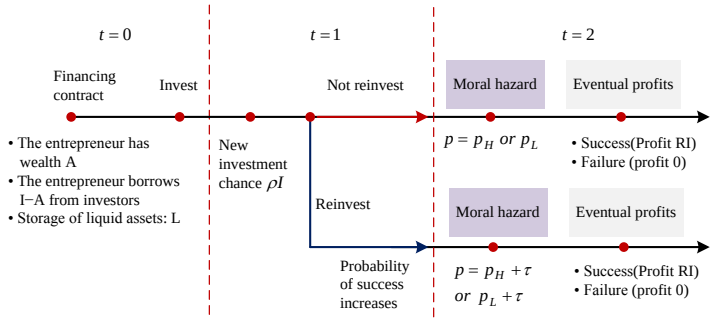

FIGURE 1 Figure of the timing

3 Optimal models

Suppose that the financing contract signed at date $t=0$ between the entrepreneur and investors takes the following state-contingent form:

$$\{I, L; (1, x); (R_b, 0), (RI - R_b, 0)\},$$

where the contract specifies an initial investment level I.

The entrepreneur can purchase L units of liquidity assets with the price q at date $t=0$.

At date $t=1$, if reinvestment level is $\rho_L I$, the entrepreneur always reinvests; contrarily, if reinvestment level is $\rho_H I$, he could only reinvests with probability x.

At date $t=2$, if the project succeed, the entrepreneur and investors get R_b and $RI-R_b$, respectively, if the project fail, both of them get 0.

The enterprise's optimal model under this kind of contract form is like that:

$$\begin{cases} \max\limits_{R_b, I, x} \{(1-\lambda)(p_H+\tau)+\lambda[x(p_H+\tau)+(1-x)p_H]\}R_b - A \\ s.t.(a_1)(p_H+\tau)R_b \geq (p_L+\tau)R_b + BI \\ \quad (a_2)\, p_H R_b \geq p_L R_b + BI \\ \quad (a_3)\, L\times 1+\tau(RI-R_b) \geq \rho_L I \\ \quad (a_4)\, L\times 1+x\tau(RI-R_b) \geq x\rho_H I \\ \quad (a_5)\lambda x[(p_H+\tau)(RI-R_b)-\rho_H I]+\lambda(1-x)p_H(RI-R_b) \\ \qquad +(1-\lambda)[(p_H+\tau)(RI-R_b)-\rho_L I] \geq I - A + (q-1)L \end{cases},$$

where the objective function is the entrepreneur's net utility. When reinvestment level is $\rho_L I$, the entrepreneur always reinvests, and the probability of success is $p_H+\tau$. When reinvestment level is $\rho_H I$, the entrepreneur could only reinvest with probability x (the success probability is $p_H+\tau$), and could not reinvest with probability $1-x$ (the success probability is p_H).

The constraint (a_1) is the entrepreneur's incentive-compatibility constraint with reinvestment. This constraint ensures the entrepreneur behaving at date $t=2$ if he reinvests at date $t=1$. Where the left side of the inequality is the expected profit if he behaves, the right side is the expected profit if he misbehaves, and (a_1) could be simplified as:

$$R_b \geq BI/\Delta p. \tag{5}$$

The constraint (a_2) is the entrepreneur's incentive-compatibility constraint without reinvestment. This constraint ensures the entrepreneur behaving at date $t=2$ if he does not reinvest at date $t=1$. Where the left side of the inequality is the expected profit if he behaves, the right side is the expected profit if he misbehaves, and (a_2) could be simplified as Equation (5). Therefore, the entrepreneur's incentive-compatibility constraint will not be affected by reinvestment. In fact, the moral hazard happens after reinvestment, so the incentive-compatibility constraint will be the same whether the project gets growth opportunity or not.

The constraint (a_3) ensures that the entrepreneur can reinvest if reinvestment level is $\rho_L I$; (a_4) ensures that the entrepreneur can reinvest if reinvestment level is $\rho_H I$. In fact, the enterprise can meet his reinvestment needs by internal liquidity if reinvestment level is $\rho_L I$, that means (a_3) is totally unnecessary. In addition, because storage of liquid assets may generate liquidity premium $q-1$ and too many storage of liquidity assets is irrational, (a_4) would hold with equality for maximizing the entrepreneur's utility, that is:

$$L = x[\rho_H I - \tau(RI - R_b)].$$

The constraint (a_5) is the investors' individual-rationality constraint. Specifically, if reinvestment level is $\rho_L I$, the investors pay reinvestment $\rho_L I$ and can get expected return $(p_H+\tau)(RI-R_b)$ at the same time. Contrarily, if reinvestment level is $\rho_H I$, the expected probability for investors getting $RI-R_b$ is $x(p_H+\tau)+(1-x)p_H$, and the investors' expected reinvestment is $x\rho_H+(1-x)\cdot 0$, $I-A$ is their initial invest at date $t=0$, $(q-1)L$ is the liquidity premium generated by L units of liquidity assets. In fact, the investors' individual-rationality constraint can be simplified as:

$$R_b \leq \frac{H\cdot I + A}{p_H + [(1-\lambda)+\lambda x]\tau + (q-1)x\tau}, \tag{6}$$

where:

$$H = p_H R + [(1-\lambda)+\lambda x]\tau R - (q-1)x(\rho_H - \tau R) - 1 - (1-\lambda)\rho_L - \lambda x\rho_H.$$

4 Optimal contracts

The optimization problem can be solved in three steps.

Step 1: Solve the optimal R_b^* and $I^*(x)$ for a given x.

In fact, all the solutions satisfied the constraint Equations (5) and (6) are called the "feasible contract set" S. The optimization problem shows that the entrepreneur needs to find one financing contract to maximize his own profit from the feasible set S. Figure 2 illustrates the "feasible contract set" of the optimization problem.

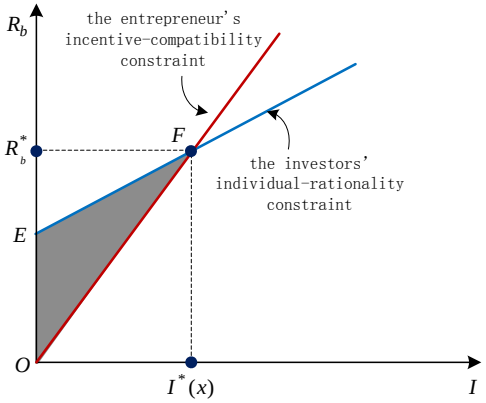

FIGURE 2 The "feasible contract set"

We can get that the "feasible contract set "from a geometric point of view, the "feasible contract set" is constituted by the shaded area OEF surrounded by the incentive-compatibility constraint, individual-rationality constraint and non-negative constraint. The objective function shows that it is the bigger the better for R_b. Therefore, the point F constitutes the optimal contract, and then:

$$R_b = \frac{BI}{\Delta p}$$

and

$$I^*(x) = A \cdot \{1-\rho_0 - [(1-\lambda)+\lambda x]\tau'\rho_0 + (q-1)x(\rho_H - \tau'\rho_0) + (1-\lambda)\rho_L + \lambda x\rho_H\}^{-1}, \quad (7)$$

where

$$\rho_0 = p_H(R - B/\Delta p), \rho_1 = p_H R, \tau' = \tau / p_H .$$

In Equation (7), $(1-\lambda)+\lambda x$ represents the probability of reinvesting or getting growth opportunity at date $t=1$, $\rho_0 + [(1-\lambda)+\lambda x]\tau'\rho_0$ expresses the expected pledge able income generated by per unit of initial investment; $(1-\lambda)\rho_L + \lambda x\rho_H$ shows the expected reinvestment cost of per unit of initial investment; $x(\rho_H - \tau'\rho_0)$ is the holding amount of liquid assets for one unit initial investment; $q-1$ is the liquidity premium.

Step 2: Consider the optimal x^* by taking R_b^* and I^* into the optimization problem.

In conclusion, the optimization problem can be expressed as:

$$\max_x \{p_H + [(1-\lambda)+\lambda x]p_H\tau'\}\frac{B}{\Delta p}I^* - A, \quad (8)$$

take I^* into the optimization Equation (8), and then it can be further simplified as:

$$\max_x \frac{\rho_1 - c(x,q)}{c(x,q)-\rho_0}A,$$

where:

$$c(x,q) = \frac{(q-1)x(\rho_H - \tau'\rho_0) + (1-\lambda)\rho_L + \lambda x\rho_H + 1}{1+(1-\lambda+\lambda x)\tau'},$$

as:

$$\max_x \frac{\rho_1 - c(x,q)}{c(x,q)-\rho_0}A \Leftrightarrow \min_x c(x,q),$$

this means the entrepreneur could get maximum utility when $c(x,q)$ takes the minimum.

Suggestion 1: When the entrepreneur needs to reinvest $\rho_H I$ because of getting the growth opportunity, his optimal strategy is closely related to the liquidity assets q it displays as that:

if $q \in [1, \bar{q})$, it is optimal to reinvest with probability $x^* = 1$;

if $q \in (\bar{q}, +\infty)$, it is optimal to reinvest with probability $x^* = 0$;

if $q = \bar{q}$, it is optimal to reinvest with probability $x^* = [0,1]$.

where $\bar{q} = 1 + \lambda\frac{\tau'[1-(1-\lambda)(\rho_H - \rho_L)] - \rho_H}{(\rho_H - \tau'\rho_0)[1+(1-\lambda)\tau']}$ represents the value of liquid assets.

Proof: Due to $\frac{\partial c(x,q)}{\partial x} = \frac{E}{F}$, where:

$$E = (q-1)(\rho_H - \tau'\rho_0)[1+(1-\lambda)\tau'] + \lambda\rho_H + \lambda\tau'[(1-\lambda)(\rho_H - \rho_L) - 1],$$
$$F = [1+(1-\lambda+\lambda x)\tau']^2$$

let:

$$\bar{q} = 1 + \lambda\frac{\tau'[1-(1-\lambda)(\rho_H - \rho_L)] - \rho_H}{(\rho_H - \tau'\rho_0)[1+(1-\lambda)\tau']},$$

which leads to:

if $q > \bar{q}$, $\partial c(x,q)/\partial x > 0 \Rightarrow x^* = 0$;

if $q < \bar{q}$, $\partial c(x,q)/\partial x < 0 \Rightarrow x^* = 1$;

if $q = \bar{q}$, $\partial c(x,q)/\partial x = 0 \Rightarrow x^* \in [0,1]$.

In fact, $\bar{q}$ is the highest liquid assets price which can be accepted by the entrepreneur?

Suggestion 1 shows three kinds of phenomena. Firstly, if the price of liquid assets is relatively higher ($q > \bar{q}$), it is the optimal strategy for the entrepreneur not to store liquid assets. In fact, holding one unit of liquid assets could generate expected return $\bar{q}$ for the entrepre-

neur that means the cost of holding liquid assets is bigger than expected earnings. Therefore, it is irrational for the entrepreneur to hold liquid assets. Secondly, if the price of liquid assets is relatively lower ($q < \bar{q}$), it is optimal to hold $\rho_H I - \tau'\rho_0 I$ units of liquid assets, in order to ensure the reinvestment in any case by getting plenty of liquidity. Thirdly, if the price of liquid assets is equal to the entrepreneur's expected return $\bar{q}$ generated by one unit of liquid assets, there is no difference whether to store liquid assets or not for the entrepreneur.

Step 3: Find the optimal investment level I^*.

Suggestion 1 and Equation (7) indicate that the optimal investment level is closely related to the liquid assets price q, specifically as follows:

if $q < \bar{q}$, the optimal investment level would be

$$I^* = \frac{1}{1-\rho_0-\tau'\rho_0+(q-1)(\rho_H-\tau'\rho_0)+\bar{\rho}} A;$$

if $q > \bar{q}$, the optimal investment level would be

$$I^* = \frac{1}{1-\rho_0-(1-\lambda)\tau'\rho_0+(1-\lambda)\rho_L} A;$$

if $q = \bar{q}$, the optimal investment level would be

$$I^*(x) = A\cdot\{1-\rho_0-[(1-\lambda)+\lambda x]\tau'\rho_0+ (\bar{q}-1)x(\rho_H-\tau'\rho_0)+(1-\lambda)\rho_L+\lambda x\rho_H\}^{-1}.$$

5 Comparative static analyses

The relationship between corporate growth and liquidity assets value will be given next.

Suggestion 2: The better the corporate growth is, the higher the enterprise can get from one unit of liquid assets, that means, liquid assets value $\bar{q}$ and corporate growth τ are positively correlated.

Proof: Proposition 1 indicates that the value of one unit of liquid assets for the enterprise is:

$$\bar{q} = 1+\lambda\frac{\tau'[1-(1-\lambda)(\rho_H-\rho_L)]-\rho_H}{(\rho_H-\tau'\rho_0)[1+(1-\lambda)\tau']}.$$

Solving the partial derivative of $\bar{q}$ with respect to τ':

$$\frac{d\bar{q}}{d\tau'} = -\lambda\frac{G}{J},$$

where:

$$J = \{(\rho_H-\tau'\rho_0)[1+(1-\lambda)\tau']\}^2,$$
$$G = [(1-\lambda)(\rho_H-\rho_L)-1](\rho_H-\tau'\rho_0)[1+(1-\lambda)\tau']+ \{\rho_H+\tau'[(1-\lambda)(\rho_H-\rho_L)-1]\}\rho_0[1+(1-\lambda)\tau']- \{\rho_H+\tau'[(1-\lambda)(\rho_H-\rho_L)-1]\}(\rho_H-\tau'\rho_0)(1-\lambda).$$

G can be simplified as:

$$G = [(1-\lambda)(\rho_H-\rho_L)-1-\rho_H(1-\lambda)](\rho_H-\tau'\rho_0)+ \{\rho_H+\tau'[(1-\lambda)(\rho_H-\rho_L)-1]\}\rho_0[1+(1-\lambda)\tau'],$$

based on Equation (3):

$$\rho_H+\tau'[(1-\lambda)(\rho_H-\rho_L)-1] \le 0,$$

it leads to:

$$(1-\lambda)(\rho_H-\rho_L)-1 \le 0$$

and as $\rho_H-\tau'\rho_0 > 0$, $G < 0$, then $d\bar{q}/d\tau' > 0$. Due to $\tau' = \tau/p_H$, $\frac{d\bar{q}}{d\tau} > 0$.

This means the better the corporate growth, the higher the liquid assets value. In other words, the highest liquid assets price $\bar{q}$ which can be accepted by the enterprise would increase with the increasing in corporate growth τ.

6 Numerical simulations

Now, some numerical calculations would be made for the theoretical results. Table 1 indicates the influence of corporate growth on liquid assets value $\bar{q}$, and then the optimal financing contract could be given in the condition of a certain liquid assets price. Where basic parameters are $q=1.5$, $A=1$, $p_H=0.4$, $p_H=0.2$, $B=0.4$, $R=3$, $\rho_H=0.6$, $\rho_L=0.3$, $\lambda=0.5$. Table 1 shows that, both of the entrepreneur's expected net utility U_b and liquid assets value $\bar{q}$ increase with the increasing in corporate growth τ. If the price of liquidity assets is higher than value, the probability of reinvestment $x=0$ in the case of higher reinvestment demand. The number of holding liquid assets $L=0$; if the price is lower than value, the enterprise will store enough liquid assets to meet his reinvestment need, and the number of holding liquid assets would decrease with increasing in corporate growth.

TABLE 1 The influence of corporate growth on liquid assets value and financing decision

7 Conclusions

Based on the external financing analysis framework under asymmetric information, this paper analyzes the influence of corporate growth on liquid assets value, and then discusses the enterprise's optimal financing decision in the condition of a given liquid assets price. The study shows that liquid assets value would increase with the increasing in corporate growth, in other words, the enterprise with higher growth is willing to pay higher price to store liquid assets. If the price of liquidity assets is higher than value, the enterprise would not hold liquidity assets, although this may make him unable to seize the growth opportunity in the case of higher reinvestment demand; if the price is lower than value, the enterprise will store enough liquid assets to meet his reinvestment need in any case for getting the growth opportunity; if the price is equal to value, there is no difference found in reinvesting or not.

Abstract

In order to measure investors' risk appetite more accurately, from the focus on the investors' demand for the capital market, this article deduces the utility level of investors in the capital market by the inverse of the investor demand (only when the demand function satisfies integrablility, then it will be deduced the utility function inversely), and thus measure and identify the investors' risk appetite. While based on this theory approach, the paper empirically analyses the risk allocation of China multi-layer capital market, and the results show that: risk allocation of China multi-layer capital market system is non Pareto efficient, the risk allocation of each market does not meet the structure of multi-layer capital market established, but these problems can be improved by adjusting the market trading mechanisms.

Keywords: Stochastic demand; Integrability problem; Risk appetite; Risk allocation

1 Introduction

By correctly understanding the investors' risk appetite in the multi-layer capital market, it can be provided a strong basis for accurately formulating the policy for multi-layer capital market, formulated more targeted policy, security policy role to achieve the desired effect. October 30, 2009 28 SME GEM official visit in China, which means China multi-layer capital market system, has taken shape. The multi-layer capital market is needed to establish by reforming and developing capital market in China, because the single capital market structure is caused by inefficient capital markets, speculative prominent, regulatory costs and other problems of the institutional reasons [1], only through effectively operating the multi- layer capital market system can reduce the high transaction costs due to a single hierarchy lead, narrow the scope of the transaction costs incurred [2]. The purpose of the establishment of multi-layer capital market is not only to optimize the allocation of resources, but also to optimize the allocation of risk. Optimal allocation of resources refers to it provides a direct financing platform for the different types of companies which they can maximally overcome the obstacles to credit constraints, the optimal allocation of risk refers to it provides investment environment for the investors with different characteristics of risk preferences which consistent with their risk appetite, and launch of the GEM adapts to the demand of risk lovers. That is to say, the establishment of multi-layer capital market is not only to improve the efficiency of resource allocation, but also to improve risk allocation efficiency by establishing different levels of market risk, namely the risk allocation should achieve Pareto efficiency, the various risks fall on the risk appetite of investors with such features [3]. Current research focuses on the study of efficiency of resource allocation, the study of risk allocation efficiency is relatively less, but this aspect of the research for the development of the market is how important it is.

Therefore, the focus of this paper is allocation efficiency of multi-market risk capital, combining the purpose of multi-purpose capital market system established, the paper aims to measure the allocation efficiency of risk by identifying the investors' risk appetite in the market. Identification of investors' risk appetite can be attributed to its utility function for the study, while investors' utility function can be obtained by studying its demand function, which is the integrable problems, and the starting point of this study from the risk appetite is not common. That is to say, based on the analysis of investors' market demand function, if the demand function satisfies the integrability, namely the demand function has a symmetrical, semi-negative definite substitution matrix, then we can get the investors' utility function which consistent with their demand function, and identify the investors' risk appetite, thereby determine whether the investors' performance in the market consistent with the purpose of the establishment of multi-layer capital market, namely whether it is Pareto efficient.

Visibly, the establishment of investors' demand function for the market does not like the conventionally established model, namely under the given investors' utility function achieving the maximum utility for solving the utility function. Since the time of establishment of multi-layer capital market system is short, not mature enough, so to some extent, the current capital market is a speculative market [4]. When making investments, its purpose is not to become a corporate shareholder, with part of its title, but trying to take advantage of price movements to get the profits arising from bid-ask spread, when making investment decisions, investors don't consider there is any

** Corresponding author's* e-mail: byndwyd@sina.com

essential difference among the listed companies, but unsteadily they see them as symbol or code, they randomly select these symbol or code according to their own subjective and objective constraints. Therefore, according to investors' performance in the market, we construct the expected demand function of random variables. If this function is able to satisfy the integrability, we can get the investors' utility function. Utility function is an important economic analytical tool, which is real, and can be proved by various methods [5][6]. At the same time, it is also been widely used in the financial field[7]: used the utility function to improve Markowitz mean – variance portfolio model, resulting in asset allocation to meet the different investors' risk preferences[8]; also based on investors' appetite for risk and return, established investors' utility function, and thus used the utility function in the insurance industry[7]; certainly, also built the utility function by direct to measure the investors' risk attitude[9]. It can be seen, in the use of the utility function to solve problems, these analysis carried out under the prerequisite condition of known investors' risk appetite, but this article is based on the premise of investors' risk appetite unknown, by the utility function to identify investors' risk appetite ; although the article also build utility function, the utility function is constructed based on the investors' real need performance in the multi-layer capital market in this paper, rather than built directly.

Construct the investors' risk appetite measurement model in accordance with their utility unction in this article. In this regard, the paper does not use the standard deviation σ or variance σ^2 proposed by Markowitz (1952) and β coefficient method proposed by William Sharpe $\beta = \frac{\mathrm{COV}_{jM}}{\sigma_M^2}$, in which: σ_M^2 is the variance of the market portfolio. Because of these two methods does not reflect the risk difference of asset purchasing at different prices, for investors' risk are different facing the same kinds of asset purchasing at different prices, the purchasing price more higher the risk more greater. Strictly speaking, by σ and β measuring the risk is the same ideologically, there is no essential difference between them, because β is the variant of σ.

Then, in the second part of this article, we first construct stochastic demand model, and validate the integrability of this model, and then get the random utility model which consistent with investors' demand model; in the third part of this article, we construct risk appetite measurement model, in the fourth part we identify the risk appetite of China multi-layer capital market, determine its validity, that is to say identify the current investors' performance on risk allocation in the multi-layer capital market, whether it is achieved Pareto efficient; in the five part we correspond the policy and recommendations.

2 Construction of utility theory model – demand

Random expectation demand model raised by Becker is the most classic, most influential. He considered individual randomly assigned their wealth among competing goods under linear budget constraints, constructs the probabilistic choice models based on the assumption of uniform distribution of two commodities, non-satiation, and found that this model was still in line with the needs of law [10]. Since then a large number of scholars have conducted research based on Becker's model, Machina and Gul and Pesendorfer proposed, even the model resulting in the non-rational behavior can contain the satisfactory and limited rational behavior depending on the utility function and random selection [11][12], Sanderson reduced the assumptions and constraints of Becker's model, he expanded the Becker's model and used the expanded model to analyze the family output, and produced better results. Visibly random expected demand model have been developed more perfect. In this article, the benchmark model is still Becker's model, but reduces the probability distribution assumptions, while expand the two products to three, because this article studies the main market, small board and GEM of capital market, according to this method it can also be adapted to model of plurality products certainly. Although the article reduces the assumptions, the model still has excellent properties.

2.1 ASSUMPTIONS

Assumption 1: $X \equiv (X_1, X_2, X_3)$ represents the market vector, $X_i = X_1, X_2, X_3, i = 1,2,3$ separately represents the three markets: main market, small board and the GEM market, assuming that all investors who choose to enter the i th market constitute a general, and the overall homogeneity is the overall unit performance has the same preferences, while the differences in the presence among the overall unit makes this general heterogeneity.

Assumption 2: $p \equiv (p_1, p_2, p_3)$ represents the price vector relatively, and w represents the individual's total wealth, individual randomly allocates his total wealth w to three markets, $w = \sum_{i=1}^{3} \pi_i w$, π_i is the probability of the total wealth randomly assigned to the i th market, the wealth allocated to the i th market is w_i, $w_i = \pi_i w$. To avoid degradation, we assume the income and price are strictly positive and finite. So their budget constraint is:

$p_1 X_1 + p_2 X_2 + p_3 X_3 \le w$,that is to say,

$$p \cdot X = \sum_{i=1}^{3} p_i X_i \le w \tag{1}$$

Assumption 3: individuals randomly choose their willingness to participate in the sub-stock market, the cumulative distribution function is:

$F(x_1, x_2, x_3) \equiv \Pr(X_1 \le x_1, X_2 \le x_2, X_3 \le x_3)$

and the probability density function is $f(x_1, x_2, x_3)$.

$x \equiv (x_1, x_2, x_3)$, and $f(x) \equiv dF(x)/dx$.

To ensure its differentiability, we assume $f(x)$ is continuous. $x \in R_+^3$ is a standard set of requirements.

2.2 RANDOM EXPECT DEMAND MODEL OF THE i TH MARKET

Investors' demand for the i th market $(i=1,2,3)$, if $p_1X_1 \le w$, then the choice of X_1 is feasible. That is, if $X_1 \le X_1^{\max}$, $X_1^{\max}$ is the maximum possible demand of X_1, $X_1^{\max} \equiv w/p_1$. In this case, the viable condition of choice X_2 is need to be considered for the part of the wealth to X_1. If X_1 is feasible, $p_2X_2 \le w-p_1X_1$ set up, then X_2 is feasible, the maximum possible amount of consumption is $X_2^{\max} = w-p_1X_1$. Similarly, if X_1 and X_2 are feasible, $p_3X_3 \le w-p_1X_1-p_2X_2$ set up, then X_3 is feasible, the maximum demand is $X_3^{\max} = w-p_1X_1-p_2X_2$, and it can be summarized as $X_i^{\max} = w-\sum_{i=1}^{2} p_iX_i$.

Therefore, we make $X^{\max} \equiv (X_1^{\max}, X_2^{\max}(x_1), X_3^{\max}(x_1,x_2))$ as the largest possible demand vector on the condition of three markets.

Define $F(p,w) \equiv F(X_1^{\max}, X_2^{\max}(x_1), X_3^{\max}(x_1,x_2))$, it ensures the establishment of the budget constraint (1), given:

$$F(p,w) = \Pr(0 \le pX \le w) = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} \int_0^{X_3^{\max}(x_1,x_2)} f(x_1,x_2,x_3)dx_3dx_2dx_1 \tag{2}$$

Investors' random expect demand for the i th market to meet the:

$$\bar{x}_i(p,w) \equiv E(X_i \mid 0 \le p\cdot X_i \le w) = \frac{\int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} \int_0^{X_3^{\max}(x_1,x_2)} x_i f(x_1,x_2,x_3)dx_3dx_2dx_1}{F(p,w)} \tag{3}$$

Model (3) is investors' random expect demand model for the i th market. In essence, $\bar{x}_i(p,w)$ is the truncated expectation of random variable X_i, truncation occurs because all of the true value of the vector must be located within the budget set. In other words, $\bar{x}_i(p,w)$ is the expectation of random variable from $f(x)/F(p,w)$. From (2) and (3), it can be concluded that the demand function is zero-order homogeneous for prices and wealth. This result is easily confirmed, for θ >0, $\bar{x}(\theta p,\theta w) = \bar{x}(p,w)$.

Define $\bar{x}(p,w) \equiv (\bar{x}_1(p,w), \bar{x}_2(p,w), \bar{x}_3(p,w))$ as the random expect demand vector.

2.3 VALIDATION OF INTEGRABILITY OF RANDOM EXPECT DEMAND MODEL

When a given set of demand function $x(p,w)$, if it has a negative semi-definite symmetric substitution matrix, then this function can be set to satisfy the integrability, namely we can get the utility function set through the function set which consistent with.

If $S(p,w)$ is Slutsky substitution matrix, Σ is the variance – covariance matrix of $\bar{x}_i(p,w)$.

$S(p,w) = -\Sigma$, and the elements of Σ as follows:

$\Sigma_{ij} = Cov(X_i,X_j) \equiv E[(X_i-\bar{x}_i(p,w))(X_j-\bar{x}_j(p,w)) \mid X_1 \le X_1^{\max}, X_2 \le X_2^{\max}(x_1), X_3 = X_3^{\max}(x_1,x_2)]$, in this case if $i \ne j$, then the elements are the covariance $Cov(X_i,X_j)$, if $i=j$, then the elements are the variance $Var(X_i)$.

So $Q_i(p_i,w_i) = \bar{x}_i(p_i,w_i) = \frac{\int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} \int_0^{X_3^{\max}(x_1,x_2)} x_i f(x_1,x_2,x_3)dx_3dx_2dx_1}{F(p,w)}$, then $\bar{x}_i(p_i,w_i) = \frac{Q_i(p_i,w_i)}{F_i(p_i,w_i)}$, and

$$\left.\frac{\partial Q_i(p,w)}{\partial p_i}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} x_i f(x_1,x_2,\ X_3^{\max}(x_1,x_2))\left(\left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_i}\right|_{\bar{w}}\right)dx_2dx_1 \tag{4}$$

$$\left.\frac{\partial F(p,w)}{\partial p_i}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} f(x_1,x_2,\ X_3^{\max}(x_1,x_2))\left(\left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_i}\right|_{\bar{w}}\right)dx_2dx_1 \tag{5}$$

1) Verification of symmetry

$$\left.\frac{\partial Q_i(p,w)}{\partial p_j}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} x_i,\ f(x_1,x_2,X_3^{\max}(x_{1,}x_2))\left(\left.\frac{\partial X_3^{\max}(x_{1,}x_2)}{\partial p_j}\right|_{\bar{w}}\right)dx_2dx_1,$$

$$\left.\frac{\partial F_i(p,w)}{\partial p_j}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} f(x_1,x_2,X_3^{\max}(x_{1,}x_2))\left(\left.\frac{\partial X_3^{\max}(x_{1,}x_2)}{\partial p_j}\right|_{\bar{w}}\right)dx_2dx_1,$$

after calculation it can be obtained:

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_j}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} (x_i - \bar{x}_i(p,w))\left(\frac{f(x_1,x_2,X_3^{\max}(x_1,x_2)}{F(p,w)} \left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_j}\right|_{\bar{w}}\right) dx_2 dx_1 \tag{6}$$

Among them, $$\left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_j}\right| = \frac{\bar{x}_j(p,w) - x_j}{p_3} \tag{7}$$

Let (7) substitute into (6), we get,

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_j}\right|_{\bar{w}} = -\int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} [x_i - \bar{x}_i(p,w)][x_j - \bar{x}_j(p,w)]\left[\frac{f(x_1,x_2,X_3^{\max}(x_1,x_2))}{F(p,w)} \frac{1}{p_3}\right] dx_2 dx_1 \tag{8}$$

Similarly it can be calculated:

$$\left.\frac{\partial \bar{x}_j(p,w)}{\partial p_i}\right|_{\bar{w}} = -\int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} [x_i - \bar{x}_i(p,w)][x_j - \bar{x}_j(p,w)]\left[\frac{f(x_1,x_2,X_3^{\max}(x_1,x_2))}{F(p,w)} \frac{1}{p_3}\right] dx_2 dx_1 \tag{9}$$

Thus, (8)=(9),that is to say, $\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_j}\right|_{\bar{w}} = \left.\frac{\partial \bar{x}_j(p,w)}{\partial p_i}\right|_{\bar{w}}$,this substitution matrices satisfy the symmetry.

2) Validation of semi-negative definite

For $\left.\frac{\partial \bar{x}_i(p_i,w_i)}{\partial p_i}\right|_{\bar{w}_i} = \left.\frac{\partial Q_i(p_i,w_i)}{\partial p_i}\right|_{\bar{w}_i} \left(\frac{1}{F_i(p_i,w_i)}\right) - \left.\frac{\partial F_i(p_i,w_i)}{\partial p_i}\right|_{\bar{w}_i} \left(\frac{Q_i(p_i,w_i)}{F^2(p_i.w_i)}\right)$, after arrangement we get:

$$\left.\frac{\partial \bar{x}_i(p_i,w_i)}{\partial p_i}\right|_{\bar{w}} = \left(\frac{1}{F_i(p_i,w_i)}\right)\left[\left.\frac{\partial Q_i(p_i,w_i)}{\partial p_i}\right|_{\bar{w}_i} - \bar{x}_i(p_i,w_i)\left.\frac{\partial F_i(p_i,w)}{\partial p_i}\right|_{\bar{w}_i}\right] \tag{10}$$

Let (4) (5) substitute into (10), after arrangement, we get:

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_i}\right|_{\bar{w}} = \int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} [x_i - \bar{x}_i(p,w)]\left[\frac{f(x_1,x_2,X_3^{\max}(x_1,x_2))}{F(p,w)} \left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_i}\right|_{\bar{w}}\right] dx_2 dx_1 \tag{11}$$

$$\left.\frac{\partial X_3^{\max}(x_1,x_2)}{\partial p_i}\right| = \frac{\bar{x}_i(p,w) - x_i}{p_3} \tag{12}$$

Let (12) substitute into (11), we get:

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_i}\right|_{\bar{w}} = -\int_0^{X_1^{\max}} \int_0^{X_2^{\max}(x_1)} [x_i - \bar{x}_i(p,w)]^2\left[\frac{f(x_1,x_2,X_3^{\max}(x_1,x_2))}{F(p,w)} \frac{1}{p_3}\right] dx_2 dx_1 \tag{13}$$

Meanwhile, $Var(X_i) \equiv E[(X_i - \bar{x}_i(p,w))^2 \,|\, X_1 \le X_1^{\max}, X_2 \le X_2^{\max}(x_1), X_3 = X_3^{\max}(x_1,x_2)]$, so

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_i}\right|_{\bar{w}} = -Var(X_i) \tag{14}$$

At this time, the price effect of expect demand is non-positive.

And because $Cov(X_i,X_j) \equiv E[(X_i - \bar{x}_i(p,w))(X_j - \bar{x}_j(p,w)) \,|\, X_1 \le X_1^{\max}, X_2 \le X_2^{\max}(x_1), X_3 = X_3^{\max}(x_1,x_2)]$, $i \ne j$,

$$\left.\frac{\partial \bar{x}_i(p,w)}{\partial p_j}\right|_{\bar{w}} = -Cov(X_i,X_j).$$

Because of the variance – covariance matrix Σ is semi-positive definite, $S(p,w)$ is semi-negative definite.

It can be seen that this model satisfies the integrability, we can get the utility function which consistent with it, that is to say we can obtain three different investtors' utility function from the main market, small board and the GEM market, that is $U(X_i) = \int_p \bar{x}_i(t,w)dt$.

3 Measurement of risk appetite

When the investors make their own choice, and at the same time they know the results they will have to bear in the future, or benefit from this choice, or bear the loss, or neither benefit nor lost, in a risk-free status. When investors choose to enter the main market, small board and GEM market, they tend to be more concerned about their possible gain or loss, if R_i represents the collection which contains all appeared unknown results after investors choose to enter the i th markets, R_i^+ means the benefit collection from investors' choice, R_i^- means loss collection from investors' choice, it is clear that $R_i^+, R_i^- = R$, $R_i^+ \cap R_i^- = \Phi$.

Risk is the possible loss due to the uncertainty to investors, more objective expression is that when investtors choose to fall R^+, investors will benefit, will not bear the loss; If when the investor's choice falls R^-, that is $R^- \neq \Theta$, at this time investors have to face the risk.

Investors bear the risk:

$$E_{R^-}(U_i) = \int_{R^-} U_i dF(U_i) = \int_{R^-} U_i f(U_i) dU_i \text{ , } E_{R^-}(U_i) < 0$$

Investors obtain the benefit:

$$E_{R^+}(U_i) = \int_{R^+} U_i dF(U_i) = \int_{R^+} U_i f(U_i) dU_i \text{ , } E_{R^+}(U_i) > 0.$$

Assuming r is risk-free return, and then we construct the measurement tools of investors' risk appetite:

$$\eta_i = r - E_{R^+}(U_i) - E_{R^-}(U_i) \tag{15}$$

When $\eta_i > 0$, investors are risk lovers, and the value of η_i the larger indicates the degree of risk investtors pursuit the higher. At this point, investors are more willing to make a choice, rather than election of fair game, because the exposure may be $-E_{R^-}(U_i)$, there is loss of revenue r (because if they don't choose, r is the opportunity costs for investors) may outweigh the benefits obtained possibly.

When $\eta_i < 0$, investors are risk averse, and the value of η_i the smaller indicates the degree of risk adverse avoidance the higher. Because the choice may not only bring greater revenue than raised losses, but also greater than the sum of r and $-E_{R^-}(U_i)$, they believes the risk of fair game is too high, so they should be risk averse.

When $\eta_i = 0$, investors consider at this time to make a choice is equal to fair game, then the investors are risk neutral, they does not behave like a risk averse too conservative, and does not behave as risk lovers too optimistic, would be more objective treatment of the problem, when $\eta_i > 0$, he will not select, on the contrary at the time $\eta_i < 0$, they will select, because at this time they believe in their favor.

Through the above theoretical analysis, we will find that: when $\eta_i = 0$ and when $\eta_i < 0$, there is the intersection between the investors' choice. Because under certain conditions, the risk netballers' choice is similar with the risk averse', that is, it is difficult to identify the similar choice whether from the risk averse investors or from the risk neutral investors. Visibly, this approach is not suitable for determining the real investors' specific type of risk appetite.

To this end, we have to be adjusted on the basis of this model, let η_i will be used to be replaced by $\eta_i^{\max}$, which is the measurement maximum of investors withstand, the model is:

$$\eta_i^{\max} = \max[r - E_{R^+}(U_i) - E_{R^-}(U_i)] \tag{16}$$

If and only if

$$E_{R^+}(U_i) = E_{R^+}^{\min}(U_i), E_{R^-}(U_i) = E_{R^-}^{\min}(U_i)$$

According to the assumptions (1) it is available that $E_{R^+}^{\min}(U_i)$ and $E_{R^-}^{\min}(U_i)$. Therefore, the model (16) can be used to identify the investors' risk preferences in different markets.

4 Empirical analysis based on the risk allocation of China multi-layer capital market

On the basis of theoretical analysis framework, this article choose the main market, small board, the GEM market as the research object, using the method of empirical analysis to analyze the investors' risk appetite and allocative efficiency in each market.

4.1 INDICATORS AND DATA SELECTION

According to the foregoing analysis, the model contains three corresponding variables: price, quantity, and has a wealth of purchase. To ensure the comparability, the paper selects the composite index. In the main market, we select the closing price on the Shanghai Composite Index and Shenzhen Composite Index as the price, and their volume (unit: million) as the corresponding quantity demanded; in the small board, select the small plate KLCI closing price, volume (Unit: million) as the corresponding variables; in the GEM, select the GEM KLCI closing price, volume (unit: million) as its variables; meanwhile, we sum the turnover (unit: million) corresponding to the Shanghai Composite Index and Shenzhen Composite Index, the small plate KLCI and GEM KLCI, then obtain the total wealth in demand market which investors can distribute. Since the GEM KLCI launches from August 20, 2010, the data in this paper is August 20, 2010 to November 21, 2013. Theoretically, the Shanghai Composite Index and Shenzhen Composite Index are main market index, should be unified analysis, but found that in the Shanghai Stock Exchange and Shenzhen Stock Exchange market there are significant differences in the degree of risk appetite, therefore, the paper retains the Shanghai and Shenzhen two main markets. The above data is from CSMAR database.

4.2 STATIONARY TEST OF DATA

Stationary test takes ADF test which is the most commonly to be used. To avoid the heteroscedasticity of estimation model, this article deals with the data to be logarithmic treatment, and do the stationary test to these variables and the variables after the first differences, the test results are shown in table 1:

TABLE 1 Stationary test results

Variables	ADF test statistic	$p-value$
ln(Shanghai Composite Index)	-1.523085	0.8198
ln(*volumeof* Shanghai Composite Index( )	-5.92698	0.0000
ln(Shenzhen Composite Index)	-1.474319	0.8364
ln(*volumeof* Sshenzhen Composite Index)	-4.567777	0.0002
ln(Small board inde)	-1.34279	0.8751
ln(volume of Small board index)	-4.878331	0.0004
ln(GEM Index)	-1.852633	0.6764
ln(volume of GEM Index)	-4.563277	0.0014
ln(Total Turnover)	-4.160081	0.0009
Variables after the first differences	ADF test statistic	$p-value$
d ln(Shanghai Composite Index)	-16.90434	0.0000
d ln(*volumeof* Shanghai Composite Index)	-18.11173	0.0000
d ln(Shenzhen Composite Index)	-16.06674	0.0078
d ln(*volumeof*Sshenzhen Composite Index)	-15.20731	0.0000
d ln(Small board index)	-15.58342	0.0000
d ln(volume of Small board index)	-15.2738	0.0000
d ln(GEM Index)	-15.94434	0.0000
d ln(volume of GEM Index)	-16.01485	0.0000
d ln(Total Turnover)	-15.44591	0.0000

The results shows that: the variables after logarithmic treatment, at 10% significance level, the Shanghai Composite Index, Shenzhen Composite Index, the small board index and GEM index are non-stationary sequence, the rest is smooth sequence; after first differential treatment with the logarithmic variables, all variables are stationary sequence.

4.3 SELECTION AND ESTIMATION OF RANDOM EXPECT DEMAND MODEL

To ensure that the estimated demand model satisfies the integrability, based on the results of stationary test, we select the first difference variables as the variables, so the model is double logarithmic first-order differential form. Also, because of the differential model, the model does not contain a constant term. In this paper, the level of significance is $\alpha = 0.05$. The basic model is:

$$d\ln x_i = \sum_{i=1}^{3} \alpha_i d\ln p_i + \beta d\ln w + \varepsilon_i \tag{17}$$

Among them, x_i is the investors' demand for i th market, p_i is the price for i th market, w is the total wealth for investors in the capital market, α, β are the parameters to be estimated.

Meanwhile, from $d\ln x_i = \sum_{i=1}^{3} \alpha_i d\ln p_i + \beta d\ln w$, we can obtain $\ln x_i = \sum_{i=1}^{3} \alpha_i \ln p_i + \beta \ln w + c$, wherein C an arbitrary constant is. To facilitate the analysis, let $c = 0$, then $\ln x_i = \sum_{i=1}^{3} \alpha_i \ln p_i + \beta \ln w$, the deformation can be obtained:

$$x_i = \prod_{i=1}^{3} p_i^{a_i} w^{\beta} \tag{18}$$

That is demand model for i th market.

1) Demand model of main Market

a. Demand model of Shanghai main market

First differential model of Shanghai main market:

$$d\ln x_{Shanghai} = 1.1289 d\ln w$$
$$(22.0965)$$
$$\bar{R}^2_{Shanghai} = 0.6296$$

Demand model: $x_{Shanghai} = w^{1.1290}$

From the above first difference model, we can see that, $\bar{R}^2_{Shanghai} = 0.6296$ indicates that the extent of the first differential model of Shanghai Stock Exchange Main Board fit well, the equation is significant, and only the total wealth variable coefficients is significant, that is to

say changes in investors' demand for the Shanghai Stock Exchange main board market is only the case with investors owned total wealth, and shows the same relationship to changes.

b. Demand model of Shenzhen main market

First differential model of Shenzhen main market:

$$d\ln x_{Shenzhen} = -2.4655 d\ln p_{Shanghai} + 6.0191 d\ln p_{Shenzhen} - 3.4643 d\ln p_{Smallboard} - 0.8143 d\ln p_{GEM} + 0.9695 d\ln w$$

(-4.3874) (3.9071) (-3.0724) (-2.8082) (79.4239)

$$\bar{R}^2 = 0.9564$$

Demand model:

$$x_{Shenzhen} = p_{Shanghai}^{-2.4654} p_{Shenzhen}^{6.0191} p_{Smallboard}^{-3.4643} p_{GEM}^{-0.8143} w^{0.9695}$$

Seen, $\bar{R}^2 = 0.9564$ indicates the model fits well, and the coefficients of prices and total wealth variables of Shanghai Stock Exchange main market, Shenzhen main market small board and the GEM market are significant, namely changes in investors' demand for the Shenzhen main market are related to the changes of price of Shanghai main market, Shenzhen main market, small board market, GEM market and investors' total wealth. And changes in investor demand of Shenzhen main market with its own price changes and changes in total wealth is in the same direction of changes, in relationships with the price changes of other alternative market such as Shanghai Stock Exchange main market, small board and the GEM market inversely to changes in market relations.

2) Demand model of small board market

First difference model of Small board:

$$d\ln x_{smallboard} = 3.1144 d\ln p_{smallboard} + 0.8891 d\ln w$$

(2.0220) ((53.3173)

$$\bar{R}^2 = 0.9077$$

Demand model: $x_{smallboard} = p_{smallboard}^{3.1144} w^{0.8891}$

Seen, $\bar{R}^2 = 0.9077$ indicates the model fits well, while the coefficients of variables of small board market price and total wealth are significant, that is, changes in investors' demand for small board market are related to its own price and investors' total wealth. And changes in investors' demand for small board market with its own price changes and changes in total wealth was the relationship in the same direction.

3) Demand model of GEM market

First differential model of GEM:

$$d\ln x_{GEM} = -7.7118 d\ln p_{Shenzhen} + 9.6736 d\ln p_{GEM} + 0.7874 d\ln w$$

(-2.9680) (8.6117) (16.6508)

$$\bar{R}^2 = 0.5275$$

Demand model: $x_{GEM} = p_{Shenzhen}^{-7.7118} p_{GEM}^{9.6736} w^{0.7874}$

Seen, $\bar{R}^2 = 0.5275$ indicates the model fits better, the coefficients of variables of prices of Shenzhen main market and GEM market and total wealth are significant, changes in investors' demand for the GEM market are related to its own market price changes, price movements of Shenzhen main market and investors' total wealth. And changes in investors' demand for the GEM market with its own price changes and changes in total wealth had a positive relationship, with the price changes of its alternative market Shenzhen main market inversely to changes in the relations.

Through the above analysis, it shows that changes in investors' demand for i th market are related to its own price in the same movement direction(except Shanghai Stock Exchange Main Market), which reflects in the actual market with the increasing price the amount of investors to buy the stock increases, with the decline in stock prices the amount reduces, namely "chase sell"; reverse changes in the relationship with the price of other alternative market(except Shanghai Stock Exchange Main Market), that is, after the prices of alternative markets increasing investors will reduce the demand for changes the original market, in the situation of wealth unchanged, will increase the wealth of assigned to the alternative markets, which is an increase of the purchase of the alternative markets, and conversely it is also be established, which once again confirms the "chase sell " phenomenon; with the same movement relationship to the investors' own overall wealth, that the total wealth increasing investors will increase their demand for the market, the total wealth reducing the investors' demand for the market will be reduced.

4.4 UTILITY FUNCTION AND DISTRIBUTION SET

1) Utility function of each market

According to the definition of the utility function of the foregoing, the utility function can be obtained in each market:

a. Utility function of Main Market

Utility function of Shanghai Main Market:

$$u_{Shanghai} = \int_{p_{Shanghai}^0}^{p_{Shanghai}^1} w^{1.1290} dp_{Shangha}$$

Among them, $p^0_{Shanghai}$ is the base price of the Shanghai main market, $p^1_{Shanghai}$ is the reporting period price of Shanghai main market.

When we get the utility function of Shanghai main market, but also shows that this layer of meaning: when investors in Shanghai main market randomly choose whether to enter the market, or increase or decrease the market demand, actually investors follow their own implied the selecting behavior when the utility function maximized in Shanghai main market, that is, investors' demand for Shanghai main market is guided to conduct under the above utility function essentially.

Utility function of Shenzhen main market:

$$u_{Shenzhen} = \int_{p^0_{Shenzhen}}^{p^1_{Shenzhen}} p_{Shanghai}^{-2.4654} p_{Shenzhen}^{6.0191} p_{Smallboard}^{-3.4643} p_{GEM}^{-0.8143} w^{0.9695} dp_{Shenzhen}$$

Among them, $p^0_{Shenzhen}$ is the base price of Shenzhen main market, $p^1_{Shenzhen}$ is the reporting period prices of Shenzhen main market.

Similarly we can see that the utility function of Shenzhen main market is the basis to guide investors' demand choice behavior in Shenzhen main market, and its conducting code is to maximize the utility function of Shenzhen main market.

Obviously, although the current main market is constitute by Shanghai main market and Shenzhen main market together, there is a big difference for the investors following the conducting code in the two main market, that is, investors follow the two different conducting codes in Shanghai and Shenzhen main markets.

b. Utility function of small board

Utility function of Small board:

$$u_{Smallboard} = \int_{p^0_{Smallboard}}^{p^1_{Smallboard}} p_{Smallboard}^{3.1144} w^{0.8891} dp_{Smallboard}$$

Among them, $p^0_{Smallboard}$ is the base market price of small board, $p^1_{Smallboard}$ is the reporting period price of small board market.

After the above analysis, investors' demand for small board market is completed under the guidance of the utility function of small board.

c. Utility function of GEM

Utility function of GEM:

$$u_{GEM} = \int_{p^0_{GEM}}^{p^1_{GEM}} p_{Shanghai}^{-7.7118} p_{GEM}^{9.67363} w^{0.7874} dp_{GEM}$$

Among them, p^0_{GEM} is the base price of GEM market, p^1_{GEM} is the reporting period price of GEM market.

Similarly, investors get the guidelines of demand of GEM, that is, actually investors' behavior is the performance when the utility function maximize in the GEM.

2) Distribution set of utility function of each market

Based on the above utility function to estimate the utility level in different markets, due to the distribution of the utility level sequence for each market is unknown, the paper carries out the empirical distribution test. The paper uses the Watson test, Cramer-von Mises test, Kolmogorov testing and other testing methods to test the four markets utility level sequences goodness of fit with the theoretical distribution (normal, chi-square distribution, exponential distribution, extreme value distribution, logistic distribution, the Pareto distribution, uniform distribution, etc.) in Shanghai main market, Shenzhen main market, small board and GEM, the results are shown in table 2:

TABLE 2 Empirical distribution test of utility level sequence (original assumptions: utility level obeys to a particular sequence of distribution)

sequence	distribution	Test method	Asymptotic distribution statistics	Limited sample adjustment statistics	$p-value$
$u_{Shanghai}$	exponential	Watson	0.1139	0.1141	0.226
$u_{Shenzhen}$	normal	Watson	0.1179	0.1181	0.239
$u_{Smallboard}$	exponential	Cramer-von Mises	0.1051	0.1051	0.2985
u_{GEM}	uniform	Kolmogorov	0.0033	0.0581	0.9933

Table 2 shows, the utility level sequences for Shanghai main market obeys to the exponential distribution by Watson test, because of $p-value=0.226>\alpha=0.05$; similarly we can see that the utility level sequences for Shenzhen main market obeys to the normal distribution by Watson test, the utility level sequences for small board obeys to the exponential distribution by Cramer-von Mises test, and the utility level sequence GEM obeys to the exponential distribution by Kolmogorov test.

Using the maximum likelihood method to estimate the parameters of each distribution density function, the results are shown in table 3:

TABLE 3 The utility level sequence probability density function and its parameters estimate

sequence	Density functional form	Associated parameter estimates and test values	
$u_{Shanghai}$	$f(u)=\frac{1}{\mu}\exp(-\frac{u-a}{\mu})$	*parameter 1* $a=21041391$ $p-value$ 0.0296	*parameter 2* $\mu=6.10E+09$ $p-value$ 0.0000
$u_{Shenzhen}$	$f(u)=\frac{1}{\sqrt{2\pi}\sigma}\exp(-\frac{1}{2\sigma^2}(u-\mu)^2)$	parameter 1 $\mu=0.0052$ $p-value$ 0.0485	parameter 2 $\sigma=0.3331$ $p-value$ 0.0000
$u_{Smallboard}$	$f(u)=\frac{1}{\mu}\exp(-\frac{u-a}{\mu})$	parameter 1 $a=3.06E+14$ $p-value$ 0.0425	parameter 2 $\mu=2.96E+17$ $p-value$ 0.0000
u_{GEM}	$f(u)=\frac{1}{b-a}$	parameter 1 $a=1.52E+08$ $p-value$ 0.0399	parameter 2 $b=8.72E+10$ $p-value$ 0.0000

In table 3, the second column shows the form of density distribution function of different markets utility level sequence obedience, third and fourth columns are given the estimate of parameters of density function and test conditions. And by determining $p-value$ and the significant level, it shows the estimate of parameters in density functions are significant ($p-value<\alpha$).

4.5 MEASUREMENT OF RISK APPETITE

Based on the each density function we can calculate the risk and gains constructed before, select the minimal risk $E_{R^-}^{\min}(U_i)$ and minimal gains $E_{R^+}^{\min}(U_i)$ and bring them into risk appetite measurement model, because the risk $E_{R^-}(U_i)$ is negative, and measure the degree of risk appetite in different markets, thus identify them. In risk appetite measurement models, this article defines the one-year bank deposit rates 3.5% as the risk free interest rate, and the measurement unit of "Fortune" indicators is million, so to keep the data caliber consistency here, we adjust the risk free rate to 350 (per million). According to the calculation we can separately get $E_{R^+}^{\min}(U_i)$, $E_{R^-}^{\min}(U_i)$ and $\eta_i^{\max}$, and the results are listed in table 4:

TABLE 4 Measurement and identification of risk appetite of multi-layer capital market

Markets	risk free interest rate r	$E_{R^+}^{\min}(U_i)$	$E_{R^-}^{\min}(U_i)$	$\eta_i^{\max}$	risk appetite
Shanghai main market	350	1079370.6029	-238860113539527	238860112460506	risk lovers
Shenzhen main market	350	0.0001	-67184.2497	67534.2496	risk lovers
Small market	350	25458830575936	-267706412381378000	267680953550803000	risk lovers
GEM	350	20301.4482	-14424635394	14424615442.5215	risk lovers

According to table 4, in China current multi-layer capital market, no matter in which capital market, investors are expressed as risk lovers, only the degree of risk appetite is different. By comparison, the degree of risk pursuit of Shenzhen main market is the weakest, followed by the GEM market, the Shanghai main market, the highest level of risk pursuit is small board market, that is to say, $\eta^{\max}_{Smallboard} > \eta^{\max}_{Shanghai} > \eta^{\max}_{GEM} > \eta^{\max}_{Shenzher}$. Although the Shanghai main market and Shenzhen main market together constitute the current overall main market, at the point of view of the degree of investors' risk loving, these two markets and can not be explained as a whole, there is a clear difference between them. The original intention of establishing multi-layer capital market is to distinguish the different levels of the capital market among them, meanwhile the performance of the internal layer of risk should be roughly the same, the performance should be the difference among the risk layer, and the investors' attitude to risk shows a progressive trend, that is, the weakest degree of market risk hobby should be the main market, the degree of small board risk hobby is in the middle, the degree of GEM risk hobby is the strongest. Through the comparison of current realities and theoretical purposes, it is not difficult to find that there is a clear departure between them, not only on the level of the layers the risk away from the hobby, but also on the level of internal layer it clearly does not conform the intention of the theory. The risk appetite of main market is not the weakest, but the situation of Shanghai Stock Exchange main market also exceeds GEM which should have been the strongest risk-loving, and small board shows the strongest degree of risk-loving. This shows that the current multi-layer capital market is not reasonable division for investors with different risk preferences, which shows the current multi-layer capital market in China is non-Pareto efficient on risk allocation, Pareto improvement be needed.

5 Policy and recommendations

We can say that it is a state of disorder China current multi-layer capital market in the risk allocation, the root cause resulting in this non-valid and disorder may be the trading mechanism of the current market. Because in the multi-layer capital market, there is difference on the basis in each market, and there is a hierarchy among market distinction, these indicate that each market has its own characteristics, and in China the basically same transaction mode is still in the use of multi-layer capital market, that is, in the use of uniform, symmetric price limits, which is obviously inconsistent with the characteristics of multi-layer capital market. To change this inconsistent situation, we must distinguish the various markets, with different trading patterns, according to the characteristics of each market to develop and implement the different price limits, such as appropriately rising the price limits of small board and GEM in accordance with their level of risk should bear, or introducing the asymmetric price limits for each market, in order to improve the Pareto efficiency, so that China multi-layer capital market can be improved.

Received 1 March 2014, www.cmnt.lv

Abstract

This paper discusses how steel enterprises choose the appropriate scrap reverse logistics operation mode from self-operation mode and the third party mode. To solve the problem, evolutionary game theory is used to research the game relation of cooperation between steel enterprises and the third -party enterprises. Firstly, the replication dynamic equations of both players are build based on payoff matrix .Secondly, the evolutionary stable strategies are acquired by stability analysis on evolution dynamic process of the game two players. Finally, combined with numerical simulation, some factors that impact stable strategy choice are analyzed such as initial state of system, extra income and risk cost of cooperation, invested initial cost and loss for cooperation. The conclusion provides theoretical reference for steel enterprises selecting scrap reverse logistics mode.

Keywords: scrap reverse logistics mode;evolutionary game theory;replication dynamic equation;steel enterprises

1 Introduction

During the twelfth five-year plan, China sped up the adjustment of its industrial structure and accelerated the transformation of its development mode to develop a low-carbon economy and circular economy. In this context, the steel industry, which is a great energy consumer and a serious polluter, was targeted to take a low carbon path. Therefore, many steel enterprises used a variety of strategies to actively meet the challenge of the low carbon economy. Among them, developing scrap steel industry and increasing scrap supply have a high practical value. Scrap which is different from the other wastes is the main steel-making raw material. Comprehensive energy consumption of steel production, carbon emissions and mineral resources exploittation can be reduced by using scrap in the steel production process [1]. So scrap reverse logistics is one of the effective means to implement a low carbon economy of steel industry. At present, there are self-operation mode, alliance mode and the third party logistics mode for enterprises [2]. This paper only discusses self-operation mode and the third party logistics mode. The former, is that steel enterprises themselves set up reverse logistics system and manage scrap steel reverse logistics activities of enterprise inner such as recycling, transport and reprocessing. The advantage of this mode is mainly that enterprises can control the operations of each link, efficiently recycle resources and reduce raw material cost. It also has disadvantages:transport costs are high, scrap reverse logistics may conflict with forward logistics, technical defects will hinder the development of reverse logistics, etc. The latter is that steel enterprises entrust scrap recycling work to the third party logistics in the form of an agreement and pay some service fees to them. The advantage of this mode is that the cost of building reverse logistics for steel enterprise can be reduced, more money can be saved to develop the main core business, the competitiveness of the enterprises can be improved. However, it also has certain disadvantages, such as product information are easily leaked, the number and time of recycling products are uncertain, the requirements of production cannot be met, the real power of the third party reverse logistics enterprises cannot be handled well enough that the quality of scrap steel may be poor. In a word, the two kinds of reverse logistics operational mode have both advantages and disadvantages. In practice, the decision of scrap reverse logistics operation mode is one of the key issues to consider for steel enterprises.

In recent years, many domestic and foreign scholars studied the decision-making of reverse logistics operation mode from different facets, such as, Ravi evaluated the reverse logistics operational decisions from the customer, internal business, innovation and learning, finance [3]. Ren Mingming used the fuzzy comprehensive evaluation method to establish mathematical model of operation mode selection [4], Chen Zhikui applied network analytic hierarchy process to analyze the decision of reverse logistics operation mode based on setting up evaluated index [5]. Cheng Guangping put forward an operation mode selection evaluation method aiming at the characteristics of domestic reverse logistics by using Fuzzy hierarchy analysis[6] .In the above literature, scholars largely carried out qualitative and quantitative analysis by considering the influencing

* ***Corresponding author***'s e-mail: liyanshangshang@dddd.com

factors of enterprise itself, few scholar considered the impact of decisions of other enterprises and the third party logistics enterprises. In fact, the problem of choosing the self-operation mode or the third party mode in scrap reverse logistics for steel enterprises can be regarded as game analysis between steel enterprises and the third-party logistics enterprises. For instance, Ceng Minggang used the "principal-agent" model to study the reverse logistics operation mode selection[7], however, he simply analyzed the game process under the assumption that two players were completely rational which did not accord with reality. Therefore, evolutionary game theory based on bounded rationality is used to study evolutionary game relation between steel enterprises and the third party logistics enterprises in the paper. The steel production enterprises choose the scrap steel reverse logistics operation mode according to the evolutionary stable strategy.

2 Evolutionary Game Model

2.1 ASSUMPTION

Evolutionary game theory originates from biological evolutionary theory. The theory based on bounded rationality hypothesis is used to analyze strategy adjustment processes, trend and local stability of limited rational players in the process of long-term repeated behavior, study subjects of the theory are groups rather than a single individual behavior[8]. In this paper, the two players are randomly assigned – one from steel enterprises group and one from the third party logistics enterprise groups respectively. The two players are random when playing the game. The game strategies of both players are cooperation and non-cooperation. The cooperation is that enterprises will contract part or all business of scrap reverse logistics out to the third party. The non-cooperation is the enterprises will not reach an agreement with the third party logistics enterprises; the enterprise itself will handle all of the scrap recycling business. Based on reference literature [9-10], one assumes that the benefits and costs of steel enterprises and third-party logistics enterprises under different strategies are as following:

D_m,D_L denote the obtained normal returns of independent operation when steel enterprises and third-party logistics enterprises choose "non-cooperation",

B_m,B_L are generated excess returns when two players cooperate,

F_m,F_L indicate risk costs of two player’s cooperation,

C_m,C_L signify the initial costs which two players invest for co-operation,

V_m is the suffered loss when steel enterprises select cooperation, while the third party logistics enterprises choose non- cooperation,

V_L is the suffered loss when the third party logistics enterprises select co-operation, while steel enterprises choose non- cooperation,

Where $B_m > F_m + C_m$, $B_L > F_L + C_L$

According to the above parameters, the payoff matrix of steel enterprises and third-party logistics enterprises is shown in Table 1.

TABLE 1 Payoff matrix of steel enterprises and third-party logistics enterprises

	The third party logistics enterprises	
	Cooperation(x)	Non- cooperation(1-x)
Cooperation(y)	$D_m + B_m - C_m - F_m$, $D_L + B_L - C_L - F_L$	$D_m - C_m - V_m$, D_L
Non-cooperation(1-y)	D_m, $D_L - C_L - V_m$	D_m, D_L

2.2 THE ESTABLISHMENT OF THE REPLICATED DYNAMIC EQUATION

The expected returns of steel enterprises group selecting cooperation strategy and non-co-operation strategy are as follows:

$$u_{s1} = x(D_m + B_m - C_m - F_m) + (1-x)(D_m - C_m - V_m), \quad (1)$$

$$u_{s2} = xD_m + (1-x)D_m. \quad (2)$$

The average payoff of steel enterprises group is as follows:

$$u_{ss} = yu_{s1} + (1-y)u_{s2}. \quad (3)$$

Similarly, the expected returns of the third party logistics group selecting cooperation strategy and non-cooperation strategy are as follows:

$$u_{x1} = y(D_L + B_L - C_L - F_L) + (1-y)(D_L - C_L - V_L), \quad (4)$$

$$u_{x2} = yD_L + (1-y)D_L. \quad (5)$$

The average payoff of the third party logistics group is as follows:

$$u_x = xu_{x1} + (1-x)u_{x2}. \quad (6)$$

According to evolutionary game theory, if the fitness or payoff of one strategy is higher than the average fitness of the group, the group will trend to adopt this strategy. Namely, the growth rate of this strategy is greater than zero, which can be expressed by the following differential equation [11]:

$$\frac{dx}{dt} = [u(k,s) - u(s,s)]x_k, k = 1,2,\ldots,K \quad . \quad (7)$$

Equation (7) is replicated dynamic equation, where x_k is the proportion of using strategy k among group, $u(k,s)$ is payoff of using strategy k, $u(s,s)$ is the average payoff of the group,k denotes a different strategy, K indicates strategy number of group, s is all strategy set of group.

The replicated dynamic equation of steel enterprises selecting the "cooperation" strategy is as follows:

$$F(y)=\frac{dy}{dt}=y(u_{s1}-u_{ss})=y(1-y)(xB_m+xV_m-xF_m-C_m-V_m)\ . \qquad (8)$$

Let $\frac{dy}{dt}=0$, the stabilized state points of replicated dynamic equation ,which mean the proportion y of steel enterprises selecting co-operation strategy in the dynamic process keep relatively stable equilibrium, are obtained:

$$y=0, y=1,\ \ x^*=\frac{C_m+V_m}{B_m+V_m-F_m}\ .$$

In the same way, the replicated dynamic equation of the third party logistics enterprises selecting the "cooperation" strategy is as follows:

$$F(x)=\frac{dx}{dt}=x(u_{x1}-u_{xx})=x(1-x)(yB_L+yV_L-yF_L-C_L-V_L)\ . \qquad (9)$$

Let $\frac{dy}{dt}=0$, the stabilized state points are obtained:

$$x=0, x=1,\ \ y^*=\frac{C_L+V_L}{B_L+V_L-F_L}$$

3 Stability Analysis Of Model

The above obtained stabilized state points are not absolute stable equilibrium. According to the stability theorem of differential equation and the nature of evolutionary stable strategy[12], the calculated state points are evolutionary stable strategy(ESS) when $\frac{dF(x)}{dx}<0$ and $\frac{dF(y)}{dy}<0$.

For the iron and steel enterprises,

$$F'(y)=(1-2y)(xB_m+xV_m-xF_m-C_m-V_m)\ . \qquad (10)$$

If $x=\frac{C_m+V_m}{B_m+V_m-F_m}$, then $F(y)\equiv 0$. This means all state points y are stable.

If $x\neq\frac{C_m+V_m}{B_m+V_m-F_m}$, $y=0$ and $y=1$ are stable state points, the two cases in this condition are as follows:

When $x>\frac{C_m+V_m}{B_m+V_m-F_m}$, $\frac{dF(y)}{dy}\Big|_{y=1}<0$, $\frac{dF(y)}{dy}\Big|_{y=0}>0$, $y=1$ is ESS;

When $x<\frac{C_m+V_m}{B_m+V_m-F_m}$, $\frac{dF(y)}{dy}\Big|_{y=0}<0$, $\frac{dF(y)}{dy}\Big|_{y=1}>0$, $y=0$ is ESS;

The conclusion can be drawn from above process analysis: when the probability of the third party logistics enterprises group choose co-operation is bigger than $\frac{C_m+V_m}{B_m+V_m-F_m}$, the final strategy of steel enterprises group is co-operation , that is to say, steel enterprises select the third party logistics mode; when the probability is smaller than $\frac{C_m+V_m}{B_m+V_m-F_m}$, the final strategy is non cooperation ,that is, steel enterprises select self-operation mode.

For the third party logistics enterprises,

$$F'(x)=(1-2x)(yB_L+yV_L-yF_L-C_L-V_L)\ . \qquad (11)$$

If $y=\frac{C_L+V_L}{B_L+V_L-F_L}$, then $F(x)\equiv 0$. This means all state points x are stable state points.

If $y\neq\frac{C_L+V_L}{B_L+V_L-F_L}$, $x=0$ and $x=1$ are stable state points, the two cases are analyzed:

when $y>\frac{C_L+V_L}{B_L+V_L-F_L}$, $\frac{dF(x)}{dx}\Big|_{x=1}<0$, $\frac{dF(x)}{dx}\Big|_{x=0}>0$ $x=1$ is ESS, that is to say, when the probability of steel enterprises groups choosing co-operation is bigger than $\frac{C_L+V_L}{B_L+V_L-F_L}$,the final strategy of the third party logistics enterprises group is co-operation;

when $y<\frac{C_L+V_L}{B_L+V_L-F_L}$, $\frac{dF(x)}{dx}\Big|_{x=1}>0$, $\frac{dF(x)}{dx}\Big|_{x=0}<0$, $x=0$ is ESS, that is, the final strategy of steel enterprises group strategy is non co-operation.

The replication dynamic equations of two players are synthetically analyzed. Their respective stable points are placed in coordinate plane $\{(x,y):0\le x,y\le 1\}$ .There are five local equilibrium points in the plane:

$(x,y)=\{(0,0),(0,1),(1,0),(1,1),(x^*,y^*)\}$, where

$$x^*=\frac{C_m+V_m}{B_m+V_m-F_m} \qquad y^*=\frac{C_L+V_L}{B_L+V_L-F_L}$$

The stability of the equilibrium is obtained by local stability analysis on Jacobean matrix of the system [12-13]. According to method of Friedman proposed, the Jacobean matrix, the corresponding determinant and trace respectively are as follows:

$$J=\begin{bmatrix}\frac{\partial F(x)}{\partial x} & \frac{\partial F(x)}{\partial y}\\ \frac{\partial F(y)}{\partial x} & \frac{\partial F(y)}{\partial y}\end{bmatrix}=\begin{bmatrix}(1-2x)(yB_L+yV_L-yF_L-C_L-V_L) & x(1-x)(B_L+V_L-F_L)\\ y(1-y)(B_m+V_m-F_m) & (1-2y)(xB_m+xV_m-xF_m-C_m-V_m)\end{bmatrix}, \tag{12}$$

$$De(J)=\begin{vmatrix}\frac{\partial F(x)}{\partial x} & \frac{\partial F(x)}{\partial y}\\ \frac{\partial F(y)}{\partial x} & \frac{\partial F(y)}{\partial y}\end{vmatrix}, \tag{13}$$

$$Tr(J)=\frac{\partial F(x)}{\partial x}+\frac{\partial F(y)}{\partial y}. \tag{14}$$

The five local equilibrium points are analyzed by local stability analysis method. The results are shown in Table 2.

It is shown from Table 2 that there are two evolutionary stable strategies, two unstable equilibrium points and a saddle point among the five local equilibrium points. Figure 1 indicates dynamic process of evolutionary game between steel enterprises and the third party logistics enterprises. The broken line-ADB which two unstable equilibrium points A(0,1),B(1,0) and saddle point D(x^*,y^*) link is critical line of system converging to different states. Because o(0,0) and C(1,1) are ESS, all members either choose win-win cooperation strategy or choose independent operation(non cooperation) when the game between steel enterprises and the third party enterprises reach a stable state. Which state the game dynamic process of two players evolve to depends on the size of the divided area ADOB and ADBC by the broken line-ADB. S_{ADBC} denotes the area of zone-ADBC ,S_{ADOB} is the area of zone-ADOB.If $S_{ADBC}>S_{ADOB}$, the system will evolve to the direction of co-operation. If $S_{ADBC}<S_{ADOB}$, the system will evolve to the direction of non-cooperation. If $S_{ADBC}=S_{ADOB}$, the direction of system evolution is uncertain.

4 Analyses of Factors Affecting Evolutionary Stability Strategy

It is known from Figure 1. that the area of zone-ADOB is determined by coordinates of saddle point $D(x^*,y^*)$, so extra incomes B_m,B_L and risk costs F_m,$F_L$of co-operation, invested initial costs C_m,C_L and losses V_m,V_L for co-operation affect the evolution stable results between steel enterprises and the third party logistics enterprises. Besides, the initial state of system also has certain influence.

TABLE 2 The stability analysis result

Equilibrium Point	De(J)	symbol	Tr(J)	symbol	result
O(0,0)	$(C_L+V_L)(C_m+V_m)$	+	$-C_L-V_L-C_m-V_m$	-	ESS
A(0,1)	$(B_L-F_L-C_L)(C_m+V_m)$	+	$B_L-F_L-C_L+C_m+V_m$	+	instability
B(1,0)	$(B_m-F_m-C_m)(C_L+V_L)$	+	$B_m-F_m-C_m+C_L+V_L$	+	instability
C(1,1)	$(B_L-F_L-C_L)(B_m-F_m-C_m)$	+	$-B_L+F_L+C_L-B_m+F_m+C_m$	-	ESS
D(x*,y*)	$-\frac{(C_m+V_m)(B_m-F_m-C_m)(C_L+V_L)(B_L-F_L-C_L)}{(B_m+V_m-F_m)(B_L+V_L-F_m)}$	-	0		saddle point

4.1 INFLUENCE OF THE INITIAL STATE OF SYSTEM ON ESS

When the initial state of steel enterprises group and the third logistics enterprises group is in III-zone, that is, the probability of steel enterprises selecting cooperation is bigger than $\frac{C_L+V_L}{B_L+V_L-F_L}$ and the probability of the third logistics enterprises selecting co-operation is bigger than $\frac{C_m+V_m}{B_m+V_m-F_m}$,the game of system will finally converge to C(1,1), namely, both steel enterprises group and the third logistics enterprises group choose cooperation strategy. When the initial state is in I-zone, the system will finally converge to point o(0,0),that is, both players choose non co-operation, thus,steel enterprises only choose self-operation mode. When the initial state is in II and IV zone, the convergence of system is uncertain, it may evolve to C(1,1) or to o(0,0). If the initial state falls into II areas, the speed of steel enterprises convergence to

y=1 is greater than the speed of the third party logistics convergence to *x=0*, the final stability strategy is C(1,1).If the initial state falls into IV area, the speed of steel enterprises convergence to *y=0* is greater than the speed of the third party logistics convergence to *x=1*,the final stability strategy is o(0,0).

4.2 INFLUENCE OF EXTRA INCOMES ON ESS

It can be seen from the coordinate D(x*,y*) that values of x^* and y^* reduce respectively, the saddle point D moves to lower left direction ,the area of zone ADBC increases , on the contrary ,the area of zone ADBO reduces when extra incomes B_m,B_L of co-operation increase under the premise of other parameters constant, so system will evolve to co-operation direction along DC path. In order to intuitively display the influence of the changed parameter on the evolution strategy, numerical simulation calculation is used in the paper. Suppose that $C_m=C_L=3$, $V_m=V_L=2$,$F_m=F_L=1$ for convenience of calculation .

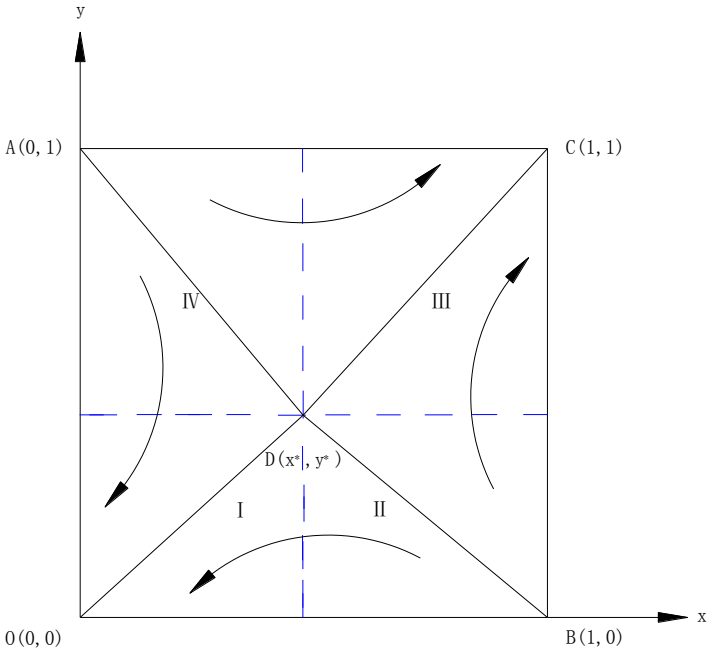

FIGURE 1 Dynamic process figure of evolutionary game between steel enterprises and the third party logistics enterprise

The calculation Process is as shown in Table 3 when the values of B_m and B_L are changed. From Figure 2, the changed path of saddle point D can be seen. The evolution path of saddle point D is from D1 to D2,D3,D4,D5, when the values of B_m and B_L are bigger and bigger.The probability of system converging to c(1,1) is larger and larger with the growing S_{ADBC} in the evolution process, so steel manufacturing enterprises and third-party logistics enterprises will be more and more inclined to choose cooperation strategy. From the above analysis , if the obtained extra incomes of the two players from cooperation become higher and higher , both sides are willing to cooperate actively.

TABLE 3 The coordinates of saddle point under different extra income

B_m=B_L	x*	y*
5	0.83	0.83
14	0.33	0.33
23	0.21	0.21
35	0.14	0.14
43	0.11	0.11

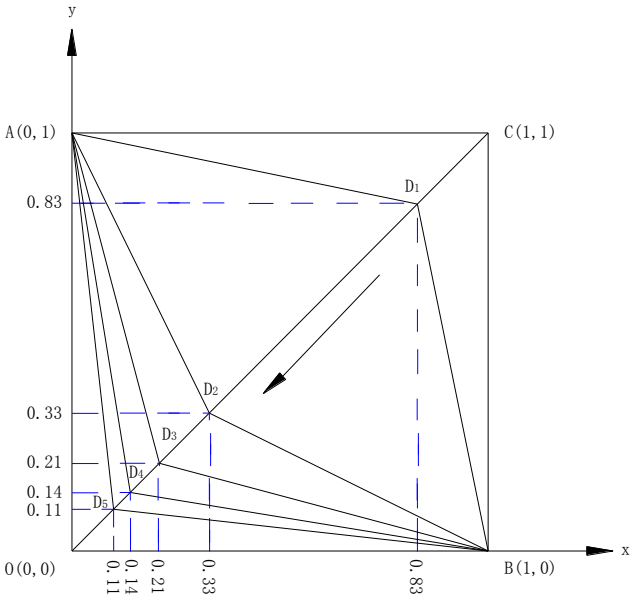

FIGURE 2 The dynamic evolution path of system in the case of extra incomes changed

4.3 INFLUENCE OF RISK COSTS ON ESS

It can be seen that values of $x^*$and y^* increase respectively, the saddle point D moves to upper right direction ,the area of zone ADBO increase , on the contrary ,the area of zone ADBC reduce when risk costs F_m,F_L of cooperation increase under the premise of other parameters constant, so system will evolve to cooperation direction along DC path. Suppose that $C_m=C_L=3$, $V_m=V_L=2$, $B_m=B_L=15$. The calculation process is as shown in Table 4 when the value of F_m and F_L is changed. From Figure.3, the changed path of saddle point D can be seen. The evolution path of saddle point D is from D1 to D2,D3,D4 when the values of F_m and F_L are bigger and bigger. The probability of system converging to o(0,0) is higher and higher with the growing S_{ADBO} in the evolution process, so steel manufacturing enterprises and third-party logistics enterprises will be more and more inclined to choose non cooperation strategy. According to the above analysis, if risk costs of the two players from co-operation are higher, both sides are not willing to co-operate.

TABLE 4 The coordinates of saddle point under different income

$F_m=F_L$	x^*	y^*
1	0.31	0.31
5	0.42	0.42
7	0.50	0.50
9	0.63	0.63

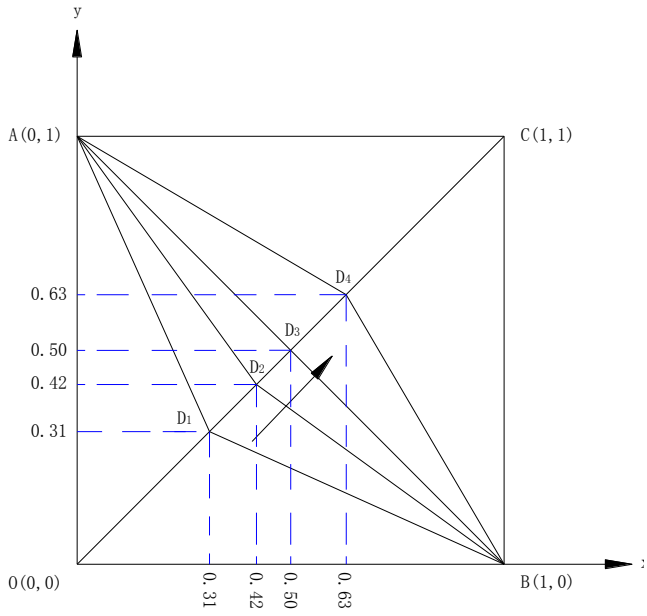

FIGURE 3 The dynamic evolution path of system in the case of risk cost changed

4.4 INFLUENCE OF THE INVESTED INITIAL COSTS ON ESS

Similarly, the values of $x^*$and y^* increase respectively, the saddle point D moves to upper right direction and approaches to C(1,1) when the risk costs C_m,C_L of co-operation increase , so the probability of system converging to o(0,0) is larger and larger, that is, the chances of steel enterprises and third-party logistics enterprises choosing non-co-operation are increasing. According to the above analysis, if the invested risk costs of the two players for cooperation are higher; both sides are not willing to co-operate.

4.5 INFLUENCE OF THE SUFFERED LOSSES ON ESS

The abscissa and ordinate of saddle point D reduce respecttively when the losses V_m,V_L of cooperation are increasing under the premise of other parameters constant. If losses V_m and V_L reduce at the same rate, the abscissa and ordinate of saddle point D keep away from c(1,1)at the same speed and approach to o(0,0) eventually. If the speeds of loss costs V_m andV_L reducing are different ,the magnitudes of saddle point D declining in horizontal and vertical direction are inequality , but it approaches to o(0,0) eventually and the region-ADBC of implement co-operation for the two players are gradually enlarged. According to the above analysis, if the suffered loss of one player choosing cooperation when the other player not cooperate is higher, they are not willing to co-operate, on the contrary, they will choose co-operation.

5 Conclusions

In the paper, the problem of steel enterprise choosing the self-operation mode or the third party mode in scrap iron reverse logistics is regarded as a game problem between steel enterprises and the third party logistics enterprise. Based on evolutionary game theory, co-operation or not between steel production enterprises and the third party logistics enterprises is analyzed. By the evolution game analysis of two players, the two evolutionary stable strategies of both co-operation and non-co-operation are obtained. Finally, the extra income and risk cost from co-operation ,invested initial cost and suffered loss for co-operation which have influence on the evolution stable result are analyzed. If the extra incomes from co-operation are higher, the risk costs from co-operation, the initial costs and losses for cooperation are lower, the two players will eventually choose co-operation development, that is, steel enterprises choose the third party reverse logistics operation mode, on the contrary, they choose the self-management mode.

A Scientific and Research Performance Evaluation model of Institutes of Higher Learning Based on Multilevel Fuzzy Comprehensive Decision Analysis

Biao Song*

Nanjing University of Information Science & Technology

Abstract

Scientific and research performance is an important part of the evaluation on the overall strength and the ability to achieve sustainable development of institutes of higher learning. With the purpose to deal with the multi-attribute, multilevel and fuzziness, this paper constructs a scientific and research performance evaluation system for institutes of higher learning and proposes an evaluation model based on multilevel fuzzy comprehensive decision analysis. After indicators are standardized, we can get the fuzzy nearness by fuzzy comprehensive decision analysis and Analytical Hierarchy Process for evaluating various schemes. It provides support for the analysis of teaching ability, research ability and the sustainable development of institutes of higher learning.

Keywords: Higher school; scientific and research; fuzzy decision analysis; performance evaluation; model

1 Introduction

Teaching ability and research ability are two integral part of the sustainable development of institutes of higher learning. High teaching ability has much to do with training hi-tech talents, establishing talent pool and sustainable talent seeking, which are the fundamental purposes of institutes of higher learning. High research ability reflects the ability to do scientific research, scientific exploration and technological application. Therefore, it is significant to do scientific and research performance evaluation on institutes of higher learning [1-3]. Given that it is a complicated process, many factors need to be taken into consideration. Many researchers have studied scientific and research performance evaluation and proposed relevant methods with fruitful results [4-8]. However, current evaluation methods are more of analysing sections in the process of implementation and lack the wholeness. Fuzzy information also brings about some limits. Therefore, based on previous researches, this paper intends to study scientific and research performance evaluation for institutes of higher learning by comprehensive fuzzy decision analysis [9-10] and AHP [11-12].

2 Scientific and Research Performance Evaluation System for Institutes of Higher Learning

It is a complicated process to construct scientific and research performance evaluation system. The selection of indicators should comply with the scientific principle, criticality, completeness and objectivity. The weight and data should be reasonable and accurate. The evaluation system is divided into three layers, namely, target layer, criterion layer and indicator layer, as is shown in Table 1.

TABLE 1 Scientific and scientific and research performance evaluation system for institutes of higher learning

Target layer	Criterion layer	Target layer
institutes of higher learning scientific and research performance evaluation system **U**	Teaching ability u_1	Ratio of full-time teachers to students u_{11}
		Proportion of professional teachers u_{12}
		Number of competitive classes u_{13}

3 Scientific and Research Performance Evaluation System for Institutes of Higher Learning Based on Multilevel Fuzzy Comprehensive Decision Analysis

3.1 INDICATOR SET AND SCHEME SET OF MULTILEVEL SCIENTIFIC AND RESEARCH PERFORMANCE EVALUATION

The evaluation system is the set of all indicators. It has hierarchy. The criterion layer is the first-class layer of indicators:

$$U=\left(u_1,u_2,u_3,u_4,u_5\right). \tag{1}$$

Under each criterion layer, there is the second-class indicator set,

$$u_{ij}=\left(u_{i1},u_{i2},\cdots,u_{is}\right), \tag{2}$$

i is the NO. of the criterion layer u_{ij}. s is the number of indicators under the criterion layer i and there are $1\le i\le 5$, $1\le s\le 5$.

Suppose there are m institutes of higher learning for evaluation, the scheme set is:

$$C=\left(C_1,\cdots,C_k,\cdots,C_m\right) \tag{3}$$

Each evaluation scheme C_k contains the indicator set of two layers.

3.2 WEIGHT ALLOCATION OF INDICATORS IN SCIENTIFIC AND RESEARCH PERFORMANCE EVALUATION

AHP can ensure the weight is allocated objectively, reliably and reasonably. This paper uses 1-9 ratio scale to measure the weighed allocation matrix $\boldsymbol{P}$:

$$\boldsymbol{P}=\begin{vmatrix} p_{11} & \cdots & p_{1i} & \cdots & p_{1n} \\ \vdots & \cdots & \vdots & \cdots & \vdots \\ p_{i1} & \cdots & p_{ii} & \cdots & p_{in} \\ \vdots & \cdots & \vdots & \cdots & \vdots \\ p_{n1} & \cdots & p_{ni} & \cdots & p_{nn} \end{vmatrix}_{n\times n}. \tag{4}$$

In the expression, p_{ij} is the ratio scale value of indicators. There are

$$1\le p_{ij}=\frac{1}{p_{ji}}\le 9,\qquad 1\le p_{ij}=\frac{1}{p_{ji}}\le 9.$$

The weighed consistency indicator R_{CI} and the consistency rate R_{CR} are:

$$\begin{cases} R_{CI}=\dfrac{max\left(\lambda_t\left(\boldsymbol{P}\right)\right)-n}{n-1} \\ R_{CR}=\dfrac{R_{CI}}{R_{RI}} \end{cases}. \tag{5}$$

In the expression, $\lambda_t\left(\boldsymbol{P}\right)$ refers to the characteristic value of indicator weight-allocation matrix $\boldsymbol{P}$. R_{RI} refers to random consistency indicator.

Under consistency requirement, the weight w_i of indicator i is:

$$w_i=\frac{\sum_{j=1}^{n}p_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n}p_{ij}}. \tag{6}$$

3.3 STANDARDIZATION OF SCIENTIFIC AND RESEARCH PERFORMANCE EVALUATION

It is clear that there are two types of indicators, quantitative and qualitative. They have different scales. Some are large and some are small. Therefore, they need to be subject to standardization to get unified indicators.

For quantitative indicators, we use fuzzy membership degree to describe them, as in Table 2.

TABLE 2 Value of indicators based on membership degree

Fuzzy membership degree	Explanation	
	Large indicators	*Small indicators*
1.0	Completely compliance	Not compliance
0.8	Fairly compliance	Poorly compliance
0.6	Compliance	Basically compliance
0.4	Basically compliance	Compliance
0.2	Poorly compliance	Fairly compliance
0	Not compliance	Completely compliance
0.9,0.7,0.5,0.3, 0.1	In between	In between

For quantitative indicators, suppose the i-th scheme about indicator j is $u_{ij}=\left[u_{ij}^L,u_{ij}^R\right],u_{ij}^L\le u_{ij}^R$ and if it is a large indictor, the standardized indicator v_{ij} is:

$$v_{ij}=\left[v_{ij}^L,v_{ij}^R\right]=\left[\frac{u_{ij}^L-\min\limits_{1\le i\le m}\left(u_{ij}^L\right)}{\left\|\Delta_{u_{ij}}\right\|_{max}},\frac{u_{ij}^R-\min\limits_{1\le i\le m}\left(u_{ij}^L\right)}{\left\|\Delta_{u_{ij}}\right\|_{max}}\right], \tag{7}$$

$\left\|\Delta_{u_{ij}}\right\|_{max}$ is the maximum norm in the fuzzy interval, there is: $\left\|\Delta_{u_{ij}}\right\|_{max}=\max\limits_{1\le i\le m}\left(u_{ij}^R\right)-\min\limits_{1\le i\le m}\left(u_{ij}^L\right)$. (8)

If it is a small indictor, the standardized indicator v_{ij} is:

$$v_{ij}=\left[v_{ij}^{L},v_{ij}^{R}\right]=\left[\frac{\max\left(u_{ij}^{R}\right)-u_{ij}^{L}}{\left\|\Delta_{u_{ij}}\right\|_{max}},\frac{\max\left(u_{ij}^{R}\right)-u_{ij}^{R}}{\left\|\Delta_{u_{ij}}\right\|_{max}}\right]. \quad (9)$$

3.4 FUZZY CLEARNESS OF INDICATORS IN SCIENTIFIC AND RESEARCH PERFORMANCE EVALUATION

After standardization, indicators are unified. Suppose there are *m* institutes of higher learning for scientific and research performance evaluation. The i-th scheme about indicator *j* is $v_{ij}=\left[v_{ij}^{L},v_{ij}^{R}\right]$, and fits $0\le v_{ij}^{L}\le v_{ij}^{R}\le 1$, then the maximum fuzzy indicator field $v_{\Delta j}$ of indicator *j* is:

$$v_{\Delta j}=\left[v_{\Delta j}^{L},v_{\Delta j}^{R}\right]=\left[\underset{1\le i\le m}{max}\left(v_{ij}^{L}\right),\underset{1\le i\le m}{max}\left(v_{ij}^{R}\right)\right]. \quad (10)$$

Similarly, the minimum fuzzy indicator field $v_{\Delta j}$ of indicator *j* is:

$$v_{\nabla j}=\left[v_{\nabla j}^{L},v_{\nabla j}^{R}\right]=\left[\underset{1\le i\le m}{min}\left(v_{ij}^{L}\right),\underset{1\le i\le m}{min}\left(v_{ij}^{R}\right)\right]. \quad (11)$$

The fuzzy clearness τ_{ij}^{Δ} between the i-th scheme and the j-th maximum fuzzy indicator field $v_{\Delta j}$ about indicator j is:

$$\tau_{ij}^{\Delta}=\sqrt[p]{\frac{\left|\underset{1\le i\le m}{max}\left(v_{ij}^{L}\right)-v_{ij}^{L}\right|^{T}+\left|\underset{1\le i\le m}{max}\left(v_{ij}^{R}\right)-v_{ij}^{R}\right|^{T}}{2}}. \quad (12)$$

The weighed fuzzy clearness ρ_{i}^{Δ} between the i-th scheme and the j-th maximum fuzzy indicator field $v_{\Delta j}$ about indicator j is:

$$\rho_{i}^{\Delta}=\sum_{j=1}^{n}\left(w_{j}*\tau_{ij}^{\Delta}\right). \quad (13)$$

Similarly, the fuzzy clearness τ_{ij}^{Δ} between the i-th scheme and the j-th minimum fuzzy indicator field $v_{\Delta j}$ about indicator j is:

$$\tau_{ij}^{\nabla}=\sqrt[p]{\frac{\left|\underset{1\le i\le m}{min}\left(v_{ij}^{R}\right)-v_{ij}^{L}\right|^{T}+\left|\underset{1\le i\le m}{min}\left(v_{ij}^{L}\right)-v_{ij}^{R}\right|^{T}}{2}}. \quad (14)$$

The weighed fuzzy clearness τ_{ij}^{∇} between the i-th scheme and the j-th maximum fuzzy indicator field $v_{\Delta j}$ about indicator *j* is:

$$\rho_{i}^{\nabla}=\sum_{j=1}^{n}\left(w_{j}*\tau_{ij}^{\nabla}\right). \quad (15)$$

The comprehensive fuzzy nearness for the i-th scheme is expressed as:

$$\rho_{i}=1/\left(1+\left(\left|\frac{\rho_{i}^{\Delta}}{\rho_{i}^{\nabla}}\right|\right)^{2}\right). \quad (16)$$

3.5 MULTILEVEL FUZZY COMPREHENSIVE EVALUATION

Based on the optimization principle of fuzzy clearness, if there is:

$$\rho_{max}=max\left(\rho_{1},\cdots,\rho_{i},\cdots,\rho_{m}\right)=\rho_{k}, \quad (17)$$

where *k* is the optimal scheme in scientific and research performance evaluation, indicating that k-th scheme has the best teaching ability and research ability among institutes of higher learning.

The specific steps of evaluation are as follows:

Step 1: Select evaluation indicators according to relevant principles and construct the evaluation system.

Step 2: Standardize different qualitative indicators as Table 2, and subject quantitative indicators to expression (7) to (9);

Step 3: Select the first-class indicator set and the second-class indicator set based on (1) to (3) and acquire the scheme set of scientific and research performance evaluation of institutes of higher learning;

Step 4: Allocate weight to indicators according to expression (4) to (6);

Step 5: Standardize indicators according to (10) to (11);

Step 6: Acquire the evaluation scheme and the fuzzy nearness of the minimum fuzzy indicator field about different indicators;

Step 7: Acquire weighed fuzzy nearness according to (13) to (15) and get the comprehensive fuzzy nearness through (16);

Step 8: Get the optimal scheme based on comprehensive fuzzy nearness.

4 Case Studies and Test

This paper takes scientific and research performance evaluation of key institutes of higher learning in a province as an example. Based on the indicator system, we can get the value of a quantity of indicators, as shown in Table 3.

TABLE 3 Value of a quantity of indicators of scientific and research performance evaluation

Criterion layer	Weight	Indicators	weight	Value of a quantity of indicators		
				Institute A	Institute B	Institute C
Teaching ability u_1	0.286	Ratio of full-time teachers to students u_{11}	0.25	12	12	16
		Proportion of professional teachers u_{12}	0.12	0.42	0.51	0.46

Research ability u_2	0.042	0.035	0.003	0.057	0.063	0.013
Talent training ability u_3	0.034	0.015	0.009	0.009	0.017	0.002
Comprehensive service u_4	0.039	0.004	0	0.041	0.023	0.019
Potential for development u_5	0.004	0.003	0.002	0.004	0.004	0.004

Through comprehensive fuzzy nearness model, we can get the comprehensive fuzzy nearness sequence of three institutes of higher learning, namely,

$$\rho = (\rho_A, \rho_B, \rho_C) = (0.266, 0.833, 0.077) \cdot$$

Institute B has the optimal scientific and research level followed by A and then C. Therefore, Institute B is the priority of development.

4 Conclusions

This paper constructs a scientific and research performance evaluation system for institutes of higher learning and proposes an evaluation model based on multilevel fuzzy comprehensive decision analysis. After indicators are standardized, we can get the fuzzy nearness by fuzzy comprehensive decision analysis and Analytical Hierarchy Process for evaluating various schemes to find out the optimal scheme. This model is clear and easy to calculate for computer aid design and intelligence design. Case study has proved that the model and the algorithm are effective. The evaluation method proposed by this paper provides a solution to analyze scientific and research performance evaluation of institutes of higher learning as well as a support to computer program.

Abstract

This paper introduces external effect of carbon emission in social welfare function, constructs two-stage trade game among three countries, analyzes partially equilibrium output of the three countries and then discusses the influences of different carbon tax policies on social welfare in each country. The study shows it is more effective for developing countries to adopt strategies about founding free trade area and domestic carbon tax collection, up to a higher social total welfare lever, when they face carbon border tax adjustments(BTAs) from developed countries under Nash game conditions. By further studying, the efficiency of domestic carbon tax policy depends on the carbon intensity relation of each country; a higher relative intensity of carbon abroad decreases the negative external effect value caused by the carbon emissions.

Keywords: border tax adjustments, social welfare function, game theory

1 Introduction

In order to limit global warming, the Intergovernmental Panel on Climate Change (IPCC) noted that worldwide annual carbon emissions need to be cut approximately in half by 2050. As an essential part of post-Kyoto international climate negotiations, carbon-based border tax adjustments (BTAs) have been proposed to "level the playing field" by the US, EU and other OECD countries against countries without compatible emissions-reduction commitments, including China [1-2]. The US House of Representatives (2009) passed the American Clean Energy and Security Act of 2009 (HR2998) on June 26, 2009, in which a carbon-based border-adjustment provision was proposed to protect the competitive advantages of American produers against their competitors in countries without comparable emissions-reduction commitments. In the EU, the EC-commissioned High Level Group on Competitiveness, Energy and Environmental Policies proposed the BTA issue in its second report early in 2006. Moreover, BTAs have been recommended as useful policy tools to protect the competitiveness of domestic industries in the EU [3-5].

Such border tax adjustments by participating countries are driven by two related objectives. One is to provide competitiveness (of energy-intensive industries) offsets for domestic producers since the added costs for domestic producers involved with domestic carbon pricing impose a competitive disadvantage on them [6]. The other is carbon leakage, that the reductions of carbon emissions in participating countries such as the EU, US and other OECD countries [7-8]. Alexeeva-Talebi utilized CGE model to analyze the effects of carbon tariff on importing and exporting countries and considered carbon tariff could effectively protect domestic competitiveness of importing countries [9]. Weber and Peters drew the conclusion that carbon tariff neither violates WTO agreement nor influenced on international industrial competitions through analysis of America implementing carbon tariff policy [2]. Based on GTAP data, Hubler analysis drew the conclusion that carbon tariff policy does not only contribute to global emission reduction, but also worsened social welfare of developing countries [10]. Manders and Veenendaal found implementation of carbon tariff policy could effectively reduce carbon leakage, which would be beneficial to EU but damage the welfare of other countries, under EU emission system [11]. Siqueira applied a two-country model to analyze the effects of domestic politics on international externality [12]. He also investigated two kinds of countries which are cooperated with carbon emission or not.

A number of researchers have examined the impacts of BTAs and related policies. Most of the researchers have focused on the effectiveness of BTAs for protecting competitiveness and avoiding carbon leakage. But no general agreement has been found to date. Gros found that BTAs would increase global welfare [13]. Dissou and Eyland found that competitiveness would be hindered by BTAs in Canada [14]. Fischer and Fox suggested that border carbon adjustments would be beneficial for domestic production but not be effective to reduce global emissions [15]. Kuik and Hofkes focused on the carbon leakage-avoidance effects of the EU Emissions Trading System and suggested that BTAs might reduce the sector leakage rate of the iron and steel industry, but the overall leakage-reduction effect was modest [16].

Most of the existing studies focused on the effects of BTAs in developed countries, only a few studies examine the international trade impacts of a carbon border tax adjustments and none seems to look at the welfare implications from a developing country point of view, the country that BTAs mainly target, either implicitly or

* ***Corresponding author*** e-mail: dining16072@163.com

explicitly. This paper focus on how the developing countries international trade patterns could be used, for the fulfillment of climate policy and social welfare objectives. While this paper focus on the strategies selected by the developing countries to maximize the social welfare that are heavily export-oriented, the developing countries trading partners (notably the developing country and the developed country) are clearly also important subjects of discussion and are discussed where relevant.

It is argued that the social welfare of free trade area agreements and domestic carbon tax strategies are higher than the strategy of passive coping. By increasing focus on the efficiency of domestic carbon tax policy, a higher relative intensity of carbon abroad increases the desirability of high import tariff imposed by the home country because a border tax shifts production to the importing country, which in this case leads to lower environmental costs.

2 Model assumption and description

On the basis of analytic framework of traditional international trade theory, this paper blends in influencing factors of carbon tariff and constructs a partial equilibrium model considering climate changes to analyze the effects of importing countries collecting carbon tariff on welfare of importing and exporting countries and analyze the countermeasures of importing countries.

2.1 FUNDAMENTAL ASSUMPTION

Consider a reciprocal market model of intra-industry trade in homogeneous goods. There are three countries (G1, G2 and G3), and each country has a manufacturer which can be regarded as the aggregation of domestic enterprises to produce the same commodity which is both sold in domestic market and exported. The developed country imports goods from developing countries but does not export goods to other countries. The market of the goods in each country is segmented and three-oligarch by Home firm and two foreign firms. A static representation of a Cournot game is useful to map equilibrium options of various tax schemes. Without loss of generality, one unit of labor produces one unit of the goods, so that the wage rate is internationally fixed to unity. Production of the goods is nationally monopolized under a constant marginal cost c ≥ 0, and emits a proportional emission. Letting means the product quantity provided to Country j by the manufacturer of Country i. Suppose international trade transportation cost is 0; the market of each country is completely divided effectively; the information among governments, between governments and enterprises as well as among enterprises is complete. Utility maximization under the budget constraint yields linear inverse demand functions:

$$P_j = P_j(Q_j) = A - Q_j \text{ , where } Q_j = \sum_{i=1}^{3} q_j^i$$

Without loss of generality, we suppose that G1 is a developed country and the pure importing country; G2 and G3 are developing countries with both import and export trade. As the representative of developing countries, China is expressed as G2. Assume all countries carry out non-discriminatory special tariff for the imported products from the countries which do not sign trade agreement with the country. (i≠j) means special import tariff collected from the manufacturer in Country i by Country j. The importing countries collect extra carbon tariff (is used to express carbon tariff collected from Country i by G1) from the countries which do not take emission reduction obligation while collecting emission tax (expressed as) domestically so as to reach the purpose of limiting emission reduction of exporting countries and relieving climatic variations.

2.2 ENTERPRISE PROFIT FUNCTION AND CONSUMER SURPLUS

On each market, manufacturers' products face competetions against other manufacturers. All manufacturers make decisions simultaneously and confirm their own output in the condition of the other manufacturers is given to maximize the profit. Enterprise profit function of the importing country (G1) is:

$$\pi_1 = q_1^1(A - c - \sum_{i=1}^{3} q_1^i - \varepsilon) \quad . \tag{1}$$

Enterprise profit functions of the importing countries (G2 and G3) are:

$$\pi_2 = \sum_{j=1}^{3} q_j^2(A - c - \sum_{i=1}^{3} q_j^i - t_j^2) - \beta_1^2 q_1^2 \quad , \tag{2}$$

$$\pi_3 = \sum_{j=1}^{3} q_j^3(A - c - \sum_{i=1}^{3} q_j^i - t_j^3) - \beta_1^3 q_1^3 \quad . \tag{3}$$

To simplify the formula, make $B = A - c$.

$$CS_j = \frac{1}{2}(Q_j^d)^2 \quad . \tag{4}$$

Consumer surplus of Country j is the function of market product demand; product demand of Country j is $Q_j^d = \sum_{i=1}^{3} q_j^i$.

2.3 EXTERNAL EFFECT OF CARBON EMISSION

This paper adopts the processing method of Daniel Gros (2009) to set negative externality of CO_2 as invariant parameter σ. In order to account for potential differences in carbon technologies and intensities in each country, it is not assumed that the production of each unit leads to the same negative external effect. Instead production abroad takes place with a potentially different carbon intensity, which relative to country j is denoted by γ_j. Furthermore there is

α_j households at Country j. Global social welfare of carbon emission is thus given by:

$(\alpha_1+\alpha_2+\alpha_3)\sigma(\gamma_1 q_1^s+\gamma_2 q_2^s+\gamma_3 q_3^s)$.

External effects of carbon emission for country j should be the function of the total supply (q_j^s) of the country:

$$W_j^{carbon}=(\alpha_1+\alpha_2+\alpha_3)\sigma\gamma_j q_j^s=M\gamma_j q_j^s \quad , \tag{5}$$

$M=(\alpha_1+\alpha_2+\alpha_3)\sigma$ for simplicity.

2.4 SOCIAL TOTAL WELFARE FUNCTION

The gain of a country as the game player is social total welfare they care for. It is composed of four parts: consumer surplus (CS), domestic enterprise profit (π); government tax revenue (TR) and subtract the external effect of carbon emission (W^{carbon}):

$$W_j=CS_j+\pi_j+TR_j-W_j^{carbon}. \tag{6}$$

3 Carbon tax policies under non-cooperative and ccooperative game equilibrium

3.1 SITUATION OF EXPORTING COUNTRIES ARE CONFRONTED WITH BTAS OF IMPORTING COUNTRIES

G1 collects carbon emission tax at home and collects carbon border tax adjustments (BTAs) for imported products of the countries which do not adopt emission reduction measures. G2 and G3 adopt Nash equilibrium of negative coping. Manufacturers of each country are equal competitive relations and take actions simultaneously when seeing carbon emission tax and BTAs policies of each government. The game sequence is that each government first formulates their own tax policy and manufacturers of each country meanwhile maximize their won profits. To solve this game with backward induction, we have:

The optimal tax policy schemes of each government are:

$$\varepsilon=3M\gamma_1-B$$

$$t\beta_1^2=t\beta_1^3=\frac{1}{2}M\gamma_1, \tag{7}$$

$$t_3^2=\frac{1}{130}(50B+30M\gamma_1+24M\gamma_2-54M\gamma_3)$$

$$t_2^3=\frac{1}{130}(50B+30M\gamma_1-54M\gamma_2+24M\gamma_3)$$

Where, $B=A-c$. Since the collecting objects and coefficients of tariff t_j^i and carbon border tax adjustments β_j^i of G1 are the same, let $t\beta_1^2=t_1^2+\beta_1^2$ and $t\beta_1^3=t_1^3+\beta_1^3$ for simplicity. Substitute the optimal tax policies confirmed by the governments into the social welfare and gain the optimal outputs of manufactures of each country are:

$$q_1^1=B-2M\gamma_1 \quad q_1^2=q_1^3=\frac{1}{2}M\gamma_1$$

$$q_2^2=\frac{1}{3}(B+t_2^3) \quad q_2^3=\frac{1}{3}(B-2t_2^3) \tag{8}$$

$$q_3^2=\frac{1}{3}(B-2t_3^2) \quad q_3^3=\frac{1}{3}(B+t_3^2)$$

3.2 SITUATION OF EXPORTING COUNTRIES SET UP FTA TO COPE WITH BTAS IMPORTING COUNTRIES

When G2 and G3 form a free trade area (FTA), internal tariff among the member countries is 0, so $t_2^3=t_3^2=0$. Each member country selects external optimal tariff to make the social welfare maximize. The game sequence is that each government first formulates their own tax policy and meanwhile manufacturers of each country maximize their won profits after seeing the tax policies.

Enterprise profit target function of G1 is the same with Formula (1). Enterprise profit target functions of G2 and G3 changes.In the second stage, enterprises of the three countries maximize their own profit through selecting the optimal output. The solving process is the same with that in Section 3.1. The optimal outputs of manufacturers of each country are:

$$q_1^1=\frac{1}{4}(B-3\varepsilon+t_1^2+\beta_1^2+t_1^3+\beta_1^3)$$

$$q_1^2=\frac{1}{4}(B+\varepsilon-3t_1^2-3\beta_1^2+t_1^3+\beta_1^3) \tag{9}$$

$$q_1^3=\frac{1}{4}(B+\varepsilon+t_1^2+\beta_1^2-3t_1^3-3\beta_1^3)$$

$$q_2^2=q_2^3=q_3^2=q_3^3=\frac{1}{3}B$$

In the first stage, each government selects tax policies to maximize social welfare function (6). The tax policies of the governments are:

$$\varepsilon=3M\gamma_1-B \quad t\beta_1^2=t\beta_1^3=\frac{1}{2}M\gamma_1 . \tag{10}$$

From here we can see that domestic carbon tax and BTAs of G1 are not influenced by FTA set up by G2 and G3. The optimal social welfare function of G1 is the same with that in Section 3.1.

3.3 SITUATION WHERE G2 ADOPTS CARBON TAX

COLLECTION AT HOME TO COPE WITH BTAS

When G3 does not take any measure, but G2 collects carbon tariff at home to cope with carbon border tax adjustments of G1, what different from setting up free trade area is that the two exporting countries select the optimal tariff by themselves to maximize their own welfare. The same batch of commodities should pay both carbon tax collected by exporting countries and BTAs collected by importing countries. According to the principle of avoidance of double taxation, G2 collects carbon tax for domestically produced products, and G1 does not collect extra carbon tariff any more for the products imported from G2.

Enterprise profit target function of G1 is the same with Formula (1). Enterprise profit target functions of G2 and G3 change. Adopting backward induction method to solve tax policies of each country and the optimal outputs of manufacturers of each country are as follows:

$$q_1^1 = B - 2M\gamma_1 + \frac{1}{7}\varepsilon^* \quad q_1^2 = \frac{1}{2}M\gamma_1 - \frac{3}{7}\varepsilon^*$$

$$q_1^3 = \frac{1}{2}M\gamma_1 + \frac{1}{7}\varepsilon^* \quad q_2^2 = \frac{1}{3}(B - 2\varepsilon^* + t_2^3) \qquad (11)$$

$$q_2^3 = \frac{1}{3}(B + \varepsilon^* - 2t_2^3) \quad q_3^2 = \frac{1}{3}(B - 2\varepsilon^* - 2t_3^2)$$

$$q_3^3 = \frac{1}{3}(B + \varepsilon^* + t_3^2)$$

Domestic carbon tax of G1 $\varepsilon = 3M\gamma_1 - B$ keeps unchanged; the tariff collected from G2 by G1 is $t_1^2 = \frac{1}{2}M\gamma_1 - \frac{3}{7}\varepsilon^*$; tariff policy of G1 for G3 is the same with the situation in Section 3.1.

4 Contrastive analysis and discussion

4.1 COMPARISON OF SOCIAL TOTAL WELFARE OF G2 UNDER 3 GAME CONDITIONS

When developed country G1 adopts import carbon tariff collection policy, we compare the social welfare about developing country G2 under three different strategies. The first is the situation adopting negative coping, the second is set up free area with G3 and the third is collecting carbon tax at home.

$$W_2^2 - W_2^1 = \frac{1}{6}t_2^3(\frac{4}{3}B - \frac{1}{3}t_2^3) + (\frac{2}{3}t_3^2 - \frac{1}{3}t_2^3)(M\gamma_1 + \frac{4}{3}B - M\gamma_2 - \frac{2}{3}t_3^2 + \frac{1}{3}t_2^3) > 0$$

Conclusion 1: on the condition of Nash game, the strategy of G2 and G3 setting up FTA can achieve higher social total welfare level than adopting negative coping strategy.

$$W_2^3 - W_2^1 = \frac{2787}{882}(\varepsilon^*)^2 + (-\frac{324}{126}B - \frac{92}{126}t_2^3 + \frac{148}{63}t_3^2 - \frac{37}{21}M\gamma_1 + \frac{37}{21}M\gamma_2)\varepsilon^* + \frac{1}{3}t_2^3(B - 2t_2^3)$$

$W_2^3 - W_2^1$ can be regarded as a unitary quadratic function about domestic carbon tax ε^* of G2. Due to $\frac{2787}{882} > 0$ and $t_2^3(B - 2t_2^3) > 0$, the opening of this function is upward and the intercept term is higher than 0. The solving equation $W_2^3 - W_2^1 = 0$ has two solutions greater than zero, i.e. ε_1^* and ε_2^* ($0 < \varepsilon_1^* < \varepsilon_2^*$). When $\varepsilon_1^* < \varepsilon^* < \varepsilon_2^*$, we have $W_2^3 < W_2^1$. Thus, for developing country G2, social welfare resulted from domestic carbon tax collection is lower than that resulted from negative coping strategy. Thus, developing countries would rather show no interest in BTAs policy of developed countries. When $0 < \varepsilon^* < \varepsilon_1^*$ or $\varepsilon^* > \varepsilon_2^*$, we have $W_2^3 > W_2^1$. Developing country G2 can effectively improve social welfare level when collecting carbon tax at home.

Conclusion 2: on the condition of Nash game, G2 which adopts domestic carbon tax collection policy is not strictly superior to negative coping strategy. When carbon tax planted to be collected by developing countries is in $[\varepsilon_1^*, \varepsilon_2^*]$, negative coping strategy can realize higher social welfare level than carbon tax collection strategy.

$$W_2^3 - W_2^2 = \frac{2728}{882}(\varepsilon^*)^2 + (-\frac{324}{126}B - \frac{92}{126}t_2^3 + \frac{148}{63}t_3^2 - \frac{37}{21}M\gamma_1 + \frac{37}{21}M\gamma_2)\varepsilon^* + \frac{1}{3}t_2^3(B - 2t_2^3)$$
$$- \frac{1}{6}t_2^3(\frac{4}{3}B - \frac{1}{3}t_2^3) - (\frac{2}{3}t_3^2 - \frac{1}{3}t_2^3)(M\gamma_1 + \frac{4}{3}B - \frac{2}{3}t_3^2 + \frac{1}{3}t_2^3) - M\gamma_2(\frac{1}{3}t_2^3 - \frac{2}{3}t_3^2)$$

Solve $W_2^3 - W_2^2 = 0$. Since the coefficient of the quadratic term is greater than 0 and the intercept term is less than 0, it is known that this equation has one positive solution and one negative solution according to the function properties, i.e. $\hat{\varepsilon}_1^*$ and $\hat{\varepsilon}_2^*$ ($\hat{\varepsilon}_1^* < 0 < \hat{\varepsilon}_2^*$). When $\varepsilon^* \geq \varepsilon_2^*$, there is $W_2^3 - W_2^2 \geq 0$. For G2, social total welfare resulted from high-level carbon tax collection at home is higher than that brought by G3 setting up free trade area. The government of G2 will choose the coping strategy of carbon tax collection at home. If $\varepsilon^* \in [0, \hat{\varepsilon}_2^*]$, we have $W_2^3 < W_2^2$. For G2, social total welfare resulted from carbon tax collection at home is lower than that brought by G3 setting up free trade area. In this case, the government of G2 will choose to set up free trade area with G3.

Conclusion 3: under the objective of pursuing maximization of social total welfare, if the carbon tax G2 plants to collect is in $[0, \hat{\varepsilon}_2^*]$, social total welfare resulted from carbon tax collection at home is lower than that brought by G3 setting up free trade area. For G2, carbon tax collection at home is not the optimal selection.

4.2 COMPARISON OF EXTERNAL EFFECTS OF CARBON EMISSION UNDER 3 GAME CONDITIONS

Under the kth game situation, external effect of global carbon emission is the function of aggregate supply of each country:

$$WW_{carbon}^{k}=\sum_{j=1}^{3}M\gamma_j q_j^s \ . \tag{12}$$

The D-value between global carbon emission externality brought by G2 and G3 setting up free trade area and global carbon emission externality brought by negative coping strategy is:

$$WW_{carbon}^{2}-WW_{carbon}^{1}=\frac{1}{3}M\gamma_2(2t_3^2-t_2^3)+\frac{1}{3}M\gamma_3(2t_2^3-t_3^2) \ . \tag{13}$$

Since carbon intensity y_j of unit product of each country is constant greater than 0, the optimal tariff between G2 and G3 (see Section 3.1) has $2t_3^2>t_2^3$ and $2t_2^3>t_3^2$. In this case we have $WW_{carbon}^{2}-WW_{carbon}^{1}>0$.

Conclusion 4: the strategy of G2 and G3 setting up free trade area are results in greater negative external effect of carbon emission than negative coping strategy.

$$WW_{carbon}^{3}-WW_{carbon}^{1}=\frac{1}{21}M\varepsilon^{*}(3\gamma_1-16\gamma_2+17\gamma_3) \ . \tag{14}$$

The influence of carbon tariff strategy of G2 collecting domestic carbon tax depends on the relations of carbon intensity of each country. When $16\gamma_2\geq 3\gamma_1+17\gamma_3$, $WW_{carbon}^{3}\leq WW_{carbon}^{1}$. G2 collecting carbon tax at home brings less negative external effect of carbon emission than negative coping strategy. In other words, this strategy has promotion effect on reduction of global carbon emission externality. When $16\gamma_2<3\gamma_1+17\gamma_3$, we have $WW_{carbon}^{3}>WW_{carbon}^{1}$. G2 collecting carbon tax at home brings larger negative external effect of carbon emission than negative coping strategy. In other words, this strategy is not beneficial to reduction of global carbon emission externality.

Conclusion 5: the influences of G2 collecting carbon tax at home on environment depends on carbon intensity relations of each country. Higher carbon intensity of developing countries means carbon tax collection is more beneficial to reduction of external effect of carbon emission.

Conclusions

This paper analyzes how developing countries dynamically choose and confirm the optimal strategy in international trade competitions when faced with BTAs and considering negative external effect of carbon emission and strategy selection of other developing countries so as to realize maximization of social total welfare level. This paper depicts the process of carbon emission externality influencing government decision-making through introducing the influence of carbon emission on environment into social total welfare function, analyzes how manufacturers of various countries dynamically decide their outputs and corresponding strategies to gain the maximum profits.

The results show when developing countries are faced with developed countries collecting carbon tax, it is more superior for them to choose free trade area strategy than negative coping strategy, but domestic carbon tax collection strategy is not strictly superior to negative coping strategy. This conclusion is different from that Dieter et al. (2009) consider carbon policy is sub-game perfect Nash equilibrium solution. Social total welfare level caused by setting up free trade area and collecting carbon tax domestically is influenced by domestic carbon tax. When the carbon tax level developing countries plan to collect is in a certain interval, it is more superior for developing countries to choose free trade area strategy than the other strategies. In terms of the influences of carbon emission on external environment, the strategy of setting up free trade area is beneficial to enterprises in developing countries expanding market to gain larger profits and meanwhile causes more negative external effects of carbon emission. The effects of domestic carbon tax collection on environment depend on the carbon intensity relation of each country. Higher carbon intensity of developing countries means carbon tax collection is more beneficial to reduction of external effect of carbon emission.

An evaluation model of sustainable development of sports tourism industry based on matter-element theory

Guishen Yu*

Henan Institute of Science and Technology, Xinxiang, Henan, China

Abstract

The sustainable development of sports tourism industry is concerned with many factors. Its evaluation is a complex system engineering. This paper studies the complexity and diversity of factors that influence the sustainable development of sports tourism industry and proposes an evaluation model of sustainable development based on matter-element theory. An indicator system is put in place. Evaluation indicators of classical field matter-elements model, section domain matter-element model and evaluation objects matter-element model are constructed based on matter-element theory. Different methods of calculating extension degree are adopted according to characteristics of the evaluation objects matter-element model to calculate the comprehensive extension degree between evaluation objects matter-element model and classical field matter-elements model. This extension degree refers to the layer of sustainable development capability of evaluation objects. It will provide strategic support for the development of sports tourism industry. Case study has proved that the model and the algorithm are effective.

Keywords: sports tourism industry; sustainable development; matter-element theory; extension degree; evaluation model

1 Introduction

With social and economic development, people have a higher requirement on life quality and their lifestyles become diversified. While enjoying a wealthy life, they are paying more attention to their health. Sports tourism industry is an emerging tourism industry. On one hand, it brings spiritual experience to tourism. On the other, it integrates sports into tourism to reach the purpose of health cultivation. Sports tourism industry is expected to have a bright future [1-4].

Limited by regions and populations, sports tourism industry needs long-term, sustainable and rapid development. And it is significant to evaluate the industry's ability to achieve sustainable development [5-8]. However, such evaluation is complicated given that many factors have to be taken into account. Some factors can be quantified and clear while others are fuzzy and require qualitative descriptions.

Thus, this paper draws merits from previous researches and proposes an evaluation model of the sustainable development of sports tourism industry based on matter-element theory [9-14]. Then the grade of the ability to achieve sustainable development is acquired. Case study proves that the model and the algorithm are feasible and effective.

2 Indicator system of Sustainable development of sports tourism evaluation

Generally speaking, the boom of the sports tourism industry has much to do with geographical locations. Though it is one of the shining points of this industry, destruction on environment may also bear its own consequences. Therefore, many factors should be taken into consideration to evaluate the ability to achieve sustainable development of sports tourism industry. Scientific, objective and effective indicators are selected tailored to real situation. Service-oriented purpose should also be emphasized to select comprehensive, key and feasible indicators.

Therefore, this paper analyzes common indicators from five perspectives, namely, social factors, economic factors, environmental factors, sports factors and tourism factors and constructs a scientific and effective indicator system of sustainable development of sports tourism evaluation, as is shown in Table 1.

3 Evaluation model of Sustainable development of sports tourism based on matter-element theory

3.1 MATTER-ELEMENT THEORY

As one of the pillars of Extenics, matter-element theory has a promising future. The analysis is based on matter-element design or object analysis and adopts extension qualitative and quantitative analysis with matter-element as the logic cell. A comprehensive use of extension mathematics, extension transformation and extension logic is adopted to address the problems as a part of the extension engineering.

Matter-element, as one of the logic cells of Extenics, describes the design objects by constructing a sequence groups with three elements $R=(N,C,V)$. N refers to the name of the design object. C refers to matter-element characteristics of the design object and V refers to the value of a quantity of the design object N about matter-element characteristic C. If the design object has only one characteristic, then $R=(N,C,V)$ is the matter-element extension model with one dimension, which is called the basic element; In particular, if the object has multiple characteristics, $R=(N,C,V)$ is the matter-element extension model with multiple dimensions. At this moment,

$$C=(c_1,\cdots,c_i,\cdots,c_n)^T,$$

$$V=(v_1,\cdots,v_i,\cdots,v_n)^T,$$

n refers to the number of dimensions of $R=(N,C,V)$. Extension distance can be used to measure the extension correlation degree between matter-element models or matter-element characteristics. Suppose the matter-element characteristics of the reference object is $X=[x_1,x_2]$, that of the target object is v, then the extension distance ρ between the two is:

$$\rho=\left|v-\frac{x_1+x_2}{2}\right|-\frac{x_2-x_1}{2}. \quad (1)$$

3.2 CONSTRUCTING THE MATTER-ELEMENT MODEL OF THE SUSTAINABLE DEVELOPMENT OF SPORTS TOURISM INDUSTRY

Definition 1 Matter-element in classic field for sustainable development evaluation the sustainable development of the sports tourism industry is in different states or has different evaluation grade. Every state or grade corresponds to a characteristic value of the matter-element model.

Thus, suppose there are n characteristics $c_1,c_2,\cdots c_n$ and their corresponding values of a quantity are $v_1,v_2,\cdots v_n$. Construct the evaluation matter-element model $R_n^C(i)$, which is the matter-element in classic field for sustainable development evaluation.

$$R_n^C=\begin{bmatrix} N_C & c_1 & v_1(i) \\ & c_2 & v_2(i) \\ & \vdots & \vdots \\ & c_n & v_n(i) \end{bmatrix}=\begin{bmatrix} N_C & c_1 & \left[v_1^L(i),v_1^R(i)\right] \\ & c_2 & \left[v_2^L(i),v_2^R(i)\right] \\ & \vdots & \vdots \\ & c_n & \left[v_n^L(i),v_n^R(i)\right] \end{bmatrix}. \quad (2)$$

Definition 2 Matter-element in section field for sustainable development evaluation Section field is defined as the collection of the development state or evaluation grade of sustainable development of the sports tourism industry.

The extreme values of n characteristics $c_1,c_2,\cdots c_n$ and their values of a quantity are part of the section field matter-element model R_n^O with n dimensions:

$$R_n^O = \begin{bmatrix} N_O & c_1 & v_1 \\ & c_2 & v_2 \\ & \vdots & \vdots \\ & c_n & v_n \end{bmatrix} = \begin{bmatrix} N_O & c_1 & \left[v_{O1}^L, v_{O1}^R\right] \\ & c_2 & \left[v_{O2}^L, v_{O2}^R\right] \\ & \vdots & \vdots \\ & c_n & \left[v_{On}^L, v_{On}^R\right] \end{bmatrix}. \quad (3)$$

Where, $v_{Oj}^L = \min_{1\le i\le m}\left(v_j^L(i)\right), v_{Oj}^R = \max_{1\le i\le m}\left(v_j^R(i)\right)$. m refers to the number of development state or evaluation grade of sustainable development of sports tourism industry.

3.2.1 EXTENSION degree evaluation model of sustainable development of sports tourism industry

Suppose the matter-element model for evaluation is R_d:

$$R_d = \begin{bmatrix} N_d & c_{d1} & v_{d1} \\ & c_{d2} & v_{d2} \\ & \vdots & \vdots \\ & c_{dn} & v_{dn} \end{bmatrix} = \begin{bmatrix} N_d & c_{d1} & \left[v_{d1}^L, v_{d1}^L\right] \\ & c_{d2} & \left[v_{d2}^L, v_{d2}^L\right] \\ & \vdots & \vdots \\ & c_{dn} & \left[v_{dn}^L, v_{dn}^L\right] \end{bmatrix}. \quad (4)$$

To effectively calculate the extension degree between the matter-element model R_d and matter-element in classic field of different state or evaluation degree, this paper discusses the followings:

(1) If the characteristic value of a quantity of the matter-element model for evaluating R_d is a point value for qualitative description, then the extension distance $\rho\left(R_d^j \mid R_n^C(i)\right)$ between R_d and the matter-element model $R_n^C(i)$ about characteristics j is:

$$\rho\left(R_d^j \mid R_n^C(i)\right) = \left|v_{dj} - \frac{v_j^L(i)+v_j^R(i)}{2}\right| - \frac{v_j^R(i)-v_j^L(i)}{2}. \quad (5)$$

Similarly, the extension distance $\rho\left(R_d^j \mid R_n^O(i)\right)$ between R_d and the matter-element model $R_n^O(i)$ about characteristics j is:

$$\rho\left(R_d^j \mid R_n^O(i)\right) = \left|v_{dj} - \frac{v_{Oj}^L(i)+v_{Oj}^R(i)}{2}\right| - \frac{v_{Oj}^R(i)-v_{Oj}^L(i)}{2}. \quad (6)$$

(2) If the characteristic value of a quantity of the matter-element model for evaluating R_d is a fuzzy interval value of quantity and if the optimal value of a quantity of the matter-element in classic field is at the middle of the interval, then the extension distance $\rho\left(R_d^j \mid R_n^C(i)\right)$ between R_d and the matter-element model $R_n^C(i)$ about characteristic j is:

$$\rho\left(R_d^j \mid R_n^C(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^C(i)\right) + \rho\left(v_{dj}^R \mid R_n^C(i)\right)\right). \quad (7)$$

Substitute (1) to (7) and get:

$$\rho\left(R_d^j \mid R_n^C(i)\right) = \frac{1}{2}\left(\left|v_{dj}^L - \frac{v_j^L(i)+v_j^R(i)}{2}\right| - v_j^R(i) + v_j^L(i) + \left|v_{dj}^R - \frac{v_j^L(i)+v_j^R(i)}{2}\right|\right). \quad (8)$$

Similarly, the extension distance $\rho\left(R_d^j \mid R_n^O(i)\right)$ between R_d and the matter-element model $R_n^O(i)$ about characteristic j is:

$$\rho\left(R_d^j \mid R_n^O(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^O(i)\right) + \rho\left(v_{dj}^R \mid R_n^O(i)\right)\right). \quad (9)$$

Substitute (1) to (7) and get:

$$\rho\left(R_d^j \mid R_n^O(i)\right) = \frac{1}{2}\left(\left|v_{dj}^L - \frac{v_{Oj}^L(i)+v_{Oj}^R(i)}{2}\right| - v_{Oj}^R(i) + v_{Oj}^L(i) + \left|v_{dj}^R - \frac{v_{Oj}^L(i)+v_{Oj}^R(i)}{2}\right|\right). \quad (10)$$

(3) If the characteristic value of a quantity of the matter-element model for evaluation R_d is a fuzzy interval value of quantity and if the optimal value of a quantity of the matter-element in classic field is $v_j^0(i) \in \left[v_j^L(i), \frac{v_j^L(i)+v_j^R(i)}{2} \right]$, the extension distance $\rho\left(R_d^j \mid R_n^C(i)\right)$ between R_d and the matter-element model $R_n^C(i)$ about characteristic j is:

$$\begin{cases} \rho\left(R_d^j \mid R_n^C(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^C(i)\right) + \rho\left(v_{dj}^R \mid R_n^C(i)\right)\right) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = v_j^L(i) - v_{dj}^x & v_{dj}^x \le v_j^L(i) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = v_{dj}^x - v_j^R(i) & v_{dj}^x \ge v_j^0(i) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = (v_j^R(i) - v_j^0(i))(v_{dj}^x - v_j^L(i))/(v_j^L(i) - v_j^0(i)) & v_{dj}^x \in (v_j^L(i), v_j^0(i)) \end{cases} . \quad (11)$$

If the optimal value of a quantity of matter-element in classic field is $v_j^0(i) \in \left[\frac{v_j^L(i)+v_j^R(i)}{2}, v_j^R(i) \right]$, the extension distance $\rho\left(R_d^j \mid R_n^C(i)\right)$ between R_d and the matter-element model $R_n^C(i)$ about characteristic j is:

$$\begin{cases} \rho\left(R_d^j \mid R_n^C(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^C(i)\right) + \rho\left(v_{dj}^R \mid R_n^C(i)\right)\right) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = v_j^L(i) - v_{dj}^x & v_{dj}^x \le v_j^0(i) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = v_{dj}^x - v_j^R(i) & v_{dj}^x \ge v_j^R(i) \\ \rho\left(v_{dj}^x \mid R_n^C(i)\right) = (v_j^L(i) - v_j^0(i))(v_j^R(i) - v_{dj}^x)/(v_j^R(i) - v_j^0(i)) & v_{dj}^x \in (v_j^0(i), v_j^R(i)) \end{cases} . \quad (12)$$

Similarly, the extension distance $\rho\left(R_d^j \mid R_n^O(i)\right)$ between R_d and the matter-element model $R_n^O(i)$ about characteristics j has two forms. If there is $v_j^0(i) \in \left[v_{Oj}^L(i), \frac{v_{Oj}^L(i)+v_{Oj}^R(i)}{2} \right]$, then:

$$\begin{cases} \rho\left(R_d^j \mid R_n^O(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^O(i)\right) + \rho\left(v_{dj}^R \mid R_n^O(i)\right)\right) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = v_{Oj}^L(i) - v_{dj}^x & v_{dj}^x \le v_{Oj}^L(i) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = v_{dj}^x - v_{Oj}^R(i) & v_{dj}^x \ge v_j^0(i) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = (v_{Oj}^R(i) - v_j^0(i))(v_{dj}^x - v_{Oj}^L(i))/(v_{Oj}^L(i) - v_j^0(i)) & v_{dj}^x \in (v_{Oj}^L(i), v_j^0(i)) \end{cases} . \quad (13)$$

If there is $v_j^0(i) \in \left[\frac{v_{Oj}^L(i)+v_{Oj}^R(i)}{2}, v_{Oj}^R(i) \right]$, then:

$$\begin{cases} \rho\left(R_d^j \mid R_n^O(i)\right) = \frac{1}{2}\left(\rho\left(v_{dj}^L \mid R_n^O(i)\right) + \rho\left(v_{dj}^R \mid R_n^O(i)\right)\right) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = v_{Oj}^L(i) - v_{dj}^x & v_{dj}^x \le v_j^0(i) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = v_{dj}^x - v_{Oj}^R(i) & v_{dj}^x \ge v_{Oj}^R(i) \\ \rho\left(v_{dj}^x \mid R_n^O(i)\right) = (v_{Oj}^L(i) - v_j^0(i))(v_{Oj}^R(i) - v_{dj}^x)/(v_{Oj}^R(i) - v_j^0(i)) & v_{dj}^x \in (v_j^0(i), v_{Oj}^R(i)) \end{cases} . \quad (14)$$

Thus, we can get the extension degree $K\left(R_d^j \mid R_n^C(i)\right)$ between R_d and the matter-element model $R_n^C(i)$ about characteristics j:

$$K\left(R_d^j \mid R_n^C(i)\right)=\begin{cases}-\dfrac{\rho\left(R_d^j \mid R_n^C(i)\right)}{\left|v_j(i)\right|} & \left[v_{dj}^L, v_{dj}^R\right]\in\left[v_j^L(i), v_j^R(i)\right] \\ \dfrac{\rho\left(R_d^j \mid R_n^C(i)\right)}{\rho\left(R_d^j \mid R_n^O(i)\right)-\rho\left(R_d^j \mid R_n^C(i)\right)} & \left[v_{dj}^L, v_{dj}^R\right]\notin\left[v_j^L(i), v_j^R(i)\right]\end{cases}. \tag{15}$$

If weight of the matter-element characteristic is considered, the weighted extension degree $\phi\left(R_d \mid R_n^C(i)\right)$ is:

$$\phi\left(R_d \mid R_n^C(i)\right)=\sum_{j=1}^{n}\left(w_j * K\left(R_d^j \mid R_n^C(i)\right)\right). \tag{16}$$

Normalize the weighted extension degree $\phi\left(R_d \mid R_n^C(i)\right)$ and get:

$$\bar{\phi}\left(R_d \mid R_n^C(i)\right)=\frac{\phi\left(R_d \mid R_n^C(i)\right)-\min\limits_{1\le i\le m}\phi\left(R_d \mid R_n^C(i)\right)}{\max\limits_{1\le i\le m}\phi\left(R_d \mid R_n^C(i)\right)-\min\limits_{1\le i\le m}\phi\left(R_d \mid R_n^C(i)\right)}. \tag{17}$$

If there is

$$\bar{\phi}\left(R_d \mid R_n^C(k)\right)=\max\left(\bar{\phi}\left(R_d \mid R_n^C(1)\right),\bar{\phi}\left(R_d \mid R_n^C(2)\right),\cdots,\bar{\phi}\left(R_d \mid R_n^C(m)\right)\right). \tag{18}$$

Then it indicates that the evaluation grade of sustainable development of sports tourism industry is of grade k.

4 Case study and test

This paper intends to combine forest areas' geographical features and regional advantage to do the analysis of the sustainable development assessment of sports tourism industry. And based on the above to do the verification and instructions for models and algorithms. The forest yard, their geographic environment is superior, the river in the forest area of diverse, both gentle rapids of the river there are rapids, relatively abundant rainfall in summer, while winter snow sources are abundant, therefore, based on the existing strengths suited to carry out forest skiing and rafting sports tourism projects. To this end, by seeking expert advice on the basis of the forest to carry out skiing, rafting and other sports tourism industry sustainability assessment into force excellent, good, fair, poor four levels, namely the force corresponding to the four sustainability assessment Classic domain matter element, the specific results is as shown in Table 2

Weigh the extension degree of each indicator and get the membership degree sequence between ability to achieve sustainable development of forest sports tourism, such as skiing, rafting, and every classic field. The conclusion reached is that the forest region is in a good state of sustainable development.

5 Conclusions

This paper proposes an evaluation model of sustainable development based on matter-element theory. An indicator system is put in place. Evaluation indicators of classical field matter-element model, section domain matter-element model are constructed to calculate the extension distance and the extension degree between different evaluation indicators and matter-element in classic field. The grade of the sports tourism industry is known. This paper provides a solution to optimize the sports tourism industry. Case study has proved that the model and the algorithm are effective.

Abstract

The quality and cost of a product rely heavily on suitable material selection, and therefore the ability to select the most appropriate material for a given application is the fundamental challenges faced by the design engineer. The general grey relational analysis (GRA) has three weaknesses, (i) the weight determination depends only on expert judgments, (ii) the qualitative indexes are simply quantified with exact numbers, and (iii) the general GRA only takes into account the relationship between the imaginarily best material and the candidate materials. Weights were determined by combining subjective and objective weights based on maximum deviation, the qualitative indexes were fuzzily quantified through trapezoidal fuzzy numbers (TFNs), and then ranked alternatives according to relative grey relation grade. The illustrative example showed that the results matched well with that using WAA and TOPSIS, proved the proposed method reasonable and trustworthy. And therefore the proposed method possesses important application values.

Keywords: material selection, combination weights (CW), relative Grey relation analysis (RGRA), fuzzy numbers, maximum deviation

1 Introduction

It is well known that materials play an important role in engineering designs. After the conceptual design stage, designers always need to select materials with specific properties which can guarantee optimum system performance by satisfying all existing constraints [1]. And it is an important step in engineering designs, since an inappropriate choice of material(s) can adversely affect the productivity, profitability, and reputation of a manufacturing organization as well [2]. When selecting materials for engineering designs, a clear understanding of the functional requirements for each individual component is required and various important criteria or attributes need to be simultaneously considered. These attributes include not only the traditional ones such as usability, machinability, and cost, but also material impact on environment, recycling, and even cultural aspects. They contradict and even conflict with each other, and furthermore Deng and Edwards [3] emphasized that the process of materials selection should be combined with structural optimazation. And therefore the ability to select the most appropriate material for a given application is the fundamental challenges faced by the design engineers. There have been much literature dealing with the material selection, and so great progress has been made in this field. Zhou et al. [4] proposed an integration of artificial neural networks (ANN) with genetic algorithms (GA) to optimize the multi-objectives of material selection, and applied it to selecting proper materials for drink containers. [5] proposed fuzzy inference method and applied it to material selection for a liquid nitrogen storage tank and spar of an aircraft wing. [6] also proposed fuzzy inference method for material substitution selection in electric industry, while combined with fuzzy weight average to extend fuzzy inference to uncertain environment. The advantage of fuzzy inference is that it does not require normalizations to ratings, but identifying membership function for each attribute is strongly subjective, depending entirely on expert's experiences. [7] presented an intelligent method to deal with the materials selection problems where the design configurations, working conditions, as well as the design-relevant information are not precisely known, and applied it to selecting optimal materials for robotic components at early stage of design.. [8] presented digital tools for material selection in product design, where about three hundred software, database and website references were collected, and 87 were selected to try to answer a few important questions to help designers, engineer students, and all kinds of professionals perform materials selection for product design.

The grey system theory proposed by Deng in 1982 [9] has been proven to be useful for dealing with problems with poor, insufficient, and uncertain information. According to it, systems can be divided into three classes: white systems, which have completely clear information, black systems, which have completely unknown information, and grey systems, which lie between white systems and black systems [10]. The grey relational analysis based on this theory can further be effectively adopted for solving the complicated interrelationships among the designated performance characteristics. Through this analysis, a grey

[*] ***Corresponding author's*** e-mail: xqw999_1@163.com

relational grade (GRD) is favourably defined as an indicator of multiple performance characteristics for evaluation. In recent years, grey relational analysis has become a powerful tool to multi-attribute decision making (MADM). In [11] used GRA to compute the weights of each decision maker: a larger weight is assignned to the expert whose preferences are more similar to the others' preferences, while a less weight is assigned to the expert whose preferences are less similar to the others' preferences. [12] adopted grey relation entropy analysis to evaluate information technology impact on business performance of biotechnology industry. There is a great deal of literature on the applications of GRA to material selection. In [13] presented an integrated methodology of performing an order pair of materials and end-of-life strategy for the purpose of material selection, where the GRA is employed to calculate the grey relational grade between the imaginarily best material and candidate materials. The material with the greatest grey relational grade is the best choice. [14] also presented GRA to select handbag materials for a leading handbag manufacturer in Guangdong Province, while combined with binary dominance matrix to specify the weights. However, the general GRA has three weaknesses, (i) the weight determination depends only on expert judgments, (ii) the qualitative indexes are simply quantified with exact number, and (iii) the general GRA only takes the relationship between the imaginarily best material and the candidate materials into account, but takes into no account the relationship between the imaginarily worst material and the candidate materials. Therefore the general GRA in a sense has limitations. The methodology of relative GRA (RGRA) is proposed, not only taking into the account the relationship between the imaginarily best material and the candidate materials but also into the account the relationship between the imaginarily worst material and the candidate materials. It is predicted that the results of RGRA are more reliable than that of general GRA. Weights are determined by combining subjective and objective weights based on maximum deviation, and the qualitative indexes are fuzzily quantified through trapezoidal fuzzy number (TFN).

The paper is structured as follows. Section 2 enunciates the mechanism of maximum deviation and gives the corresponding formulations to calculate combination weights. Section 3 explains the concept of trapezoidal fuzzy numbers and their operation rules. The calculation procedure for relative grey relation grade is enunciated in Section 4. Section 5, taking the bearing material selection for example, details the decision making process, and each ways to determine weights. Section 6 closes the paper with a short discussion of the issues raised and pointing the way to future research direction.

2 Combination weights based on maximum deviation

The way of identifying weights largely includes subjective weighting and objective weighting. The former identifies weights depending only on the subjective preferences or experiences of an expert, such as Delphi method, analytic hierarchy process (AHP) etc., while the latter does depending only on the information of a matrix of decision making and the mathematical model based on it, like entropy weight, principal component analysis, multi-objective optimization, etc [15]. Subjective weights fully reflect decision makers' empirical judgments, not violating common sense in identifying the relative importance of attributes, but with much more arbitrariness and poorer accuracy and reliability. However, objective weights enjoy objective criteria, but neglect subjective preferences or experiences of an expert, sometimes resulting in irrational practice. To make the selection more scientific, the subjective weights and objective ones are combined to obtain the better ones, combination weights (CW), which reflect not only subjective information but also objective one. Supposing a MADM problem, there are m alternatives, expressed as $\mathbf{s}=\{s_1, s_2, \cdots, s_m\}$, and n attributes, expressed as $\mathbf{p}=\{p_1, p_2, \cdots, p_n\}$. Letting a_{ij} be the ratings of s_i with respect to p_j, $i=1,2,\cdots,m$, $j=1,2,\cdots,n$ and $A=(a_{ij})_{m\times n}$ be decision making matrix, ratings may be in different units (e.g. material cost expressed in dollars, yield strength expressed in MPa), resulting in incommensurability, which hence entails normalizations. Suppose the normalized decision making matrix is $\mathbf{b}=(b_{ij})_{m\times n}$ with any element within [0, 1], and the larger the b_{ij}, the better the performance.

If the ratings of the *j*-th attribute are nearly same to all alternatives, then it contribute little or nothing to the alternative rank, and zero should be assigned to the weight of the attribute. Otherwise, if the ratings of the *j*-th attribute vary greatly to all alternatives, then it contributes greater to the alternative rank, and greater weight should be assigned to it. Deviation is the index in statistics reflecting the differences to all alternatives under an attribute, and as such, the weighting vector $\boldsymbol{\omega}_c$ should be selected, which enables the total deviation sum of all n attributes to reach the maximum, called maximum deviation principle.

Suppose there are l methods of weighting and the weight vector according to *k*-th method is:

$$\boldsymbol{\omega}_k=(\omega_{1k}, \omega_{2k}, \cdots, \omega_{nk})^T \quad k=1,2,\cdots,l, \tag{1}$$

where $\omega_{jk}\geq 0$ and $\sum_{j=1}^{n}\omega_{jk}=1$. Combination weight vector can be taken as $\boldsymbol{\omega}_c=(\omega_{c1}, \omega_{c2}, \cdots, \omega_{cn})$, where $\boldsymbol{\omega}_c=\theta_1\boldsymbol{\omega}_1+\theta_2\boldsymbol{\omega}_2+\cdots+\theta_l\boldsymbol{\omega}_l$ and $\theta_1, \theta_2, \cdots, \theta_l$ represent linear coefficient respectively of $\boldsymbol{\omega}_1, \boldsymbol{\omega}_2, \cdots, \boldsymbol{\omega}_l$ satisfying $\theta_k\geq 0, k=1,2,\cdots,l$, and $\sum_{k=1}^{l}\theta_k^2=1$. According to [16],

the value of θ_k based on maximum deviation principle can be taken as:

$$\theta_k = \mathbf{C}\boldsymbol{\omega}_\mathbf{k} / \sqrt{\sum_{k=1}^{l} (\mathbf{C}\boldsymbol{\omega}_\mathbf{k})^2}\,, \tag{2}$$

where $\mathbf{C}$ is a row vector with n dimensions and can be calculated as:

$$\mathbf{C} = (c_1, c_2, \cdots, c_j, \cdots, c_n) = \left(\sum_{i=1}^{m}\sum_{i_1=1}^{m} \left| b_{i1} - b_{i_1 1} \right|, \sum_{i=1}^{m}\sum_{i_1=1}^{m} \left| b_{i2} - b_{i_1 2} \right|, \cdots, \sum_{i=1}^{m}\sum_{i_1=1}^{m} \left| b_{in} - b_{i_1 n} \right| \right). \tag{3}$$

3 Fuzzy quantification for linguistic information

3.1 TRAPEZOIDAL FUZZY NUMBERS

Suppose $\tilde{A}$ is a bounded and convex fuzzy subset in the domain of R $(R \in [0,1])$, and possesses the continuous membership function $u_{\tilde{A}}(x)$ as:

$$u_{\tilde{A}}(x) = \begin{cases} u_{\tilde{A}}^{L}(x) & a < x < m \\ 1 & m \le x \le n \\ u_{\tilde{A}}^{R}(x) & n < x < \beta \\ 0 & others \end{cases}, \tag{4}$$

where $u_{\tilde{A}}^{L}(x)$ is strictly increasing function in the domain of $[a,m]$, called the left membership function, while $u_{\tilde{A}}^{R}(x)$, strictly decreasing function in the domain of $[n,\beta]$, called the right membership function. Trapezoidal fuzzy numbers (TFNs) are the widely used fuzzy numbers, whose membership function is shown in Figure 1, and can be expressed as (a,m,n,β), also as $(m,n;\gamma,\delta)$ where $\gamma = m-a, \delta = \beta - n$. If $m = n$, then trapezoidal fuzzy numbers reduce to triangle fuzzy numbers, and it can be said that triangle fuzzy numbers are the special case of trapezoidal fuzzy numbers.

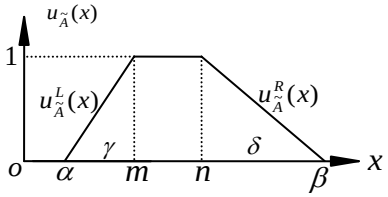

FIGURE 1 Membership function of TFN

For qualitative attributes, they are usually expressed in linguistic information. Table 1 shows their corresponding TFNs, while Figure 2 shows their membership function.

TABLE 1 Representations of linguistic information in trapezoidal fuzzy numbers

Linguistic information	**In the form of** (α,m,n,β)	**In the form of** $(m,n;\gamma,\delta)$
Very poor (VP)	(0.0, 0.0, 0.0, 0.2)	(0.0, 0.0; 0.0, 0.2)
Poor (P)	(0.0, 0.0, 0.1, 0.3)	(0.0, 0.1; 0.0, 0.2)
Medium poor (MP)	(0.0, 0.2, 0.2, 0.4)	(0.2, 0.2; 0.2, 0.2)
Fair (F)	(0.3, 0.5, 0.5, 0.7)	(0.5, 0.5; 0.2, 0.2)
Medium good (MG)	(0.6, 0.8, 0.8, 1.0)	(0.8, 0.8; 0.2,0.2)

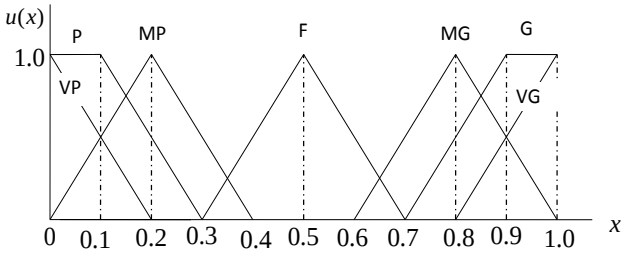

FIGURE 2 Representations of linguistic information in TFNs

3.2 OPERATIONS FOR TFNS

Suppose the two trapezoidal fuzzy numbers $M_1 = (m_1,n_1;\gamma_1,\delta_1)$ and $M_2 = (m_2,n_2;\gamma_2,\delta_2)$, then according to [17] the operators of multiplication and division can be respectively defined as:

$$M_1 \cdot M_2 \approx (m_1 m_2, n_1 n_2; m_1 \cdot \gamma_2 + m_2 \cdot \gamma_1 - \gamma_1 \cdot \gamma_2, n_1 \cdot \delta_2 + n_2 \cdot \delta_1 - \delta_1 \cdot \delta_2), \tag{5}$$

$$M_1 / M_2 \approx [m_1 / n_2, n_1 / m_2; (m_1 \cdot \delta_2 + n_2 \cdot \gamma_1) / n_2(n_2 + \delta_2), (n_1 \cdot \gamma_2 + m_2 \cdot \delta_1) / m_2(m_2 + \gamma_2)]. \tag{6}$$

By means of the approximate calculation, the operation of trapezoidal fuzzy number can be dramatically simplified, and the calculation precision in most cases meets the project requirements, but it cannot be repeatedly used, otherwise, the cumulative error would lead to erroneous results.

3.3 TOTAL EXPECTATIONS OF TFNS

Supposing $\tilde{A}$ is a fuzzy number, and $g_{\tilde{A}}^{L}(y)$, $g_{\tilde{A}}^{R}(y)$ respectively the inverse function of $u_{\tilde{A}}^{L}(x)$, $u_{\tilde{A}}^{R}(x)$. Letting $I_L(\tilde{A}) = \int_0^1 g_{\tilde{A}}^{L}(y)dy$ and $I_R(\tilde{A}) = \int_0^1 g_{\tilde{A}}^{R}(y)dy$, then $I(\tilde{A}) = [I_L(\tilde{A}) + I_R(\tilde{A})]/2$ is called as the total expectation of fuzzy number $\tilde{A}$. As for the TFN $\tilde{A} = (m,n;\gamma,\delta)$, the total expectation can be calculated as:

$$I(\tilde{A}) = (2m + 2n + \delta - \gamma)/4. \tag{7}$$

4 Relative Grey relation analysis (RGRA)

4.1 NORMALIZATION

The purpose of normalization is to obtain dimensionless values of the different criteria so that all of them can be compared with each other, which, in grey system theory, is also called grey relation generation.

1) For benefit type attributes

$$b_{ij} = \frac{a_{ij}}{\max\limits_i a_{ij}}. \tag{8}$$

2) For cost type attributes

$$b_{ij} = \frac{\min\limits_i a_{ij}}{a_{ij}}. \tag{9}$$

3) For fixation type attributes

$$b_{ij} = \begin{cases} \dfrac{\min\limits_i \left|a_{ij} - g^j\right|}{\left|a_{ij} - g^j\right|} & a_{ij} \neq g^j \\ 1 & a_{ij} = g^j \end{cases}, \tag{10}$$

where, g^j is the optimum value to fixation attribute *j*.

4.2 GREY RELATION COEFFICIENT

Suppose comparison sequences are $\mathbf{b_i}(i = 1,2,\cdots,m)$, $\mathbf{b_i} = (b_{i1}, b_{i2}, \cdots, b_{ij}, \cdots, b_{in})$, namely, the ratings of the each alternative material. Suppose the positive reference sequence is $\mathbf{b_o^+}$, $\mathbf{b_o^+} = (b_{o1}^+, b_{o2}^+, \cdots, b_{oj}^+, \cdots b_{on}^+)$, $b_{oj}^+ = \max\{b_{1j}, b_{2j}, \cdots, b_{mj}\}$, namely, the ratings of the hypothetically optimal material, and the negative reference sequence is $\mathbf{b_o^-}$, $\mathbf{b_o^-} = (b_{o1}^-, b_{o2}^-, \cdots, b_{oj}^-, \cdots b_{on}^-)$, $b_{oj}^- = \min\{b_{1j}, b_{2j}, \cdots, b_{mj}\}$, namely, the ratings of the hypothetically worst material. Then grey relational coefficient between the hypothetically optimal material $\mathbf{b_o^+}$ and the alternative material $\mathbf{b_i}(i = 1,2,\cdots,m)$ in the *j*-th attribute is defined as:

$$r_{io}^+(j) = \frac{\min\limits_i \min\limits_j \left|b_{oj}^+ - b_{ij}\right| + \rho \max\limits_i \max\limits_j \left|b_{oj}^+ - b_{ij}\right|}{\left|b_{oj}^+ - b_{ij}\right| + \rho \max\limits_i \max\limits_j \left|b_{oj}^+ - b_{ij}\right|}. \tag{11}$$

The grey relational coefficient between the hypothetically worst material $\mathbf{b_o^-}$ and the alternatives $\mathbf{b_i}(i = 1,2,\cdots,m)$ in the *j*-th attribute is defined as follows:

$$r_{io}^-(j) = \frac{\min\limits_i \min\limits_j \left|b_{oj}^- - b_{ij}\right| + \rho \max\limits_i \max\limits_j \left|b_{oj}^- - b_{ij}\right|}{\left|b_{oj}^- - b_{ij}\right| + \rho \max\limits_i \max\limits_j \left|b_{oj}^- - b_{ij}\right|}, \tag{12}$$

where ρ is the distinguishing coefficient with $\rho \in [0,1]$, usually set as 0.5 in this study. Suppose ω_{cj} is the CW of the *j*-th attribute, and then grey relational grade (GRD), the weighted sum of the grey relational coefficient, can be defined as:

$$\gamma_{io}^+ = \sum_{j=1}^n \omega_{cj} \gamma_{io}^+(j), \tag{13}$$

$$\gamma_{io}^- = \sum_{j=1}^n \omega_{cj} \gamma_{io}^-(j). \tag{14}$$

4.3 RELATIVE GREY RELATION GRADE

The relative grey relation grade can be calculated as:

$$\gamma_{io} = \frac{\gamma_{io}^+}{\gamma_{io}^+ + \gamma_{io}^-} \quad (i = 1,2,\cdots,m) \tag{15}$$

The larger the value γ_{io}, the better the performance of the alternative. It should be noted that the greater γ_{io}^+ does not always lead to the less γ_{io}^-, and therefore selecting materials only depending on γ_{io}^+ can be biased. It can be inferred from Equation (14) that the greater γ_{io}^+ and the less γ_{io}^- must result in the greater γ_{io}.

5 Case Study

Suppose a bearing works under the conditions of higher speed with stable, light load, and the task is to select the best material for the bearing. According to the rigid attributes, which, if a material to be accepted, must be fully satisfied, the materials not satisfying any of the requirements of rigid attributes are firstly eliminated. The materials initially screened out and their ratings are shown in Table 2. The procedure for the material selection is as follows.

5.1 NORMALIZATIONS

For the qualitative attributes, such as fatigue durability, corrosion durability, abrasion durability, and anti-seizing, they were expressed in TFNs. Benefit type, like fatigue durability, corrosion durability, abrasion durability, and anti-seizing, was normalized by Equations (6) and (8) and then converted into total expectations by Equation (7), fixation type, like hardness with optimum value of hardness specified as 45HBS normalized using Equation (10), and cost type by Equation (9). The normalized ratings are shown in Table 3.

TABLE 2 Raw ratings of the candidate materials

No.	Materials	Cost	Hardness (HBS)	Fatigue durability	Corrosion durability	Abrasion durability	Anti-seizing
1	*Zchsn3*	*15*	*24*	MP	VG	MP	VG
2	*Zchpb1*	*100*	*30*	MP	G	MG	VG
3	*ZQpb30*	*70*	*25*	VG	MG	MG	MP
4	*ZznM7-5*	*80*	*100*	G	VG	VG	MP

TABLE 3 Normalized ratings

No.	Materials	Cost	Hardness (HBS)	Fatigue durability	Corrosion durability	Abrasion durability	Anti-seizing
1	*Zchsn3*	1.0000	*0.7143*	0.1933	1.0000	0.1933	1.0000
2	*Zchpb1*	*0.1500*	1.0000	0.1933	0.9496	0.8319	1.0000
3	*ZQpb30*	*0.2143*	*0.7500*	1.0000	0.8319	0.8319	0.1933
4	*ZznM7-5*	*0.1875*	*0.2727*	0.9496	1.0000	1.0000	0.1933

5.2 COMBINATION WEIGHTS

5.2.1 Objective weights

1) Entropy method: according to Shannon's entropy method [18], if the ratings of each alternative under an attribute have more obvious differences, such an attribute plays a more important role in choosing the best alternative, and a greater weight should be assigned to it. The entropy value for the attribute j can be defined as:

$$H_j = -k\sum_{i=1}^{m} f_{ij} \ln f_{ij}\,, \tag{16}$$

where $k = 1/\ln m$ (m denoting the number of alternatives), $f_{ij} = b_{ij} / \sum_{i=1}^{m} b_{ij}$. The weight of attribute j can be defined as:

$$\omega_j = \frac{1 - H_j}{\sum_{j=1}^{n}(1 - H_j)}. \tag{17}$$

In the special case where under an attribute, say attribute *j*, the ratings of all alternatives are the same, it can be calculated $H_j = 1$ and $\omega_j = 0$. According to Table 3, the entropy weight vector $\boldsymbol{\omega}_1$ can be calculated as

$$\boldsymbol{\omega}_1 = (0.3332, 0.0795, 0.2334, 0.0027, 0.1127, 0.2386)^T.$$

2) Principal component analysis (PCA). Its main advantage is significantly alleviating loading and complexion of information by simplifying several correlated variables into fewer uncorrelated and independent principal components, at the same time preserving as much original information as possible using linear combination. In recent time, PCA has gradually become an analytical tool for the optimization of a system with multiple performance characteristics. Firstly calculate the correlation coefficient matrix to the normalized decision making matrix $\mathbf{b} = (b_{ij})_{m\times n}$ using the function $\mathbf{S} = corrcoef\,(\mathbf{b})$ in Matlab, then calculate eigenvalues and corresponding eigenvectors, and finally select the eigenvector corresponding to the maximum eigenvalue, after normalization, as the weight vector $\boldsymbol{\omega}_2$, and the resultant weight vector is

$$\boldsymbol{\omega}_2 = (0.1747, 0.1100, 0.2080, 0.1067, 0.1923, 0.2084)^T$$

5.2.2 Subjective weights

1) Analytic Hierarchy Process (AHP) [19-20], developed first by Satty as a popular tool for MADM, has been increasingly widely used in more and more domains. Its main steps include: (i) Against total goal, the six criteria are compared in pair, consequently constituting a judgment matrix; (ii) Calculating eigenvalues and corresponding eigenvectors to the judgment matrix; and finally (iii) selecting the eigenvector corresponding to the maximum eigenvalue, after normalization, as the weight vector $\boldsymbol{\omega}_3$. The resultant weight vector is

$$\boldsymbol{\omega}_3 = (0.2856, 0.2380, 0.1904, 0.0476, 0.0952, 0.1428)^T \quad .$$

2) Delphi method: suppose the weight vector is

$$\boldsymbol{\omega}_4 = (0.1700,\ 0.1600,\ 0.1900,\ 0.1000,\ 0.1800,\ 0.2000)^T.$$

5.2.3 Combination weights

The row vector $\mathbf{C}$ according to Equation (3) can be calculated as $\mathbf{C} = (5.1400, 4.4352, 6.300, 1.1002, 4.8000\ 6.4000)$, then the linear coefficient according to Equation (2) as $\theta_1 = 0.5371, \theta_2 = 0.4857, \theta_3 = 0.4929, \theta_4 = 0.4823$, and finally the combination weight as

$$\boldsymbol{\omega}_c = (0.2436,\ 0.1455,\ 0.2062,\ 0.0623, 0.1440,\ 0.1984)^T.$$

[21] provides a method to determine θ_l according to the consistency degree between any two ranking vectors generated by the two weight ones. Supposing the two ranking vectors as $p^{(t)} = (p_1^{(t)}, p_2^{(t)}, \cdots, p_1^{(t)})$, $p^{(k)} = (p_1^{(k)}, p_2^{(k)}, \cdots, p_1^{(k)})$ according respectively to the *t*-th and *k*-th weighting methods, the consistency degree in the light of Speaman rank correlation coefficient can be defined as:

$$\rho_{kt} = 1 - \frac{6}{n(n^2-1)}\sum_{j=1}^{n}(p_j^{(k)} - p_j^{(t)})^2\,, \tag{18}$$

where *n* is the number of attributes.

And then the consistency degree of the *k*-th weighting method can be averaged as:

$$\rho_k = \frac{1}{l-1}\sum_{t=1,t\neq k}^{l}\rho_{kt}, \tag{19}$$

θ_k can be calculated as:

$$\theta_k = \rho_k / \sum_{k=1}^{l}\rho_k . \tag{20}$$

With the method in [21], the combination weight

$\hat{\boldsymbol{\omega}}_c = (0.2364, 0.1307, 0.2086, 0.0650, 0.1520, 0.2072)^T$

can be obtained. The Speaman rank correlation coefficient between $\hat{\boldsymbol{\omega}}_c$ and $\boldsymbol{\omega}_c$ is 0.9429, implying strong correlation and consistency degree between the two methods.

According to Table 3, the positive reference sequence is $\mathbf{b}_o^+$, $\mathbf{b}_o^+ = (1.0000, 1.0000, 1.0000, 1.0000, 1.0000, 1.0000)$, and the negative reference sequence, $\mathbf{b}_o^-$, $\mathbf{b}_o^- = (0.1500, 0.2727, 0.1933, 0.8319, 0.1933, 0.1933)$.

According to Equations (11)-(15), the $\gamma_{oi}^+, \gamma_{oi}^-, and\ \gamma_{oi}$ are respectively calculated shown in Table 4. It can be concluded from Table 4 that in the light of $\gamma_{oi}^+, or\ \gamma_{oi}$ the material 1 is the best choice, followed by material 2, material 3, and material 4. The methods, weighted arithmetic averaging (WAA) and technique for order preference by similarity to ideal solution (TOPSIS), are widely used two ones in multi-attributes decision making, the results of which are also tabulated in Table 4. It can be seen that whether using the WAA or the TOPSIS the ranking results is the same, which proves selecting the *Zchsn3* for the bearing is trustworthy and reliable.

5.3 RELATIVE GREY RELATION GRADE

TABLE 4 Ranking results

No.	Materials	γ_{io}^+	Rank	γ_{io}^-	Rank	γ_{io}	Rank	WAA	Rank	TOPSIS	Rank
1	Zchsn3	0.7121	1	0.6159	1	0.5363	1	0.6759	1	0.5179	1
2	Zchpb1	0.6511	2	0.6783	3	0.4913	2	0.5993	2	0.5164	2
3	ZQpb30	0.5996	3	0.6695	2	0.4725	3	0.5775	3	0.4910	3
4	ZznM7-5	0.5964	4	0.7363	4	0.4475	4	0.5258	4	0.4519	4

6 Conclusions

From the performed research work using relative grey relation degree combined with combination weights, the main conclusions and directions for future research can be summarized as follows:

1) The proposed method expresses qualitative attributes with trapezoidal fuzzy number, more in conformity with actual situations than the traditional method with exact numbers.
2) Weights play a very significant role in the ranking results of the materials, Combination weights based on maximum deviation both considering subjective and objective weights are more appropriate for determining criteria weights than the subjective or objective weights alone. In comparison with the results by the method in literature [21], the speaman rank correlation coefficient is 0.9429, further implying the proposed method of computing combination weights is feasible.
3) The result using the proposed method in this paper matches well with the other methods such as WAA, TOPSIS, further indicating its feasibility and validity.

An analysis of landscape characteristics of urban rivers – with the case of Chengdu

Jian Zhang, Zhongwei Shen, Hao Shen*

School of Architecture, Southwest Jiaotong University, Chengdu, Sichuan, China

Received 1 September 2014, www.cmnt.lv

Abstract

Urban river landscape is a key ecological regulating system in cities, attracting increasing attention from people. Our research conducted a systematic and comprehensive research of landscape characteristics of main rivers in Chengdu from some new perspectives, including the city in the large, city location and Single River. This research is intended to better understand the landscape structure along main rivers in Chengdu, to facilitate the evaluation of macro-regional ecological environment, and to provide references for the study of regional ecological environment.

Keywords: urban rivers, landscape characteristic, city location, tree crown sizes, canopy contribution rate, landscape area

1 Background research

Since the birth of city, it has formed irreconcilable opposite to the natural ecosystem [1], which is rooted in the absolute destruction and demand of ecosystem during the urban development. The urban ecologicalization is an inexorable trend in urban development, as well as a new trend of world urban development [2]. Urban rivers are key constituent parts in the urban ecosystem. These urban rivers provide important water sources and material transport channels for cities, which also enhance the diversity of urban landscape and enrich the lives of residents. Urban rivers prepare a vital material foundation for the comfort, stability and sustainability of cities.

Urban rivers indicate rivers or river sections originated from urban areas or running through urban areas, including some historical canals excavated by human but now showing characteristics of natural rivers after years of evolution [3]. Human activities intensely influence the hydrological characteristics, physical structure and ecological environment of urban rivers. Besides, the socio-economic system and daily life of residents in cities depend on the benefits of urban rivers. Compared with natural rivers, the interaction between human and urban rivers is very significant [4-10]. Gallery of urban rivers are vital multi-functional service body in urban landscape. It can be defined as line and area combination zone connecting the aquatic-terrestrial ecotone at both banks in the urban area and forest cover with forest structure and functions. It includes the vegetation on the flood plain in streamside space of cities, in the protection forest of riparian zone, and in a certain area from the bunding. According to the widely accepted landscape type rating, waterfront space with natural banks, meandering shoreline, open sight, diverse space activities, and pseudo-classic architecture is relatively ideal. (1) According to the comprehensive rating of "Eight Scenes of Shahe River", from the high to low rating, Xinlv Grinding Grain (Z2)> North Lake(Z1)> Sandong Ancient Bridge (Z3)>Mashi Stones (Z5)> the Hakkas in Shahe River (Z6)>Spring in Tashan Mountain (Z7)>Cuihu Lake (Z8)>Technology Garden (Z4).

2 Research method and range

In recent years, the research of landscape characteristics of urban rivers has become a focus in the research area of landscape ecology and global change. It is hard to obtain high-resolution aerial photos so that Google Earth map was used in our research to replace aerial photos as the analysis data. From 500m at the overhead view (a comparatively optimal position in terms of the overhead view contour sharpness of canopy and river landscape patch), a total of 700 screenshots were used. These photos were processed in Photoshop, and generated the remote-sensing image of rivers in Chengdu. Next, the boundary of canopy and river landscape patch was drawn. A new file folder was created in ArcCatolog to establish personal data. In Arcmap, diagrams in Google Earth were used as base maps so as to establish canopy cover shape pictures with meter as the unit. These files were saved in the form of tables for further calculation and analysis. This research focused on the analysis of similarities and differences of landscape characteristics in the above mentioned areas. The landscape index and canopy cover rate of vegetables along rivers were used as major reference indexes. Indexes including landscape characteristics to the highest degree were selected to demonstrate the landscape condition in the research area so that the landscape structure along main rivers in Chengdu could be under-

* ***Corresponding author's*** e-mail:737006315@qq.com

stood. This could facilitate the evaluation of the macroscopic regional ecological environment, and could provide references for the ecological environment and management of the research area. Statistics of the index rating rsi are shown in Table 1:

TABLE 1 Statistics of index rating rsi

Index	Very Satisfactory (V1)	Satisfactory (V2)	Average (V3)	Unsatisfactory (V4)	Extremely Unsatisfactory (V5)
A	0.1080	0.3991	0.4554	0.0376	0.0000
B	0.1174	0.5258	0.2817	0.0751	0.0000
C	0.0845	0.3052	0.4272	0.1080	0.0751
D	0.1737	0.5070	0.2535	0.0376	0.0282
E	0.2911	0.5164	0.1268	0.0469	0.0188
F	0.1362	0.4178	0.3474	0.0986	0.0000
G	0.1502	0.4836	0.2817	0.0845	0.0000
H	0.1174	0.2441	0.4554	0.1643	0.0188
I	0.0563	0.2160	0.4554	0.2441	0.0282
J	0.0751	0.3709	0.4272	0.1174	0.0094
K	0.0798	0.4085	0.4554	0.0376	0.0188
A	0.1080	0.3991	0.4554	0.0376	0.0000

Waterfront vegetation rating was satisfactory, which was larger than 4.0. Ratings of naturalness of river banks, the breadth of vision, the degree of bending, river bank hydrophilia and river flow were also satisfactorily larger than 3.5. The ratings of other indexes were between 3.0 and 3.5.

The overall evaluation results of waterfront landscape reached a rating larger than 3.5. This was satisfactory.

According to the index of criterion layer, the ratings of indexes can be prioritized from high to low as: Natural Ecology>Entertainment and Ornamental Function>Social Environment. Among them, ratings of natural ecology and entertainment and ornamental function exceeded 3.5, which were satisfactory. The rating of social environment was average.

In this research, according to landscape characterristics, the entire research area were further divided into: inside 1st Ring Rd, 1st Ring Rd to 2nd Ring Rd, 2nd Ring Rd to 3rd Ring Rd, outside the 3rd Ring Rd. Besides, according to the regional relation of Chengdu, Chengdu was divided with Tianfu Square as the center into four research areas, including northeast area, northwest area, southwest and southeast areas.

The range of research areas: the east, north and west boundaries were ring roads of Chengdu. Due to the migration of city center towards the south, the south boundary was the intersection between Fuhe River and JiangAnhe River in Huayang Town, including the urban area of Chengdu. Rivers in our study were 4 main rivers with the greatest influence on the urban area of Chengdu. The average monthly designed flow in different water periods is shown in Table 2:

TABLE 2 Average monthly designed flow in different periods, Units: (m^3/s)

`	Dry Season	Prior Normal Water Period	Wet Season	Post Normal Water Period
Qingshuihe River (Supo Bridge)	1.1	12.4	35.3	19.9
Nanhe River (Baihuatan Bridge)	1.5	12.1	38.4	22.3
Shahe River (Gaoqiao Bridge)	19.6	23.5	52.3	37.2
Shahe River (Gate of Dongzikou)	15.0	14.8	17.4	16.6
Fuhe River (Branch of Dongzikou)	4.6	8.6	34.9	20.6

The river landscape model is shown in Equation (1):

$$NMSE = \frac{1}{N\sigma^2}\sum_{K=1}^{N}\left[x(k)-\hat{x}(k)\right]^2 . \quad (1)$$

3 Specific Research

This research first explored landscape characteristics of the entire research area. On this basis, the research area was divided into: inside 1st Ring Rd, 1st Ring Rd to 2nd Ring Rd, 2nd Ring Rd to 3rd Ring Rd and outside the 3rd Ring Rd. Next, with Tianfu Square as the center, Chengdu was divided into northeast area, northwest area, southwest and southeast areas. Finally, each river was systematically researched.

3.1 ANALYSIS OF THE ENTIRE RESEARCH AREA

Comparison of the canopy cover rate of each river in the research area is shown in Table 3. According to Table 3, it is known that the total canopy cover area of trees of urban river landscape in the research area was 828 hm2, and the canopy cover rate was 45.2%.Within the research area, the difference of canopy cover rates of each river in the research area was significant: Shahe River showed the highest canopy cover rate of 63.52%, which was mainly attributed to the role of Shahe River as the protected water source in Chengdu. Therefore, the ecological environment and the surrounding green space system of Shahe River are the best in Chengdu, thus generating the highest tree coverage rate of landscape around the river. It was followed by 46.8% (Fuhe River), 45.17% (Qing-

shuihe River and Modihe River), 44.36% (Dongfeng Canal) and 31.8% (JiangAnhe River). In terms of the comparison of canopy cover area, Fuhe River has the largest canopy cover area, followed by Dongfeng Canal > Shahe River > JiangAnhe River > Qingshuihe River and Modihe River.

TABLE 3 Comparison of canopy cover rates in each river of the research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of All Rivers (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in Landscape Area of All Rivers (%)
Fuhe River	635.1599	34.66	297.1229	46.8	35.87
Qingshuihe River	148.3505	8.09	67.012	45.17	8.09
Shahe River	223.4577	12.19	141.9364	63.52	17.14
JiangAnhe River	350.7365	19.14	111.5229	31.8	13.46
Dongfeng Canal	475.0198	25.92	210.7339	44.36	25.44
Total	1832.7244	100	828.3281	45.2	100

The data model is shown in Equation (2):

$$\hat{x}_{(k+1)}^{(1)} = \left(x_{(1)}^{(0)} - \frac{u}{a} \right) e^{-ak} + \frac{u}{a}. \tag{2}$$

Subsequently, the contribution level of canopy cover of each river was compared. Shahe River contributes a canopy cover rate of 17.14% with 12.19% land area, followed by the canopy cover rate of Fuhe River, Qingshuihe River and Modihe River, Dongfeng Canal (35.87%, 8.09% and 25.44%) with a land area of 34.66%, 8.09% and 25.92% respectively. Lastly, JiangAnhe River contributes a canopy cover rate of 13.46% with a land area of 19.14%. The control rate of fracture surface is shown in Table 4:

3.2 ANALYSIS OF FOUR MAIN RESEARCH AREAS

The comparison of the canopy cover rate of river landscape in each ring road of the research area is shown in Table 5. According to Table 5, the areas with the canopy cover rate ranking from high to low are respectively: 2nd Ring Rd to 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd, inside 1st Ring Rd and outside the 3rd Ring Rd. Among them, the canopy cover rates of 2nd Ring Rd to 3rd Ring Rd and that of 1st Ring Rd to 2nd Ring Rd were similarly highest. This could be attributed to the distribution of dense resident complexes near rivers from 2nd Ring Rd to 3rd Ring Rd and from 1st Ring Rd to 2nd Ring Rd. Therefore, the mode of landscape was relatively stable. Besides, due to the requirements of residents on river landscape, the landscape was diverse. However, the canopy cover rate inside 1st Ring Rd was lower than the above two areas because the area inside 1st Ring Rd was the urban center. The rivers are mainly surrounded by commercial lands or lands for other purposes, with huge visitors' flow rate. Since the human activity imposes huge demand on river landscape, the area of green space was narrowed, and the canopy cover rate became smaller. Moreover, the area outside the 3rd Ring Rd was close to the nature and the density of vegetation was smaller than that of the urban area, and the cover rate of trees was the lowest.

TABLE 5 Comparison of canopy cover rate of river landscape in each ring road of our research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of All Rivers (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas (%)
Inside 1st Ring Rd	56.9955	3.11	25.0592	43.97	3.02
1st Ring Rd to 2nd Ring Rd	84.9036	4.33	45.0156	53.02	5.44
2nd Ring Rd to 3rd Ring Rd	432.8825	23.62	230.3341	53.21	27.81
Outside 3rd Ring Rd	1258.0248	68.64	527.9192	41.96	63.73
Total	1832.7244	100	828.3281	45.2	100

In terms of contribution rate: the area from 1st Ring Rd to 2nd Ring Rd had the highest contribution rate, which contributes a canopy cover rate of 5.44% with a land area of 4.33%. This was mainly caused by the contribution of large ecological gardens like Huahuaxi Park. This was followed by that from 2nd Ring Rd to 3rd Ring Rd, which contributed a canopy cover rate of 27.81% with a land area of 23.62%. This was mainly caused by the considerable number of ecological wetland parks in the flow area of Shahe River from 2nd Ring Rd to 3rd Ring Rd. The ecological wetland parks remarkably improved the tree coverage in this area.

It can be seen from the results that the ratings of evaluation indexes of landscape types prioritized from high to low are as follows: (1) river flow (A): A3 gentle slope waterfront for people to enjoy > A1 water level lower than the river bank by 0-2m > A2 water level lower than the river bank by 2 – 5m; the rating model of river landscape evaluation indexes is shown in Equation (3):

$$\hat{x}^{(0)}(k) = (x^{(0)}_{(1)} + \frac{u}{a})e^{ak} - \frac{u}{a}. \quad (3)$$

Degree of river bending (B): B3 relatively meandering > B2 slightly meandering > B1 straight;

Environmental quality of waterfront (C): C1 Waterfront vegetation width larger than 50m> C2 waterside vegetation width between 20 and 50m > C3 waterside vegetation width less than 20m;

Naturalness of River Banks (D): D3 natural and Nature-Imitated banks > D2 stacking of natural stones > D1 grass planted on artificial banks;

Waterfront vegetation (E): E3 mainly grass + shrub + tree > El mainly grass + tree > E2 mainly grass + shrub;

Hydrophily of river banks (F): F2 with fishing available along rivers > F3 with viewing platform > F1 with walking along banks allowed;

Next, the area inside 1st Ring Rd and outside the 3rd Ring Rd contributed a canopy cover rate of 3.02% and 63.73% respectively with a land area of 3.11% and 68.64%. The data model of waterside vegetation and water flow is shown in Equation (4):

$$X^{(0)}_{(t)} = \left\{x^{(0)}_{(1944)}, x^{(0)}_{(1945)}, ..., x^{(0)}_{(1990)}\right\} = \{261, 465, ..., 432\}. \quad (4)$$

3.2.1 Comparison of canopy cover rates of different rivers inside 1st Ring Rd

The comparison of canopy cover rates of different rivers inside 1st Ring Rd is shown in Table 6. According to Table 6, it can be found that the canopy cover rate of Fuhe River, Qingshuihe River and Modihe River inside 1st Ring Rd was almost identical, so was their contribution to the canopy cover rate. Fuhe River, Qingshuihe River and Modihe River inside 1st Ring Rd contributed a canopy cover rate of 56.74% and 43.26% with a land area of 55.83% and 44.17% respectively. This indicates that the establishment and operation modes of these river landscapes inside 1st Ring Rd were almost identical. Meanwhile, a limited canopy cover rate also reflects the large demand from human activity, which is closely related with the land nature of commercial space around rivers.

TABLE 6 Comparison of canopy cover rate of different rivers inside 1st ring rd of the research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area Inside 1st Ring Rd (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas Inside 1st Ring Rd (%)
Fuhe River	31.8389	55.83	14.2292	44.62	56.74
Qingshuihe River and Modihe River	25.1566	44.17	10.83	43.07	43.26
Total	56.9955	100	25.0592	43.92	100

3.2.2 Comparison of canopy cover rates of different rivers inside 1st Ring Rd to 2nd Ring Rd

The comparison of canopy cover rates of different rivers from 1st Ring Rd to 2nd Ring Rd is shown in Table 7. According to Table 7, within the area from 1st Ring Rd to 2nd Ring Rd, the canopy cover rate of three rivers showed remarkable significance. Fuhe River had the highest canopy cover rate of 60.91% mainly because Fuhe River runs through some urban parks with flourishing vegetations like Wangjiang Park. These parks substantially increased the tree coverage rate of river landscape in this area. This was followed by the tree coverage rate of 50.93% of Shahe River. Compared the

overall tree coverage rate of Shahe River, the tree coverage rate of this section was reduced because it mainly flowed through the resident area of old cities. The high participation rate of citizens influenced the river landscape area of Shahe River to a certain degree. Next, the tree coverage rate of Qingshuihe River and Modihe River reached 47.84. In terms of tree coverage contribution rate, Fuhe River, Shahe River, Qingshuihe River and Modihe River contributed a tree coverage rate of 04%, 33.34% and 30.62% respectively with a land area of 31.32%, 34.74% and 33.94%.

TABLE 7 Comparison of canopy cover rate of different rivers from 1st ring rd to 2nd ring rd of the research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area from 1st Ring Rd to 2nd Ring Rd (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas from 1st Ring Rd to 2nd Ring Rd (%)
Fuhe River	26.6437	31.32	16.228	60.91	36.04
Qingshuihe River and Modihe River	28.8636	33.94	13.797	47.84	30.62
Shahe	29.3963	34.74	14.9906	50.93	33.34
Total	84.9036	100	45.0156	53.04	100

3.2.3 Comparison of canopy cover rates of different rivers inside 2nd Ring Rd to 3rdc Ring Rd

The comparison of the canopy cover rate of different rivers from 2nd Ring Rd to 3rd Ring Rd is shown in Table 8. According to Table 8, rivers with the tree coverage rate ranking from high to low are Shahe River (65.42%), Dongfeng Canal (45.47%), Qingshuihe River and Modihe River (42.07%), and Fuhe River (41.91%). The tree coverage rate of Shahe River was the highest in this section, which was mainly attributed to the large number of ecological wetland parks and urban parks at both sides of it, as well as the extensive green belts. In terms of tree coverage contribution rate, Shahe River topped by contributing a tree coverage rate of 55.11% with a land area of 44.84%, followed by that of Fuhe River, Qingshuihe River and Modihe River as well as Dongfeng Canal. They contributed a tree coverage rate of 19.84%, 6.93% and 18.12% with a land area of 25.2%, 8.76% and 21.2%.

TABLE 8 Comparison of canopy cover rate of different rivers from 2nd ring rd to 3rd ring rd of the research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area from 2nd Ring Rd to 3rd Ring Rd (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas from 2nd Ring Rd to 3rd Ring Rd (%)
Fuhe River	109.0456	25.2	45.7025	41.91	19.84
Qingshuihe River and Modihe River	37.9232	8.76	15.9572	42.07	6.93
Shahe	194.0614	44.84	126.9458	65.42	55.11
Dongfengqu Canal	91.7703	21.2	41.7286	45.47	18.12
Total	432.8005	100	230.3341	53.21	100

3.2.4 Comparison of canopy cover rates of different rivers outside 3rdc Ring Rd

The comparison of canopy cover rates of different rivers outside the 3rd Ring Rd is shown in Table 9. According to Table 9, the tree coverage rate was realized from high to low by Fuhe River, Qingshuihe River and Modihe River, Dongfeng Canal, as well as JiangAnhe River. The tree coverage contribution rate was realized from high to low by Qingshuihe River and Modihe River, Fuhe River, Dongfeng Canal and JiangAnhe River. They contributed a tree coverage rate of 5.01%, 41.86%, 32.01% and 21.12% with a land area of 4.48%, 37.17%, 30.46% and 27.89% respectively. This indicated that the urbanization level of areas near Fuhe River, Qingshuihe River and Dongfeng Canal was comparatively consistent. Meanwhile, the overall urbanization level of areas near JiangAnhe River was lower than that of the other three rivers.

TABLE 9 Comparison of canopy cover rate of different rivers outside the 3rd ring rd of the research area

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area outside 3rd Ring Rd (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas outside 3rd Ring Rd (%)
Fuhe River	467.6317	37.17	220.9632	47.25	41.86

JiangAnhe River	350.7365	27.89	111.5229	31.8	21.12
Total	1258.0248	100	527.9192	41.96	100

3.3 ANALYSIS OF REGIONAL LOCATION OF CHENGDU

In this research, Chengdu was divided with Tianfu Square as the center into four research areas, including northeast area, northwest area, southwest and southeast areas. Besides, this division was integrated with 1st Ring Rd, 2nd Ring Rd, 3rd Ring Rd, outside the 3rd Ring Rd to analyze the river landscape of Chengdu. The comparison of the canopy cover rate of river landscapes at different locations is shown in Table 10. According to Table 10, the changing patterns of canopy cover rates in northwest area, northeast area and southeast area are: the canopy cover rate was the highest from 2nd Ring Rd to 3rd Ring Rd, followed by that in the area from 1st Ring Rd to 2nd Ring Rd, and that inside 1st Ring Rd and outside the 3rd Ring Rd. This was consistent with the previous conclusion without the division of directions. The southwest area, however, was an exception. In this area, the canopy cover rate was highest in the area from 1st Ring Rd to 2nd Ring Rd, followed by that inside 1st Ring Rd, the area from 2nd Ring Rd to 3rd Ring Rd and finally the area outside the 3rd Ring Rd. This was mainly attributed to the Huanhuaxi park in the section of Qingshuihe River and Modihe River. Huanhuaxi Park is located in the area between 1st Ring Rd and 2nd Ring Rd in the southwest, thus substantially increasing the canopy cover rate of the area. Around the rivers from 2nd Ring Rd to 3rd Ring Rd in this area, there were the main resident complexes of Chengdu, with large density of populations. Residents present strong demand on the activities in the river landscape. Hence, the river landscape area was comparatively narrow, and the canopy cover rate was lower than other areas. Variance analysis of location difference rating is shown in Table 11.

TABLE 10 Comparison of canopy cover rate of river landscape in different regions

Type	Within 1st Ring Rd		1st Ring Rd to 2nd Ring Rd		2nd Ring Rd to 3rd Ring Rd		Outside 3rd Ring Rd

Waterside Land Utilization	3.63	3.76	3.72	1.020	0.362	(n,s)
Traffic	3.15	3.38	3.33	2.477	0.085	(1,2)
Safety	2.85	3.09	3.19	6.005	0.003 ¨	(1,2)(1,3)
Total Average	3.13	3.52	3.59	14.971	0.000 ¨	(1,2)(1,3)

As can be drawn from Table 11, with different distances from the river, significant differences were observed among the waterside environment quality, waterside land utilization and traffic indexes, showing a small degree of influence (3/12 = 25%). Our assumption that the difference of resident locations would influence the overall evaluation of waterside landscape was partially established. We conducted multiple comparisons through the L.S.D least significant difference method, and obtained that differences of the three indexes were mainly reflected between areas near river, urban area of Chengdu and other cities. According to the above indexes, the rating of population living near the river was the lowest. It was because overall the waterside landscape had a width smaller than 50m, except the large width of vegetation buffer area. A large part of the river sections between 2nd Ring Rd and 1st Ring Rd was less than 20m wide. Its inner relation can be expressed by Equation (5):

$$\bar{A} = \sum_{i=1}^{M} \left| q^{(0)}(j) \right| M , \tag{5}$$

In terms of changes in the river patch area, changes at four directions were different. In the northwest, the river patch area increased successively from inside the city to outside the city, which was consistent with our previous conclusion without the division of directions. In the northeast, the river patch area increased successively from 1st Ring Rd to 3rd Ring Rd. However, compared with the patch area from 2nd Ring Rd to 3rd Ring Rd, the patch area outside the 3rd Ring Rd decreased again. This could be attributed to the main drainage basin of Shahe River that is located in the area from 2nd Ring Rd to 3rd Ring Rd. This substantially increased the river landscape area of the

area. In the southwest, the overall trend is consistent with our previous findings. This was because the river flew through the main resident complexes of Chengdu in the area from 2nd Ring Rd to 3rd Ring Rd. Residents' demand on activities dominated so that the river landscape area was limited and the changes in the trend were produced. In the southeast, in addition to a decreasing trend in the area from 1st Ring Rd to 2nd Ring Rd, trends in other sections were increasing. The declining trend from 1st Ring Rd to 2nd Ring Rd was attributed to the geological location of the river section, which is close to key roads of Chengdu and the campus of Sichuan University. In order to ensure the smooth traffic and sufficient campus area, the river landscape area was greatly reduced.

The comparison of river landscape patch number in different directions and the average patch area is shown in Table 12. According to Table 12, in northwest, the patch number decreased from the area outside the 3rd Ring Rd, from 2nd Ring Rd to 3rd Ring Rd, from 1st Ring Rd to 2nd Ring Rd and the area inside 1st Ring Rd. The average area of patch decreased successively from the area outside the 3rd Ring Rd, the area inside 1st Ring Rd, from 2nd Ring Rd to 3rd Ring Rd, and from 1st Ring Rd to 2nd Ring Rd. In northwest, the patch number and patch area fell from the area outside the 3rd Ring Rd, from 2nd Ring Rd to 3rd Ring Rd, inside 1st Ring Rd, and from 1st Ring Rd to 2nd Ring Rd; from 2nd Ring Rd to 3rd Ring Rd, outside the 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd, inside 1st Ring Rd; In southwest, the patch number and patch area fell from the area outside the 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd, inside 1st Ring Rd, 2nd Ring Rd to 3rd Ring Rd; outside the 3rd Ring Rd, 2nd Ring Rd to 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd, inside 1st Ring Rd; In southeast, the patch number and patch area fell from the area outside the 3rd Ring Rd, 2nd Ring Rd to 3rd Ring Rd, inside 1st Ring Rd, 1st Ring Rd to 2nd Ring Rd; outside the 3rd Ring Rd, 2nd Ring Rd to 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd and the area inside 1st Ring Rd. Thus, it can be concluded that the patch number in northwest progressively increased from the urban area to external areas. In northwest, the patch area was smallest in the urban area and larger in external areas. In northeast, the patch number progressively increased from 1st Ring Rd and the urban area to external areas. The patch area progressively increased from the area inside 1st Ring Rd to 3rd Ring Rd. Area outside the 3rd Ring Rd had smaller patch area than that from 2nd Ring Rd to 3rd Ring Rd. Compared with the situation in southeast, these trends were similar in southwest. They both presented a smallest number of patches in urban area, which was smaller than external areas. The changing trend of patch areas was the progresssive increase from the urban center to the external.

TABLE 12 Comparison of patch number and average patch area in different regions of the research area

Type	Within 1st Ring Rd		1st Ring Rd to 2nd Ring Rd		2nd Ring Rd to 3rd Ring Rd		Outside 3rd Ring Rd	
	Average Patch Area (hm2)	Patch Number	Average Patch Area (hm2)	Patch Number	Average Patch Area (hm2)	Patch Number	Average Patch Area (hm2)	Patch Number
Northwest Area	1.4766	3	0.49	38	1.15	82	2.88	126
Northeast Area	0.87	21	1.55	19	3.93	42	2.8	54
Southwest Area	1.07	14	1.15	21	3.01	6	4.41	87
Southeast Area	0.71	27	1.34	10	4.85	32	10.31	35

Comparison of patch density in different regions of the research area is shown in Table 13. According to Table 13, through the calculation of the river landscape area in per square kilometer, we obtained the size of river landscape in different locations of Chengdu and their trend of variation. In northwest, the patch density decreased from the area from 2nd Ring Rd to 3rd Ring Rd, outside the 3rd Ring Rd, 1st Ring Rd to 2nd Ring Rd and the area inside 1st Ring Rd. In northeast, the patch density decreased from the area from 1st Ring Rd to 2nd Ring Rd, 2nd Ring Rd to 3rd Ring Rd, inside 1st Ring Rd and outside the 3rd Ring Rd. In southwest, the patch density decreased from the area from 1st Ring Rd to 2nd Ring Rd, outside the 3rd Ring Rd, inside 1st Ring Rd and from 2nd Ring Rd to 3rd Ring Rd. In southeast, the patch density decreased successively from the area outside the 3rd Ring Rd, from 2nd Ring Rd to 3rd Ring Rd, inside 1st Ring Rd, and from 1st Ring Rd to 2nd Ring Rd. It can be concluded that only the patch density in the area outside the 3rd Ring Rd in northwest declined. In other areas, the patch density generally increased from the urban area to the external areas. In northeast, the patch density was high in the middle and lower at both ends. The patch density of the inner city area was higher than that of the external areas. In southwest, the patch density was lower in the area from 2nd Ring Rd to 3rd Ring Rd, and the patch density of other sections remained similar. In southeast, the patch density in the area from 1st Ring Rd to 2nd Ring Rd was slightly lower but presented an increasing trend from urban area to external areas.

TABLE 13 Comparison of patch density in different regions of the research area

Type	Within 1st Ring Rd		1st Ring Rd to 2nd Ring Rd		2nd Ring Rd to 3rd Ring Rd		Outside 3rd Ring Rd	
	Average Patch Area (hm2)	Patch Density (hm2/km2)	Average Patch Area (hm2)	Patch Density (hm2/km2)	Average Patch Area (hm2)	Patch Density (hm2/km2)	Average Patch Area (hm2)	Patch Density (hm2/km2)

3.4 ANALYSIS OF THE TEGIONAL LOCATION OF UNDIVIDUAL RIVER

The comparison of canopy cover rate in each section of Fuhe River landscape is shown in Table 14. In Table 14, the variation patterns of river patch area and canopy cover area were identically increasing from center area to the external areas. The area outside 3rd Ring Rd in the direction of southwest had the highest canopy cover rate, which was mainly caused by the Fuhe River that flew through the new city area of Chengdu. The river banks of the new city area were larger than those of old city areas. Besides, the vegetable types were greatly diverse. Therefore, this area had the highest canopy cover rate, followed by that from 1st Ring Rd to 2nd Ring Rd in southeast, from 3rd Ring Rd to 2nd Ring Rd in northwest, from 2nd Ring Rd to 1st Ring Rd in northwest, inside 1st Ring Rd in southeast, inside 1st Ring Rd in northwest, expressway to 3rd Ring Rd in northwest, outside the 3rd Ring Rd in southeast and the area inside 1st Ring Rd in northeast. We could come up with a conclusion that the area of Fuhe River in southeast had the highest canopy cover rate, followed by that in northwest. Their variation pattern was constant increase of canopy cover rate from the urban center to areas outside the city. The variation pattern of canopy cover rate in another two directions was larger canopy cover rate in external areas than urban areas.

TABLE 14 Comparison of canopy cover rate in the landscape of each section of Fuhe River

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of Fuhe River (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas of Fuhe River (%)

Outside 3rd Ring Rd (Southwest)	76.4328	12.03	57.9376	75.8	19.5
Total	635.1599	100	297.1229	46.78	100

Comparison of canopy cover rate in the landscape of each section of Shahe River is shown in Table 15. It can be drawn from Table 15 that river patch area and canopy cover area presented a pattern of increasing from urban center to the area outside the city. The highest canopy cover rate and canopy contribution rate occurred in areas from 3rd Ring Rd to 2nd Ring Rd in northeast and southeast. Both presented a pattern of larger canopy cover rate and canopy contribution rate in external areas than those in urban center.

TABLE 15 Comparison of canopy cover rate in the landscape of each section of Shahe River

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of Shahe River (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas of Shahe River (%)
3rd Ring Rd to 2nd Ring Rd (Northwest)	19.573	8.76	10.471	53.5	7.34
3rd Ring Rd to 2nd Ring Rd (Northeast)	55.7578	24.95	40.6303	72.87	28.63
2nd Ring Rd to 1st Ring Rd (Northeast)	29.3963	13.16	14.9906	50.99	10.56
2nd Ring Rd to 3rd Ring Rd (Northeast)	31.0193	13.88	14.3813	46.36	10.13
2nd Ring Rd to 3rd Ring Rd (Southeast)	87.7113	39.25	61.4632	70.07	43.34
Total	223.4577	100	141.9364	63.52	100

Comparison of canopy cover rate in the landscape of each section of Dongfeng Canal is shown in Table 16. In Table 16, river patch area and canopy cover area of Dongfeng Canal presented a pattern of successively increasing from urban center to the area outside the city. The canopy cover rate from 3rd Ring Rd to 2nd Ring Rd in northeast was highest, and that from 2nd Ring Rd to 3rd Ring Rd in southeast was lowest. Generally, the canopy cover rate of each section was similar, which could mainly be attributed to the artificial excavation of Dongfeng Canal with basically consistent channel width and river landscape width. Therefore, the canopy cover rate was basically identical.

TABLE 16 Comparison of canopy cover rate in the landscape of each section of Dongfeng Canal

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of Dongfengqu Canal (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas of Dongfengqu Canal (%)
Expressway to 3rd Ring Rd (Northwest)	41.1611	8.67	18.6568	45.33	8.85
Expressway to 3rd Ring Rd (Northeast)	150.9815	31.78	65.7182	43.53	31.16
3rd Ring Rd to 2nd Ring Rd (Northeast)	78.2561	16.47	36.5122	46.66	17.33
2nd Ring Rd to 3rd Ring Rd (Southeast)	13.5142	2.84	5.2164	38.6	2.48
3rd Ring Rd to Expressway (Southeast)	191.1069	40.22	84.6303	44.28	40.18
Total	475.0198	100	210.7339	44.36	100

Comparison of canopy cover rate in the landscape of each section of Jianganhe River is shown in Table 17. According to Table 17, although the main drainage basin of JiangAnhe River was outside 3rd Ring Rd, its canopy cover rate showed significant difference. This was mainly because Jianganhe River flew through farmlands outside the 3rd Ring Rd, then the towns. Since the tree density of towns is much larger than that in farmlands, this difference has been formed.

TABLE 17 Comparison of canopy cover rate in the landscape of each section of Jianganhe River

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of JiangAnhe River (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas of JiangAnhe River (%)
Outside 3rd Ring Rd (Northwest)	43.3783	12.38	16. 138	37.2	14.17
Outside 3rd Ring Rd (Southwest)	307.3582	87.62	95.3849	31.03	85.53
Total	350.7365	100	111.5229	31.8	100

Comparison of canopy cover rate in the landscape of each section of Qingshuihe River and Modihe River is shown in Table 18. According to Table 18, river patch area and canopy cover area of Qingshuihe and Modihe River presented a pattern of successively increasing from urban center to the area outside the city. The canopy cover rate was highest in the area from 2nd Ring Rd to 1st Ring Rd in southwest, generally performing the feature of high in the middle but low at both ends.

TABLE 18 Comparison of canopy cover rate in the landscape of each section of Qingshuihe and Modihe Rivers

Type	Floor Area and Ratio		Canopy Cover Characteristics		
	Area (hm2)	Percentage in Landscape Area of Qingshuihe and Modihe River (%)	Canopy Cover Area (hm2)	Canopy Cover Rate (%)	Percentage in All the Canopy Areas of Qingshuihe and Modihe River (%)
Expressway to 3rd Ring Rd (Northwest)	56.4071	38.02	26.4278	46.85	39.44
3rd Ring Rd to 2nd Ring Rd (Northwest)	19.862	13.39	8.4574	42.58	12.62
3rd Ring Rd to 2nd Ring Rd (Southwest)	18.0612	12.18	7.4998	41.52	11.19
2ndRing Rd to 1st Ring Rd (Northwest)	15.4979	10.45	7.3647	47.52	10.99
2nd Ring Rd to 1st Ring Rd (Southwest)	13.3657	9.01	6.4323	48.12	9.6
Inside 1st Ring Rd (Southwest)	14.9724	10.09	6.5162	43.52	9.72
Inside 1st Ring Rd (Southeast)	10.1842	6.86	4.3138	42.36	6.44
Total	148.3505	100	67.012	45.17	100

To sum up, the patch number, average patch area and the total patch area of urban river landscape generally presented a trend of successively increasing from urban center to areas outside the city. This can be attributed to the fact that most river landscapes were artificial landscapes in the city, showing substantial interference from human. Besides, the degree of landscape fragmentation was high. In cities, when rivers flow through old resident areas, the patch area and canopy cover rate of river landscape become minimal. However, when rivers flow through new resident areas, the patch area and canopy cover rate of river landscape become maximum. The patch area of river landscape in different regions should be balanced to the greatest extent so as to realize the maximum balance of river ecosystems in different regions of a city. In this way, the urban ecosystem can be regulated to the largest extent.

4 Conclusions

Urban river landscape is a vital ecological regulating system for cities. In our research, from perspectives of the overall urban, city location and single river, a systematic and comprehensive research of landscape characteristics of main rivers in Chengdu was conducted so that the landscape characteristics of major rivers in Chengdu could be perceived. This research is intended to provide references for evaluating the macro-regional ecological environment of Chengdu, the ecological environment and management.

Analysis of flood disasters from 206 BC to 1949 in China

Zhenhua Liu*

Department of Municipal Engineering, Zhejiang University of Water Resources and Electric Power, Hangzhou, China, 310018

Received 3 September 2014, www.cmnt.lv

Abstract

Flood disasters produces not only direct economic losses but also serious environmental problems, the government attaches great importance to flood disasters prevention from ancient times to the present. A variety of analytic methods are adopted, for example mathematical model analysis, chart analysis, qualitative and quantitative analysis. Some mathematical models are constructed by means of statistical analysis of historical data for flood disasters, such as mathematical model for flood cycle each dynasty. There are the following results. First, there are 1037 times flood disasters from 206 BC to 1936, once every 2.07 years. According to analysis of mathematical model for flood cycle each dynasty from 206 BC to 1936, the flood cycle is the declining concave curve, except for the Five Dynasties. Second, in modern history, the most number of catastrophic floods is the Yellow River reaching 8 times, the Yangtze River 5 times. Finally, water pollution caused by floods can not be ignored. In 2012 92 percent of untreated rural sewage was discharged dispersedly.The vast majority of pollution load on the ground runs into directly riverway through stormwater runoff. Water wells are easily contaminated for germs and parasite. We should pay attention to water pollution caused by floods and combine organically flood control with water environment protection.The government coordinates closely ideas, rule of law, technology and investment with rural residents for governing rural sewage to reduce the risk of water pollution caused by floods.

Keywords: flood disasters, flood cycle model, qualitative and quantitative analysis, rural sewage, water pollution

1 Introduction

The flood is one of the major natural disasters not only in China but also in the rest of the world, governments around the world are very concerned about flood control issues. The Chinese government has pay high attention to flood and drought disasters involving livelihood issues [1,2]. The number of serious flood disasters from 1950 to 2004 reached 2606 times all over the world, involving 172 countries and regions, the total affected population of 2.75 billion, the economic loss of 347.235 billion dollars [3]. According to historical records and incomplete statistics, there is about once every two years [4]. The Yangtze River is vulnerable to flood disasters, during the 20th century, there are basin-wide floods in 1998, 1954 and 1931 [5]. The impact of floods on China's national economy is much larger than the impact on the United States [6]. It is necessary to research on flood disaster, which can provide a reference for government policy makers.

Floods has also produced a series of environmental issues, for example, the destruction of the ecological environment, the destruction of arable land, the destruction of the river system, the pollution of the water environment,especially water pollution.In 2012, the discharge of rural waste water across the country was 32.2 million t every day, most of sewage is discharged directly. Rural sewage, acid rain, agricultural pollutants, and other rural pollutants will enter into natural water environment by surface runoff. Therefore, we need to focus on the impact of floods on the water environment.

There are many effects of flood hazards.Analysis of flood disasters should choose a variety of analytic methods combined with qualitative analysis and quantitative analysis, such as mathematical models, mapping analysis, spreadsheet analysis, comparative analysis.

2 The national flood disasters in ancient times

Chinese history is usually divided into ancient history, modern history and New China, ancient history means the period before 1840, modern history means the period from 1840 to 1949, New China means the period since 1949. In ancient times in China, there are many legends about disasters of flood and waterloging, due to lack of historical data records and physical proof, it is difficult to analyze the conditions of disasters of flood and waterloging in detail. Until the Qin and Han dynasties, there are more historical data, historical records are quite specific. According to the history of the Chinese famine writed by Deng Tuo [7], there are 2142 years during the period from 206 BC to 1936, the flood disasters statistics is shown in Table 1, the flood frequency is shown in Figure 1. The mathematical model of the flood cycle is constructed by means of statistical analysis of historical data for flood disasters. 1 corresponds to the Han dynasty. 2 corresponds to the Weijin dynasty. 3 corresponds to the Northern and Southern Dynasties. 4 corresponds to the Sui and Tang Dynasties. 5 corresponds to the Five Dynasties. 6 corresponds to the Song dynasty. 7 corresponds to the Yuan dynasty. 8 corresponds to the Ming dynasty. 9

* ***Corresponding author's*** e-mail: liuzhh@zjweu.edu.cn

corresponds to the Qing dynasty. 10 corresponds to the Republic of China for the mathematical model of the flood cycle as follows:

$$y = 5.9307x^{-0.6763}, \quad (1)$$

where y is the flood cycle of dynasty, x is 1, 2, …, 10.

The flood cycle is the declining concave curve from 206 BC to 1936 in China, except for 5 representing for the Five Dynasties.

TABLE 1 The flood disasters statistics from 206 BC to 1936

Dynasty	Number of flood disasters
The Han dynasty	76
The Weijin dynasty	56
The Northern and Southern Dynasties	77
The Sui and Tang Dynasties	120
The Five Dynasties	11
The Song dynasty	193
The Yuan dynasty	92

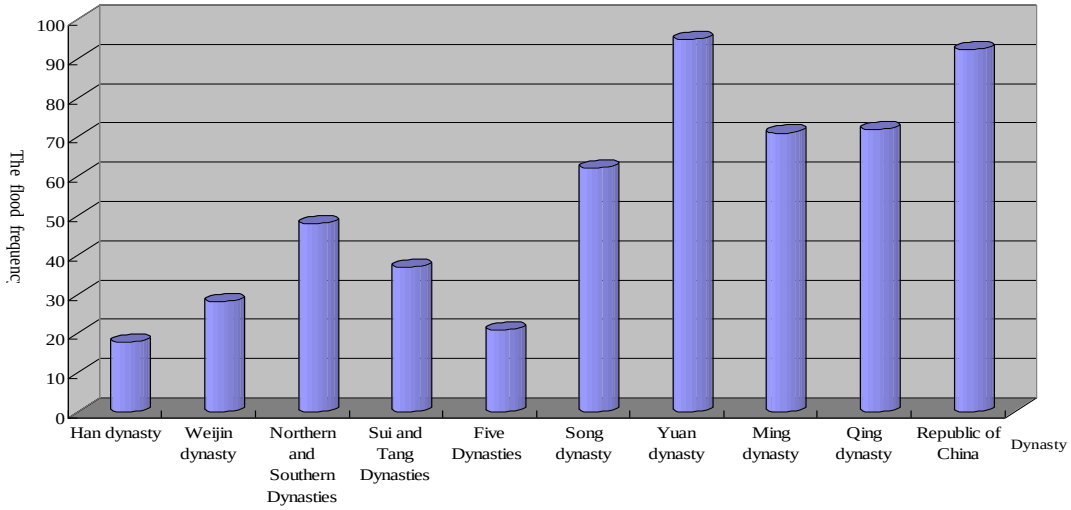

FIGURE 1 The flood frequency (%) of flood disasters from 206 BC to 1936

Table 1 shows that there are 1037 times of flood disasters from 206 BC to 1936 in China.At the same time, changing characteristics of flood frequency is depicted by graphing method. Figure 1 shows that the trends in flood frequency is divided into two phases in ancient times in China. The first stage from the Han dynasty to the Five Dynasties, flood frequency is relatively lower. The second stage from the Song Dynasty to the Qing Dynasty, flood frequency is relatively higher. There are 1165 years from the Han dynasty to the Five Dynasties,and 340 times of flood disasters, the flood frequency of 29.2 percent on average; 951 years from the Song Dynasty to the Qing Dynasty, times years of flood disasters,the average flood frequency 70.8 percent. However, the average flood frequency in Yuan Dynasty reached 94.8 percent, which is the highest flood frequency in the ancient Chinese dynasties, and is the dynasty of the most frequent occurrence of floods. Meanwhile, the flood frequency reached 92.3 percent from 1911 to 1936 in Republic of China. The average flood frequency from the Song Dynasty to the Qing Dynasty is 2.4 times from the Han dynasty to the Five Dynasties. Therefore, whether it is the first stage or second stage, basically first increase and then decrease, but generally speaking, the flood frequency is the rising trend from the Han dynasty to the Qing Dynasty. In ancient flood statistics, due to various conditions limits,it is difficult for precise statistics,but there is a very obvious trend that the flood frequency is higher and higher.

3 The flood disasters in ancient times in the yellow river valley

The Yellow River valley is the China's political, economic and cultural center in ancient times, in the Spring and Autumn and Warring States Period, there are historical records of flooding of the Yellow River. According to the records statistics of history books and local chronicles [7], the flood disasters statistics in the Yellow River valley is shown in Figure 2 in ancient times. Here, the flood disasters indicates the scope of flood disasters including most parts of middle reaches or the middle and lower reaches of the Yellow River,the flood situation is very serious disaster.

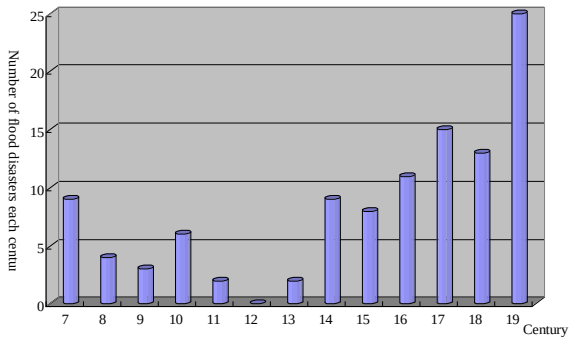

FIGURE 2 The flood disasters situation in the Yellow River valley from the 7th century to 19th century

The mathematical model of flood disasters is constructed in the Yellow River valley from the 12th century to 19th century. If 1 means the 13th century, 2 means the 15th century, 3 means the 17th century, 4 means the 19th century,as follows for the mathematical model of flood disasters:

$$y = 7.6x - 6.5, \quad (2)$$

where y is the number of flood disasters each century, x is 1,2,3,4.

1 corresponds to the 12th century, 2 corresponds to the 14th century, 3 corresponds to the 16th century, 4 corresponds to the 18th century for the mathematical model of flood disasters as follows:

$$y = -1.75x^2 + 12.85x - 10.75, \quad (3)$$

where y is the number of flood disasters each century, x is 1,2,3,4.

At the same time, changing characteristics of flood disasters is depicted by graphing method. Figure 2 shows that on the whole number of flood disasters first decrease and then increase in the Yellow River valley from the 7th century to 19th century. Number of flood disasters reached 26 from the 7th century to 13th century, average 3.7 times per century, in other words, floods occur once every 27 years. At the same time, the flood did not happen in the 12th century. Number of flood disasters reached 81 from the 14th century to 19th century, average 13.5 times per century, once every 7.4 years. On the whole, number of flood disasters reached 107 from the 7th century to 19th century, average 8.2 times per century, once every 12.2 years, but once every 4 years in the 19th century. It can be seen that the flood disasters is relatively severe from the 16th century to 19th century, particularly in the 19th century.

4 The flood disasters in ancient times in other river basins and region

In other river basins in China, floods also often occur, and caused huge losses of people's lives and property. According to the historical data of the main river and region in china, through further statistical analysis, flood disasters statistics of the main river and part of region in china is shown in Table 2 in ancient times [7-19], the flood cycle is shown in Figure 3.

TABLE 2 The flood disasters statistics of the main river and part of region

River and region	Time	The flood frequency (%)
The Yellow River	From 602 BC to 1938	62.60
The Huaihe River	From 1279 to 1840	12.46
The Haihe River	From 1368 to 1840	65.54
The Yangtze River	From 618 to 1911	17.23
The Yellow Sea coast	From 798 to 1949	125.00
The Southeast coast	From 66 to 1911	91.39
The Jiangsu and Zhejiang coast	From 1368 to 1911	3.13
Hunan province	From 221 BC to 1644	3.16
The Jianghan Plain	From 1276 to 1911	55.56
The Guanzhong Reach of Weihe River	From 1600 to 1859	41.15
Kaifeng Area	From 1644 to 1911	29.10
The middle reaches of river Fenhe	From 1644 to 1911	38.81
The Sushui River	From 1368 to 1911	16.18
Jinan city	From 1644 to 1911	41.04
Wuzhong region of Ningxia	From 1644 to 1911	34.33
Yulin Area	From 1369 to 1644	42.75
Jinghe River valley	From 618 to 907	28.28
Luohe River Basin	From 1368 to 1644	20.22
Liaoning Province	From 1791 to 1911	64.46

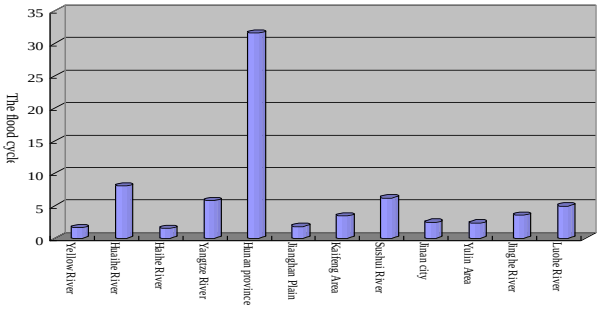

FIGURE 3 The flood cycle in the main river and part of region

According to records of governance and development of the Yellow River, the Yellow River flooding reached 1590 from 602 BC to 1938, there are a total of 543 years of flooding, the larger watershed change course 26 times. On the basis of the rough estimate based on historical data, the Yangtze river basin flooding reached 223 from 618 to 1911, once every 5.8 years on average. Among them, 16 times in Tang dynasty, once every 18 years; 79 times in Song and Yuan dynasty, once every 5.2 years;128 times in Ming and Qing dynasty, once every 4.2 years. Figure 3 shows that Hunan's flood cycle is longest, once every 31.6 years; The shortest cycle in Haihe River, once every 1.5 years, which shows a very high flood frequency of Haihe River; The remaining flood cycle, once every 3.8 years, in addition to Hunan Province.

Because historical records of floods is relatively simple in ancient times in China, it is difficult for accurate statistics of flood conditions. But some historical documents record the floods situation of part of the river and the areas, it can be used as one of research information. Currently, there are some other scholars researching on flooding of part of the rivers and regions, some research results are as follows. The floods disasters in the Tang Dynasty in Jinghe River valley can be divided into three periods, the medium-term flood-prone period, early and late period of less frequent floods [18]. Annual total flood duration day's and annual average flood duration days increase in the period from 1736 to 1948 in china [19]. The dominant periods are different in different times, which are the centennial scale oscillation during from 1644 to 1833 [20].130 flood disasters occurred in the Guanzhong region of the Weihe River Basin in the Qing Dynasty, once every 2.06 years on average, the occurring frequency of flood disasters increased obvio-

usly in the middle and late stages of the Qing Dynasty [21].

The major kinds of floods were mountain torrents and river torrents in Ancient Hunan, which brokes out more and more frequently from distribution of time [8].The earliest record of flood disasters in Liaoning Province is the first year of Ming King Emperor in 237. According to the historical records of Wei Kingdom Survey in History of the Three kingdoms, in the fall of the July, there were ten days of continuous rainfall, the water level of the Liaohe River rised. According to the statistical analysis of recorded data, there were a total of 78 floods during the period from 1791 to 1911,of which: catastrophic floods 4 times, serious floods 24 times, common floods 50 times; consecutive 3-year floods 3 times, consecutive 4-year floods once, consecutive 5-year floods 5 times, consecutive 6-year floods 2 times, consecutive 7-year floods once, consecutive 9-year floods once; in flood years, the interval of 1 year 11 times, the interval of 2 year 4 times, the interval of 3 year 4 times, the interval of 5 year once. Flood period in Liaoning Province is 1.6 years on average once, the average flood frequency is 64.5 percent.

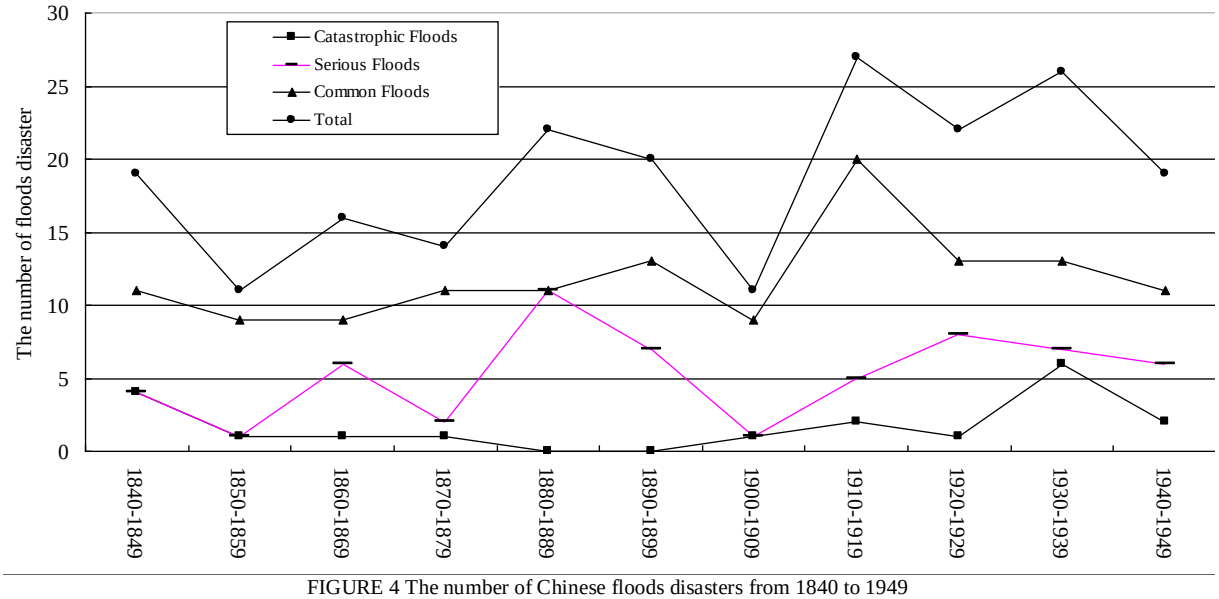

FIGURE 4 The number of Chinese floods disasters from 1840 to 1949

5 The national flood disasters in modern times

Although there was still in semifeudal and semicolonial society, the historical records of flood disasters in modern history is relatively better than in ancient times in China.The national and local flood situations were recorded in accordance with flood time, flood danger and the different basins. In order to better record the actual situation of the flood, the flood is divided into catastrophic floods, serious floods and common floods. Catastrophic floods means flood frequency below 5 percent, serious floods from 5 percent to 10 percent, common floods from 10 percent to 20 percent. Meanwhile, according to the distribution of China's major rivers, the flood situation was recorded in different rivers. According to the Chinese flood disasters chronology from 1840 to 1949 [4,7], 10 years as a unit of measurement, the number of Chinese floods disasters is shown in Figure 4 from 1840 to 1949, the number of affected counties is shown in Figure 5 every 10 years.

1 corresponds to the period from 1840 to 1849, 2 corresponds to the period from 1850 to 1859, 3 corresponds to the period from 1860 to 1869, 4 corresponds to the period from 1870 to 1879, 5 corresponds to the period from 1880 to 1889, 6 corresponds to the period from 1890 to 1899, 7 corresponds to the period from 1900 to 1909, 8 corresponds to the period from 1910 to 1919, 9 corresponds to the period from 1920 to 1929, 10 corresponds to the period from 1930 to 1939, 11 corresponds to the period from 1940 to 1949 for the mathematical model of the flood cycle as follows:

$$y = 0.12x^2 - 1.3224x + 4.1394, \quad (4)$$

where y is the number of catastrophic floods, x is 1, 2,…, 11.

Figure 4 shows the number of floods disasters in different time periods, 10-year as a time period, including the number of catastrophic floods, serious floods, common floods and total floods. The most number of catastrophic floods is the period from 1930 to 1939 reaching 6 times, secondly from 1940 to 1949 4 times, then from 1910 to 1919 and from 1940 to 1949 2 times, but from 1880 to 1889 and from 1890 to 1899 zero time. The most number of serious floods is the period from 1880 to 1889 reaching 11 times, secondly from 1920 to 1929 8 times, then from 1890 to 1899 and from 1930 to 1939 7 times. The number of catastrophic floods and serious floods is the most period from 1930 to 1939 totaling 13 times, meanwhile,the affected counties most totaling 2339.

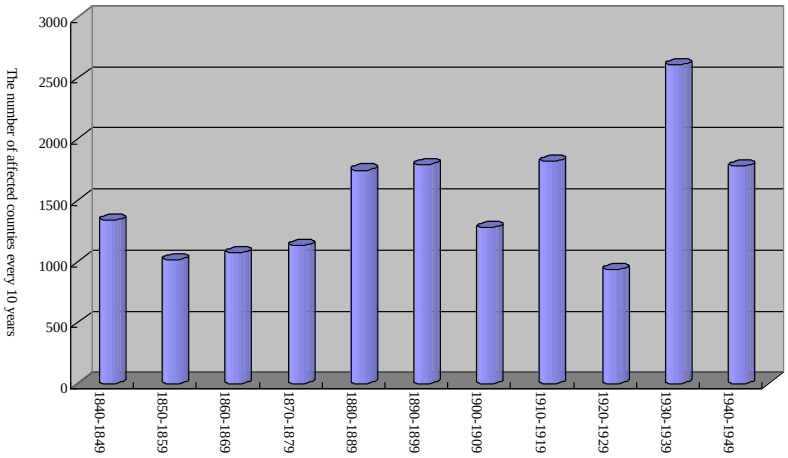

FIGURE 5 The number of the covered counties every 10 years from 1840 to 1949

Figure 5 shows that the number from 1840 to 1949 is the most affected counties in 1931 reaching 592, secondly in 1935 368. The catastrophic floods frequency or serious floods frequency is 130 percent during the period from 1930 to 1939; from 1880 to 1889 110 percent, but no catastrophic floods; from 1920 to 1929 90 percent; from 1840 to 1849 and from 1940 to 1949 80 percent; only the lowest frequency in the period from 1850 to 1859 and from 1900 to 1909 20 percent. It can clearly be seen that there is a increasing trend in floods disasters in the late modern history, especially during the period from 1930 to 1939.

6 The flood disasters of the major rivers in modern history

There are seven major rivers in China, including the Yangtze River, the Yellow River, the Pearl River, the Huaihe River, the Hailuanhe River, the Liaohe River, the Songhua River. In modern history, the major rivers in china occurred the serious floods, according to the Chinese flood disasters chronology from 1840 to 1949[4], by further analysing, the number of floods disasters of the major rivers is shown in Figure 6, the flood cycle is shown in Figure 7, the size distribution of flood is shown in Figure 8.

Figure 6 shows the number of floods disasters in different river. Figure 8 shows the size distribution of flood in modern history. China's seven major river floods is mainly the common floods, secondly the serious floods, and then the catastrophic floods. The most number of catastrophic floods is the Yellow River reaching 8 times, secondly the Yangtze River 5 times, then the Pearl River 3times, the Huaihe River 2 times, the Hailuanhe River and the Songhua River once, but the Liaohe River no catastrophic floods. The most number of serious floods is the Yangtze River reaching 21 times, secondly the Yellow River 11 times, and then the Liaohe River 7 times, the least the Songhua River only 2 times. Basically, the trend of the common floods and the total number of floods is same as the serious floods, the most number the Yangtze River, secondly the Yellow River, and then the Liaohe River, the least the Songhua River. This shows that china's seven major river floods are basically the same trends with the exception of catastrophic floods, but catastrophic floods mainly focusing on the Yellow River, the Yangtze River and the Pearl River, especially the Yellow River and the Yangtze River.

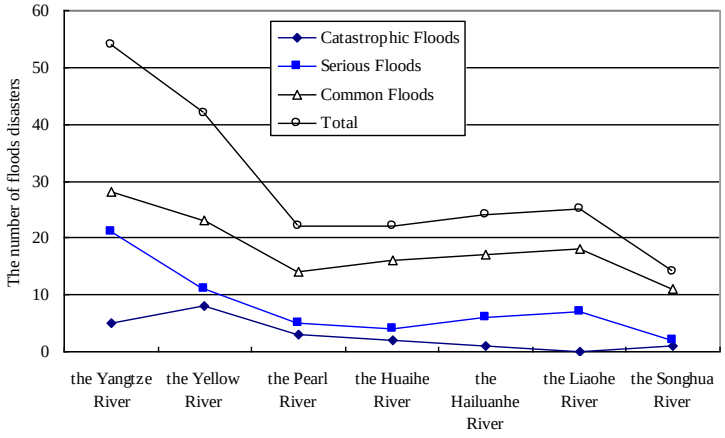

FIGURE 6 The number of floods disasters of the major rivers from 1840 to 1949

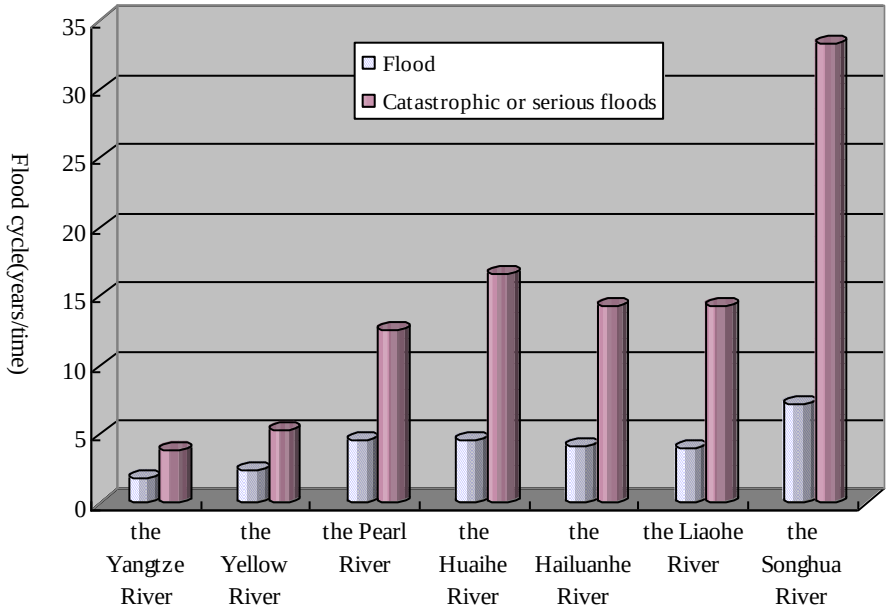

FIGURE 7 The flood cycle of the major rivers from 1840 to 1949

Figure 7 shows the flood cycle of the major rivers. The shortest cycle of the major rivers in China is the Yangtze River, the flood cycle once every 1.85 years, the catastrophic floods or serious floods once every 3.85 years; Secondly, the flood cycle of the Yellow River once every 2.4 years, the catastrophic floods or serious floods once every 5.3 years; This shows the flood happened in very high frequency in the Yangtze River and the Yellow River, on the whole the flood frequency of the Yangtze River higher than the Yellow River, But the number of catastrophic floods in the Yellow River is more than 60 percent of the Yangtze River. However, the longest cycle is the Songhua River, the flood cycle once every 7.1 years, the catastrophic floods or serious floods once every 33.3 years. Generally speaking, the variation trend of flood cycle is same as the catastrophic or serious floods with high similarity.

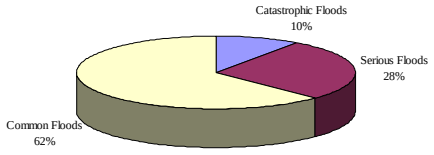

FIGURE 8 The size distribution of flood from 1840 to 1949

7 The water pollution caused by floods

Water pollution caused by floods can not be ignored. Rural sewage, garbage, dead animals, agricultural pollutants, toxic substance diffuse with the flow during the flood. Rivers, ponds and wells are easily contaminated for germs and parasite, which results in a variety of disease outbreaks and endanger seriously people's health. For example, in 1991, in the hardest-hit areas caused by floods in Anhui, the total number of bacteria was 10 times higher than standards for drinking water quality, escherichia coli was 700 times higher than standards for drinking water quality. In 2012, the discharge of rural waste water across the country was 11.7 billion t. Because operation and management for rural sewage treatment is relatively backward, sewage treatment rate is very low [22]. 92% of rural sewage untreated was discharged dispersedly on the ground. Agricultural pollution has become the dominant source of water pollution in China. In 2009, the total COD discharge of agricultural pollution was 12.8 million t, the total TN discharge was 3.46 million t, the total TP discharge was 460 thousand t [23]. Excessive amounts of pesticides and chemical fertilizer is on the ground. The vast majority of pollution load on the ground for rural sewage and agricultural pollutants runs into directly riverway through stormwater runoff. According to Report on the State of the Environment in China 2013, in 2013, among the 473 cities (counties) under monitoring, 210 cities (counties) had acid rain, accountting for 44.4%; 130 cities had acid rain frequency over 25%, taking up 27.5%; 43 had acid rain frequency over 75%, taking up 9.1%. In 2013, 29.6% of the cities (counties) had the annual average of precipitation pH value less than 5.6 (acid rain), 15.4% of the cities (counties) had the annual average of precipitation pH value less than 5.0 (relatively heavy acid rain) and 2.5% of the cities (counties) had the annual average of precipitation pH value less than 4.5 (heavy acid rain). For example, pH value for some reservoir in Zhejiang is low, which meet quality standards of water sources. In short, we should pay attention to the impact of flood on water environment.

8 Conclusion and suggestion

There are the characteristics of flood disasters in china including a wide range of floods, the frequent occurrence, the strong sudden and the large losses. In this paper, the flood disasters are analysed in ancient history, modern history and the impact of flood on water environment, conclusion and suggestion are the following:

First, before 206 BC, the relative lack of historical records of floods, until the Qin and Han dynasties, there are more specific historical records of flood. Therefore, the floods from 206 BC to 1840 are mainly analysed. There are 1037 times of flood disasters from 206 BC to 1936 in China. The flood cycle is the declining concave curve from 206 BC to 1936, except for the Five Dynasties. The trends in flood frequency is divided into two phases in ancient times in China, the first stage from the Han dynasty to the Five Dynasties, flood frequency is relatively lower; The second stage from the Song Dynasty to the Qing Dynasty, flood frequency is relatively higher. The flood disasters is relatively severe from the 16th century to 19th century in the Yellow River valley, particularly in the 19th century.

Second, in order to better record the actual situation of the flood, the flood is divided into catastrophic floods, serious floods and common floods. The most number of catastrophic floods is the period from 1930 to 1939 reaching 6 times, secondly from 1940 to 1949 4 times, then from 1910 to 1919 and from 1940 to 1949 2times,but from 1880 to 1889 and from 1890 to 1899 zero time. China's seven major river floods is mainly the common floods, secondly the serious floods, and then the catastrophic floods. The variation trend of flood cycle is same as the catastrophic or serious floods with high similarity.

Finally, we should pay attention to Water pollution caused by floods and combine organically flood control with water environment protection. By the rule of law and the media, the government strengthens publicity to raise public awareness of disaster prevention and water environmental protection, and organizes regularly the exercises of water pollution and flood disaster prevention. The government coordinates closely ideas, rule of law, technology and investment with rural residents for rural sewage governance. At present, there are no laws and regulations for rural sewage treatment in China. It is very important for urban and rural residents to change ideas of rural sewage treatment. It is good for rural sewage treatment, which can reduce the impact of floods on water pollution, especially the spread of germs and disease. Therefore, the government and residents should attach great importance to not only the direct loss of flooding but also the impact of the floods on water pollution.

Abstract

To formulate a hospital management evaluation system and conduct empirical research, Delphi, analytic hierarchy process, and fuzzy comprehensive evaluation are used to build a hospital management evaluation system and conduct hospital management empirical research. And then a hospital management evaluation system is built. This system contains five first-level indices, namely, administrative management, human resource management, medical management, financial management and logistical support, and 23 second-level indices. Empirical research shows that the comprehensive evaluation of hospital management is above average and that service quality and infrastructure construction have the highest and lowest evaluation scores, respectively. This evaluation system is an effective tool for studying hospital management. Chinese hospital management requires further improvement, especially in terms of infrastructure construction.

Keywords: fuzzy mathematics, hospital management, evaluation system, analytic hierarchy process

1 Introduction

Hospital is a health and medical institution that treats and prevents diseases and protects people's health. Thus, hospital development and management are important concerns of all social sectors [1]. At present, hospital functions change from simple diagnosis and treatment into prevention, heath care, diagnosis and treatment, and rehabilitation, making services within hospitals extend forward and backward hospitals [2]. Hospital management shall adapt to such changes, adjust service structure and mode, and optimize and reorganize hospital resources. The increasingly fierce competitions in the medical market and the increasing medical service demands have brought new problems, changes, and challenges to hospital management. Hospital management innovation is an inevitable requirement of constantly changing objective hospital conditions and is an eternal theme of sustainable development of health cause. Hospitals should continuously innovate and improve management concept to remain invincible in the fierce market competition [3]. Therefore, hospital administrators need to actively innovate hospital management concept.

WHO introduces a new framework to analyze the performance of health systems in different countries and believes that the health system shall have three objectives [4], namely, promote good health, strengthen reaction capacity that people expect, and ensure financing fairness. It also proposes that a health system should possess four main functions, namely, management, financing, service provision, and raising resources. Hospital management quality can reflect the comprehensive strength and level of a hospital. The actual situation of Chinese hospital management reflects the urgent need for the guidance of hospital management innovation theory. Currently, all levels and categories of Chinese hospitals have inaccurate market and functional positioning, outdated operation and management concepts, low operating efficiency, and weak driving force and capital support for sustainable development [5]. Practical exploration and theoretical research of hospital management innovation should be vigorously conducted to make modern Chinese hospitals truly become subjects of market economy with independent management, self-discipline, and self-development. Changes in social medical and health demands urgently require hospitals to study management system innovation, management operation innovation, and management technological innovation, among others [6].

A few domestic and international studies have evaluated hospital management quality. Hospital management quality has its own features, and the particularity of comprehensive evaluation of hospital management quality is worthy of exploration and research. This study builds a hospital management evaluation index system by analytic hierarchy process (AHP). This process can scien-

[*]***Corresponding author's*** e-mail: sunmei1111@yeah.net

tifically, objectively, and accurately evaluate hospital management performance and promote hospitals to strengthen connotation construction. Then, fuzzy comprehensive evaluation is used to assess the management quality of six hospitals in a city. The evaluation results on hospital management quality are discussed for administrators to compare work quality and work development among hospitals in different times. This study may serve as a basis for evaluating hospital management quality.

2 Methods

2.1 EXPERT INTERVIEW

On the basis of literature reading, experience reference, and individual visit, this study begins with important and key contents that reflect hospital management, preliminarily selects hospital management evaluation indices, and initially builds a hospital management evaluation index system that contains 5 first-level indices and 37 second-level indices.

2.2 DELPHI

A qualified expert group and screen indices are selected from studies on social indices through Delphi, a scientific, relatively objective, and strongly operational method [7]. We seek advices of experts on selected hospital management evaluation index systems by distributing questionnaires and finally determine an evaluation system that contains 5 first-level indices and 23 second-level indices according to the advices and suggestions of experts.

2.3 AHP

Weight coefficients of all levels of indices can be calculated by AHP [8].

2.4 FUZZY COMPREHENSIVE EVALUATION

Hospital management involves a wide scope. Hospital management evaluation is a multifactor and multilevel process with highly complex influencing factors. Evaluation indices are both qualitative and quantitative. In addition, medical staff evaluates hospital management on the basis of subjective factors, fuzzy index factors, and asymmetric information. The introduction of the hybrid multi-attribute evaluation model can efficiently solve this problem. Triangular fuzzy numbers in fuzzy multi-attribute decision making can effectively handle index quantification and evaluators' subjective preference values [9,10]. Fuzzy comprehensive evaluation is realized by MATLAB7.0 program package.

3 Building of hospital management evaluation system

3.1 BUILDING OF INDEX SYSTEM

In accordance with the basic principles of SERVQUAL [11], a large number of hospital management indices are collected through literature and semi-structured interviews, and then Delphi is used to preliminarily select 37 indices and determine hospital management evaluation indices, including 5 first-level indices (i.e., administrative management, human resource management, medical management, financial management, and logistical support) and 23 second-level indices. An evaluation system is established through experts' scores of indices by pair-wise comparison combined with AHP. A questionnaire is designed according to the established system, and the questionnaire is scored by the Likert five-level scale. Finally, a model is established by fuzzy mathematical modeling combined with exploratory and confirmatory analyses.

3.2 DETERMINE INDEX WEIGHT

The weight of hospital management evaluation indices plays an important role in the evaluation system. It is related to the importance degree of hospitals' management of influencing factors. In terms of social evaluation, the weights of evaluation indices are currently directly determined by a few experts according to experience, which is an insufficient basis for data analysis [12]. In addition, their experience may significantly deviate from the actual situation, thereby affecting the accuracy of evaluation results. Thus, this study uses AHP to determine index weights. The index weight of the hospital management evaluation system is calculated by AHP according to the following steps:

Step 1: establish a hierarchical index system structure, i.e., build index hierarchy according to the basic relations of the evaluation index system.

Step 2: build a pair-wise comparison matrix.

Step 3: check consistency.

$$C.I. = \frac{\lambda_{\max} - n}{n-1}, \qquad C.R. = \frac{C.I.}{R.I.}. \tag{1}$$

In this study, CR = 0.017 < 0.10, indicating that weight coefficients are available.

The index weight coefficients of the evaluation index system can be determined according to the above three steps. The weight of all levels of indices can be finally determined as shown in Table 1 on the basis of the scores provided by 10 experts on 5 first-level indices and 23 second-level indices.

TABLE 1 Evaluation index system and weight

First-level index (U_i)	Weight (W_i)	Second-level index (U_{ii})	Weight (W_{ii})	Index connotation
Administrative management U1	0.18	Organizational structure U11	0.22	Rational hospital management organizational structure
		Leaders' management responsibilities U12	0.31	Leaders devote themselves to hospital management
		Management accountability U13	0.21	Management accountability, to implement reward and punishment system
		Development planning U14	0.26	Formulate and implement development planning and annual working plan
Human resource management U2	0.21	Human resource allocation U21	0.23	Rational allocation of department human resources
		Talent echelon construction U22	0.22	Talent echelon construction system, continuing education system
		Physician structure U23	0.18	Rational three-level physician employment structure
		Nursing staff U24	0.19	Rational amount and echelon structure of nursing staff
		Educational background and professional knowledge U25	0.18	Rational educational background and professional knowledge structure of medical staff
Medical management U3	0.32	Medical quality U31	0.21	Medical treatment, medical matters and other management organizations, and working system
		Department supervision U32	0.19	Manage and supervise the quality of clinical and medicine departments
		Medical risk warning U33	0.09	Medical risk warning system, response and handling capacities
		Doctor–patient relationship U34	0.19	Deal with medical disputes timely and properly, and coordinate doctor–patient relationship
		Emergency management U35	0.15	Deal with emergencies and public disasters
		Medical attitude U36	0.17	Attitude of medical staff toward patients
Financial management U4	0.13	Accounting posts U41	0.24	Set accounting posts scientifically according to needs
		Accounting U42	0.27	Set accounting items for financial accounting according to provisions
		Budgeting U43	0.22	Formulate and implement budget for revenues and expenditures scientifically and rationally
		Financial control U44	0.27	Strengthen cost accounting and control, and reduce operating costs
Logistical support U5	0.16	Basic facility construction U51	0.28	Carry out basic construction items according to national laws and regulations
		Equipment management U52	0.26	Manage equipment scientifically
		Equipment renewal U53	0.19	Perfect medical equipment purchasing, maintenance and renewal system
		Logistical work U54	0.27	Meet needs of clinical work and patients' treatment

3.3 EVALUATION METHODS

Fuzzy comprehensive evaluation mathematical models can be divided into one-level models and multilevel models. Analysis of evaluation factors shows that some factors are coordinating while some are causal. In other words, evaluation factors have different levels, causing a practical issue that objectively exists.

Multilevel fuzzy comprehensive evaluation model: low-level factors are initially comprehensively evaluated, and then results are subjected to high-level comprehensive evaluation by the following specific steps:

1) Confirm the factor set of evaluation object $F=\{f_1, f_2, \ldots, f_n\}$. For hospital management evaluation indices, first-level evaluation factors include f_1 (administrative management), f_2 (human resources), f_3 (medical management), f_4 (financial management), and f_5 (logistical support) while second-level evaluation sub-factors include those of the indices in Table 1.

2) Confirm evaluation category set $E=\{e_1, e_2, \ldots, e_n\}$. Hospital management evaluation grades are determined as E= {very high, quite high, general, quite low, very low} grades, which correspond to scores of 90, 80, 70, 60, and 50, respectively.

3) Determine weight set W_f.

4) Perform single-factor evaluation. Establish fuzzy mapping f from factor set F to comment set E, derive a fuzzy relation R_f from f, and its matrix representation can be denoted as $R_i = R_f = (\gamma_{ikj}\ m\times n)$.

5) Comprehensive evaluation. Calculate comprehendsive evaluation vector S and comprehensive evaluation value μ according to the following formulas. $S = W_f R$, $\mu = W_e S^T$.

4 Empirical research of hospital management based on fuzzy mathematics

A questionnaire is formulated in accordance with a hospital management evaluation system to investigate hospital management quality, and the questionnaire is scored by the Likert five-level scale with "1" representing "dissatisfied" and "5" representing "very satisfied." Medical staff members select according to perceived actual situation and thus complete the test of hospital management quality. A total of 600 questionnaires are sent out, and 586 valid ones are recovered with an effective recovery rate of 97.67%.

With different emphasis on factors in U, each factor shall be given different weights, which can be expressed as a fuzzy subset $\underset{\sim}{A}(a_1, a_2, \cdots, a_n)$ of U, and stipulate $\sum_{i=1}^{n} a_i = 1$.

With $\underset{\sim}{R}$ and $\underset{\sim}{A}$, comprehensive evaluation is $\underset{\sim}{B} = \underset{\sim}{A} \cdot \underset{\sim}{R}$, $\underset{\sim}{B} = (b_1, b_2, \cdots, b_m)$ is a fuzzy subset of V, where

$$b_j = \overset{n}{\underset{i=1}{V}}(a_i \wedge r_{ij})(j = 1, 2, \cdots, m). \quad (2)$$

The statistical data from the sample survey are substituted into the established model, and the vectors of all levels of fuzzy comprehensive evaluation are calculated.

4.1 ESTABLISH AN EVALUATION SET

An evaluation set consists the evaluation of all indices and all possible results of total evaluation. Hospital management evaluation may have five possible results. The evaluation set can be denoted as $R = \{r_1, r_2, r_3, r_4, r_5\}$ = {very low, quite low, general, quite high, very high}.

The index "organizational structure U11" is "very high" for 48 people, "quite high" for 169 people, "general" for 228 people, "quite low" for 37 people, and "very low" for 104 people. On the basis of normalization calculation, the evaluation set of organizational structure U11 is r1 = (0.178, 0.063, 0.389, 0.289, 0.081).

Similarly, the single-factor evaluation matrix of administrative management obtained by combining the evaluation grades of the sub-indices of administrative management is as follow:

$$R_1 = \begin{pmatrix} r_1 \\ r_2 \\ r_3 \\ r_4 \end{pmatrix} =$$

$$\begin{pmatrix} 0.17848 & 0.063194 & 0.388557 & 0.288642 & 0.081127 \\ 0.099915 & 0.098207 & 0.447481 & 0.268147 & 0.086251 \\ 0.24509 & 0.020495 & 0.378309 & 0.288642 & 0.067464 \\ 0.207515 & 0.076003 & 0.41076 & 0.293766 & 0.011956 \end{pmatrix}$$

TABLE 2 Index evaluation scores

First-level index	Second-level index	Evaluation scores
Administrative management U1	Organizational structure U11	70.30743
	Leaders' management responsibilities U12	71.42613
	Management accountability U13	69.12895
	Development planning and management U14	68.26644
Human resource management U2	Human resource allocation U21	77.42101
	Talent echelon construction U22	76.13151
	Physician structure U23	78.94962
	Nursing staffs U24	78.65073
	Educational background and professional knowledge U25	69.12041
Medical management U3	Medical quality U31	76.65243
	Department supervision U32	78.924
	Medical risk warning U33	68.93254
	Doctor–patient relationship U34	68.94108
	Emergency management U35	68.7105
	Medical attitude U36	62.50213
Financial management U4	Accounting posts U41	68.77882
	Accounting U42	68.33476
	Budgeting U43	70.40137
	Financial control U44	63.57814
Logistical support U5	Basic facility construction U51	77.30999
	Equipment management U52	71.04184
	Equipment renewal U53	68.51409
	Logistical work U54	66.191289

According to fuzzy membership degree, the evaluation matrix shows that the organizational structure and leader management responsibilities are general while the management accountability and development planning are low. In terms of comprehensive evaluation scores, physician structure evaluation has the highest scores; whereas medical attitude evaluation has the lowest scores (Table 2).

Similarly, the single-factor evaluation matrix of human resource management obtained by combining the evaluation grades of sub-indices of human resource management is shown as follow:

r1	0.17848	0.043553	0.050384	0.312553	0.41503
r2	0.172502	0.072588	0.081981	0.315115	0.357814
r3	0.013664	0.003416	0.326217	0.387703	0.269001
r4	0.032451	0.051238	0.228864	0.393681	0.293766
r5	0.187874	0.097353	0.389411	0.265585	0.059778

In terms of fuzzy membership degree, the evaluation of human resource allocation, talent echelon construction, physician structure, and nursing staff is general, whereas the evaluation of educational background and professional knowledge is low. In terms of evaluation scores, human resource allocation has the highest scores, whereas educational background and professional knowledge have the lowest scores.

Similarly, the single-factor evaluation matrix of medical management obtained by combining the evaluation grades of sub-indices of medical management is shown as follow:

r1	0.184458	0.071734	0.052946	0.275833	0.415030
r2	0.028181	0.071734	0.169086	0.441503	0.289496
r3	0.220325	0.000854	0.482494	0.257899	0.038429
r4	0.189582	0.057216	0.458582	0.258753	0.035867
r5	0.247652	0.008540	0.429547	0.253629	0.060632
r6	0.232280	0.436379	0.252775	0.005978	0.072588

In terms of fuzzy membership degree, medical quality and department supervision have general evaluation, whereas medical risk warning, doctor–patient relationship, emergency management, and medical attitude have low evaluation. In terms of evaluation scores, medical quality has the highest scores, whereas medical attitude has the lowest scores.

Similarly, the single-factor evaluation matrix of financial management obtained by combining the evaluation grades of the sub-indices of financial management is shown as follow:

r1	0.222886	0.042699	0.40222	0.298036	0.034159
r2	0.245090	0.047822	0.360376	0.321947	0.024765
r3	0.168232	0.035013	0.455167	0.271563	0.070026
r4	0.203245	0.400512	0.273271	0.081127	0.041845

In terms of fuzzy membership degree, accounting posts, accounting, and financial control have low evaluation, whereas budgeting has general evaluation. In terms of evaluation scores, budgeting has general scores, the other aspects of financial management have low scores, and financial control has the lowest scores.

Similarly, the single-factor evaluation matrix of logistical support obtained by combining the evaluation grades of sub-indices of logistical support is shown as follow:

r1	0.222886	0.042699	0.402220	0.298036	0.034159
r2	0.245090	0.047822	0.360376	0.321947	0.024765
r3	0.168232	0.035013	0.455167	0.271563	0.070026
r4	0.203245	0.400512	0.273271	0.081127	0.041845

In terms of fuzzy membership degree, basic facility construction and equipment management have general eva-

luation, and equipment renewal and logistical work have low evaluation. Basic facility construction has the highest scores, whereas logistical work has the lowest scores.

4.2 ESTABLISH A WEIGHT SET

Weight set of second-level index layer: The corresponding weight of each index is provided according to the above expert scoring and AHP analysis results.

Weights of administrative management indices:
$A_1 = c$ **(0.22, 0.31, 0.21, 0.26)**
Weights of human resource management indices:
$A_2 = c$ **(0.23, 0.22, 0.18, 0.19, 0.18)**
Weights of medical management indices:
$A_3 = c$ **(0.21, 0.19, 0.09, 0.19, 0.15, 0.17)**
Weights of financial management indices:
$A_4 = c$ **(0.24, 0.27, 0.22, 0.27)**
Weights of logistical support indices:
$A_5 = c$ **(0.28, 0.26, 0.19, 0.27)**

Weight set of first-level index layer: The corresponding weight of each index is provided according to the AHP analysis results: $W = c$ (0.18, 0.21, 0.32, 0.13, 0.16).

4.3 COMPREHENSIVE EVALUATION

With the above weight sets and single factor evaluation sets, we can calculate the following:

The comprehensive evaluation vector of administrative management is:

$$B_1 = A_1 \times R_1 = (0.22 \quad 0.31 \quad 0.21 \quad 0.26)$$
$$\begin{pmatrix} 0.17848 & 0.063194 & 0.388557 & 0.288642 & 0.081127 \\ 0.099915 & 0.098207 & 0.447481 & 0.268147 & 0.086251 \\ 0.24509 & 0.020495 & 0.378309 & 0.288642 & 0.067464 \\ 0.207515 & 0.076003 & 0.41076 & 0.293766 & 0.011956 \end{pmatrix} =$$
$$(0.175662 \quad 0.068412 \quad 0.410444 \quad 0.283621 \quad 0.061862).$$

In terms of fuzzy membership degree, at administrative management has low evaluation, and its comprehensive evaluation scores are:

$$0.1756618\times 50 + 0.06841161\times 60 + 0.4104441\times 70 + 0.2836208\times 80 + 0.06186166\times 90 = 69.87609.$$

Similarly, the comprehensive evaluation vector of human resource management is:

$$B_2 = (0.121443 \quad 0.05386 \quad 0.201921 \quad 0.333604 \quad 0.289172).$$

In terms of fuzzy membership degree, human resource management has general evaluation, and its comprehendsive evaluation scores are:

$$0.1214432\times 50 + 0.05385995\times 60 + 0.2019214\times 70 + 0.3336038\times 80 + 0.2891716\times 90 = 76.15201.$$

Similarly, the comprehensive evaluation vector of medical management is:

$$B_3 = (0.176576 \quad 0.115107 \quad 0.281204 \quad 0.253245 \quad 0.173869).$$

In terms of fuzzy membership degree, medical management has general comprehensive evaluation, and its evaluation scores are:

$$0.1765756\times 50 + 0.1151067\times 60 + 0.2812041\times 70 + 0.2532451\times 80 + 0.1738685\times 90 = 71.32724.$$

Similarly, the comprehensive evaluation sector of financial management is:

$$B_4 = (0.211554 \quad 0.139001 \quad 0.367754 \quad 0.240103 \quad 0.041588).$$

In terms of fuzzy membership degree, financial management has quite low comprehensive evaluation, and its comprehensive evaluation scores are:

$$0.2115542\times 50 + 0.1390009\times 60 + 0.3677541\times 70 + 0.2401025\times 80 + 0.04158839\times 90 = 67.6117.$$

Similarly, the comprehensive evaluation sector of logistical support is:

$$B_5 = (0.197874 \quad 0.050325 \quad 0.324355 \quad 0.308121 \quad 0.119325).$$

In terms of fuzzy membership degree, logistical support has general comprehensive evaluation, and its comprehensive evaluation scores are:

$$0.1978736\times 50 + 0.05032451\times 60 + 0.3243553\times 70 + 0.3081213\times 80 + 0.1193254\times 90 = 71.007.$$

With the above comprehensive evaluation and weights of three first-level indices, the comprehensive evaluation scores of hospital management can be calculated as follow:

$$C = W \times \begin{pmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \\ B_5 \end{pmatrix} (0.18 \quad 0.21 \quad 0.32 \quad 0.13 \quad 0.16)$$
$$\begin{pmatrix} 0.176 & 0.068 & 0.410 & 0.284 & 0.062 \\ 0.121 & 0.054 & 0.202 & 0.334 & 0.289 \\ 0.177 & 0.115 & 0.281 & 0.253 & 0.174 \\ 0.212 & 0.139 & 0.368 & 0.240 & 0.042 \\ 0.198 & 0.050 & 0.324 & 0.308 & 0.119 \end{pmatrix} =$$
$$(0.173 \quad 0.087 \quad 0.306 \quad 0.283 \quad 0.152).$$

In terms of fuzzy membership degree, comprehensive evaluation is general, and the comprehensive evaluation scores of hospital management are:

$$0.1779046\times 50 + 0.06538295\times 60 + 0.3063106\times 70 + 0.2908957\times 80 + 0.1595061\times 90 = 71.89.$$

On the basis of the above results, a summary table of first-level indices and comprehensive evaluation scores can be obtained (Table 3).

TABLE 3 First-level indices and comprehensive evaluation

First-level index Ui	Satisfaction membership	Evaluation scores
Administrative management U1	Quite low	69.876
Human resource management U2	General	76.152
Medical management U3	General	71.327
Financial management U4	Quite low	67.612
Logistical support U5	General	71.007
Comprehensive evaluation	General	71.89

5 Conclusions

This study establishes a hospital management evaluation system containing 5 first-level indices (i.e., administrative management, human resource management, medical management, financial management, and logistical support) and 23 second-level indices. It also determines the weights and evaluation methods of indices in this evaluation system.

The hospital management evaluation system in this study can scientifically and rationally solve the problem of irrational evaluation by considering the main quantitative factors in previous evaluation methods.

Empirical analysis of hospital management shows that the comprehensive evaluation score of current hospital management is 71.89 while that of hospital management level needs further improvement. Particularly, administrative and financial managements have low evaluation scores and need to be improved urgently. Meanwhile, human resource management, logistical support, and medical management have general evaluation scores and also need further improvement.

Abstract

Focusing on the basic model of the riverside landscape of Chengdu's five major rivers, this paper conducts contrastive analysis on the model characteristics of urban riverside landscape, location of the city where it locates and the urban construction status and explains in detail about the relation between the formation reasons of urban riverside landscape and the level of urbanization development. It discusses the effect of urban development and residents demand on urban riverside landscape design so as to perfect the design thought about it.

Keywords: cause analysis, landscape model, correlation analysis, land property, river status

1 Introduction

Water is a resource closely connected to human life and production. Human being is born to be water-loving and "to live by the riverside" and "to build cities in places surrounded by water" was the basic principle of city construction in the ancient time. In nowadays society, urban river is playing a decisive role in urban establishment and development [1]. Owing to the high correlation of urban river with urban development and the lives of residents, human needs and human participation become particularly important in the design and formation of urban riverside landscape.

Focusing on eight most influential rivers which also spread most widely within the urban area of Chengdu, this paper conducts targeted study on the model difference of the riverside landscape models of these rivers and the forming reason of such difference in varied locations in the urban and suburban area. Paying special attention to the development status of urban riverside landscape under the integrative action of various factors such as level variance of urbanization, intra-city location difference and difference of residential demand for rivers, this paper tries to find out the general rule of urban riverside landscape development during urbanization and in the context that the degree of human participation in landscape development increases, and then discusses the development tendency of urban river landscape and the theory of man-water harmony river landscape construction of modern city.

With rainless spring and winter but rainy summer and autumn, Chengdu enjoys ample rainfalls and has a mean annual precipitation of 1,124.6 millimeters. The amount of Chengdu's annual precipitation varies little and the ratio between the maximum and minimum annual precipitation is about only 2:1. Densely covered by waterways, the city has the Minjiang River system in the southwest and Tuojiang River system in the northeast. There are more than 40 rivers in the city, covering a water area of over 700 square kilometers. The average annual water resources quantity is 30.479 billion cubic meters, of which 3.158 billion cubic meters is underground water and 18.417 billion cubic meters is transit water, can basically satisfy the needs of life, production and construction of Chengdu people and the requirements of river landscape. The Minjiang River, Tuojiang River and other ten main streams and dozens of tributaries have constituted a cross-linked river system of Chengdu of a density as high as 1.22km/sq.km; in addition to the world famous Dujiangyan Irrigation Project, various reservoirs, pools, weirs and canals are spreading all over the city.

2 Research method and definition and division of research scope

Research method: The author mainly uses field investigation, literature consultation and comparative research method to conduct a four-season one-year survey on the eight major rivers in the urban area of Chengdu. The visual language of the river landscape is finally made out of pictures and freehand sketching produced based on field shooting and on-spot section and plane drawing of the landscape pattern.

Definition and division of research scope: In terms of scope, the research involves all the river basins all over Chengdu. As for the definition of urban area, the eastern, western and northern parts are all limited by cycle-city roads. Since the city center is now moving toward south, the boundary of the southern part is where Fuhe River and Jiang'anhe River meets in Huayang Town. Then the research scope is further divided into four survey regions according to the city pattern: the intra-First-Ring-Road-region, First Ring Road-Second Ring Road region, Second Ring Road-Third Ring Road region and extra-Third-Ring-Road region.

3 Abstraction and classification of river landscape model

Abstraction of river landscape model: To be specific, the eight major rivers are the Fuhe River, Qingshuihe River, Jiang'anhe River, Shahe River, Dongfengqu River and its tributaries, Xiaojiahe River, Xiaojiahe River and Modihe River. The Fuhe River, Qingshuihe River, Jiang'anhe River, Shahe River, Xijiaohe River, Xiaojiahe River and Modihe River are natural while Dongfengqu River is artificial (illustrated with a drainage map of Chengdu urban area). First of all, according to the spatial difference of the universal space of the riparian green land, the author divides the riverside landscapes of these eight rivers and abstracts the model chart of the landscape types. The model chart includes the planar graph of each landscape type and the sectional drawing of the riverbank [2-13]. 100 models are abstracted in all, including 36 models of the Fuhe River, 24 of the Qingshuihe River, 10 of the Jiang'anhe River, 20 of the Shahe River, 14 of the Dongfengqu River and its tributaries, 4 of the Xijiaohe River, 5 of the Xiaojiahe River and 6 of the Modihe River. The Fuhe River comes from the Shidiyan Sluice of Tuanjie Town, Pixian County. At the upstream, there is the Botiaohe River- the main canal of Dujiang Dam, and the Xuyanhe River-a tributary of Zoumahe River. The water passes through the sluice and is divided into two: the left Pihe River heading the Tuojiang River and the right Fuhe Tributary (the current Fuhe River) of which the discharge capacity is 68m3 / s. The Fuhe River begins to flow southeastward at the Shidiyan Sluice and is divided into the Dongfengqu River by the left in Anjing township of Pixian County then the water flows southward into the Jinniu District of Chengdu. The monthly average discharge of the Fuhe River by the Gaoqiao reach has maintained stable in the past ten years. In Dongzikou, the water is divided to the Shahe River (which is further divided into the right Zhuantou Bam and the left Xiwa Bam) by the left and Fuhe River by the right. The monthly average discharge of the Fuhe River is 17.0 m3/ s, which reduces a bit after being split in Dongzikou. In the southeast direction, the river flows across the northern and eastern part of city center and goes through Mengzhuiwan in the east. By the right side at the Nanhe River Estuary in Hejiangting, the river includes the Nanhe River, which comes from the Qingshuihe River, the downstream of the Zoumahe River; then it passes the Jiuyanqiao Bridge and the Wangjianglou Hydrologic Station, covering an intra-regional drainage area of 505 km2. The Fuhe River has a monthly average discharge of 45.9 m3 /s by the Wangjianglou reach. Before the diversion, the average annual discharge of the Dongfengqu River is 59.1 m3 / s, which reduces to 33.7 m3 / s with 5.5 m of water level amplitude after the diversion, as shown in Equation (1):

$$Q' = \beta Q \,,\ \beta = \sqrt{L/h_a}\sqrt[4]{(2h_a - L)/h_a} \,. \tag{1}$$

Classification of river landscape model. Rivers within Chengdu urban area are classified by region, i.e., rivers of the intra-First-Ring-Road-region, rivers of the First Ring Road-Second Ring Road region, rivers of the Second Ring Road-Third Ring Road region and rivers of the extra-Third-Ring-Road region. River landscape models are compared within the research scope. Rivers with similar landscape models are included into one category, and there are ten categories of river landscape models in Chengdu.

3.1 CATEGORY 1

The typical model of category 1 is as shown in Figure 1. Region: beyond the West Third Ring Road and in the direction of the North Third Ring Road.

Major rivers: Fuhe River, Qingshuihe River & Modihe River.

Status of riparian land: Most lands are villages, towns and farmlands; low level of urbanization.

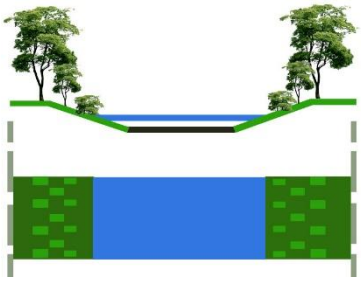

FIGURE 1 The typical model chart of category 1

Status of river: Natural rivers and watercourses; riverbanks are in near-natural status; hardly any manual damming.

Status of landscape: The river landscape is essentially natural. Habitat of the patch core is barely affected by human disturbance, and the landscape patch has high integrity, high species diversity low human participation.

Forming reason for landscape: the status of landscape within this region shows the basic human needs for rivers. Irrigation is the only requirement to be met. Hardly any manual treatment has been exerted upon the rivers.

3.2 CATEGORY 2

The typical model of category of category 2 is as shown in Figure 2. Region: beyond the East Third Ring Road and in the direction of the North Third Ring Road.

Major rivers: Dongfengqu River and its tributaries

Status of riparian land: This region was the industrial and logistics distributing area of Chengdu in the past. Today it has been transformed into a land for residential construction and commercial finance. It also involves some culture and entertainment (in construction).

Higher urbanization level than the western and northern regions beyond the Third Ring Road.

Status of river: Artificial river courses.

Status of landscape: Simple artificial landscape acces-sories and high landscape integrity. Although human

participation has been taken into consideration in the landscape design of some reaches, the level is low.

The 117km Dongfengqu River (with 71km from the Wangjianglou reach to Jiangkou reach) is about 14km long within the city and 28km long out of the city, reaching an average gradient of 1/1000. It is about 100m wide from the Shuangliu Dejiang Temple to the Er'jiangqiao Bridge and about 150m wide from the Erjiangqiao Bridge to the Huanglongxi. The widest part of the Jiandaoyan Bam reach is 265m. The 27km long Zoumahe River, 38km Long Qingshuihe River, 2km long Huanhuaxi River and 6km long Nanhe River, all together, reach a total length of 73km and an intra-regional drainage area of 305 km2. After the integrative waterway regulation of the Dunanhe River, the riverbank has got artificially-built vertical stone embankments and three rubber water dams. The Shahe River is an artificial watercourse built in the industrial zone of the eastern suburbs. After the diversion at Dongzikou, it flows along Chengdu's eastern suburbs toward the southwest and falls into the Fuhe River at around Sanwayao. The reach is about 22km. With a monthly average discharge of 16. 25 m3 / s, the Shahe River is the main source of Chengdu industry and domestic water. It spans 55m at its widest part and only 18.58m at the narrowest part. With an average depth of about 4m, the river can be 2m, 5m, 6m or 7m deep. The average annual discharge is 0.49 billion cubic meters. The total hydrologic discharge is as shown in Equation (2):

$$Q = 1.366KS\left[\frac{L+S}{\lg\frac{2b}{t_0}} + \frac{L}{\lg\frac{0.66L}{t_0} - 0.22arsh\frac{0.44L}{b}}\right]. \quad (2)$$

Forming reason of landscape.

Human needs for rivers: irrigation and human activities.

With the improvement of urbanization, simple artificial landscape begin to appear by the riverbank; human activity is taken into consideration (artificial trails)

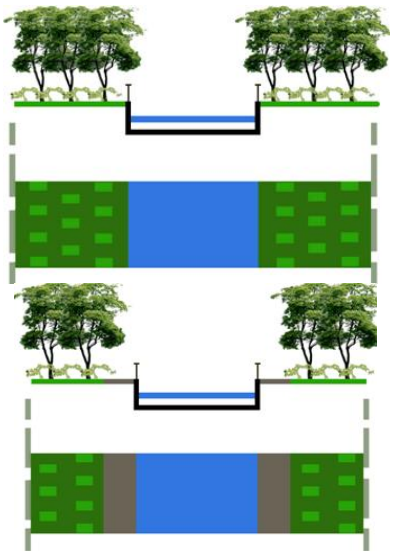

FIGURE 2. The typical model chart of category 2

Due to the factors of regional land property (industrial &logistics distributing area), human requirement for river landscape hasn't been fully considered in the initial landscape setting. Although there is human participation, the level is low.

3.3 CATEGORY 3

The typical model of category 3 is as shown in Figure 3. Region: beyond the West Third Ring Road and in the direction of the South Third Ring Road.

Major rivers: Jiang'anhe Rive.r

Status of riparian land: Most of the city-rounding water runs through farmlands and enters into the city in the direction of southwest before flowing through the residential district. The level of urbanization turns from very low to high gradualll.

Status of riparian land: Natural watercourse with both near-natural and artificially treated reaches.

Status of landscape: transformation from static natural landscape to artificial landscape model.

Forming reason of landscape:Human needs for rivers: irrigation and human activities. With the improvement of urbanization, the riverside landscape transforms gradually from static natural model to artificial model. The degree of human participation increases significantly within the landscape patch when the river flows through the residential district.

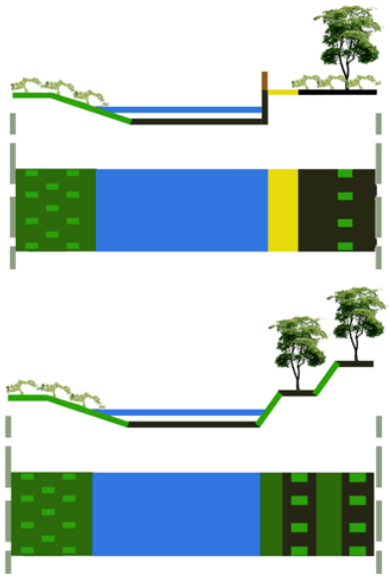

FIGURE 3 The typical model chart of category 3

3.4 CATEGORY 4

The typical model of a category 4 is as shown in Figure 4. Region: beyond the Third Ring Road toward the south of the city.

Major rivers: Fuhe River & Xiaojiahe River.

Status of riparian land: Locating in the High-tech Zone and New Tianfu Zone of Chengdu, it will become the core area of the future urban construction of Chengdu

with integrated function of residence, finance and government administration. Very high level of urbanization.

Status of river: natural rivers and complex artificial landscape after manual treatment.

Status of landscape: Large green area Particularly effective laying in landscape design. Complex landscape structure. Abundant plant species.

Since the landscapes of this region are all artificially developed and the degree of human participation is extremely high, landscape habitat suffers intense interfere. Thus, although the landscape patch covers a large and complete area, the biological diversity is low.

Forming reason of landscape:Human needs for rivers: urban style & human participation;The landscape of this region, playing an important role in city image display, is developed based on strongly goal-directed artificial modification of rivers.

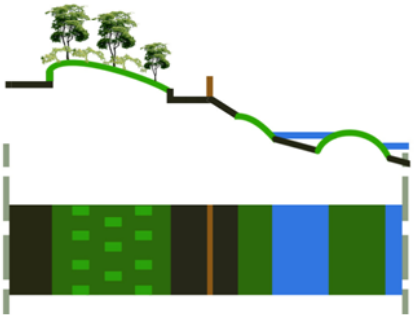

FIGURE 4 The typical model chart of category 4

3.5 CATEGORY 5

The typical model of category 5 is as shown in Figure 5. Region: between the North Third Ring Road and the North Second Ring Road.

Major rivers: Fuhe Rive.r

Status of riparian land: Residential communities increase from the Third Ring Road to the Second Ring Road. Wholesale and distributing zone of commodity and building materials. Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: Artificial landscape with low degree of human participation. Human participation hasn't been taken into consideration in the landscape design of some reaches.

Forming reason of landscape: Human needs for rivers: irrigation and human activities. Owing to the goal-oriented property of land, human participation hasn't been taken into consideration in the landscape setting of some reaches. Landscape mod1els are mixed and disorderly with low use ratio. There is no effective maintenance for the rivers and river landscape. After flowing into the residential zone, the landscape models tend to be the same and the degree of human participation in river landscape increases.

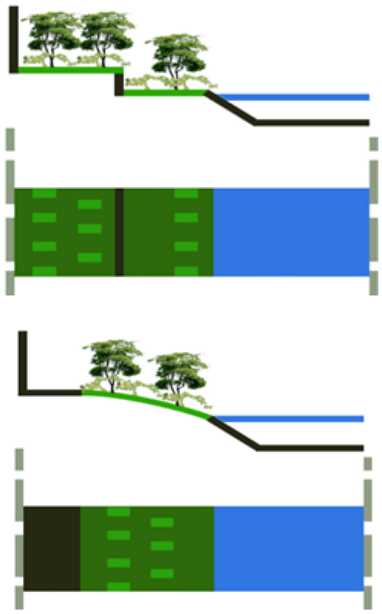

FIGURE 5 The typical model chart of category 5

3.6 CATEGORY 6

The typical model of category 6 is shown in Figure 6. Region: between the North Third Ring Road and the North Second Ring Road & between the East Second Ring Road and the East Third Ring Road.

Major rivers: Shahe River.

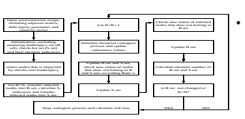
Status of riparian land: Shahe River Source Region Ecological Preservation Area, Wetland parks (Tazishan Park, etc.), Culture and entertainment industry (Eastern Music Park), Residential zone, Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: The landscape patch is large, and the green land area is larger than all the other river landscape patches of Chengdu. The degree of human participation is relatively low; it also has rich tree species, the maximum vegetation quantity and high biological diversity.

Forming reason of landscape:Original ecological (river ecological preservation area) and artificial landscapes (residential zone and city park) are cross-linked. In a natural state under artificial protection and treatment, the landscape of this region is artificial transformation based on the ecological preservation of river landscape.

The model of the landscape environment of this region is as shown in Equation (3):



(3)

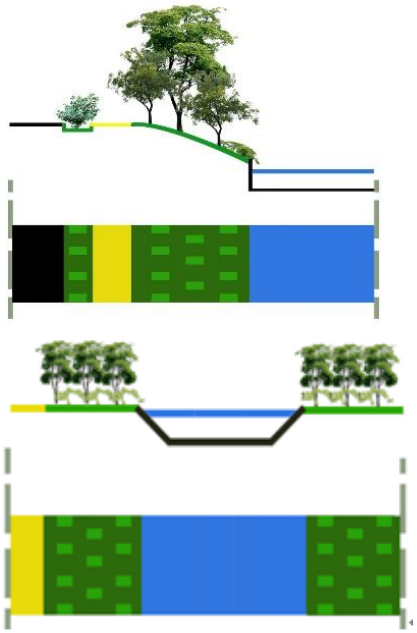


FIGURE 6 The typical model chart of category 6

3.7 CATEGORY 7

The typical model of category 7 is as shown in Figure 7. Region: between the South Third Ring Road and the South Second Ring Road.

Major rivers: Fuhe River.

Status of riparian land: Central urban area (mainly residential communities). Wetland parks. New urban zone (mainly residential communities). Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: as described in the region within the First Ring Road: Shahe River Wetland Park and New South Zone.

Forming reason of landscape: Conditions of central urban area (within the First Ring Road). Transition from protected natural state to the strongly artificially treated state beyond the Third Ring Road.

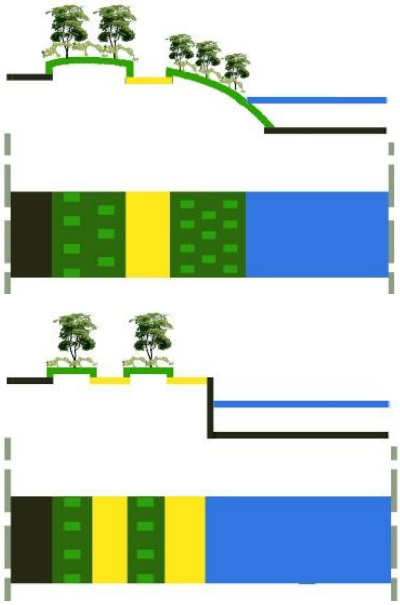

FIGURE 7 The typical model chart of category 7

3.8 CATEGORY 8

The typical model of category 8 as shown in Figure 8. Region: between the Second Ring Road to the First Ring Road.

Major rivers: Fuhe River, Nanhe River (the alternative name of the Qingshuihe River within the Second Ring Road) & Shahe River.

Status of riparian land: Central urban area (mainly residential communities). Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: narrow green areas and small patches.

Forming reason of landscape: The landscape setting is mainly human-activity and human-demand oriented. Residential land demand leads. On the premise of maximum residential lands and satisfaction of human needs for riparian green space landscape, the landscape model with small green area in landscape patch and high degree of human participation is formed.

The relation between landscape green & degree of human participation and hydrologic data is as shown in Equation (4):

$$\begin{cases} \frac{\partial}{\partial x}(K_{xx}\frac{\partial h}{\partial x})+\frac{\partial}{\partial y}(K_{yy}\frac{\partial h}{\partial y})+\frac{\partial}{\partial z}(K_{zz}\frac{\partial h}{\partial z})-W+Q_i\delta(x-x_i,y-y_i,z-z_i)=S_i\frac{\partial h}{\partial t}t \\ H(x,y,z,t_0)=H_a(x,y,z)\big|_{t=0} \\ H(x,y,z,t)=H_b(x,y,z,t)\big|_{t\neq 0} \\ K_{xx}\frac{\partial h}{\partial x}\cos(n,x)+K_{yy}\frac{\partial h}{\partial y}\cos(n,y)+K_{zz}\frac{\partial h}{\partial z}\cos(n,z)\big|\Gamma_1=0, t\geq t_0, x,y,z\in\Gamma_1 \\ K_{xx}\frac{\partial h}{\partial x}\cos(n,x)+K_{yy}\frac{\partial h}{\partial y}\cos(n,y)+K_{zz}\frac{\partial h}{\partial z}\cos(n,z)\big|\Gamma_{2,3}=q_1(x,y,z,t), t\geq t_0, x,y,z\in\Gamma_{2,3} \end{cases} . \quad (4)$$

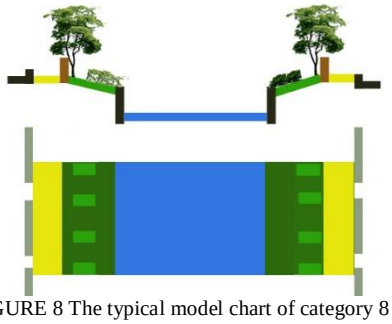

FIGURE 8 The typical model chart of category 8

3.9 CATEGORY 9

The typical model of category 9 is as shown in Figure 9. Region: within the First Ring Road.

Major rivers: Fuhe River & Nanhe River (the alternative name of the Qingshuihe River within the Second Ring Road).

Status of riparian land: Central urban area (mainly residential communities and commercial districts); Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: Landscape node accounts the most in landscape setting. It has complex node patches and simpler design of corridor landscapes that connect the nodes.

Forming reason of landscape: the landscape setting is mainly directed at city image display (landscape avenues) and human needs. City style display, landscape avenues, broad greenbelts, exquisite landscape design, abundant vegetation, complex structure and high degree of human participation.

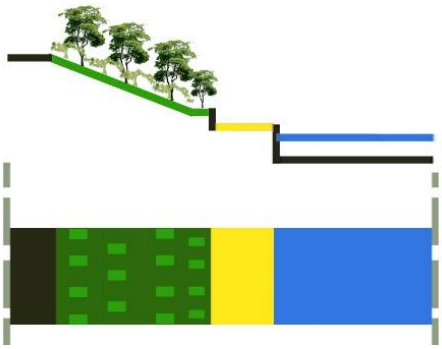

FIGURE 9 The typical model chart of category 9

3.10 CATEGORY 10

The typical model of category 10 is as shown in Figure 10. Region: within the First Ring Road.

Major rivers: Xijiaohe River and its tributaries.

Status of riparian land: Central urban area (mainly residential communities); Very high level of urbanization.

Status of river: natural rivers & artificial river landscape.

Status of landscape: Since both sides of the river landscape are very close from the residential communities, the river landscape is quite narrow. For the landscape setting, there are only very narrow green lands and one or two rows of border tree.

Forming reason of landscape: The primary goal of the landscape setting is to meet the human needs in residence and transportation, thus the width of the riparian landscape is narrow and the landscape is monotonous. The model of this category is as shown in Equation (5):

$$R = \left\{ r_0^2 + 30 \times K \times S^2 (1 + 0.00015 r_0^2) \right\}^{0.5} \quad (5)$$
$$r_0 = \sqrt{A/\pi}$$

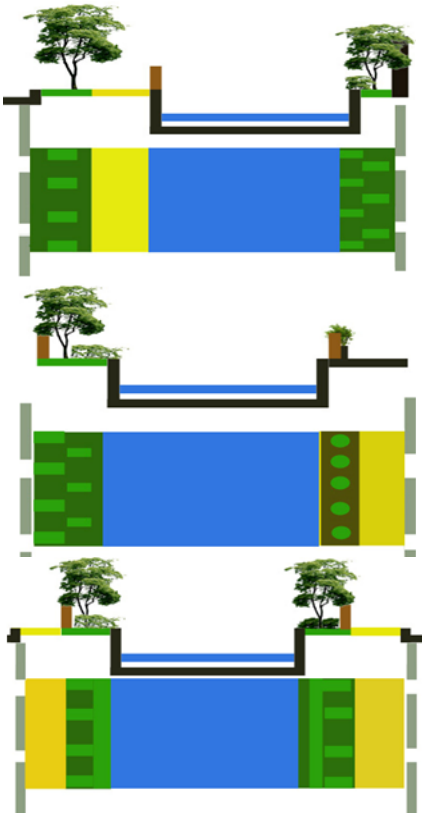

FIGURE 10 The typical model chart of category 10

4 Summary

The landscape model of urban rivers develops gradually with the urbanization process. As city develops, river landscape of areas with low level of urbanization goes through artificial transformation and gradually turns from the original state to a highly artificialized state.

With the improvement of theories of urban planning and urban landscape design, urban river landscape design changes from the old urban center model (Landscape nodes are artificially developed within the First Ring Road, and the links between nodes are weak) to the new city urban center model (large complete landscape).

Based on the correlation analysis between the status of landscape model and the property of the surrounding land, the future river landscape model of a certain region can be predicted.

River landscape models adapting to the property of various urban lands and regions with different levels of economic development can be found out through the study.

5 Conclusion

Based on the correlation analysis between the status of landscape model and the property of the surrounding land, this paper finds out various typical river landscape models under the influence of various land properties and different levels of economic development and explores the formation reasons of these models, so that referable models and practical design thoughts can be provided for the prospective river landscape design directed at different reaches of the city.

Abstract

Coal is the main energy resource in China, with its extraction and utilization playing an important role in national economic development. However, coal mining may be causative with respect to critical land subsidence and damage to land. The eastern plain coal mining region of China represents an example of overlapping crop cultivation and coal extraction, and is considered a coal mining area characterized by a high water table. Accordingly, declining ground elevation and seasonal water logging of land due to mining subsidence have become major concerns within the region. Based upon the existing procedure for land reclamation planning, both land damage boundaries and land damage magnitude were determined for the region via subsidence prediction and vertical displacement, respectively. In the current study, a coal mine in Shandong province was employed as a case study area with the following work phases implemented: 1) subsidence prediction was implemented, with land damage magnitude demarcated via the proposed standard; 2) mining induced water area and wetland was extracted via use of remote sensing; 3) comparative analyses of the aforementioned methodologies were undertaken, with a revised methodology proposed for effective provision of improved land damage demarcation. Results indicate that land subsidence at Dongtan coal mines during May 2013 was 1616.70 hm^2, of which categorically mild, moderate, and severe lands were 22.54 hm^2, 257.67 hm^2, and 436.49 hm^2, respectively.

Keywords: Landsat-8, high groundwater, mining subsidence, land damage information, subsidence prediction, damage assessment

1 Introduction

Coal mining induced mining subsidence is a pressing current issue in China as 92% of coal resources are currently extracted from subsurface mining operations [1]. Land characterized by mining induced subsidence in China reached one million hectares by late 2013 and is expected to increase at a rate of 70,000 hectares per year [2]. Regions in eastern China, including Henan province, Shandong province, Jiangsu province and Anhui province, are typified by high water tables and extensive coal mining operations, thus resulting in widespread surface water-logging. The aforementioned provinces produced a total of 230 million tons during the first half of 2014, representing 15.35% of national extraction. It is estimated that half of the land which has undergone subsidence may be entirely inundated due to high groundwater tables in parts of eastern China [3]; subsequent decreases in grain production may result from farmland having undergone subsidence.

Land damage assessment and classification is crucial for effective land reclamation and compensation, with compensatory standards based primarily on vertical displacement or water-logging extent [4,5]. The spatial extent of water-logging may vary due to topographic undulations, however, the use of vertical displacement as a single indicator for demarcation of land damage magnitude is not an appropriately accurate reflection of actual conditions.

With the recent development of remote sensing (RS) techniques, much attention has been given to subsidence boundary extraction based upon multi-source remote sensing data [6]. High resolution imagery is now customarily employed, with RS and geographic information system (GIS) technology also utilized within land subsidence monitoring [7-9]. The data used in these studies are typically high resolution imagery (e.g. Quickbird, D-InSAR or SAR) [10] and characterized by complex workflows. The Landsat-8 satellite was launched in February 2013, thus providing a new data source. Coal mining subsidence data extraction and verification in high groundwater areas based on Landsat-8 imagery and subsidence prediction may thus represent an effective and accurate reference for land compensation and reclamation efforts. Accordingly, the current study objectified the development of methodologies for coal mining subsidence data extraction based on Landsat-8 imagery and land subsidence prediction.

2 Study Area

The current study investigated the DT (Dongtan) coal mine which was developed and is managed by the Yanz-

[*]***Corresponding author's*** e-mail: xiaowuwx@126.com

hou Coal Group. The DT coal mine is located in the southwest of the Shandong province, China (Longitude; 116°50′49″ - 116°56′56″ Latitude; 35°24′11″ - 35°31′25″ (Figure 1). The natural elevation is 42-54 m above mean sea level, in concurrence with a relatively flat pre-mining geomorphology, with a higher elevation to the northwest. The region is characterized by a continental marine transitional climate, with abundant sunshine and four distinct seasons. Annual precipitation occurs within the range 259 - 1263 mm (Annual Mean 715 mm), with the majority occurring during August and September. The area encompasses five districts, spanning three counties within Jining City.

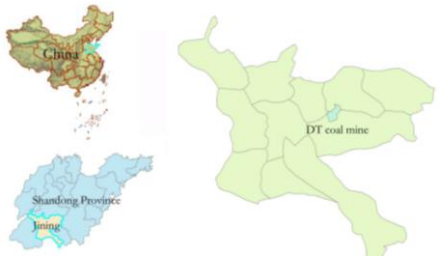

FIGURE 1 Study area: DT coal mine, Shandong province, China, with county boundaries

DT coal mine has an overall spatial extent of 59.96 km^2, and is thus one of the largest underground coal mines in eastern China, with a designed annual level of production equating to 7.5 million tons (Figure 2). By late 2010, the volume of proven coal reserves was 123.85 million tons. Due to the mines location within a highly productive agricultural district within the eastern Chinese plains, the area is characterized as a primary region for both coal and grain production. Mining activities have an inherent potential for damage to adjacent agricultural areas; accordingly, a local conflict of interest between people and land-use may arise, with land protection considered a priority. Thus, in order to effectively implement reclamation and/or compensatory measures, accurate subsidence monitoring and land damage demarcation is imperative.

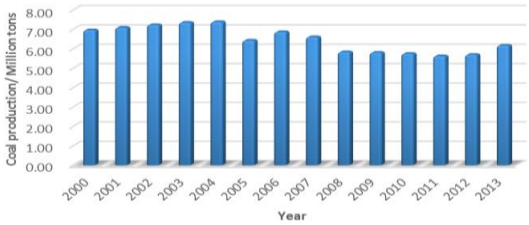

FIGURE 2 Coal production at DT coal mine from 2000 to 2013

3 Land damage magnitude

3.1 LAND DAMAGE MAGNITUDE DEMARCATION

Both surface and subsurface coal mining are characterized by potentially adverse impacts with respect to adjacent land. Subsurface mining may cause significant land subsidence, in addition to coal waste dumping at the surface. Accordingly, numerous environmental challenges arise, including soil erosion, dust and noise production, water pollution and impacts on local biodiversity. Subsided land arising from adjacent subsurface mining operations may undergo tensile and compressive forces, with subsequent horizontal and vertical displacement.

Within eastern China, due to its high mean groundwater table and relatively flat topography, the potentially adverse influence on adjacent agriculture caused by subsidence ponding is considered the most pressing issue. Thus, vertical displacement represents a key indicator for the reflection of local land damage. According to the Land Damage Assessment Rule as set out by Jining city administrative authority, subsided land may be divided into three distinct categories (Table 1), thus enabling classification of the magnitude of land damage.

TABLE 1 Land damage assessment standards in eastern China

Damage degree	Vertical displacement	Description
1 (Mild)	≤2m	Soil erosion, soil and water loss due to the changing inclination of the land
2 (Moderate)	2m~4m	Seasonal land water logging
3 (Severe)	≥4m	Water logging

3.2 DT COAL MINE LAND DAMAGE MAGNITUDE

The probability integration method of mining subsidence is the most frequently used subsidence prediction method in China; according to the probability integration method, the entire mining area is sub-divided into infinite mining units, with adverse influences caused by mine exploittation equal to the sum total of all mining units. The subsidence basins produced by mining units are represented by a normal (Gaussian) distribution and are consistent with the probability density distribution based upon stochastic medium theory. Accordingly, the subsidence profile equation represented by mine exploitation may be expressed as the integral formula of the probability density function. The subsidence basin may be expressed as follows:

$$w_e(x) = \frac{1}{r} e^{-\pi \frac{x^2}{r^2}}, \tag{1}$$

where r is the major influencing radius (primarily related to mining depth and major influencing angle). As shown in Equation (1), the functional form of the subsidence basin is analogous to the normal probability density function [11]. Based on the probability integration method, mining subsidence contours were obtained with respect to coal mining initiated from May 2013, with land damage magnitude demarcation concurrently undertaken (Figure 3).

FIGURE 3 Demarcation of land damage based on predicted vertical displacement

4 Land classification using Landsat-8 data

Landsat data have enabled continuous global monitoring of anthropogenic and natural land cover disturbance since 1972. Recent deteriorations in performance and service intermittence with respect to the Landsat-7 and Landsat-5 sensors have raised concerns surrounding the condition of global observation programs. Nonetheless, Landsat imagery remains a valuable data source for landscape change detection. Landsat-8 data are processed and presented as 185 × 180 km Level-1 terrain-corrected (L1T) products, with a 950 MB compressed GeoTiff file size (over twice that of previous Landsat L1T products). All OLI and TIRS spectral bands are stored as geo-located 16-bit digital numbers within the same L1T file [12]. All 100 m TIRS bands are re-sampled via cubic convolution to 30 m resolution and co-registered with 30 m OLI spectral bands. An associated metadata file stores spectral band gain and offset numbers that may be employed for linear conversion of digital numbers to 'at-sensor' radiance and conversion of OLI digital numbers to 'at-sensor' reflectance (i.e. unitless). Accordingly, it is not necessary to perform non-linear transformation from radiance to reflectance [13].

4.1 MATERIALS

In the current study, contemporary Landsat-8 satellite imagery with OLI Land Imager data was selected for May 21, 2013 (Path/Row No122/35, 122/36). Employed imagery included nine bands, with an associated spatial resolution of 30 m and a 15 m panchromatic band; Landsat-8 imagery increased two-band data, thus resulting in increasingly subtle division, in comparison with ETM+ imagery.

Data were subjected to both radiometric and geometric correction (UTM-WGS84 projection), with pre-treatment of raw data comprising radiometric calibration and atmospheric correction. Original images underwent integration of multi-bands and the panchromatic band, thus improving the resolution of multi-band imagery. The Gram-Schmidt pan sharpening method provided by ENVI 5.1 was employed expressed as follows:

$$HMS_i = LMS_i + w_t(HRP - LRP), w_t = \rho(LMS_i, LRP)\frac{\sigma(LMS_i)}{\sigma(LRP)}, \quad (2)$$

where *LMS* represents multispectral imagery after re-sampling, *HMS* represents multispectral imagery after sharpening, *LRP* represents low-resolution panchromatic imagery, *HRP* represents high resolution panchromatic imagery, w represents spatial detail injection coefficient, ρ represents the correlation coefficient and σ represents standard deviation.

The DT coal mine boundary vector layer was used to obtain the subset image originally acquired from Landsat-8 via overlaying the vector layer with RS imagery.

4.2 CLASSIFICATION

In order to accurately classify land use, a false color composite with Band 5, 4, 3 was selected Figure 4:

FIGURE 4 DT coal mine land use false colour composite with Band 5, 4, 3

With Bayes maximum likelihood classification function utilized for image classification. Based on fieldwork and visual interpretation of the subset image, a supervised classification was performed using a classification workflow tool on the ENVI 5.1 platform. Five land-use classes were identified including farmland, construction land, land under water, wetlands and bare land. Classification accuracy was verified via a stratified random sampling method, with 60 samples randomly distributed into five land-use classifications. Reference data were collated via fieldwork and land-use mapping. Overall classification accuracy was 80.15%. Land cover classification using Landsat-8 imagery is presented in Figure 5.

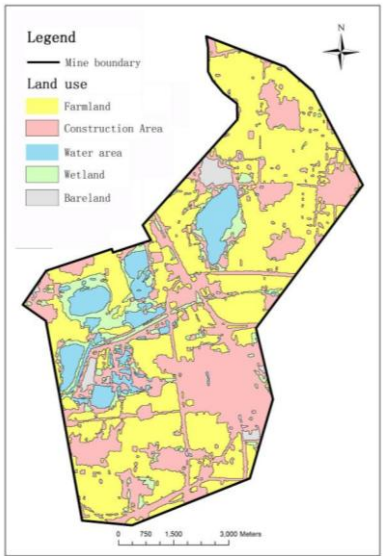

FIGURE 5 Land use classification of DT coal mine based on Landsat-8 imagery

5 Results and Conclusions

5.1 RESULTS

In accordance with the Chinese Law of Land Management, coal mining operations must undertake appropriate requisition and compensation for damaged agricultural land, based upon crop yield reduction due to mining-induced subsidence. According to the Land Reclamation Regulation (LRR), as issued and implemented by State Council, coal mines are required to provide an appropriate land reclamation plan, including identifycation of disturbed adjacent land and reclamation arrangements [14]. Lands requiring reclamation are divided into one of three functional categories (mild, moderate or severe); moderately and severely damaged lands correspond with seasonal and permanent area under water, reflected by wetlands and land under water in Landsat-8 imagery. Due to undulating topography, predicted maps developed as part of the current study cannot reflect true conditions (Figure 6).

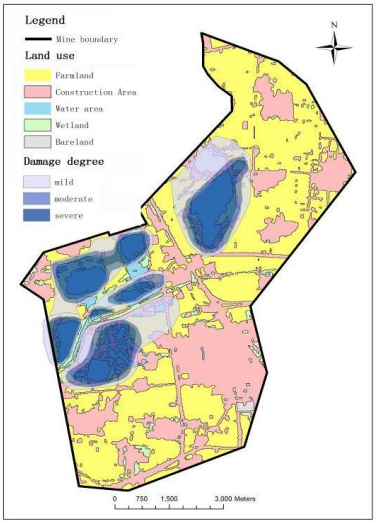

FIGURE 6 Overlapped Landsat-8 imagery and predicted vertical displacement

Results from the current study predict a total subsided area (up to May 2013) of 1616.7 hm^2 within the study area, with categorically mild, moderate and severe land damage predicted to be 622.99 hm^2, 251.44 hm^2 and 742.27 hm^2, respectively. Based upon Landsat-8 imagery extraction, the true conditions equate to 922.54 hm^2 (mild), 257.67 hm^2 (moderate) and 436.49 hm^2 (severe) (Table 2).

TABLE 2 Subsided area comparison between study predictions and Landsat-8 extraction

No	Degree	Predicted/hm^2	Extracted by Landsat-8/hm^2
1	Mild area	622.99	922.54
2	Wet land	251.44	257.67
3	Water area	742.27	436.49
Total		1616.70	1616.60

As shown (Table 2), there were significant differences noted between study predictions and Landsat-8 extractions; accordingly, a comprehensive methodology and associated workflow has been proposed in order to provide increasingly accurate land damage imagery:

1) Implementation of mining subsidence predictions based upon mine layout. Subsidence boundary obtained via 10mm vertical displacement.
2) Land use classification based upon contemporary Landsat-8 imagery, particularly with respect to wetlands and areas under water
3) Overlapping of maps obtained from Steps 1 and 2; determination of damaged land boundary from Step 1, with regions characterized by moderate and severe land damage represented as wetlands or areas under water from Landsat-8 imagery.

Via application of the proposed methodology outlined above, DT coal mine land damage demarcation was undertaken, as shown in Figure 7.

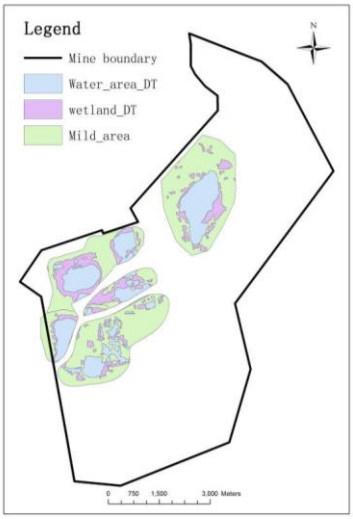

FIGURE 7 Land management map based on vertical displacement predications and Landsat-8 extraction

5.2 CONCLUSIONS

The current study presents a novel methodology for accurate determination and assessment of zones of damaged land for subsequent crop compensation, land requisition and land reclamation in the eastern plain coal mining area of China. The primary study findings and conclusions were as follows:

1) Subsidence prediction was implemented, and land damage magnitude was demarcated via the current proposed standard.
2) Mining induced areas under water and wetlands were extracted by using remote sensing technology.
3) A comparison between these two methodologies revealed that the comprehensive method could provide a more realistic reflection of conditions for subsided land demarcation. Taking DT coal mine as a case study area, the predicted subsided land total was 1616.70 hm^2, comprising 922.54 hm^2 mild, 257.67 hm^2 moderate and 436.49 hm^2 severe.

Computational model of implicit interaction for entertainment

Wei Wang*, Xiaodan Huang

School of Information & Electrical Engineering, Hebei University of Engineering, Hebei Handan 056038, China

Received 21 May 2014, www.cmnt.lv

Abstract

Implicit interaction between human and computer is worthy of being researched, especially in the entertainment application. The reason is that in order to be more natural, computers need to interact and collaborate with persons actively. For this purpose, a computational model of implicit interaction is proposed and applied to a computer for entertainment. Firstly, emotional Hidden Markov Model (eHMM) as a part of the computational model of implicit interaction is researched. Then, three parts of ACT-R cognitive architecture are integrated into it to apply for entertainment. Finally, some experiments are carried out with styles of game process recording. Results indicate that the proposed model is helpful to make computers more active and adaptive to persons by adjusting entertainment process, which illustrates a good prospect of application.

Keywords: implicit interaction, ACT-R, affective computing, entertainment

1 Introduction

In order to make the participants more focus on interactive content without interaction devices, human-computer interaction (HCI) need to be expanded from the traditional interactive style, explicit HCI (EHCI), to the ubiquitous one, implicit HCI (IHCI). This new interactive style can reduce the user's cognitive burden. So research on its theories and technologies becomes more and more important.

As a frontier of HCI area, IHCI has draw lots of attention from many research organizations [1]. Nicole Kaiyan in Swinburne University of Technology in Australia proposed the concept of IHCI in 1996, but did not research deeply [2]. Gradually, from 2005, universities and institutes in many countries, such as USA, Germany, China, Australia, and so on, studied on IHCI deeper and deeper. Albrecht Schmidt in the University of Karlsruhe in Germany worked on IHCI theories earlier. He regarded perception and interpretation as the key point of IHCI, considered that context information is extremely important for the interactive process, and modelling the interaction based on extensible markup language (XML) [3]. With computer vision technologies, Andrew Wilson and Nuria Oliver in Microsoft Research of the USA developed four systems to realize IHCI process [4]. In 2007, adaptive vision system was developed by Tao Linmi in Tsinghua University in China, which can detect and understand users' behavior through implicit interactive style [5]. At the same time, Tian Feng in the Institute of Software, Chinese Academy of Sciences, researched on the implicit interaction features from the aspect of post-WIMP [6]. The development of IHCI is sorted as shown in Figure 1.

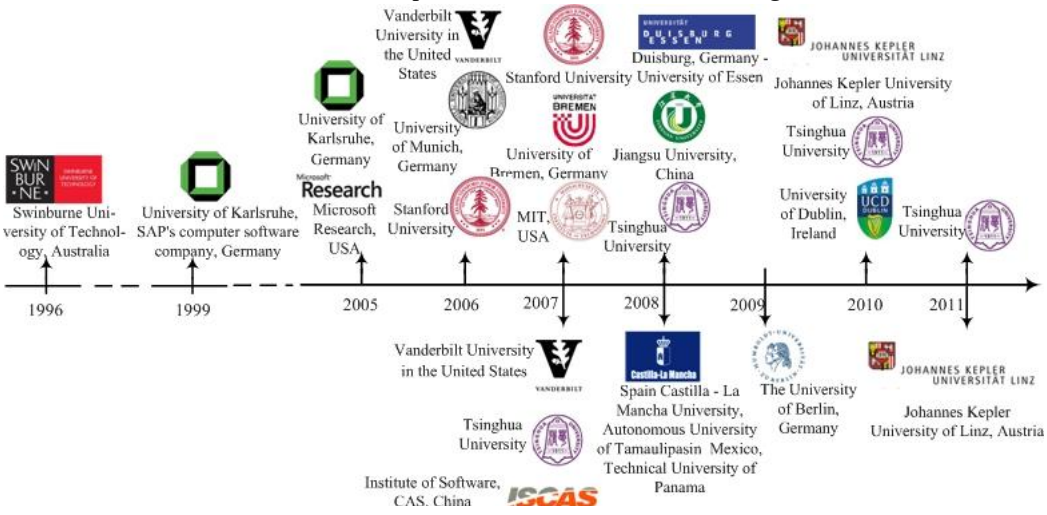

FIGURE 1 Developing process of IHCI

*Corresponding author's e-mail: wangwei@hebeu.edu.com

Entertainments also need the IHCI. With users' context information, such as behavior, emotional states, physiological status, location, and et al, the amusement quality can be improved by context perception and interpretation.

The rest of the paper is organized as follows. In Section 2, a brief literature review is provided on affection modeling and cognitive-affective interactions in entertainment. Section 3 presents a computational model of implicit interaction for entertainment based on adaptive control of thought-rational (ACT-R) cognitive architecture model. Section 4 discusses realizations of a card and a chess playing processes with the model above, analyzes the real experiment results and compare with the processes without the model. Section 5 provides the conclusions and the future work.

2 Related Works

2.1 AFFECTION MODELING

Currently, there are lots of affective models proposed by international and national research institutes. For instance, the OCC affective model is the first one for computing and used more widely [26]. By analyzing various affections connecting with events in the physical world and interactions with another subject, the relations based on rules can be got. Moreover, the theory of OCC affective model also suggests that the reason why affection generates includes event result, agent's action, and the feel to object.

Kismet affective model is used in a robot named Kismet, which is designed by C Breazeal in MIT [27]. It combines environment, inner stimuli with action and includes four parts. They are stimuli, evaluation, arousing and expression. Based on this model, the robot acts differently by considering outside stimuli and inner demand.

Based on the emotional psychology, Euclidean space affection model is proposed by regarding basic emotion as base vector [7]. In the affection space, the author discusses transition between one emotion and the other. But this model is a discrete one. Teng models the affective changing process by using Markov chain and hidden Markov model in probability space [8]. Affective transition can be described well whatever stimuli happen or not.

Moreover, Salt & Pepper model proposed by Botelho [9], affection model of a humanoid robot WE-4R researched in Waseda University [10], and some ones based on random event [11] and self-organization theory [12] are also discussed by researchers with different views.

2.2 COGNITIVE-AFFECTIVE INTERACTIONS IN ENTERTAINMENT

With the development of cognitive and affective computing, related theories and technologies apply in the human computer interactions. There are two ways bringing cognition and affection into entertainment application. One is analyzing the human being's affection [13-15], the other is integrating cognitive-affective model into the application [16-18]. In search of suitable methods for measuring the affective state of video-game players, Jonathan Sykes investigates the hypothesis that the player's state of arousal will correspond with the pressure used to depress buttons on a gamepad. A video game was created that would detect the force of each button press during play. It was found that as the difficulty level of the game increased, players would hit the gamepad buttons significantly harder [13]. Abdullah Al Mahmud propose to incorporate psycho-physiological measurements as a part of the gaming experience, and to integrate a desktop game within its real surrounding (i.e., the entire room) in order to promote more physical activity [14].

Moreover, in AI (Artificial Intelligence) game, authentic behaviours of NPC (Non-Player Character) are great challenges to NPC intelligence. Emotions help to enhance the quality and intelligence of behaviours, contribute to increase entertainment value of game. Zhou and Yu describe several common emotional behaviours of NPC, construct a simple emotion-behaviour model for emotion transition, and simulate in their developing project [15]. The quality and intelligence of NPC's behaviours are improved by the emotion to increase the game entertaining. And Munoz K is focused on a qualitative and quantitative approach to recognizing the learner's achievement emotions. Learners' emotions are inferred from two sources: from observable behaviours and from answers to questions in a game dialogue. The analysis and design involved in the creation of this affective student model are the central focus here. PlayPhysics, an emotional games learning environment, is being implemented for teaching Physics at undergraduate level. When our results are finalized our affective student model will be incorporated into PlayPhysics. To ensure accuracy of the recognition method, a preliminary prototyping study has been conducted. The results from this prototyping phase are presented and discussed [16].

Yannakakis provides taxonomy of PCG algorithms and introduces a framework for PCG driven by computational models of user experience. Personalization of user experience via affective and cognitive modelling, coupled with real-time adjustment of the content according to user needs and preferences are important steps toward effective and meaningful PCG. Games, Web 2.0, interface, and software design are among the most popular applications of automated content generation.

Wang proposed a method to investigate the effects of Cognitive Affective Interaction (CAI) strategy on novices' creative performance in game design. The CAI strategies, including the visualization and the discrepancy strategies, were administrated and served as the experimental treatment [18].

3 Computational Model Generation

3.1 OVERVIEW

IHCI required equipment, hardware and software, to provide active services. Moreover, the users are no longer focused on the task process, and only receive services without notice. So building a computable model of human cognitive behaviours is necessary in order to organize knowledge and produce intelligent behaviours in ICHI. ACT-R (Adaptive Control of Thought-Rational) cognitive architecture, proposed by the American psychologist Anderson in 1976, is widely used to simulate different aspects of the human being's cognition behaviours, such as perception and attention, learning and memory, problem solving and decision making, language processing, intelligent agents, intelligent tutoring systems, and human-computer interaction. Because its characteristics fit needs of the implicit interaction precisely, we can build a computable model of human cognitive behaviours, which is based on ACT-R cognitive architecture for different applications, to realize implicit human-computer interaction and improve interactive quality effectively.

This paper focuses on IHCI in entertainments. By designing ACT-R production rules and bringing in emotional factors, computable model of IHCI for entertainment is established as shown in Figure 2.

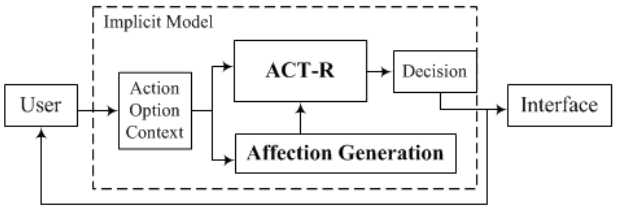

FIGURE 2 Computational model of implicit interaction for entertainment

The devices acquire inputs by users in entertainment, such as behaviours, selections, and situations. Under the influence of emotions, judge user's implicit interaction information after pattern matching and reasoning with ACT-R. And then adjust the interaction process adaptively to improve interaction quality. It is obviously seen that the realization of the model contains two main parts: 1) the generation of machine emotion; 2) the design and implementation of implicit interaction computable model based on ACT-R cognitive architecture in entertainment.

3.2 AGENT AFFECTION

To simulate the emotion generating and changing of human being, an affective model is necessary. As stated above, given the computable feature, we select one named eHMM, for emotional stimuli transferring process proposed in [15] as an emotional engine.

Based on a probability space, Teng regarded an emotional stimuli transferring process as a random one which could be described using hidden Markov model [15]. In other words, a quintuple form determines the model, where N is the number of emotional dimension; M is the number of stimuli type; is an initial emotional state vector; is a state transferring probability matrix, which is calculated by:

$$\hat{A}=\{\hat{a}_{ij}\}_{N\times M}=\begin{bmatrix} \frac{\hat{\theta}\hat{\pi}_1^*-(N-1)}{\hat{\theta}\hat{\pi}_1^*} & \frac{1}{\hat{\theta}\hat{\pi}_1^*} & \cdots & \frac{1}{\hat{\theta}\hat{\pi}_1^*} \\ \frac{1}{\hat{\theta}\hat{\pi}_2^*} & \frac{\hat{\theta}\hat{\pi}_1^*-(N-1)}{\hat{\theta}\hat{\pi}_1^*} & \cdots & \frac{1}{\hat{\theta}\hat{\pi}_2^*} \\ \vdots & \vdots & \cdots & \\ \frac{1}{\hat{\theta}\hat{\pi}_N^*} & \frac{1}{\hat{\theta}\hat{\pi}_N^*} & \cdots & \frac{\hat{\theta}\hat{\pi}_N^*-(N-1)}{\hat{\theta}\hat{\pi}_N^*} \end{bmatrix}, \quad (1)$$

where, $\hat{\theta}$ is a parameter that will be discussed later. $\hat{\pi}^*=[\hat{\pi}_1^*,\hat{\pi}_2^*,\cdots,\hat{\pi}_N^*$ is a limiting probability. $\hat{B}_{N\times M}$ is an observation matrix, supposing that $M=N$ in this paper, it could be deduced that:

$$\hat{B}=\begin{bmatrix}\hat{B}_1\\ \hat{B}_2\\ \vdots\\ \hat{B}_N\end{bmatrix}=\begin{bmatrix} a & b & \cdots & b\\ b & a & \cdots & b\\ \vdots & \vdots & \cdots & \vdots\\ b & b & \cdots & a\end{bmatrix}, \quad (2)$$

Where $\begin{cases} a=\dfrac{r}{N-1+r}\\ b=\dfrac{1}{N-1+r}\end{cases}$, $r>1$, r is a parameter that will also be discussed later.

The user's current behaviour reflects the current level during entertainment. If the current user's behaviour indicates that the entertainment level is higher, the computer treats the entertainment process with caution, and is of positive machine emotion. Otherwise, it indicates that user's entertainment level is not high. The computer generates negative emotions. Based on the eHMM, for emotional stimuli transferring process, emotional value can be got by positive and negative stimulus, which shows the user's current entertainment level.

3.3 MODEL CONSTRUCTION

For the implicit interaction in entertainment applications, three parts of ACT-R cognitive architecture, basic modules, buffering, and pattern matching, are designed as shown in Figure 3. The first part, basic module, has two types of sub-modules. They are a motion perceiving sub-module, which is responsible for interacting with the outside world, and a memory sub-module. The input information of this module is user's mouse or keyboard actions and selecting tendency; and the output is visual and auditory information, including reminders and evaluation for user's entertainment process and feedbacks after entertaining. The second part, buffer, is an interface for generation rules interacting with other basic module. And the contents in buffer identify the current status of ACT-R.

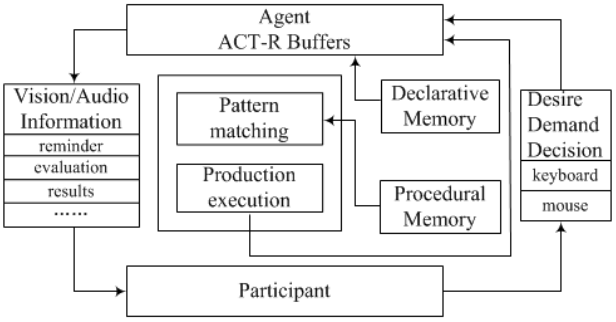

FIGURE 3 Three parts of ACT-R cognitive architecture

The third part, pattern matching, is implemented based on fuzzy inference. Suppose language variables are: the total number of errors X_1, the maximum number of consecutive errors X_2, the average time for thinking X_3, the user's historical entertainment level Y. And the corresponding universes are

$$U_{X1} = U_{X2} = \{x_i | 0 \le x_i \le Sup, x_i \in \aleph\},$$
$$U_{X3} = \{x_3 | 0 < x_3 \le Sec, x_3 \in \Re\},$$
$$U_Y = \{y | 0 < y \le Gra, y \in \Re\},$$

where Sup, Sec and Gra are the maximum number of errors, the maximum time for thinking and the highest user's entertainment level. Their values are determined according to different applications. Linguistic variables are $T(X_1) = T(X_2) = T(X_3) = few + middle + many$ and $T(Y) = low + middle + high$. So the fuzzy sets of the total number of errors X_1 and the maximum number of consecutive errors X_2 are determined as below:

$$F_{xi}^{few} = [few] = \sum \frac{\mu_{Xi-few}(x_j^i)}{x_j^i} = \sum_{j=0}^{Sup} \frac{\left[1 - \frac{1}{Sup} j\right]}{x_j^i}, \quad (3)$$

$$F_{xi}^{mid} = [middle] = \sum \frac{\mu_{Xi-mid}(x_j^i)}{x_j^i} = \sum_{j=0}^{Sup/2} \frac{\left[\frac{j}{Sup/2}\right]}{x_j^i} + \sum_{j=Sup/2}^{Sup} \frac{\left[2 - \frac{j}{Sup/2}\right]}{x_j^i}, \quad (4)$$

$$F_{xi}^{many} = [many] = \sum \frac{\mu_{Xi-many}(x_j^i)}{x_j^i} = \sum_{j=0}^{Sup} \frac{\left[\frac{1}{Sup} j\right]}{x_j^i}. \quad (5)$$

The fuzzy set of the average thinking time X_3 is,

$$F_{X3}^{few} = [few] = \int \frac{\mu_{X3-few}(x)}{x} = \int_{0<x\le Sec/4} \frac{1}{x} + \int_{Sec/4<x\le Sec} \frac{\left[1 + \left[\frac{(x - Sec/4)}{10}\right]^2\right]^{-1}}{x}, \quad (6)$$

$$F_{X3}^{mid} = [middle] = \int \frac{\mu_{X3-mid}(x)}{x} = \int_{0<x\le Sec} \frac{\left[1 + \left[\frac{(x - Sec/2)}{10}\right]^2\right]^{-1}}{x}, \quad (7)$$

$$F_{X3}^{many} = [many] = \int \frac{\mu_{X3-many}(x)}{x} = \int_{0<x\le 3\times Sec/4} \frac{\left[1 + \left[\frac{(x - 3\times Sec/4)}{10}\right]^2\right]^{-1}}{x} + \int_{3\times Sec/4<x\le Sec} \frac{1}{x}. \quad (8)$$

The fuzzy set of the user's historical entertainment level Y is,

$$F_Y^{low} = [low] = \int \frac{\mu_{Y-low}(y)}{y} = \int_{0<y\le Gra/4} \frac{1}{y} + \int_{Gra/4<y\le Gra} \frac{\left[1 + \left[\frac{(y - Gra/4)}{10}\right]^2\right]^{-1}}{y}, \quad (9)$$

$$F_Y^{mid} = [middle] = \int \frac{\mu_{Y-mid}(y)}{y} = \int_{0<y\le Gra} \frac{\left[1 + \left[\frac{(y - Gra/2)}{10}\right]^2\right]^{-1}}{y}, \quad (10)$$

$$F_Y^{high} = [high] = \int \frac{\mu_{Y-high}(y)}{y} = \int_{0<y\le 3\times Gra/4} \frac{\left[1 + \left[\frac{(y - 3\times Gra/4)}{10}\right]^2\right]^{-1}}{y} + \int_{3\times Gra/4<y\le Gra} \frac{1}{y}, \quad (11)$$

The production rules for pattern matching are shown in Table 1.

The inferring part of this ACT-R model infers user's historical entertainment level, which demonstrates the user's whole performance in entertainments, with the total number of errors, the maximum number of consecutive errors and the average thinking time. Moreover, consi-

dering the user's current entertainment level, which is demonstrated by computer's emotion, the computer's entertainment level is determined. The level is able to change dynamically with the user's whole entertainment level to enhance the playability entertainment process and improve the quality of human-computer interaction.

4 Experimental and analysis

In this paper, we use the computational model of implicit interaction in horn chess playing entertainment. Firstly, introduce the method to use it, and secondly, analyze results after several rounds. It is called Horn Chess because the board looks like a horn shown in Figure 4.

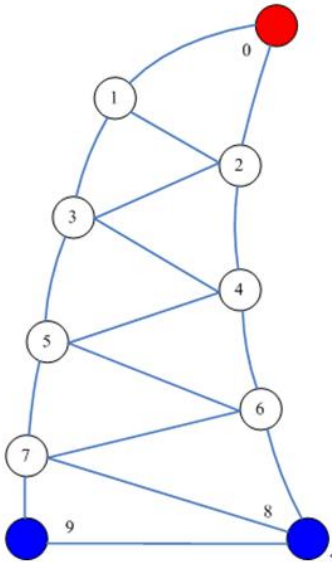

FIGURE 4 Board of horn chess. Positions (0-9) are marked to state conveniently.

On the checkerboard, there are three pieces. One player takes the red, and the opponent takes the blue. The initial pieces position is shown in Table 1. Two players move in turn. And they can only move forwards or backwards one step along lines, rather than no crossing over a piece or moving to the position where there is a piece. If the player taking the blue forces player taking the red to a dead end (position 0 in the board), the former wins. And if the player taking the red could run away to position 8 or 9 of the board, he wins. In order to keep balance, when a new game starts, the player, who takes the red piece, moves first.

4.1 DESIGN OF PLAYING PROCESS WITH IHCI

In this paper, we discussed implicit interaction in Horn Chess gaming based on the affective model for entertainment above. First of all, we suppose the computer has emotion. And in the game process, when the player has an excellent move, or the computer predicts his human opponent's move correctly, the computer's emotion is affected. As we know, it usually influences the computer's next moving strategy to produce excellent or bad move. The game-tree searching algorithm adopts a depth-first mini-max method which is embedded  pruning technique in. Because this paper focuses on the implicit interaction problem of gaming process, the details on game playing algorithm is not discussed more.

In order to manifest the Horn Chess playing process obviously, we named the two chess players, a person and a computer, Alice and Bob respectively. So affecting by the person's entertainment level, the whole process repeats two basic steps. One is Bob's move; the other is Alice's move. Two steps are designed as shown briefly in Figure 5.

The left part of the figure shows that human and the computer move in turn. The process is described as follows:

Step 1: Bob calculates optimal move according to the maximum depth *Maxdeep* based on a game-tree searching algorithm. While searching to the leaf of the game-tree, the best potential situation of Alice's next move is evaluated and recorded, which is signed as $Mark_{Est}$. Then, move to its optimum position. The calculating situation method is $\max\{r\times100+b_1\times10+b_2, r\times100+b_2\times10+b_1\}$, where r, b_1, b_2 are the numbers signed in Figure 4. Their values are integer in domain [0, 9] .

Step 2: Alice thinks and moves according to gaming situation.

Step 3: Bob calculates actual situation $Mark_{Act}$ after Alice moves again.

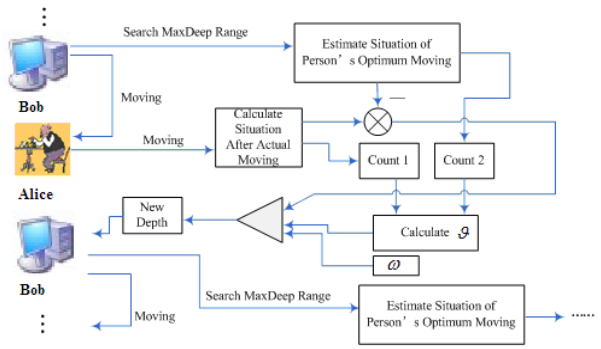

FIGURE 5 Basic steps of Horn Chess gaming affected by the person's entertainment level

Step 4: In the whole process, we need a computational model of implicit interaction for entertainment, especially for Horn Chess Game. To build this model, we can reference the mechanism of the model for Iowa Gambling Task context [19]. Stimuli intensity of emotion is calculated with:

$$I(t) = INT\left(\frac{abs(Mark_{Est} - Mark_{Act})}{\Delta Mark_{Max}} \times I_{Max}\right), \quad (12)$$

where, $\Delta Mark_{Max}$ *s* a maximum difference value of evaluating and actual situations, which could be calculated by $\delta = abs(Mark_{Est} - Mark_{Act})$. While Alice holds the red piece and Bob holds the blue ones, the maximum value $\Delta Mark_{Max}=100$ may occurs. I_{Max} is a legal maximum value of stimuli intensity. In this paper, $I_{Max}=55$. While game is continuing, given that whether $Mark_{Est}$ and $Mark_{Act}$ is equal. If yes, it is explained that Alice's game level is higher. So Bob should play carefully. And His positive emotion is stimulated. Otherwise, for Alice is bad at gaming, Bob is of proud emotion. Negative emotion $\bar{p}_{,Em}$ could be calculated with $I(t)$ based on the statements in the section 3.2 [8]. Equation (12) only shows influence on Bob's emotion caused by Alice's single move, but according to long-memory effect, historical game level scored with *Y* should be considered too.

Considering one situation that Alice plays badly both in a single step and in history, Bob becomes proud to moves unwarily. So there will be much error steps. It can be realized by diminishing the maximum searching depth *Depth* of the game-tree. Update *Depth* as:

$$Depth(t+1) = Depth(t) + \omega \cdot [y(t+1) - y(t)] \cdot \bar{p}_{Em} . \quad (13)$$

Step 5: Run the game-tree searching algorithm again with updated maximum depth $Depth(t+1)$. Repeat step 1.

4.2 EXPERIMENT AND ANALYSIS

Alice and Bob play the Horn Chess game with the rules one by one based on the computational model of implicit interaction above. In order to avoid the searching depth increasing continually, we set the maximum searching depth is 15. As stated above, while stimuli occur and Alice's historical entertainment level is calculated, it could be clearly seen that Bob's emotions is stimulated. And then it influences on his decision-making, such as adjustment of maximum searching depth, width or something else. This paper focuses on the adjustment of maximum searching depth. It changes along with Alice's game level dynamically. Explicit and implicit interactions coexist too.

Alice and Bob carry on a gaming process four times which are Bob moves first and Alice moves first separately, shown in Table 2, 3. To show the experiments result obviously, six aspects, such as the move, the best potential situation of Alice's next move estimated by a Bob $Mark_{Est}$, the actual situation $Mark_{Act}$ after Alice moves, Bob's negative emotion $\bar{p}_{,Em}$, Alice's historical playing level *y* and the self-adjusting maximum searching depth $Depth(t+1)$ are recorded.

In the gaming process recorded in Table 2(b), B represents Bob's moving step, and A represents Alice's moving step. Bob moves first. Taking the first row for example, from row view, B: 0→1 A :(8, 9) → (7, 9) indicates that Bob holds the red piece, and moves from position 0 to position 1 according to Figure 4. Simultaneously, Alice holds blue pieces. One of his pieces moves from position 8 to position 7. And the other keeps still. After Bob's moving, the best potential situation of Alice's next move is estimated, $Mark_{Est}=169$, which is corresponding to Alice's best move. Then, Alice moves, and Bob calculates the current actual situation $Mark_{Act}=179$. While the negative emotion $\bar{p}_{,Em}=0.80624$ and Alice's historical playing level is set to 0.5 initially, we can obtain the maximum searching depth $Depth(t+1)=8$ with the model above.

In addition, the smaller situation is, the more advantaged to Alice's move is according to the min-max game-tree searching theory, when Bob moves first from column view. Alice usually does not move best. So, generally speaking, the actual situation $Mark_{Act}$ is larger than $Mark_{Est}$. That is $Mark_{Est} \leq Mark_{Act}$. When Alice's move is not the best one estimated by Bob, his proud emotion is stimulated. The negative emotion $\bar{p}_{,Em}$ is larger than its initial value (0.5). Moreover, the worse move is, the larger $\bar{p}_{,Em}$ is. When Alice's gaming level is lower, and Bob is proud, Bob reduces the maximum searching depth automatically. Otherwise, the searching depth will be increasing to reflect that emotion and historical game level influences on entertainment process. Similarly, another experiment process in which Bob moves first is recorded in Table 2(a). The analysis to this continued table is the same as statement above.

TABLE 2 Gaming process when Bob moves first

When Alice moves firstly, recorded in Table 3, the bigger situation is, the more advantaged to Alice's move is according to the min-max game-tree searching theory, when he holds the red piece from column view. Moreover, Alice usually does not move best. So, actual situation $Mark_{Act}$ is smaller than $Mark_{Est}$. The rest analysis is the same as Table 2.

Moreover, record the detail information of four experiment processes above to contrasting and analyzing. They are total number of errors x_1, the maximum number of consecutive errors x_2, and the average thinking time x_3. With their maximum values shown in Tables 2 and 3, the percentages (TE, MCE, ATT, MaxSD, and MinSD) can be calculated and demonstrated in Figure 6. TE, MCE, ATT, MaxSD, and MinSD means the percentage of total number of errors, the percentage of maximum number of consecutive errors, the percentage of average thinking time, the percentage of maximum searching depth and the percentage of minimum searching depth respectively.

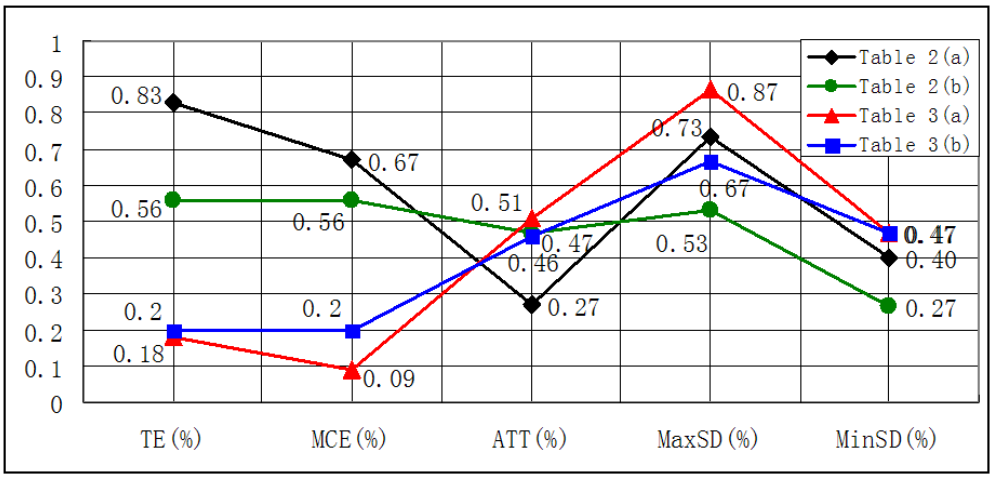

FIGURE 6 Statics of the four gaming processes

In this figure, five percentages of every experiment are put together. No matter Alice or Bob moves firstly, generally speaking, MaxSD and MinSD are bigger when TE, MCE and ATT are smaller, which means Alice is good at gaming and has a high level in entertainment, so Bob must take the game process seriously by thinking deeply. But for the line of Table 2(a), because ATT influences more than TE and MCE, MaxSD and MinSD are getting bigger.

5 Conclusions

In this paper, a computational model of implicit interaction based on emotional Hidden Markov Mode (eHMM) and ACT-R cognitive architecture is devised, which will be used for human computer interaction or corporation, especially for entertainment. We considered the influence of agent's affection and cognition. So eHMM and ACT-R are merging with each other.

The focus of present research is how to construct a hierarchical structure to link agent's affection and cognition. From our point of view, agent's affective state is influenced by current behaviors coming from the inner world and environment. It makes agent react rapidly. Moreover, because of memory and inference, cognition reflects long-term influences. So we integrated them together. No matter in simulation experiments or in practice, there are good results. The proposed model is effective.

Construction and effect evaluation of the college English multimedia teaching system based on the Blended-learning model

Jingtao Liu*

Foreign Language Department, Heze University, Heze 274000, Shandong, China

Received 13 September 2014, www.cmnt.lv

Abstract

As network technology develops, an increasing number of new technologies and concepts have entered the traditional college teaching system. To improve the education quality and level of domestic college English, as well as to meet the demand for the reform of domestic college English education, the Blended-learning model is introduced to construct a new multimedia teaching system based on the traditional multimedia teaching model of college English. Moreover, a questionnaire analysis is conducted among all staff members that participate in the new multimedia teaching system. Questionnaire analysis indicated that the construction of the Blended-learning model-based traditional multimedia teaching system of college English proposed in this study is practically operable. The effect of this model is significantly better than that of the traditional English teaching model.

Keywords: Blended-learning model, college English, multimedia teaching, system construction

1 Introduction

The first specification on subjects included in the college entrance examination in China is *Provisions on New Students Recruitment of Higher Institutions in the Summer of 1950*, which can be dated back to 1950 [1]. This specification was a programmatic document for English examination instructions in college entrance examinations. Since the reformation and opening up, the national economy has rapidly developed, the public has directed increasing attention toward English [2], initially from senior English at to junior English, primary English, kindergarten English, and even bilingual teaching (refers to English solely) [3], which undoubtedly highlights the importance of English. Since the recovery of the college entrance examination system in 1977 [4], considerable progress has been made in English in terms of continuous learning and reform. Gradually, as a group of freshmen enters university and a wave of graduates enters society, many employers [5], enterprises and scientific research institutes have gradually found that the English level of college students is not direct proportional to English learning time. Many college students learn English just to learning [6]. The starting point seriously deviates from the concept and essence of English teaching. Some students even abandon learning, which has gradually aroused discussion in domestic society and in the education department regarding the reform of English education [7]. Higher institutions should continue to be relevant as well as improve the teaching environment and learning effect through information technology and network technology while relying on education informatization [8]. With this background, in combination with the Blended-learning model that has recently emerged, the author has researched and analyzed the Blended-learning model to construct the existing college English multimedia teaching system innovatively through actual investigation. Meanwhile, all staff members who participated in the construction of this system are involved in the investigation. The actual construction effect is evaluated and analyzed using a questionnaire to provide a preliminary exploration of the construction of the college English multimedia teaching system based on the Blended-learning model.

2 Analysis on Blended-learning model

The blended-learning model was introduced by foreign enterprises, which trained their clerks involved in income and profits. In other words, this model was used to reduce input and make the enterprises gain more profits through training [9]. Domestic educators also call it mixed learning. The key learning objective of Blended-learning is optimization, i.e., the use of appropriate learning skills and methods at appropriate times and with appropriate targets to adapt to and match appropriate learning target habits to convert them into appropriate skills [10].

2.1 BASIC CONCEPT

In domestic education, Professor He Kekang of Beijing Normal University introduced the concept of "Blended-learning." Professor He believes students can only become the subject of learning when new information technology (network or digital or information learning) and the advan-

* ***Corresponding author's*** e-mail: liujingtao22@yeah.net

tages of the traditional learning method are combined [11]. Moreover, the enthusiasm of students can be fully stimulated and their enthusiasm, initiative, and creativity can be included in the process of learning. Teachers can also optimize their roles in guiding, monitoring, and enlightening students when they take the lead. As a result, the process of teaching and learning becomes more saturated and enriched, and the learning effect is optimized. This consensus has been uniformly recognized in the field of domestic education.

2.2 ELEMENTS

In short, the blending-learning model includes face-to-face learning and online learning. However, the two are not single or interdependent. Before the college English multimedia teaching system based on blended-learning was constructed, the components of Blended-learning model must first be introduced and clarified. By doing so, college English multimedia teaching system of Blended-learning model combined with practice can be constructed.

Blended-learning model is divided into two parts: off-line learning and online learning (Table 1).

TABLE 1 `Blended-learning model module classification and comparison of advantages and disadvantages

Module name	**Offline learning (traditional class)**	**Offline learning (E-learning)**
Main characteristics	Teacher oriented, dominated by knowledge impartation	Teaching by internet or in digital form
Advantages	➢ Beneficial to motivating teachers to take the lead ➢ Beneficial to cultivating student cooperation ➢ Beneficial to cultivating student competition awareness ➢ Beneficial to cultivating student's sense of collectiveness ➢ Beneficial for communication between teachers and students and optimizing affectivity in learning	• Wide coverage, flexible transmission means • Learning is not limited by time and space • Rich learning resources • Self-planning, individual learning
Disadvantages	➢ Excessive emphasis on uniformity, rigid ➢ Easily ignores students' independence ➢ Easily ignores students' uniqueness ➢ Excessive reliance on teachers' capability ➢ Limited learning scale	• Teachers and students have less time fact-to-face • Aloof teachers and students • Learners learn alone • Students require strong self-learning and discipline

2.3 LEVEL AND STAGE DIVISION

Blended-learning model can be divided into different learning levels and learning stages, as shown in Table 2.

TABLE 2 learning level division of Blended-learning model

Complexity	**Specific contents and forms**	**Specific roles**
Simple ↓ Complex	Rapid approach to releasing course information and implementing course management	Learning content support
	Method for visiting additional online materials	
	Provides communication between teachers, students, and other relevant personnel	Learning activity and evaluation support (basic knowledge learning)
	Provide computer assisted learning support	
	Have more test exercises and implement summative beginning	
	Provide practical opportunity and extra support for in-school students	Learning activity and evaluation support (senior knowledge learning)
	Student coordination platform based on project learning	
	Transmit complete online courses with completely comprehensive activity	Typical online learning

Although Professor He Kekang has introduced the concept of Blended-learning for some time, it has been applied and popularized in China. His research mainly concentrated on principle, design, and strategy. However, through the domestic researches and according to close combination of learning mode, the application of the blending learning model can be roughly divided into four stages [5] according to the level division above, as shown in Table 3.

TABLE 3 Learning stage division of Blended-learning model

Stage	**1st stage**	**2nd stage**	**3rd stage**	**4th stage**
Representation form	Combination level	Integration level	Coordination level	Expansion level
Description	• Different learning models are simply combined • No correlation between learning modes	• Different learning modes are combined into a correlative structure • Learning modes supplement each other	• The agglomeration method between learning modes is higher • Learning objective oriented	• Learning is combined with practice through various means
Application	• Relatively simple form • Adapts to perfect online learning schools	• Learning contents and methods must be planned in detail • A simple means for activity evaluation must be established	• A more detailed plan must be established • Centered on the learning objective	• Combines learning with practice centered on learning personnel • The system is optimized and various learning methods are combined to promote learning objectives and accurately master the effect of learning

3 Research on college English multimedia teaching system structure based on Blended-learning model

After analyzing the Blended-learning model, we aim to determine how to recognize the blended-learning model and introduce it to the college English multimedia teaching system. By doing so, we can construct a good college English multimedia teaching system.

3.1 RESEARCH TARGET AND INVESTIGATION ANALYSIS

A university in China was selected for investigation. Tracking analysis was conducted from September 2013 for a term. English teachers and students, assisted by relevant education institutions of schools, dominated the investtigation targets.

3.1.1 English teacher investigation analysis

The key factors that influence the construction of the college English multimedia teaching system under blended-learning are found from the preliminary investigation result. By analyzing the actual investigation result, different influential factors are subject to unified optimal management and are organized in a coordinative manner. The factors that disturb the construction of the multimedia teaching system effect are eliminated. Moreover, the proportion of factors beneficial for realizing teaching objectives is increased to realize dynamic adjustment gradually (Figure 1-4).

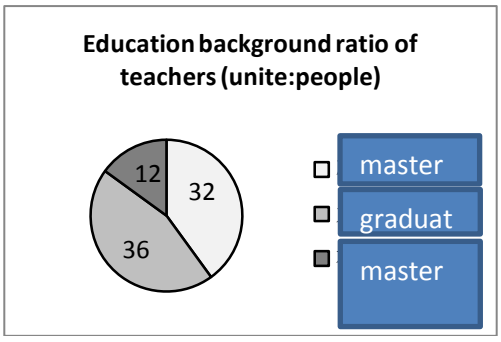

FIGURE 1 Education background ratios of teachers

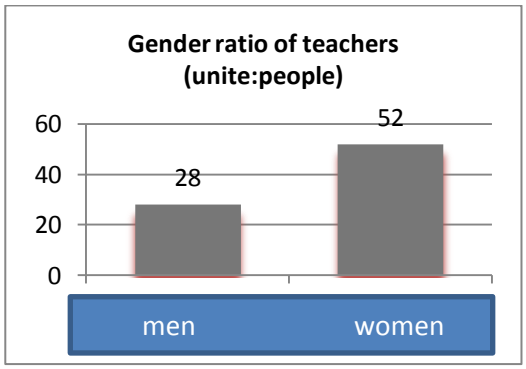

FIGURE 2 Gender ratio of teachers

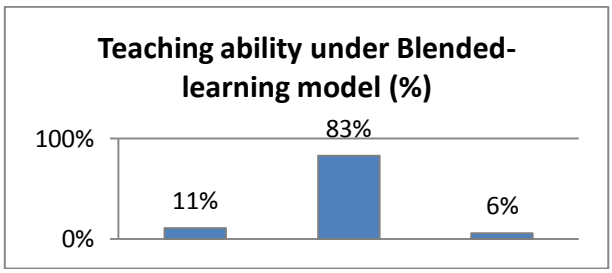

FIGURE 3 Satisfaction of teaching capacity under Blended-learning model

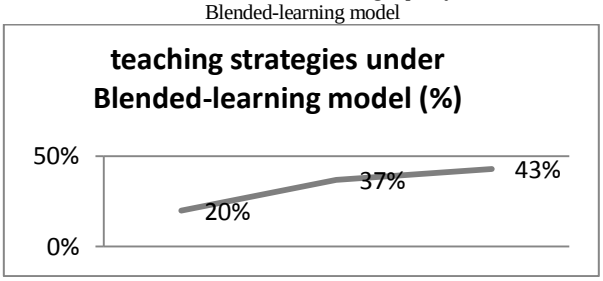

FIGURE 4 Use of teaching strategies under Blended-learning model

The basic information of the teachers selected as research targets can be roughly determined. Many factors from this information influence the success and effect difference of college English multimedia teaching system construction under Blended-learning model.

3.1.2 Investigation analysis on students and relevant teaching reform departments

The students selected were all freshmen that entered the university in September. A total of 60 students from two English major classes were selected, and 60 students from one science and engineering class. For the students that participated in the research, statistical analysis on the factors that might influence the teaching effect under the blended-learning model was conducted through a questionnaire. An English admittance scores examined students' capability to accept fresh concepts, self-discipline capability, self-learning capability, network knowledge acquaintance and multimedia acquaintance. An overall statistical analysis was also conducted. The 120 students were divided into several small classes according to their specific statistical result. The difference among students was minimized for the benefit of uniform planning, teaching, and assessment in the follow-up multimedia teaching system. In addition, relevant English teaching departments that participated in the research were also investigated. The university support for English teaching reform, attitude toward the blended-learning model, as well as their opinions and suggestions on the construction of college English multimedia teaching system based on blended-learning model were mainly investigated.

After the preliminary investigation and analyzing the English teaching reform department, teachers and students, the college English multimedia teaching system,

the Blended-learning model was constructed according to the actual analysis factors in the following.

3.2 CONSTRUCTION OF COLLEGE ENGLISH MULTIMEDIA TEACHING SYSTEM BASED ON BLENDED-LEARNING MODEL

Before an English teaching system is understood, system construction and its meaning should be understood. In our traditional cultural-loaded words, "the system" generally refers to its popular meaning or integrity composed according to a certain order and internal connection within a certain scope, a new system composed of different systems. Such system is an organic integrity with certain functions that is generally established directionally, comprehensively, deeply and even dimensionally for construction.

For the English multimedia teaching system, an English subject must be constructed within in the university. According to the blended-learning model, multimedia teaching resources (including teaching facilities, materials, faculties, education departments, technical forces, etc.) form a highly coordinative, blending, objective, and optimal organic integrity with students as the center. The teacher leads and is assisted by the competent education department in terms of comprehension, multiple angles, and depth.

3.2.1 Construction model and frame

We divided the stages of the model. The specific model, characteristic, and effect of each stage are shown. Stages are countered in the process of constructing the college English multimedia teaching system. We cannot construct this system completely, substantially, and optimally simultaneously. However, our basic model is consistent with model architecture. The specific model architecture constructed is as shown below (Figure 5):

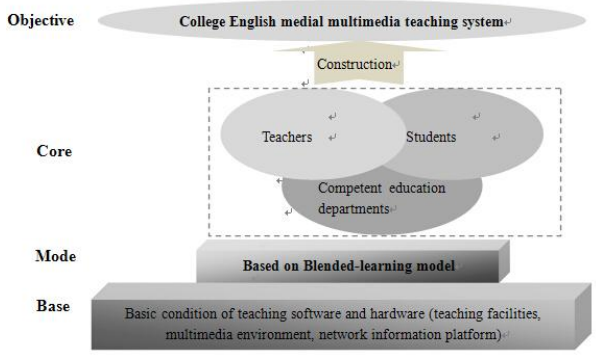

FIGURE 5 System construction model

In this model diagram, the base, model, core, and objective are not constant. Rather, they are in a dynamic adjustment state. The restriction factors should be adjusted according to actual experience and problems. The dynamic change cycle of each department might be different. Such cycles include blending, mixing, and method of students and teachers, and competent education departments, which depends on many factors. However, such blending and coordination will have an important influence on the objective. Therefore, continuous adjustment is required and the blending degree should reach the fourth stage of the blending-learning model or better.

3.2.2 Construction of model core of potential category analysis

The constructing multimedia teaching system model mainly analyzes core modules (i.e. blending of students, teachers and competent education departments). The potential category analysis principle in the statistics is introduced. This principle is established based on probability multivariate analysis so that comprehensive structural equations and linear equations can be used. The correlation among variables with the minimum key latent class is explained, and the statistical thought of local independence is constructed. Through latent class analysis (LCA), the potential factors that influence the construction of multimedia teaching system and mark the theoretical relation between explicit variables and potential variables through the statistical model are used in a questionnaire. Then, the core modules are modeled through analyzing, evaluating, comparing and explaining the latent class model.

The early investigation conditions are selected. These conditions can belong to a certain level of r existing categories in a potential variable x, and each level can be mutually blended. According to the measured external factors, the condition of local independence can be met among them after considering the potential property of the observation data. Such condition can be expressed using a probability function.

If we take students (a), teachers (b), and the school (c) as three external variables, then the core module of latent category model should contain a non-conditional probability that belongs to the latent factor, which we express with π_t^X and constitutes the essential latent factor model together with the three condition probabilities constituted by the latent class structure that influences the core module.

$$\pi_{ijk}^{abc}=\sum_{t=1}^{T}\pi_t^X\pi_{it}^{\bar{a}X}\pi_{jt}^{\bar{b}X}\pi_{kt}^{\bar{c}X}\ , \tag{1}$$

where, π_{ijk}^{abc} represents the joint probability of a latent factor model; π_t^X represents the probability of specific latent class when the observed data belongs to a latent factor x, i.e., $P(X=t),t=1,2,...,T$; $\pi_{it}^{\bar{a}X}$ represents the

probability condition of latent influential factor of model $_t$, i.e., $P(a=i \mid X=t), t=1,2,...,I$, and so on.

According to the probability parameterization of latent class mode, a significant latent variable X has at least two latent classes, which can be expressed as:

$$\pi_{ijk}^{\sum_{M=1}^{N} KX} = \pi_t^X \pi_t^{K1} \pi_t^{K2} \pi_t^{K3} \pi_t^{K4} \pi_t^{KN} X \cdot \quad (2)$$

The second factor is the relative size of each latent class. The larger the scale is, the more important the latent variable is, i.e., the higher the proportion. In LCA, the sum of various latent class probabilities is 1.00:

$$\sum_{t=1} \pi_t^X = 1.00 . \quad (3)$$

In the LCA model, the investigation targets are taken at random, and the probability in the explicit variable is called the condition probability. For the relation and coordination degree among students, teachers, and schools, under different environments of latent variable X, the condition probabilities are respectively marked as $\pi_{it}^{\bar{a}X}$, $\pi_{jt}^{\bar{b}X}$ and $\pi_{kt}^{\bar{c}X}$, according to the model, and the following relation is met:

$$\sum_{t=1}^{T} \pi_{it}^{\bar{a}X} = \sum_{t=1}^{T} \pi_{jt}^{\bar{b}X} = \sum_{t=1}^{T} \pi_{kt}^{\bar{c}X} = 1.00 , \quad (4)$$

where the latent factor within the explicit class and that the sum of condition probabilities of all explicit variables is 1.00. The probability sum of the latent model is also 1.00.

Moreover, in addition to estimating the factor probabilities that influence the construction of the multimedia teaching system, LCA can also be described briefly using a traditional linear model. The LCA estimation model is as follows:

$$\ln(f_{ijkt}^{abcX}) = \eta + \eta_t^X + \eta_t^a + \eta_t^b + \eta_t^c + \eta_{it}^{aX} + \eta_{jt}^{bX} + \eta_{kt}^{cX} . \quad (5)$$

The LCA model contains latent variable factors, and local independence only appears after considering the latent factors for the external variables. Thus, when evaluating the LCA of Equation (5), various items under the second-order term of the latent factors and various external variables should be introduced in pairs to the model for factor estimation.

3.2.3 Model construction optimization

Optimization can be conducted from the following three aspects:

First, English teaching reform departments should provide much support. In addition to software and hardware facilities, corresponding regulations and systems should be established by drawing on the wisdom of the masses. Listening to the opinions of the investigated teachers with successful experience is very important. Moreover, multimedia network environment should be used collect students' personal evaluations and feelings, such that the college English multimedia teaching system based on the blending-learning mode becomes beneficial and optimizes factors that restrict the multimedia teaching system. Then, this system will gradually perfect the English multimedia teaching system of the whole university.

Second, English teachers should be trained to participate in the construction of a college English multimedia teaching system based on blended-learning irregularly. The training form should follow no set form and should be diversified and in depth. The training should mainly be conducted in terms of the following aspects:

1) Cultivating the identity of English teachers in terms of the new teaching system;
2) Participating in the discussion on successful cases of Blending-learning mode for absorptive learning;
3) Unifying the teaching concept "students oriented and teachers guiding";
4) Clarifying and unifying the role of teachers in new multimedia teaching classes;
5) Continuously improving and innovating the English teaching method under the blended-learning model;
6) Improving English teaching ability and strategy under the blended-learning mode;
7) Using scientific research in college English multimedia teaching system based on Blended-learning model;
8) Encouraging and supporting English teachers under the system for multimedia or network technology training, and the exploring and innovating on various learning methods or approaches based on Blended-learning model;

Finally, based on the principle of student oriented, we cannot ignore the role of the students in the whole construction of college English multimedia teaching system based on Blended-learning model because they are the key to inspecting whether the system is perfect. Thus, students must continuously give feedback regarding various difficulties in the new system, discover problems in a timely manner, and communicate with the teachers to gradually perfect and optimize the whole new multimedia teaching system. The process involves joint cooperation, coordination, learning, growth, and the perfection of three parties and thus cannot be accomplished in one action.

3.3 EVALUATION AND ANALYSIS

After a tracing investigation for one year based on investtigating and analyzing the factors influencing construction of college English multimedia teaching system under the blended-learning model. The following findings were obtained through actual research:

First, the construction of a college English multimedia teaching system based on blended-learning improves the enthusiasm of students and incentivizes English learning. The system also continuously cultivates their enthusiasm,

self-discipline, and innovation in the whole process, allowing them to learn many skills and knowledge beyond their language ability.

Second, for teachers, constructing such a small range of college English multimedia teaching system based on the blended-learning model also stimulates the atmosphere for mutual learning among English teachers, which greatly improves the whole English teaching and English teaching of the whole university. Moreover, under such a benign learning and training atmosphere, other majors of the university will also be enlightened and guided, which will popularize the blended-learning concept greatly.

Finally, for the university itself, constructing this college English multimedia teaching system based on the blended-learning model allows English teachers to feel the support and encouragement of the university, which gains the trust of the teachers. With this trust, they continuously innovate and blend new teaching strategies and methods, allowing students to trust the university and their teachers. Thus, under the multimedia teaching system based on the blended-learning model, university leaders and relevant education departments praise and recognize students and teachers are obtained, which provide a new concept for English teaching model reform and innovation.

4 Conclusion

The blended-learning model has a significant influence in many aspects of the domestic education field and is significant to the development of education reform. The principle of Blended-learning model was analyzed, and this model was introduced for the construction of a college English multimedia teaching system. Through actual investigation questionnaires, the factors that influence the construction of college English multimedia teaching system under Blended-learning model were determined. Statistics were used to dynamically adjust the restriction factors in time. The results show that with the support of relevant education departments, on one hand, the teachers are trained for restriction factors. On the other hand, the abilities of students are divided differentially. Thus, professional and non-professional classifications are adopted, limitation is set to the multimedia teaching scale and different students are taught according to their own conditions. The college English multimedia teaching system constructed through this dynamic optimization process is energetic and brings relatively optimal benefits to the university, teachers, and students.

Construction quality risk management of projects on the basis of rough set and neural network

Jianbing Liu*, Fang Guo

School of Economics and Management, Jiangxi University of Science and Technology, Ganzhou, Jiangxi, China, 341000

Received 19 August 2014, www.cmnt.lv

Abstract

Construction quality associated with the life of construction enterprises. Risk assessment of construction quality referred to a comprehensive evaluation of the degree of risk confronting construction units during the construction process. Construction units provide a decision-making basis for employers and supervisors, who considered the evaluations of construction quality and accidents in their decisions. The risk factors of construction project quality were classified into personal risk and material risk and machinery and equipment risk and method risk and environment risk. On the basis of these factors, we constructed an index system of project construction quality risk. The risk evaluation model of project construction quality was constructed on the basis of rough sets and neural networks. Finally, a case study residential building projects in the Ganzhou Development Zone and research tools of Rosetta based on rough sets and MATLAB7.0 based on neural networks were used to test model accuracy and reason ability. Empirical results showed that the model has great practical significance.

Keywords: construction quality risk assessment, projects, rough set, neural networks

1 Introduction

The rapid development of the national economy has caused project constructions to exhibit a growing trend. However, such projects are confronted with numerous sun foreseen interference factors during the construction process. These factors give rise to the requirement for project participants to discuss and consider various risks. Uncontrolled risks may pose serious problems to the whole project. Thus, improving the risk management level of project construction quality is a task that project managers must focus on.

The construction quality risk assessment of a project is the most effective management means to improve construction quality and to avoid construction quality accidents. Such assessment is the core link of project quality risk management.

Construction quality risk assessments have yet to establish a unified and comprehensive index system. The lack of effective data sources causes a low construction quality risk management level of a project, such that the project manager is believed to possess a generally weak risk consciousness. These issues must be mitigated as continuous economic globalization has made international competition increasingly fierce.

Given this background, this study employs modern project management theory and incorporates advanced foreign project quality risk management experiences. Considering the inherent nature of construction quality risk management of a project, we propose project quality risk management methods that our suitable for the Chinese construction industry.

The risk factors that influence construction project quality are identified as personal risk, material risk, machinery and equipment risk, method risk, and environment risk. The index system of project construction quality risk was constructed, and the risk evaluation model of project construction quality was established on the basis of rough sets and neural networks.

2 Status of foreign and domestic research

2.1 STATUS OF FOREIGN RESEARCH

Risk management is a rapidly developing integrated discipline. The emergence of risk management can be traced back to ancient human productive labor. As societies constantly progress, enterprises encounter all types of risk during the development process. To help enterprises survive and grow, risk management, as an important part of enterprise management, was developed to reduce the risk of loss. Risk management has been employed to deal with risks, to facilitate stabilization after the occurrence of a financial risk, and to achieve the effective use of enterprise resources.

Early foreign research on risk management has been limited to enterprise risk. However, with the increase in construction engineering projects, the frequency of engineering project risk occurrence and the rapid development of engineering project management technology, risk management has been included in the scope of project management. Thus, project risk management was established.

* ***Corresponding author's*** e-mail:liujb71@sina.cn

Many uncertain factors in project construction may cause projects to fail and economic interests to be lost. Based on the experiences of and lessons from researchers abroad, the quality of project risk management has gradually been enhanced. With the continuous development of engineering project construction, project quality risk management has improved. Since the 1960s, foreign project quality risk management has become increasingly professional, systematic, and scientific, employing professional research personnel and specialized research institutions to address future adverse events.

Project quality risk assessment research abroad has various characteristics. First, most project quality risk research scholars focused on the technical level, including project decision analysis, coping strategies, project risks, and international economic research. Second, with the rapid development and wide application of computer technology, calculation methods have become more accurate and foolproof. The combination of qualitative and quantitative risk analysis methods was the primary approach employed in project quality risk management research [1-5].

2.2 STATUS OF DOMESTIC RESEARCH

Although domestic risk management started late, risk manage men has been widely used in project construction, finance, real estate development, and other fields. Many studies have been conducted on project quality risk, and research results have been beneficial. It has analyzed the causes of engineering quality accidents in detail and used the theory of project management system to discuss how to improve project quality further [6]. It combined fuzzy mathematics and analytic hierarchy process, constructed a quality risk evaluation index system for housing construction project construction, and proposed the housing construction project construction quality risk assessment model [7]. Additionally, it proposed a project risk evaluation model based on cost, time, and quality. They combined the analytic hierarchy process and fuzzy comprehensive evaluation method in a detailed study on risk factors, including cost, time, and quality of influence [8]. It believed that project quality risk exists throughout the whole construction period of a project, such that measures should be implemented at all stages of project quality risk assessment [9]. Steps must be taken to reduce the quality of engineering project risks. Further more, it used analyses of natural risk, material risk, and construction risk to establish a risk evaluation index system of quality and then evaluated the quality of a project risk with the use of the fuzzy evaluation method [10]. It established a project quality risk evaluation index system based on the cause of project quality risk factors, evaluated the quality of the project risk using the fuzzy comprehensive evaluation method, and established a quality risk response according to evaluation results [11]. Finally, it established a project quality risk management model based on Bayesian network and conducted risk identification, risk evaluation, risk diagnosis, and risk control and achieved results using the project quality risk model [12].

3 Identification of construction project quality risk factors

Project construction can be characterized as long-term, outdoors, and large-scale, such that the process is easily influenced by natural and social conditions. Combining the construction technology of production and that of liquid variability and other characteristics reveals that numerous factors affect project quality. These factors may result in construction quality accidents. Applying the principles of system engineering and the Delphi method to a large number of construction quality accident investtigations and data analyses, we identify the main factors influencing engineering project construction quality as man, materials, method, mechanical, and environment. These factors are called 4M1E.

Under normal circumstances, most project construction quality accidents are caused by factors related to 4M1E, such that identifying and analyzing these factors can ensure that the project runs smoothly with high construction quality.

3.1 THE HUMAN FACTORS

Man refers to the project managers, leaders, and operators involved in the project. Man directly and indirectly affects construction quality because of personal, ideological, cultural, business, and quality attributes, among others.

3.2 THE MATERIAL FACTOR

Material refers to raw materials, auxiliary materials, semi-finished products, components, and fittings, among others. The quality of the material determines the level of project quality. If the material quality does not meet the requirements, meeting the project quality standards is impossible.

3.3 MECHANICAL FACTORS

Mechanical, machinery, and equipment generally refer to construction equipment, construction machinery, and construction tools and instruments. With the continuous expansion of project scale, machinery and equipment have become indispensable parts of a facility.

3.4 THE FACTORS OF METHOD

Methods refer to the employed technology programs, processes, construction designs, and construction technology measures during the construction phase. To some extent, choosing the construction program reasonably and correctly directly affects project quality control.

3.5 ENVIRONMENTAL FACTORS

Environmental factors associated with the construction quality of a project include three major factors: the scene of the natural environment, construction quality management, and engineering labor work environment factors. The environmental factors change constantly during construction phase, such that these factors directly affect the project.

4 Quality risk assessment of construction project on the basis of rough sets and neural networks

4.1 CONSTRUCTION OF THE INDEX SYSTEM

Based on the above analysis of the risk factors affecting the quality of the construction phase and combined with the principles and basis of indicators, the quality of risk evaluation index system of the construction phase of a project was built, as shown in Table 1.

TABLE 1 Project quality risk assessment index system of construction stage

Evaluation index	First Indicators	Number	Second indicators	Degrade				
				I	II	III	IV	V
U	U_1 Human factor	1	U_{11} Degree of compliance manager qualifications					
		2	U_{12} Degree of operator qualification standards					
	U_2 Material factors	3	U_{21} Standards of the material quality					
		4	U_{22} Soundness of the material properties					
	U_3 Mechanical factors	5	U_{31} Degree of compliance with the quality of machinery and equipment					
		6	U_{32} Rationality of machinery and equipment selection					
		7	U_{33} Standardized machine operators					
	U_4 Method factors	8	U_{41} The rationality of the construction technology program					
		9	U_{42} Construction technology and construction methods of the advanced and rationality					
		10	U_{43} Rationality of construction detecting methods and construction technical measures					
	U_5 Environmental factors	11	U_{51} Natural environment of construction site					
		12	U_{52} Quality assurance system of construction unit					
		13	U_{53} Quality management system of construction unit					
		14	U_{54} Technical and economic conditions					
		15	U_{55} Construction work environment					

Description: I very good, II good, III fair, IV poor, V very poor.

4.2 PROJECT CONSTRUCTION QUALITY RISK ASSESSMENT ON THE BASIS OF ROUGH SET AND NEURAL NETWOKKS

This study proposes a neural network risk assessment method using a combination of weak coupling methods, namely, rough sets and neural networks. With rough theory as a neural network front-end system, the sample data input of the neural network is first simplified. The simplified sample data are then imported to the neural network, and the mature classification model is produced through training. Finally, the quality of the risk level of the project is evaluated on the basis of the output of the classification model network, which can provide an objective basis for the decision-making of project managers.

Given the basic idea of rough set and neural network risk assessment methods and the actual characteristics of the construction quality risk assessment, a quality risk assessment model of construction projects can be established on the basis of neural networks and rough sets. The basic idea is as follows:

1) Collecting data: by collecting detailed information on the construction site of a project, possible accidents caused by the project construction quality risk factors can be identified;
2) Data processing: discrete data processing is performed;
3) Identified the smallest risk factor set of construction quality of projects: by the means of the theory of rough set attribute reduction of the construction quality of construction project risk evaluation index system, the smallest project quality indicators of the risk factor set can be identified;
4) Data training and establishing network model: training of the neural network data can aid in establishing an appropriate network model;
5) Testing the network model: the network model is tested by using specific project data, which are compared with the actual risk value;
6) Calculating the risk assessment result: the quality risk evaluation index data are used as input to the project construction to be evaluated. The value risk assessment objectives are then derived.

5 Empirical analysis

This study takes the characteristics of project construction as a foundation to establish the quality of the risk assessment model of construction on the basis of rough sets and neural networks. Data collected in the field will be applied and tested.

5.1 DATA COLLECTION

Data were collected at the Ganzhou Development Zone, a high-rise residential building project with two underground floors, 11 floors above ground, and underground parking lot. The project has a total gross floor area of 3,802m^2, a building height of 34.2m, take-situ concrete construction, columns, beams, plates, and concrete strength grade of C30.The project was constructed during summer. The construction site has various facilities, convenient transportation, and good work environment. In accordance with the construction process established in this study and the construction quality of the project risk evaluation index system, we selected the high-rise residential building project layer cast concrete columns for this study.

5.2 CALCULATING THE INDEX WEIGHT AND FORMATION THE SAMPLES SET OF THE RISK FACTORS

Based on the collected data, the number of samples in this article does not meet the required number of samples for the model. Thus, 14 projects of similar nature were added to the sample data for analysis. However, these projects are not listed here.

These projects were in the construction phase. In-site concrete columns and quality risk assessment indicators for each construction stage sample are presented in the Table 2. The symbols "" represent the level of the actual situation, which can be "very good, good, fair, poor, or very poor."

TABLE 2 Actual situation for each sample indicator

Sample	U_1		U_2		U_3			U_4			U_5				
	U_{11}	U_{12}	U_{21}	U_{22}	U_{31}	U_{32}	U_{33}	U_{41}	U_{42}	U_{43}	U_{51}	U_{52}	U_{53}	U_{54}	U_{55}
1	I	II	II	II	II	III	II	II	II	III	III	II	II	I	II
2	II	II	II	II	III	II	III	II	III	III	II	II	II	II	III
3	II	II	II	II	III	III	III	II	III	II	II	II	II	III	IV
4	II	III	II	II	III	II	II	II	II	II	III	II	II	III	III
5	I	II	III	III	III	III	III	II	II	II	IV	II	II	III	IV
6	II	IV	II	II	III	III	II	I	II	II	II	III	III	III	II
7	III	III	III	III	I	II	II	I	I	II	II	II	II	III	II
8	II	I	II	II	III	III	III	II	II	III	II	II	II	II	I
9	II	IV	III	III	II	III	III	II	II	II	I	II	II	II	I
10	III	III	III	III	II	III	III	II	II	III	IV	III	III	III	IV
11	II	III	II	II	II	I	I	II	III	III	Ⅱ	III	III	II	III
12	I	II	II	II	III	III	III	III	II	II	III	I	I	II	III
13	II	III	II	II	II	III	III	II	II	III	II	II	II	IV	II
14	II	I	III	III	II	II	II	I	II	III	II	II	II	II	III
15	II	II	II	II	III	III	II	I	II	II	II	III	III	II	II

On the basis of the original data, we used the AHP-Fuzzy evaluation method was used to calculate the right weight of each site and the quality of the risk of each sample. The risk sample sets of neural networks were then reduced.

First, we determine the weight of paper using AHP. Eight staff members with extensive experience are employed to compare the risk factors in the construction site. These staff members include project managers, construction workers, technicians, security staff, chief super vision engineers, quality engineers, and so on. The judgment matrix is then established. The U_1–U_5 layer-right weight set is: U= (0.271,0.311,0.236,0.104,0.079). Other indexes are calculated in the same manner as the criterion level U_1–U_5. The final weight is determined as follows: U_1 = (0.500, 0.500), U_2 = (0.500, 0.500), U_3 = (0.333, 0.333, 0.333), U_4 = (0.489, 0.291, 0.220) and U_5 = (0.333, 0.111, 0.111, 0.333, 0.111).

Second, each sample of construction quality risk is calculated using the fuzzy comprehensive evaluation method. Similarly, the quality of the risk can be drawn from all the construction site samples, as shown in Table 3.

TABLE 3 Construction quality risk assessment of each site samples

Sample	Risk	Sample	Risk	Sample	Risk
1	0.163	6	0.369	11	0.317
2	0.236	7	0.335	12	0.212
3	0.289	8	0.218	13	0.352
4	0.258	9	0.343	14	0.326
5	0.392	10	0.421	15	0.265

The risk of sample sets of the neural networks was determined, from which the former 10 sample sets were selected for learning neural network training, and the other five sample sets were selected as the test samples for the neural network.

5.3 CONSTRUCTION QUALITY RISK ASSESSMENT PROCESS OF PROJECTS BASED ON ROUGH SET AND NEURAL NETWORK

Construction project quality risk assessment processes were established on the basis of rough set sand neural networks. The index system was simplified with the ge-

netic algorithms in Rosetta software, and the discrete set of post-processing was incorporated into the calculation in the software. The set of simplified data is reduced by the software, as shown in Figure 1.

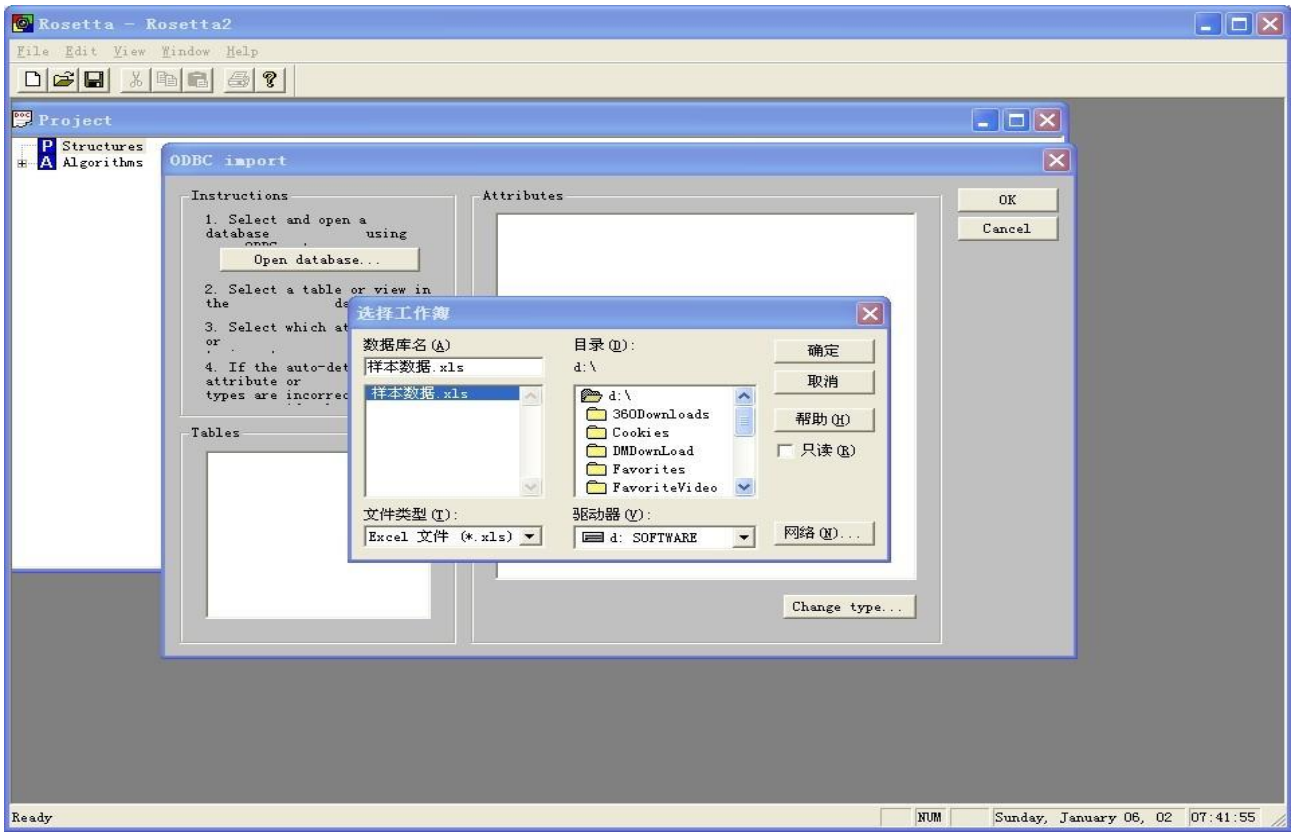

FIGURE1 Rosetta import data manipulation

In this study, considering the support and reduction lengths of the two factors, we selected an optimal set of conditions as follows: U = (U_{11}, U_{12}, U_{21}, U_{22}, U_{31}, U_{33}, U_{41}, U_{54}).

MATLAB7.0 was then used to define, train, and test a back propagation BP neural network. The specific steps are as follows:

Creation of the input and output data. Ten former sets of sample data were selected as the training sample set. The input matrix has a total of 10 lines, representing 10 samples, and a total of eight rows, with eight data points for each row in each sample.The eight data points represent the value attribute of U_{11}, U_{12}, U_{21}, U_{22}, U_{31}, U_{33}, U_{41}, U_{54}. The output matrix t has a total of 10 rows, which represent the value of quality risk attribute in the construction of a project.

Creation of a BP neural network. The specific statement is as follows: net=newff([0 1; 0 1; 0 1; 0 1; 0 1; 0 1; 0 1; 0 1;],[17,1],{'tansig', 'tansig'},'traingdx'). The range description of each value input unit from the first parameter input is [0,1]. The second parameter [17,1] describes node values of 17 and 1 in the hidden layer and output layer, respectively. The third parameter {'tansig', 'tansig'} illustrates that the hidden layer and output layer transfer functions are all tansig functions. The fourth parameter 'traingdx' illustrates the training function selected for the function of neural networks.

Setting of training parameters. The specific statement is as follows:

net. Train Param. show=50
net.trainParam.lr = 0.09
net. trainParam. epochs = 10000
net. trainParam. goal = 0.001

Start training network. Specific statement is follows as:

[net, tr]=train(net, p', t')

Inspection of data. The five remaining sets of data are used for testing *.pt* is the testing matrix that has a total of five linesand eight rows. The specific statement is as follows:

a=sim (net, pt')

Each of the above statements are used as input for MATLAB7.0 software to obtain the final training results as shown in Figure 2.

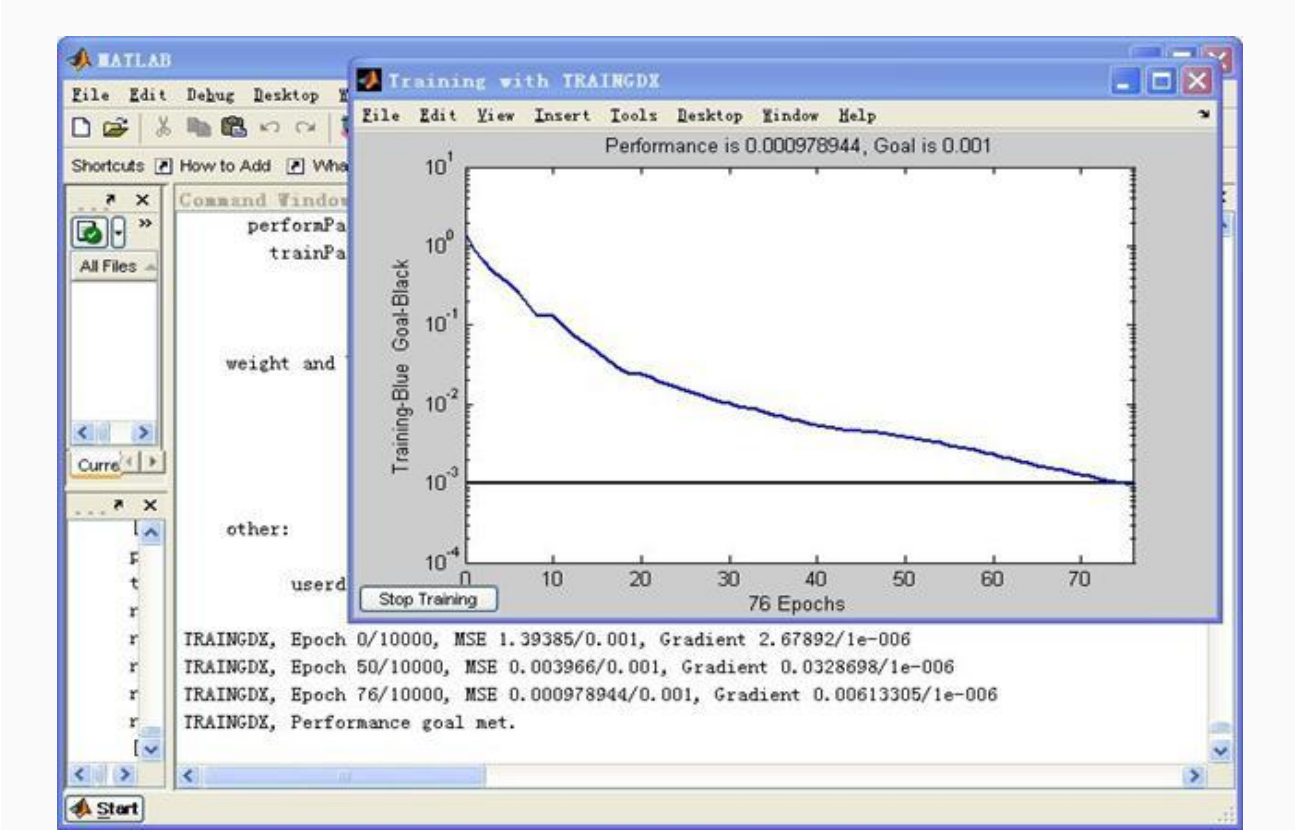

FIGURE 2 Training error curve

As shown in Figure 2, after 76 iterations through the training, the accuracy of the model is less than 0.001. The remaining five groups of samples were used to test the accuracy of the neural network model. The result of the command a = sim (net, pt ') is as follows:

a=sim(net, pt')
a =0.3204 0.2221 0.3433 0.4069 0.2747

The results of the output show that the actual output risk values of sample sites 11 to 15 (i.e., the risk value) were 0.3204, 0.2221, 0.3433, 0.4069, and 0.2747, respectively. The quality risks of construction from the model of site evaluation samples 11 to 15 were smaller, smaller, smaller and smaller, general, and smaller. The results of the model are then compared with the actual value of the output. The difference between the absolute value of the error rate of the output value and the true value is divided by the actual value, as shown in Table 4.

TABEL 4 Output samples

Sample	**11**	**12**	**13**	**14**	**15**
True Value	0.317	0.212	0.352	0.326	0.265
Output Value	0.3204	0.2221	0.3433	0.4069	0.2747
Error rate	1.07%	4.76%	2.47%	24.82%	3.66%

Table 4 shows that the actual output value and the true value of the model are broadly consistent, indicating that the quality risk assessment of the accuracy rate after training and learning of the sample set in project construction is became higher, which is in line with the actual situation of the project. Most error rates were acceptable. The error rate of sample site13is relatively high. However, the average error rate of the five groups of samples was 7.356%, indicating that a higher evaluation model training accuracy results in a more ideal the evaluation.

6 Conclusion

6.1 ESTABLISHING CONSTRUCTION QUALITY RISK ASSESSMENT MAODEL OF PROJECTS ON THE BASIS OF ROUGH SET AND NEURAL NETWORKS

Neural network software programs (e. g., Rosetta and MATLAB7.0) were used as basic research tools in this study. The quality risk assessment model was tested through empirical analysis on the basis of rough sets and neural networks. The results of the empirical analysis show that higher accuracy of model training results in a more ideal evaluation.

6.2 THE INNOVATIVE APPLICATION OF ROUGH SET TO NEURAL NETWORK IN CONSTRUCTION QUALITY RISK ASSESSTMENT

Rough set theory knowledge was taken as a neural network front-end system, and the input data were preprocessed and compared with those derived from the traditional BP neural network, which effectively simplified the complex structure of the neural network, shortened the neural network training time, and improved the accuracy of generalization and training of the neural network.

Rough set and neural network risk assessment model can accurately simulate the decision-making process of construction quality experts on risk assessment of the project, thus artificially reducing uncertainties in the risk assessment process and effectively combining knowledge acquisition, functional expert systems, and fuzzy reasoning.

Abstract

Container transport has played an important role in international trade. This paper mainly focuses on the container transport modes selection between inland terminals and seaports through a comprehensive comparison of multiple decision factors. According to the multi-object fuzzy mathematics decision-making theory and the container transport processes, the main factors influencing the container transportation mode decision are analyzed. Moreover, a fuzzy decision model of container transport modes between inland terminals and seaports is built by introducing varied weight factors. Thereafter, the proposed model for the final selection of container transport modes between Changsha city and Shanghai harbor is demonstrated through an illustrative example. The results of this example indicate that the model can reflect dynamically importance degrees of related decision factors and different demands of decision makers, and this approach provides a more accurate, effective, and systematic decision support tool for the optimized intermodal mode selection between inland terminals and seaports.

Keywords: container transport, transport mode, route optimization, fuzzy decision making

1 Introduction

The vast majority of liner cargo is containerized – that is, it is carried in sealed metal containers from point of origin to destination. Containers are moved with common handling equipment enabling high-speed intermodal transfers in economically large units [1]. The container, therefore, serves as the load unit rather than the cargo contained therein, making it the foremost expression of intermodal transportation. As an advanced mode of transport [2], container transport has been an important element of not only maritime activity, but also of world trade and of global industrial structure. Since the 1970s, with growing container transport as the main driver, most seaports have evolved into port communities [3].

At present, seaport business is increasingly focused on inland terminals through which the hinterland is served. Seaports are no longer purely considered intermodal transfer centers, but are now becoming comprehensive flow-through areas within logistics chains, which are functionally linked to distribution developments in the hinterland. Seaports and inland terminals belong to a tiered intermodal transport system serving the whole supply chains [4]. Intermodal transport mode involves the use of at least two different modes in a trip from an origin to a destination through an intermodal transport chain, which is facilitated by the use of containers allowing the transport by different modes of transport namely ship, truck and rail [5]. Each transport mode has different economic and technical structures, and provides different quality of transport services. The decision on mode choice is complex. As for how to get the optimum scheme, a suitable method is needed to make a comprehensive, reasonable and comparative study. The wide application of the fuzzy mathematics theory has offered a scientific way to solve the transportation route decision issue.

2 Influence factor analysis of container transport mode selection

2.1 TRANSPORTATION COST

Transport cost is important for transport mode selection. Transport cost includes rates, loading and unloading charges, and special services available (e.g., stopping in transit) from carriers [6]. Transport cost varies from mode to mode owing to the different cost structures of the modes, whereas there are cost variations among carriers within a transport mode because of their dissimilarities in cost structure [7]. While choosing the transport route, different schemes will produce different transport costs, and this factor usually becomes a primary one.

2.2 TRANSPORTATION TIME

In general, transport time includes the time required for pickup, handling, and delivery [8]. Containers transport time between inland terminals and seaports should be linked up with the lading time of arrived liner ships, and more fees such as storing fees, keeping fees should be paid if containers are delivered more ahead of time.

[*] ***Corresponding author's*** e-mail: zlycsu@163.com

2.3 TRANSPORTATION SECURITY

In the container transport industry, the importance of adopting technology for enhancing transport security has been well acknowledged [9]. To guarantee the security of the containers, delivered goods and the bills enclosed during the process of transporting is the basic requirement for transportation, and also it is a primary condition that must be considered while drafting all the transportation schemes that are prepared to be chosen.

2.4 TRANSPORTATION RELIABILIGY

Transport reliability refers to the carrier's capability and accessibility for providing the service over the route in question, and it determines whether a particular carrier can physically perform the transport service desired. While choosing the transportation route schemes, it is necessary to make an investigation and analysis about the possibility degree of gaining transportation capacity and the punctual conditions of transportation.

3 Decision making issue description of container transport modes

Consignors want to choose the optimal container transport mode between inland terminals and seaports, and the consignors have specified the nature of goods and transportation requirements [10]. After a detailed market has been conducted to identify the potential transport modes, m schemes available are educed through the initial screening. As for the m schemes available such as $b_1, b_2, \cdots, b_m$ between inland terminals and seaports. There are n evaluation factors such as $a_1, a_2, \cdots, a_n$ (transport time, transport cost, transport security, transport reliability, etc.), respectively corresponding to the varied weight of decision factors $w_1, w_2, \cdots, w_n$. Every scheme $b_j (j = 1, 2, \cdots m)$ in reserve has one index eigenvector $f_{ij} (i = 1, 2, \cdots, n; j = 1, 2, \cdots, m)$ corresponding to n evaluation factors $a_i (i = 1, 2, \cdots n)$ and the membership degree of its eigenvalue is r_{ij} to individual appraisal factor "excellent". To utilize a method that weighted relative warp interval is the minimum to choose the optimum scheme. Thereby, it is necessary to calculate the ideal scheme. The standard value vector of the ideal scheme is:

$$f^0 = (r_{11} \vee r_{12} \vee \cdots \vee_{1m}, r_{21} \vee r_{22} \vee \cdots \vee r_{2m}, \cdots, r_{n1} \vee r_{n2} \vee \cdots \vee r_{nm}) = (f_1^0 \wedge f_2^0 \wedge \cdots \wedge f_n^0) \quad . \tag{1}$$

The eigenvector of each available scheme that is the most close to the ideal scheme is illustrated as: $R_j = (r_{1j}, r_{2j}, \cdots, r_{nj})^T$, the weight of decision factors:

$$W = ((1+\varepsilon_1)w_1, (1+\varepsilon_2)w_2, \cdots, (1+\varepsilon_n)w_n)^T .$$

Among them: $\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_n$ and $w_1, w_2, \cdots, w_n$ are respectively the varied weight factor and constant weight items of each factor index. Hamming closing degree with weight is used to describe the quality degree of the scheme in reserve [11], namely:

$$N(f^0, R_j) = 1 - \sum_{i=1}^{n} W_i (f_i^0 - r_{ij}) . \tag{2}$$

If $T_j = \max[N(f^0, R_j)]$, $1 \le j \le m$, scheme b_j is an optimum scheme.

4 Building the fuzzy decision model of container transport modes

4.1 CALCULATING MEMBERSHIP DEGREE OF QUANTITATIVE FACTOR INDEX

When the index value f_{ij} of factor index i corresponding to scheme j is a quantitative index, the membership degree of the factor index is calculated based on the comprehensive decision-making method as:

$$r_{ij} = \begin{cases} 0.1 + \dfrac{f_{i\max} - f_{ij}}{d} & \text{if } f_i \text{ is a minus index} \\ 0.1 + \dfrac{f_{ij} - f_{i\min}}{d} & \text{if } f_i \text{ is a plus index} \end{cases} . \tag{3}$$

In the Equation (3), d is a grading value $d = \dfrac{f_{i\max} - f_{i\min}}{1 - 0.1}$, r_{ij} is the membership degree of factor item i to scheme j in reserve. In $n \times m$ dimensional space, n evaluation values of m schemes constitute a fuzzy evaluation matrix R.

4.2 CONFIRMING MEMBERSHIP DEGREE OF QUALITATIVE FACTOR INDEX

As for the confirmation of the membership degree of qualitative factor index, a comprehensive decision method is adapted to make an evaluation, when every factor index value f_{ij} is a qualitative index, the evaluation of the fuzzy matrix R can be made by experts. The specific way is that the factor index is to be divided into seven grades (worst, worse, bad, general, good, better, best), and the evaluation value can be get according to the standard shown in Table 1.

TABLE 1 The table of evaluation standard

Remark	Worst	Worse	Bad	General	Good	Better	Best
Evaluation value	0.05	0.20	0.35	0.50	0.65	0.80	0.95

4.3 CONFIRMING THE WEIGHT OF EVERY FACTOR INDEX

It is necessary to confirm the importance degree of every factor to the container transport schemes according to the true environment [12]. And the importance degree, namely, is the corresponding factor weight value of n evaluation factors: $w_1, w_2, \cdots, w_n$. In order to dynamically reflect the different importance degrees of each factor

index to each transportation route scheme, the varied weight factors of every factor index $\varepsilon_1, \varepsilon_2, \cdots, \varepsilon_n$ should be given a corresponding value [11]. The weight set with varied weight of each factor, namely $W = ((1+\varepsilon_1)w_1, (1+\varepsilon_2)w_2, \cdots, (1+\varepsilon_n)w_n)^T$, can be gained, which shows the dynamic features of the evaluation factors.

4.4 EDUCING THE OPTIMUM SCHEME

Make a calculation according to Equation (2), and get the result $T_j = \max[N(f^0, R_j)]$. Therefore, scheme b_j is an optimum scheme.

5 Case study

5.1 TRANSPORT MODE INVESTIGATION AND SCHEME ANALYSIS

The land-based transportation section of the containers, sent from the Changsha city and exported via Shanghai Harbor, is chosen as a case of route scheme. The container transport routes between Changsha and Shanghai Harbor are illustrated in Figure 1.

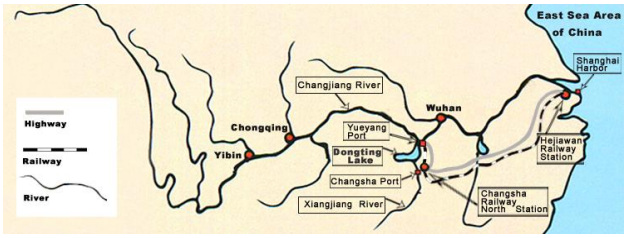

FIGURE 1 Container transport routes between Changsha and Shanghai Harbor in China

Scheme b_1: the railway + highway transport scheme, namely after the exported containers being sent at Changsha North Station, then they are transported to Hejiawan Station of Shanghai by railway, then transshipped on container trucks. Again they are transported to Shanghai Harbor by the short-distance road transport [13].

Scheme b_2: the whole highway transport scheme, namely after exported containers are loaded on container trucks in Changsha and transported to Shanghai Harbor by highway.

Scheme b_3: the whole inland water transport scheme, namely after exported containers are loaded into the ship in Changsha Port and transported through the Xiangjiang River, by way of Tongting Lake and Yueyang, to Changjiang River, then transported to Shanghai Harbor through the Changjiang River.

After Scheme b_1, Scheme b_2 and Scheme b_3 are designed based on the multi-modal freight transport network theory [14], the three schemes in reserve are chosen to be compared with each other. The index values of schemes in reserve have been educed in Table 2.

TABLE 2 The index values of schemes in reserve

	Scheme b_1	**Scheme** b_2	**Scheme** b_3
Transportation costs	￥3100 RMB /TEU	￥8300 RMB/TEU	￥2500 RMB /TEU
Transportation time	4 days	3 days	7 days
Transportation security	Better	Between "better" and "good"	Good
Transportation reliability	Worst	Best	Better

5.2 CALCULATING THE MEMBERSHIP DEGREE OF EVERY FACTOR INDEX

According to Table 2, the two indexes of "transportation costs" and "transportation time" are quantitative and minus indexes, so their membership degrees are calculated according to the Equation (3). The two indexes of "transportation security" and "transportation reliability" are qualitative indexes, so their membership degrees are calculated with corresponding assessed values of fuzzy comments, then the fuzzy matrix *R* is got:

$$R = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \\ r_{41} & r_{42} & r_{43} \end{bmatrix} = \begin{bmatrix} 0.91 & 0.10 & 1 \\ 0.78 & 1 & 0.10 \\ 0.80 & 0.7 & 0.65 \\ 0.20 & 0.95 & 0.80 \end{bmatrix}.$$

According to the Equation (1), the index standard value vector of an ideal scheme is f^0 = (1, 1, 0.80, 0.95).

5.3 CONFIRMING THE WEIGHT OF EVERY FACTOR INDEX

With Delphi method, through the consultation investigation of two experts engaged in the Third Party Logistics, four experts engaged in international freight agency business and four experts engaged in transportation for imports and exports enterprises, and they are invited to evaluate every index weight. The result that the constant weight values w_1, w_2, w_3, w_4 of the 4 factor indexes of transportation costs, transportation time, transportation security and transportation reliability are 0.41, 0.22, 0.11, 0.26 respectively after the data of assigning the weight are collected and processed. After introducing varied weight factor, the weight value is:

$$W = ((1+\varepsilon_1)w_1, (1+\varepsilon_2)w_2, (1+\varepsilon_3)w_3, (1+\varepsilon_4)w_4)^T = (0.41(1+\varepsilon_1), 0.22(1+\varepsilon_2), 0.11(1+\varepsilon_3), 0.26(1+\varepsilon_4)).$$

5.4 CALCULATING THE HAMMING CLOSING DEGREE TO GET AN OPTIMUM SCHEME

Calculate Hamming closing degree of every scheme with Equation (2), the result is got as following:

$$b_1: N(f^0, R_1) = 1 - \sum_{i=1}^{n} W_i (f_i^0 - r_{i1}) = 0.720 - 0.037\varepsilon_1 - 0.048\varepsilon_2 - 0.195\varepsilon_4 ,$$

$$b_2: N(f^0, R_2) = 1 - \sum_{i=1}^{n} W_i (f_i^0 - r_{i2}) = 0.620 - 0.369\varepsilon_2 - 0.011\varepsilon_3 ,$$

$$b_3: N(f^0, R_3) = 1 - \sum_{i=1}^{n} W_i (f_i^0 - r_{i3}) = 0.746 - 0.198\varepsilon_2 - 0.017\varepsilon_3 - 0.039\varepsilon_4 .$$

When the weight of every factor index is constant weight and varied weigh factors are not considered, namely if $\varepsilon_i = 0 (i = 1, 2, 3, 4)$, then:

$$T_j = \max[N(f^0, R_j)] = \max[0.720, 0.620, 0.746] = 0.746 .$$

Thereby, scheme b_3 is the optimum scheme. If varied factors are evaluated, there are differences to some extent in the gained result of the scheme compositor.

6 Conclusions

The major contribution of this paper lies in the development of a comprehensive methodology for the planning of transport modes between inland terminals and seaports. According to the multi-object fuzzy mathematics decision-making theory and the centralized and evacuated transportation features of the containers, a fuzzy decision model of container transport modes between inland terminals and seaports is constructed, which is under the restriction of multiple qualitative and quantitative decision factors and based on varied weight factors. The introduction of varied weight, which can reflect dynamically importance degrees of related decision factors, adapts the decision model to the dynamic changes of the decision factors. This study raises several important issues that warrant further research. Evaluation and refinement of the model using additional field studies may prove beneficial, and its applicability may be expanded to other similar decision problems. Further, the intelligent software based on the methodology may also be developed.

Location of competitive basketball athletes based on RSR comprehensive evaluation method

Xiaohua Ma*

Institute of Physical Education, Taishan University, Taian City, Shandong Province, China, 271000

Received 6 September 2014, www.cmnt.lv

Abstract

Rank sum ratio (RSR) positions each research index to superior or inferior index, conducts rank allocation of these indices in all evaluation objects according to rank principles, sorts them, and carries out grading according to the RSR value. In this way, the superior and inferior indices can be clearly determined. For complex open sports, good sport decisions can make each member give play to their strong points to achieve good results. However, most existing research methods belong to non-quantitative research methods. Research on the location of competitive basketball athletes is rare. This study adopts RSR comprehensive analysis method to assess examination indices for 15 members in a basketball team of a college to select the members that are most suitable for five locations in basketball competitions and corresponding benches and candidates. A general method is provided to decide the location of commercial basketball athletes.

Keywords: sport decision-making RSR comprehensive evaluation method, commercial basketball athlete

1 Introduction

Rank sum ratio (RSR) was proposed by Tian Feng (a famous scholar in China and former professor in Chinese Academy of Preventive Medicine) in 1998 [1]. RSR is a statistical analysis method that integrates the advantages of classical parametric statistics and modern nonparametric statistics [2]. This method was mainly applied in medical field in the early stage. RSR comprehensive analysis method is applicable to statistics and analysis of form and measurement data [3]. The main thought is as follows: in a form including n samples and m characteristics, dimensionless statistical magnitude RSR is gained through rank conversion calculation, and evaluation objects with RSR values are sorted; grading (many comparable groups) is then conducted according to the comparable groups, or a credibility interval of RSR square root arc sine transformation values (few comparable groups) is obtained [4].

Sport decision making means the process that athletes feel information, understand information, and take actions under sport situations [5]. The major differences of sport decision making from general decision-making process are the heavy mental stress in limited time, inconsiderable available decision-making information, and uncertain results [6]. Sport decision making mainly includes cognitive decision making dominated by logical thinking and intuitive decision making dominated by intuitive thinking [7]. For complex open sport events, sport decision making has vital influences on athlete performance and final results [8]. Thus, the study of sport decision making is an important issue in sport field. Basketball sport is a confrontational sport mainly based on shooting, lay-up, and slam dunk [9]. Both teams own five players. The team able to shoot the basketball into the basketball hoop can gain the score. Thus, in basketball competitions, selection and decision of strategies and tactics are vital. In recent years, research on competitive basketball tactic system mainly includes the following two trends:

1) the differences in the technologies are compared to discuss the differences in offensive and defensive techniques of the teams;

2) the scores gained and lost are predicted to conclude the factors that influence the team gaining and losing the score to analyze the offensive and defensive strategies of the teams [10]. The former stresses "to know others," whereas the latter stresses "to know you." As a saying goes, if you know others and know yourself, you will not be imperiled in every battle [11].

Based on the perspective of "knowing yourself," the best location for basketball athletes can be gained through analyzing each index of team members according to RSR comprehensive analysis method [12]. This study introduces classical RSR comprehensive analysis method in competitive basketball decision making, conducts statistical analysis according to the given sample data of the team members to be tested, obtains corresponding conclusions, and provides methods to make decisions about the location in competitive basketball sport [13]. This study has important practical significance and certain innovative significance.

2 RSR comprehensive analysis methods

2.1 BASIC THOUGHT OF RSR

Samples with a large RSR value are generally considered as good. Therefore, the superior and inferior indices during

* ***Corresponding author's*** e-mail: mxh8682067@163.com

ranking must be confirmed. The examination level of students is considered for example. High scores mean good performance. Score is thus the superior index. A long duration to answer questions leads to poor performance. The duration to answer questions is thus the inferior index.

Apart from simply differentiating superior and inferior indices, slightly superior indices and slightly inferior indices should be set in some complex problems. Ranking should generally be considered according to the problem itself.

2.2 GENERAL CALCULATION STEPS OF RSR

The basic steps of RSR are as follows: each research index is first positioned to superior or inferior index through survey, statistics, and professional knowledge; ranking allocation of these indices in all evaluation objects is then conducted according to ranking principle and sorted; they are finally filed according to RSR value. Figure 1 shows the specific flow chart for calculations.

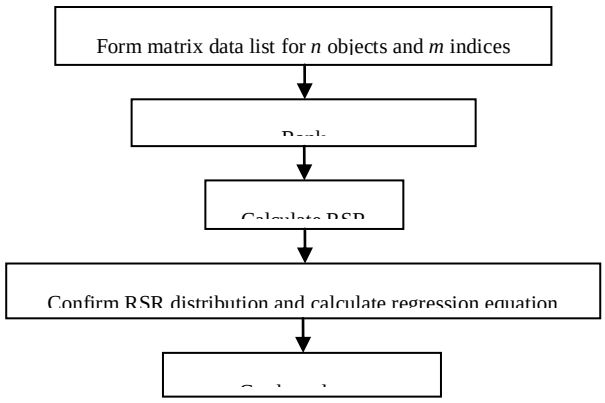

FIGURE 1 Flow chart of RSR calculation

The specific steps are as follows.

2.2.1 Formulation of data table

Formulation of data table is the calculation foundation of the whole RSR method. Follow-up calculation and grading can be effectively conducted only through selecting proper indices or characteristics and measuring them with data. n characteristics of m examples will generally be chosen. They are then ranked to $m \times n$ data table.

2.2.2 Ranking

Each index must be confirmed to superior or inferior index according to experience. The ranking principle is that superior indices are sorted in a descending order, whereas inferior indices are sorted in an ascending order. If the order is the same, the mean value is obtained. Equation (1) is the ranking calculation formula of superior indices. Equation (2) is the ranking calculation formula of slightly superior indices. Equation (3) is the ranking calculation formula of inferior indices. Equation (4) is the ranking calculation formula of slightly inferior indices. This study selects superior and inferior indices to rank for calculation convenience.

$$\text{Ranking of superiorindexes} = \frac{(\text{superiorranking} + \text{n}/2 + 0.5)}{2}, \tag{1}$$

$$\text{Ranking } \textit{ofslightly} \sup \textit{eriorindexes} = \frac{\{(\sup \textit{eriorranking} + \text{n}/2 + 0.5)/2 + \text{n}/2 + 0.5\}}{2}, \tag{2}$$

$$\textit{Rankingof} \inf \textit{eriorindexes} = \frac{(\inf \textit{eriorranking} + \text{n}/2 + 0.5)}{2}, \tag{3}$$

$$\textit{Rankingofslighly} \inf \textit{eriorindexes} = \frac{\{(\inf \textit{eriorranking} + \text{n}/2 + 0.5)/2 + \text{n}/2 + 0.5\}}{2}. \tag{4}$$

2.2.3 Calculation of RSR

RSR is a statistical magnitude with rich connotation and shows the comprehensive level of multiple indices with different measuring units. Calculation of RSR is often conducted according to row or line. The three main calculation methods are shown below.

In Formulas 5 and 6, m is the number of indices, and n is the number of samples. Equation (7) is the RSR calculation formula with weight, where w is the weight. Thus, this study adopts Equation (5) as the calculation foundation.

$$RSR = \sum_{1}^{m} \frac{R}{m \times n}. \tag{5}$$

$$RSR = \sum_{1}^{n} \frac{R}{m \times n}. \tag{6}$$

$$RSR = \sum \frac{RW}{n}. \tag{7}$$

2.2.4 Confirmation of RSR distribution and calculation of regression equation

One row is a group. Ranking R of each group of RSR is confirmed. The probability unit is $profit = \frac{R}{n} \times 100\%$. The regression equation of RSR is calculated. Equation (8) is the regression equation. Equations (9)-(11) are the linear fittings conducted according to least square method. Equation (9) is the augmented matrix of profit, and Equation (10) is the fitting equation of least square method.

$$\hat{RSR} = w_0 + w_1 \times profit. \tag{8}$$

$$A^T = \begin{pmatrix} 1 & 1 & \ldots 1 \\ profit_1 & profit_2 & \ldots profit_n \end{pmatrix}. \quad (9)$$

$$b^T = \left(R\hat{S}R_1 \; R\hat{S}R_2 \quad \ldots R\hat{S}R_n \right). \quad (10)$$

$$A^T A \begin{pmatrix} w_0 \\ w_1 \end{pmatrix} = A^T b. \quad (11)$$

2.2.5 Grading and sorting

Each sample is evaluated and sorted according to optimal principle and calculated in accordance with 95% CI. The computational formulas are Equations (12) and (13).

$$y = \sin^{-1} \sqrt{RSR}. \quad (12)$$

$$Filingvalue = y \pm \sqrt{\frac{820.7}{m \times n}}. \quad (13)$$

2.2 STEPS FOR APPLICATION OF RSR IN COMPETITIVE BASKETBALL SPORT

The detailed steps for application of RSR in competitive basketball sport are as follows:

1) a data structure statistic table similar to Table 1 is established;

2) the indices are positioned to superior or inferior indices according to experience and basketball knowledge;

3) they are ranked according to line, and numerical values of the samples of each index are gained;

4) RSR value is calculated, i.e., $RSR = \sum \frac{R}{m \times n}$;

5) RSR distribution is confirmed, and site selection, analysis, and decision making are conducted according to optimal principle.

3 Five locations in competitive basketball sport and analysis of relevant examination indices

Basketball sport location was only divided according to the locations of rear guard, forward, and center during offensive and defensive in the past. In fact, global basketball development trend gradually divides the five locations according to the distinction of "technical functions" of basketball athletes on the court. Each location is introduced one by one as follows. Superior and inferior indices are also selected.

3.1 CENTER

The center should own a tall figure, explosive power, balance, and the ability to resist collision. The center plays important work in scoring in the forbidden zone, passing, grasping the rebound, and defense.

First, the center should own strong ability to seize the rebound.

Second, the forbidden zone is a place of strategic importance. One team should not let the opponents to enter the forbidden zone easily. Thus, the ability of offensive resistance and block shot is essential.

Finally, during offensive, the center often has the opportunity to catch the ball in the forbidden zone near free-throw line. The center should therefore have favorable ball-leading ability and deliver the ball at the proper corner.

To sum up, eight important indices should be considered when selecting the center, such as inside shot, close shot, low-post shot, free-throw, block shot, backboard, height, and strength.

3.2 POINT GUARD

The point guard primarily protects ball handling over the half court and drives the pace of the entire team to attack and defend. He should be capable of rapid traverse, ball handing, assisting offense, having a high range of three point line and commanding the pace for offense and defense.

Therefore, the eight most important considerations for selecting the point guard are: three-point shot, ball-controlling ability, passing ability, ball handling, shooting, stealing, physical agility, and speed.

3.3 SHOTTING GUARD

The shooting guard is the second ball controller and the one who initiates offense. The shooting guard is responsible mainly for scoring. He should have good three-point shot rate and stability.

Moreover, the shooting guard must be fast enough to seek the gap for a three-point shot. He sometimes has to seek gaps or opportunities for conducting singles because his shooting distance is usually quite remote. Thus, his shooting rate will not be high.

Therefore, when selecting the shooting guard, the factors mainly considered are: three-point shot, speed, perimeter shot, lay-up, close shot, passing, and physical agility.

3.4 SMALL FORWARD

First, the small forward should have a good bodily form and speed. Second, he should be capable of controlling and passing the ball well. Third, the small forward should handle the ball to enter, or enter empty-handed and catch the ball to score a lay-up. Fourth, he should be capable of long shooting. Fifth, if necessary, he must know how to conduct singles in the forbidden zone and have certain destruction ability.

In fact, the fundamental requirement for the small forward is scoring through long shot. His shot rate is not necessarily high.

In selecting the small forward, the following should be considered: perimeter shot, lay-up, slam dunk, free throw, block shot, backboard, height, and strength.

3.5 POWER FORWARD

The power forward should be tall and capable of grabbing the rebound. Meanwhile, he should be flexible, well-coordinated, and assist offense, defense, and covering. He also should be capable of perimeter shots and low-post singles.

Generally speaking, the indices to be considered in selecting the power forward are inside shot, close shot, perimeter shot, defensive, block shot, backboard, height, and strength.

4 Data statistics and analysis

In summary, the present paper selects 35 members of a college basketball team as the samples and the center of a competitive basketball game as basis for data, with each index scored by the coach (0-100 scores). The scores represent the mean performance of each member in basketball games. Table 2 is the table of center selection decision-making.

It can be seen from Table 2 that, in terms of the inside shot, No.35 performs most outstandingly; members No.17, No.22, No.13, No.25, and No. 32 perform relatively well. In the aspect of close shot, No.35 still performs best; members No. 10, No.17, No.9, and No.22 perform relatively well. In the perimeter shot, No.35 member still performs best, followed by members No. 15, No.13 and, No. 25. No.35 performs best in free throws, followed by members No.13, No.16, No.22 and No.33. For block shots, No.33 performs most outstandingly this time, and No.13, No.24 and No.35 perform favorably. In terms of grabbing the rebound, No.35 member performs best again; No.13, No.17, and No.22 are relatively excellent. No.17 is the tallest player, followed by No.13, No.25, No.32 and No.35 members, whereas the strongest member is No.35 followed by members No.33, No.22, No.24, and No.25 members.

31	5	35.0	10	33.0	20	34.0	23	33.0	37	32.0	2	34.0	17	34.0	17	32.0	0.95
32	82	5.0	63	8.0	54	20.5	67	11.0	68	10.5	58	9.5	75	3.0	77	6.0	0.26
33	79	8.5	49	17.0	75	5.5	77	4.0	78	1.0	52	14.5	54	21.0	80	3.0	0.27
34	45	25.0	5	34.0	52	23.0	52	24.5	57	21.0	11	32.0	62	18.0	35	29.0	0.74
35	87	1.0	80	1.0	93	1.0	85	1.0	77	2.5	82	1.0	73	4.0	96	1.0	0.04

Consequently, the primary conclusion is that member No.35 gains good scores in each index and may be the best candidate for the center. No.17 and No. 24 members are also excellent and can be considered as the center bench.

To make decisions more accurately, the 35 members are graded using the data in Table 2.

Table 3 shows the RSR value distribution of Table 2.

0.74	71.4	5.5651
0.78	74.3	5.6526
0.82	77.1	5.7421
0.83	80.0	5.8416
0.83	82.9	5.9502
0.86	85.7	6.0669
0.87	88.6	6.2055
0.88	91.4	6.3658
0.95	94.3	6.5805
0.99	97.1	6.8957

For the data in Table 4 is obtained using least squares fitting, and the linear regression equation of RSR is: $\hat{RSR} = 0.256\,profit - 0.787$.

TABLE 4 The four categories for 35 members

	Most suitable (RSR<0.109)	Bench (0.109<RSR<0.493)	Candidate 0.493<RSR<0.877	Inappropriate RSR>0.877
Member No.	35	2, 4, 9, 10, 13, 14, 16, 17, 20, 21, 22, 24, 25, 26, 27, 28, 29, 30, 32, 33	1, 6, 7, 11, 12, 15, 18, 19, 23, 34	3, 5, 8, 31

Among 35 members, No. 35 member the most suitable center. The members listed in the second line of Table 4 are suitable for being the center bench. When members are lacking, members can be selected from the third line. Members in the last line are not suitable for being the center.

5 Conclusions

Traditionally, RSR is mainly used in the medical field. However, as a visual quantitative classification statistics method, RSR can be introduced in decision-making in sports. The present paper introduces classical RSR comprehensive statistics method in basketball decision-making. 35 members in a basketball team were chosen as the research samples. They were scored according to different indices and the RSR value of their scores were calculated and used as bases for selecting the optimal center player and benches.

The feasibility of using RSR comprehensive analysis in decision-making in basketball is proven through data. The ability of each member in different aspects is visualized through data, which is beneficial to targeted training and cultivation. In conclusion, this paper determines the athletes' location according to RSR comprehensive analysis, which makes the members harness their strong points in practical competitions and gain the best state and the optimal result. Thus, RSR has certain practical significance.

Abstract

College track and field sports involve numerous participants and events. Moreover, recording and announcement jobs are complex. The requirements for accuracy and precision are high. The traditional manual management mode cannot adapt to development needs. Based on the advantages of Radio Frequency Identification (RFID) such as no-barrier read, remote penetration, speed scanning, large memory space, anti-pollution capacity, durability, diversified shapes, reusability, and good security, an RFID-based infrared radiofrequency technique is designed to achieve automatic identity verification for athletes and to construct a complete score management information system. An automatic check mode is used to identify athletes by combining an ID card, a card reader, and a computer. This mode can rapidly identify the personal information of athletes and prevent cheating. This system has important significance for improving management level and reducing manpower.

Keywords: RFID, track and field games, management information system, card reader

1 Introduction

Radio Frequency Identification (RFID) uses inductive space coupling (inductive or electromagnetic coupling) to automatically identify objects [1]. RFID is a non-contact automatic identification technology. This technology can identify specific objectives through a radio signal, and read and write relevant data without mechanical contact or optical contact between the identification system and the specific objective [2]. Common techniques include low frequency (125 k–134.2 k), high frequency (125 k–134.2 k), super high frequency, and microwave. In this study, infrared light is selected as the radio frequency signal source [3]. Common barcode technology has unparalleled obvious advantages in the following aspects: amount of information, read-write capacity, confidentiality, intelligence, photopathy, environmental adaptation, speed identification, running speed, reading distance, service life, and multi-tag identification [4]. RFID technology is used to achieve the fully-automatic management of college track and field sports; it is used to construct an automated score management information system, which can simplify management process and improve management efficiency [5].

Track and field is an important means to improving health [6]. Many methods and means in track and field sports are adopted by other sports and serve as the main means to improving athletic performance and promote metabolism, improve the functions of visceral organs, and comprehensively develop physical quality [7]. Track and field is an effective way to inspecting the effects of the proposed system. In various track and field sports, grassroots track and field sport has the strongest fundamentality and the widest generalization performance [8]. Given that national fitness consciousness is continuously increasing, physical education for college students enters a period of rapid expansion [9]. College track and field sport as an important link in college physical education is characterized by numerous participants and events, complex recording and announcement work, and high accuracy and precision [10]. College track and field sports are traditionally managed manually or artificially. Such management mode involves heavy workloads and a large amount of manpower. Moreover, errors may easily occur [11]. Thus, it cannot meet the requirements of college track and field sports.

The advantages of RFID (such as no-barrier reading, remote penetration, speed scanning, large memory space, anti-pollution capacity, durability, diversified shapes, reusability, and good security) have received much attention from many fields [12]. This study analyzes college track and field sports to confirm the functional objectives of this system as well as to design functional software, select hardware, and complete the design of score management system for college track and field sports.

2 RFID

2.1 RFID SYSTEM COMPOSITION

Given that RFID systems have different applications, their compositions also differ. Typical FRID is mainly

[*]***Corresponding author's*** e-mail: wenxin20142014@163.com

composed of an e-tag, a reader, RFID middleware and application system software. Table 1 shows the functions of each part and their composition.

TABLE 1 RFID system composition

Composition	Function	Composition
E-tag	Identify objects/articles; own data storage mechanism; capable of receiving electromagnetic field modulating signal of the reader and return data carrier of corresponding signals	Active tag and passive tag; low-frequency/high-frequency/superhigh-frequency e-tags; active/semi-active/passive tags
Reader	The device writes or reads data for RFID tags through radio-frequency coupling	Carries out the read-write function through integrated or split-type antenna
RFID middleware	Hardware management, data collection, data processing and data transmission; the "nerve center" of RFID systems	The software that connects RFID hardware, leads and controls data collection, filtering, and application; between RFID devices (reader and labeling machine) and backend application system
Application system software	Control coordination work of the tag and reader through middleware; processes all data collected using the RFID system; computes, stores, and transmits data	Application software developed according to the specific needs of different industries; can effectively control the reader when reading and writing e-tag information; carries out concentrated statistics and processing of target information collected

2.2 REALIZATION PROCESS OF RFID SYSTEM FUNCTIONS

When the tag enters the radiation range of reader aerial, it receives the radio-frequency signal sent by the reader. The passive tag sends the data stored in the tag chip through the energy gained from induced current; the active tag actively sends the data stored in the tag chip. The reader is generally equipped with middleware with certain functions. The middleware can read data, decode, directly perform simple data processing, and send the data to the application system. The application system judges the legality of the tag according to a logical operation and conducts corresponding processing and control in allusion to different settings.

3 Design of score management system for track and field athletics

3.1 ANALYSIS OF CUSTOMER BASE DEMAND OF SCORE MANAGEMENT SYSTEM FOR TRACK AND FIELD ATHLETICS

The main customer base of the score management system for track and field athletics includes athletes, in-charge persons of each department, referees, and management committees. System demand analysis for each type of users is shown in Table 2.

TABLE 2 Demand analysis for each type of customers of track and field athletics

Customer composition	Customer demand
Athletes	Registers, competes, and inquires about the scores
In-charge persons of each department	Athlete registration management; submit registration information to the management committee
Referees	Types in, modifies, and inquires about the cores of the items
Management committee	Works before the application: prepare sport events, sets competition schedules, sets competition events, divides the work between referees (1) Before the competition: athlete information entry, grouping, competition schedule preparation, preparing and printing the competition sequence (2) In the competition: athlete registration, score input, score modification (3) After the competition: competition result announcement, score printing, prize presentation

3.2 OVERALL DESIGN OF SCORE MANAGEMENT SYSTEM FOR TRACK AND FIELD ATHLETICS

3.2.1 Overall system objective

The overall system objective is to realize computer-automated management of college track and field sports, establish a perfect track and field athletics management system, change semi-labor management to computer automated management, and realize the following functions: athlete information tracking, automatic pre-competition reminding, historical score comparison, automatic score release, etc.

The development of this system can free athletes, in-charge persons of each department, referees, and management committees from heavy repeated data entry and statistics, realize information network sharing, and lay the foundation for information automation.

3.2.2 Functional design

According to customer demand analysis and the overall system objective mentioned above, the score management system mainly achieves the following functions: user management, athlete information management, score management, and database management, as shown in Table 3.

TABLE 3 Design of main functions of management system

Function	Object	Inclusion
User management	System administrator	Maintains uniform management of the management system customer base; maintains software security and stability
Athlete information management	In-charge persons of departments, management committees	Adds, modifies, and deletes personal information of athletes
Score management	Referees, management committees	Inputs, modifies, deletes, and publishes, scores
Database management	System administrator	Inputs current useful data; calls out of the database; maintains data security

In traditional college track and field sports, due to laggard means, athlete registration, i.e., personal information checking before the competition and score input after the competition, takes much time.

1) Athlete registration before the competition. This activity gives referees a very heavy workload and long waits also affect the state of athletes. Moreover, traditional registration modes cannot effectively prevent cheating, which affects competition fairness. In such case, RFID-based automatic registration can greatly shorten registration time as well as effectively prevent cheating and ensure competition fairness.

2) Post-competition Score management. In the traditional score input mode, referees must first confirm the list of athletes according to the scores and then input the data, a process that consumes much time and energy.

If athletes can be automatically identified, pre-competition registration and post-competition score input will be very simple. The following processing can be carried out:

1) Before the sports meeting starts, according to athlete information submitted by each department, the management committee uniformly manages athlete information. The information includes the name, ID number, gender, department, grade, photo, etc., of the athletes.

2) Before every competition, the administrative staff calls out the information of the athletes participating in this competition and inputs their IC cards based on RFID technology. Before registration, IC cards are distributed to athletes participating in registration.

3) During registration, the athletes wear the IC card at the registration site and the card reader is used for identification. Through scanning the IC card, the computer displays the registration information of the athlete including the photo. The referee can directly contrast the photo for registration and judge for consistency and cheating behavior.

4) When the competition is over, the card reader reads the IC card of the athlete. Then, the referee can complete score input.

After the competition is over, ID cards are collected uniformly. They can be used in the next competition again according to the above process. The specific application process is shown in Figure 1.

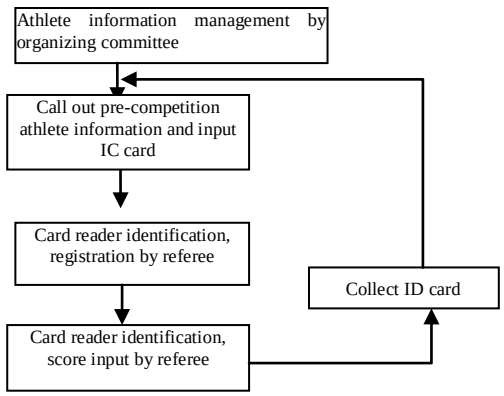

FIGURE 1 RFID-based ID card automatic athlete identification and application process

3.2.3 Network design

RFID uses a radio-frequency signal, space coupling, and the transmission characteristics of radio frequency signal to automatically identify static or mobile articles and data exchange. This technology uses a radio frequency to conduct non-contact both-way communication for identification and data exchange. Thus, the network design of track and field athletics site is also an important link of this management system.

Usually, optional network types include Wireless Local Area Network (WLAN) and wireless LAN.

LAN connects computers distributed in different places in the specified range. Using network software, computer resource sharing or communicative network system can be realized. Wired LAN usually uses copper wire or a cable as the main transmission medium of computer networking.

WLAN is the extension of fixed LAN that uses radio frequency technology to connect to a network without being limited by a cable and replaces traditional LAN made using twisted-pair copper wire. For users, it is completely transparent. Users can clearly establish the network meting their demands according to the simple architecture of WLAN.

TABLE 4 Design of main functions of management system

Type	Advantages	Disadvantages
Wired LAN	Work stably; fast communication speed	Fixed place, complex wiring. Complex work
WLAN	Move flexibly; easy t extend; convenient to use; easy to plan and adjust	Unstable signal, poor communication quality

Through comprehensive consideration, wired LAN and WLAN are combined to construct the overall network of the score management system.

Wired connection: 1) LED large screen and control computer; and 2) control computer and score input computer.

Wireless connection:

1) control computer and registration computer;

2) RFID card reader and registration computer; and

3) RFID card reader and score input computer.

The wired network connection depends on planning for wiring to completely establish a wired network. Wireless network establishment is based on the school wireless network. The router is set up based on the original wireless network to establish LAN. Through LAN settings, the computer on the platform is set to the mainframe to realize information sharing between the mainframe and extension. Thus, the mainframe can obtain competition information, which is convenient for comprehensive organization and uniformly printing information for sports meetings.

3.2.4 Analysis of system design rationality

After the system objective setting, functional design, confirmation of the ID card identification process, and

network design are completed, the Delphi method is used for opinion collection and modification to ensure effective and rational system design. The Delphi method uses predicted questions and background materials to create objective and scientific questionnaires, which are sent to the experts through door-to-door delivery or mail. The experience and knowledge of experts are used to make predictions. Through synthesis, concluding, and much feedback, opinions can basically remain consistent to improve the accuracy of predictions.

This study chooses 20 people including physical exercise experts, large-scale competition organizers, management experts, and software scholars to fill in the questionnaires, as shown in Table 5.

TABLE 5 Interview expert composition

Type	Title	Number	Proportion
Physical exercise experts	Associate professor	7	35%
Large-scale competition organizers		6	30%
Management experts	Professor	4	20%
Software scholars	Associate professor	3	15%

Expert consultation is divided into three rounds. Questionnaire collection and statistics are shown in Table 6.

TABLE 6 Results of expert consultation

Round	Number of questionnaires not collected	Number of questionnaires connected	Number of questionnaires issued
The first round	2	18	20
The second round	1	19	20
The third round	2	18	20

The questionnaire evaluation experts of 20 experts are shown in Table 7.

TABLE 7 Results of expert evaluation

Type	Effective	Basically effective	Invalid
Number	4	16	0

Table 6 shows that, to experts, the functional design of this management system is basically effective and rational. They also find that it can be used for score information management in college track and field sports.

4 Realization of information management system software for track and field athletics

4.1 DEVELOPMENT TOOL AND TECHNOLOGY

ASP.NET operates on Windows platforms under the .NET framework. It is a part of the Microsoft .NET strategy and mainly promotes the technology of Microsoft. ASP.NET is completely based on modules and components. ASP.NET has good expandability and customizability. It is established on the basis of CLR (Common Language Runtime), and mainly used to develop Web applications with strong functions in the server.

As a part of NET Framework, ASP.NET can use all services provided by this framework, including networking, data access, security, and other services. Thus, ASP.NET can create richer Web application programs and constructs building blocks needed by the application program conveniently and swiftly the logic of the application program can be focused on. Visual Basic 6.0 (vb6.0 download) is an event-driven programming language developed by Microsoft. This software includes assistance development environment. VB has the largest number of users. VB6.0 is derived from BASIC programming language. Visual Basic 6.0 has a graphical user interface (GUI) and a rapid application development (RAD) system. Thus, it can easily use DAO, RDO, and ADO to connect the database or easily create ActiveX control.

This study comprehensively applies VB language and ASP.NET technology for he management information system software for track and field athletics.

4.2 OVERALL BLOCK DIAGRAM OF SYSTEM SOFTWARE

System software design is the core content of the whole information management system for sports meetings. The system must complete backstage management interface and system functions must be completed. Thus, software design is an important constituent part of a system. VB language was selected to program the system software. Three major contents are included: backstage management, identity identification, and data information management. The overall block diagram of system software is shown in Figure 2.

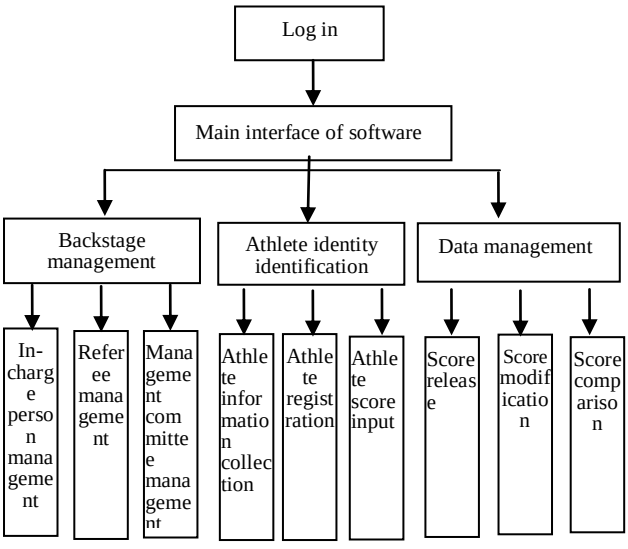

FIGURE 2 Overall block diagram of system software

4.3 REALIZATION OF USER LOG-IN FUNCTION

Use log-in process is shown in Figure 3. Specific codes written by VC are as follows:

```
Set adoRS = New Recordset
adoRS.Open "SELECT * FROM user where user name="& Textl.Text &"", db, adOpenStatic, adLockOptimistic
If adoRS.EOF Then
    Label4.Caption =""
Else
   If Textl.Text""Then
        Label4. Caption = adoRS.Fields("privilege")
        If Trim(Text2.Text) = adoRS.Fields("password")Then
            Unload Me
            db.Close
            MDIForml.Show
        Else
            MsgBox " wrong password"
            Text2.Text = ""
        End If
    End If
End If
```

If user information has been added in the corresponding user database, users can log in through the above process. After new user information is added, the following codes can be used to timely update backstage database, such that new users can promptly log in. The code is as follows:

```
Adodcl.ConnectionString -
"Provider=MicrosoftJet.OLEDB.4.0;Persist Security Info=False;Data Source=" & App.Path & "\name.mdb;Jet OLEDB :Database Password=abc;"
Adodcl .RecordSource = ”SELECT * FROM user”
Adodcl .Refresh
MSHFlexGndl.Refresh
```

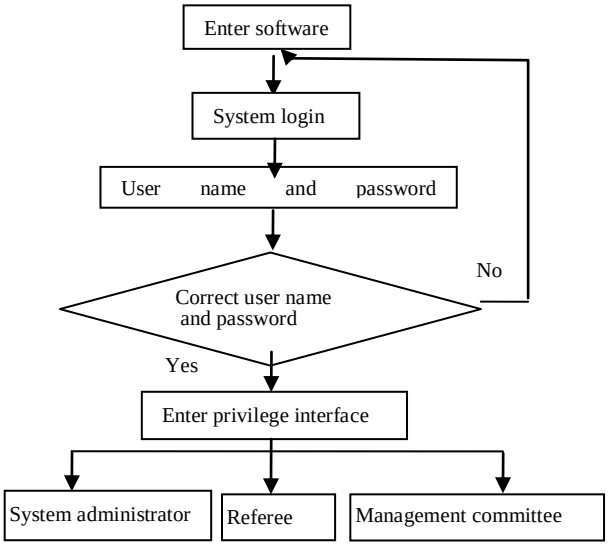

FIGURE 3 Flow diagram of user login function

4.4 REALIZATION OF ATHLETE IDENTITY IDENTIFICATION FUNCTION

Athlete identity identification is the core of the whole management system and was realized through the mutual recognition of IC card and card reader, wireless network connection to the computer, and data transmission. The reader serves as the slave computer, whereas the computer serves as the principal computer. The two conduct serial port communication through a RS-485 serial port.

Before the serial port is used for communication, an initialized setting of the parameters of the serial port is needed: the communication port number must be selected and the size of the buffer, the number of characters of the transmission buffer, the parameters of Baud rate, odd-even check, data bit, and stop bit must be set. The specific process is shown in Figure 4.

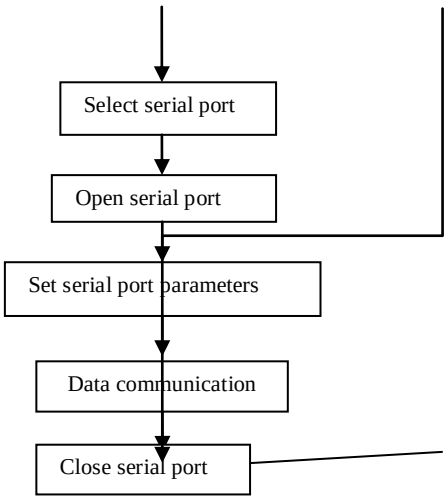

FIGURE 4 Flow diagram of serial port communication

The realization of specific codes is as follows:

```
MSComml.CommPort = 1                                    //set COMl
MSComm 1 .Settings = "9600, N, 8, r"
MSComm l.InputLen = 0// tell the control to read the whole buffer
MSComml .PortOpen = True //open serial port
MSComml.RThreshold = 16 // set to receive a byte to generate OnComm event
//Rem judge whether communication port is open (used in the button of “open serial port”)
If MSComml .PortOpen = False Then
MSComml .PortOpen = True //open communication port
If Err Then
                                                        // error handling
MsgBox "invalid serial port communication”
End If
```

4.5 REALIZATION OF SYSTEM PRINTING FUNCTION

The main functions of print module include printing athlete files for each event, competition results of each event, department scores and total scores, as well as competition arrangements. To realize this function, the score management computer is connected to the printer. The code is as follows:

```
Printer.Print
```

The system interface also has other functions, such as introducing competition rules of the sports meeting, which are not difficult to realize. We can click the toolbar button and apply VB code to connect the interface and WORD document and then click the event code of the button:

```
Dim wordObj
    Set wordObj = CreateObject("Word.Application") //create a word object
    With wordObj.Documents.Open("C:\Documents and Settings\Administratoi\ desktop\sports meeting new \new\ sports meeting rules.doc")
End With
```

5 Hardware design for score management system of track and field athletics

The hardware architecture of score management system for college track and field sports is shown in Figure 5.

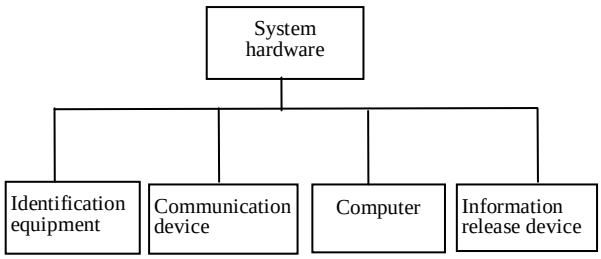

FIGURE 4 System hardware architecture

The card reader is a main part of the identification equipment and connects ID cards to the computer. EM-100T radio-frequency card reader is selected. EM-100T is a non-contact radio frequency IC card reader with a working frequency of 125kHz. The embedded micro-controller is designed with a radio-frequency receiving line and receives a 64-bit compatible ID card uein4100 combined with a decoding algorithm. The microcontroller has high receiving sensitivity, a small working current, and a single DC power supply.

Technical parameters of EM-100T are as follows:

Working frequency: 125 kHz

Working voltage: 9 VDC

Working current: 200 mADC

This system uses a close-loop wrist-strap ID card, which has high resilience and is easy to wear without affecting athlete performance. The watch-shaped card includes a non-contact chip that can send infrared signal to identify the athlete.

The hardware list for constructing the whole system is as follows: 4 computers including 1 host computer, 1 computer for releasing information, and 2 computers for registration; a large LED screen located on the platform of the sporting meeting; 8 card readers including 2 fixed-type card readers and 6 handheld card readers; 80 watch-type ID cards; and extra 20 IC cards for standby applications. The hardware list is shown in Table 7.

TABLE 7 Results of expert evaluation

Hardware equipment	Quantity
Computer	4
LED	1
Card reader	8
ID card	100
Router	4
RS serial port	2

6 Conclusions

This study uses college track and field sports as an example. Then, it starts from practical application and combines RFID technology, database technology, and network technology to establish a RFID-based sport information management system. This study focuses on the features of college track and field sports, such as numerous competition events, many athletes, tight time and heavy workload, and proposes an automatic checking mode for athlete identification combined with ID cards, an card reader, and a computer. Given that RFID technology is unique, it can rapidly identify personal information of athletes, prevent cheating, and improve sport management level. The completion of this system serves a promotional function for the development of college sports. Moreover, using RFID technology in college sports also significantly promotes sports as a whole.

Models for measuring and predicting value creation during merger and acquisitions: a study of bank industry

Guo-yi Chen*

Chongqing three gorges university, Wanzhou City, Chongqing, China, 404120

Received 6 September 2014, www.cmnt.lv

Abstract

This paper employs event study methodology with a 36-day event window to assess the value effects of the US bank mergers occurring between 1994 and 2003. A 38-transaction sample is chosen from the top fifty US bank mergers (according to the assets of targets) occurred during the period from 1994 to 2003. Through analysis, result indicates that the average cumulative abnormal return of the bidders in the chosen sample is negative (-0.99%), while the targets and combined firms are both positive (15.07% and 2.57% respectively). Significance testing also verified that the negative bidder return is confirmed to be insignificant, whilst the positive return of the target and combined firm are both significant. Combined together, It indicates that the 3,517 US bank mergers occurred between 1994 and 2003 create insignificantly negative value for bidders, whilst benefit the target and the integrated banks with significant positive gains.

Keywords: mergers, acquisitions, event study, value effects, measurement model

1 Introduction

The US bank sector has experienced a couple of merger waves. The first one occurred in the 1960s and the second started from the late 1980s and has not finished yet [1]. During the second wave, till 1998, the number of US bank mergers accounted for 15 percent of all public mergers compared to 8 percent before [2]. Such outstanding proportion encourages researchers to search for the reasons of the popularity of M&A in the US bank sector, particularly in terms of the value effects, i.e. whether M&A creates value for the participants and its magnitude.

This study chooses stock market reaction approach as the method to assess the value effects of US bank mergers. A 38-transaction sample is chosen from the top fifty mega-bank mergers occurring from 1994 to 2003, which has not been analysed comprehensively by previous researchers. A 36-day event window is adopted for the event study considering the trade-off between the market efficiency and avoiding the impacts of irrelative noisy events. The stock market data are collected through software Datastream Advance 3.5. This paper observes negative average cumulative abnormal return for bidders and positive ones for both targets and their combinations. Further, t-test, sign test and Wilcoxon signed rank test are used to test the statistical significance of the above results.

2 Establishing value creation measurement model

The primary methodology of this research is event study. Event study is an empirical study of prices of an asset just before and after some event, like an announcement, of merger or dividend. It contains three main steps, namely identifying the event, calculating the average cumulative abnormal return and testing its statistical significance [3]. This paper follows Becher's (2000) 36-day event window (30 trading days prior to and 5 trading days after the announcement date) to test the value effects of bank mergers [4]. 5-day after the announcement date takes account of the under reaction of the stock market and, on the other hand, beneficial for avoiding the unwanted noisy events. 30-day prior to the event aims to involve the advance market reaction caused by the semi-strong form efficiency of the realistic stock market.

2.1 EVENT IDENTIFICATION

The sample used in this study initially contains fifty US bank mergers occurred between 1994 and 2003. They are the top fifty US bank mergers according to the ranking of the targets' assets. Through searching for relative data, including announcement date, share price, market value and S&P 500 Composite Index, there are eventually 38 transactions whose required data are completely available. The rest 12 cases are abandoned due to the lack of data of either the merging or merged firm. In this case, in Datastream Advance 3.5, which is the main source of stock market data for this study, the record under the current name actually reflects the historical data of the merging bank before and after the combination. The record of the acquired bank has thus been covered and cannot be found any more. This situation is severe especially for those banks that experienced several mergers and changed their name in the preceding way. The typical examples include Firstar Corporation and JPMorgan Chase. The main reason of choosing a sample comprised of large bank mergers lies in that it represents the most influential bank mergers in this ten-year period. The distribution of the sampled 38

* ***Corresponding autor's*** e-mail: cgy_22@126.com

bank mergers across years is illustrated by the following Table.

TABLE 1 Number of sampled transactions of each year

Year	Number
1994	2
1995	3
1996	7
1997	5
1998	8
1999	2
2000	1
2001	7
2002	2
2003	1

2.2 CUMULATIVE ABNORMAL RETURNS

After data collection, the next step is to calculate abnormal returns. As explained by Frame and Lastrapes, abnormal return is calculated by subtracting estimated normal return from actual return during the event period [5]. Estimated normal return may be attained through three most widely used methods, namely single-index model, Capital Asset Pricing Model (CAPM), and Market Model [6]. This study follows Becher (2000) to employ single-index model in estimating normal return. The standard and poor (S&P) 500 Composite Index is adopted in this study. S&P 500 Composite Index is a market value-weighted index containing 500 widely held common US stocks that measures the general performance of the stock market. Through observing its daily figures over the event period, the estimated normal return can be obtained by calculating the difference of the S&P 500 Composite Index between a certain day (n) and its previous day (n-1), and then dividing the difference by the index of the previous day (n-1),

$$NR_n = \frac{I_n - I_{n-1}}{I_{n-1}}, \tag{1}$$

where NR_n is the normal return of day n, I_n is the S&P 500 Composite Index of day n and I_{n-1} is that of day (n-1). The similar Equation is used to compute the change of share price (the actual return).

$$\Delta P_n = \frac{P_n - P_{n-1}}{P_{n-1}}, \tag{2}$$

where ΔP_n refers to the change in share price of day n from that of its previous day (n-1); P_n is the share price in day n and P_n-1 is that in day (n-1). Based on these calculations, the abnormal return (AR_n) can be attained through subtracting the normal return from the change of share price.

$$AR_n = \Delta P_n - NR_n. \tag{3}$$

The daily data of both S&P 500 Composite Index and stock price are collected through the software Datastream Advance 3.5. The cumulative abnormal return (CAR) can be computed using either arithmetic or geometric process. The arithmetic process computes the sum of the daily abnormal returns.

$$CAR = \sum_{n=-30}^{5} AR_n . \tag{4}$$

Compared to the simply summing, geometric process multiplies the abnormal return of a certain day (n) with the geometric CAR of its previous day (n-1), and then subtract 1 (Becher 2000).

$$CAR_n = (1 + AR_n) \times (1 + CAR_{n-1}) - 1. \tag{5}$$

Therefore, the geometric CAR over the selected event window, i.e. the geometric CAR of day (+5), is actually the product of every daily abnormal return minus 1.

$$CAR = \prod_{n=-30}^{5} (1 + AR_n) - 1. \tag{6}$$

In order to calculate the cumulative abnormal return of the combined bidder and target (CCAR), this study follows the method of Houston and Rygaert (1994), which is also employed by Becher (2000). The Equation is as below:

$$CCAR = \frac{MV_b \times CAR_b + MV_t \times CAR_t}{MV_b + MV_t}, \tag{7}$$

where MV_b and MV_t are respectively the market value of the bidder and target 30 days prior to the announcement date, which are also collected from Datastream Advance 3.5. The CCAR is the market value-weighted CAR of the combined bidder and target. It takes account of not only their separate CAR over the event window, but also their joint contributions towards the integrated CAR from the stock market. Being weighted by their market values at the beginning of the 36-day event window, the combined cumulative abnormal return reflects the cumulative abnormal increase in terms of the combined market value. This is an effective representative of the market reaction to the bank merger.

From the mathematic perspective, this method exactly calculates the abnormal increase of the combined market value over the event period. It can be proved through the following calculations. Firstly, the change of market value (ΔMV) equals the market value of the last day minus that of the first day of the event window.

$$\Delta MV = MV_1 - MV_0, \tag{8}$$

where MV_1 represents the market value at the end of the event window (in this case the day +5), and MV_0 represents that at the beginning (day –30). Subtracting the normal increase of the market value (NMV, the increase derived from the normal return) from it, ΔMV can be transferred to abnormal increase of market value (AMV), that is:

$$AMV = MV_1 - MV_0 - NMV \,. \tag{9}$$

Equation (9) indicates that the abnormal increase of market value is only composed of the cumulative abnormal return of all issued common shares.

$$AMV = n \times NAR \,, \tag{10}$$

where *n* refers to the number of common shares.

As the *CAR* here is a proportional increase of share price, to attain the net abnormal return per share (*NAR*), we need to multiply *CAR* with the share price of the beginning of the event window (P_0):

$$CAR = \frac{NAR}{P_0} \,,$$

$$NAR = P_0 \times CAR \,. \tag{11}$$

Combining Equation (10) and Equation (11), the next Equation is available:

$$AMV = n \times P_0 \times CAR \,. \tag{12}$$

Then it assumes the number of shares retains unchanging over the event window (through analyzing the sampled banks, none of them issued new shares during the event period), i.e. n1 = n0, then Equation (12) can be further transferred to Equation (13).

$$AMV = n_0 \times P_0 \times CAR = MV_0 \times CAR \,. \tag{13}$$

The proportional abnormal increase of the market value, i.e. the cumulative abnormal increase of market value (*CAMV*), is dividing abnormal increase of market value by the beginning market value.

$$CAMV = \frac{AMV}{MV_0} \tag{14}$$

When the bidder and target are treated as a whole, its beginning market value is the sum of their respective beginning market values (MV_b+MV_t), and the total abnormal increase of market value equals the sum of their individual abnormal increase of market value. Thereby, the cumulative abnormal increase of the combination's market value is:

$$CAMV = \frac{MV_b \times CAR_b + MV_t \times CAR_t}{MV_b + MV_t} \,. \tag{15}$$

Equation (15) is identical with Equation (8) which is used to determine the cumulative combined abnormal return. Therefore, the combined cumulative abnormal return determined by weighting their CARs is equivalent to the combined abnormal increase of market value, which reflects the integrated market reaction to the bank merger. Alternatively, this relationship can also be proved by simply combining Equation (13) and Equation (14):

$$CAMV = \frac{AMV}{MV_0} = \frac{MV_0 \times CAR}{MV_0} = CAR \,. \tag{16}$$

Most of these sampled transactions occurred at different time. Even if being announced at the same day, such as NationsBank' merger with BankAmerica and BankOne acquiring First Chicago NBD, the transactions did not dependent on each other. From this perspective, all the transactions in the sample can be regarded as independent and therefore the average combined cumulative abnormal returns of the sample ($\overline{CCAR}$) can be expressed by their arithmetic mean.

$$\overline{CCAR} = \frac{1}{N} \sum_{n=1}^{N} CCAR_n \,. \tag{17}$$

where *N* stands for the sample size.

2.3 SIGNIFICANCE TESTING

The final stage is to test the statistical significance of the sample mean ($\overline{CCAR}$). There are 3,517 bank mergers occurring in America from 1994 to 2003 [7]. What is chosen is thus a small sample relative to the population. After calculating the mean of the accumulative abnormal returns of all the 38 transactions, it is necessary to test the statistical significance of the result. This study applies t-test, sign test and Wilcoxon signed rank test in this stage. The reasons of choosing these three methods and their respective procedures are demonstrated as follow.

The t-test is the standard and most sensitive test for interval data [8]. It deals with the issues associated with the inference based on small samples. However, the t-test is subject to the assumption of a normal distribution. According to the central limited theorem that the mean of a sample is normally distributed if the size of the sample is over 30 [9], the 38-transaction sample in this study is large enough to consist with the required assumption and hence the result of the t-test should be valid.

The standard Equation of t-statistic is:

$$t = \frac{\bar{x} - u}{s} \sqrt{n} \,, \tag{18}$$

where $\bar{x}$ is the sample mean and u is the population mean; *n* is the sample size and s is the standard deviation [10]. Another parameter is p-value, which indicates how accurately the regression coefficient has been estimated. The p-value can be obtained through checking the Confidence Limits Table according to the t-statistic.

These two parameters above will assist the hypothesis testing. The null hypothesis will be set as that the population mean equals zero:

$H_{0:}$ u = 0.

Using the t-test and the corresponding p-value, we can decide whether to reject or accept the null hypothesis as well as how accurate the decision is. If the t-statistic is located within the confidence interval (under the condition of 37, (*N*-1), degrees of freedom and 5 percent significance level, i.e. p≥5%, we will accept the null hypothesis [11]. Otherwise, if p<5% the null hypothesis is unacceptable, i.e. u≠0. The p-value will provide the exact degree of significance of this decision. To calculate the p-value, according to Watsham and Parramore (1997), this paper firstly identify that the t-statistic can be interpolated in the interval between β_1 and β_2 [12].

Through checking the Confidence Limits Table, this interval corresponds to a interval of significance level between a_1 and a_2. Then the calculation of p-value can be based on the following Equation:

$$p = \alpha_1 - (t - \beta_1) \times (\alpha_1 - \alpha_2). \tag{19}$$

In this study, both the t-test and p-value will be calculated with the assistance of the statistical software Stata-8.

In order to ensure the accuracy of the statistical significance testing, this study also employs two nonparametric statistics, Wilcoxon signed rank test and sign test. Although the 38-transaction sample can be treated to consist with the normal distribution assumption, the actual distribution is still unknown. Under this circumstance, it is necessary to apply nonparametric statistics which are most appropriate when the sample is small. In contrast with t-test, sign test is not subject to any assumption on distribution and hence treated as the most insensitive test and also the most convincing and easiest test to be applied. It only uses the signs to test the null hypothesis that the number of + signs (the probability of observing a + sign is denoted as p, + sign represents the positive abnormal return) is equal to the number of – signs (the probability of observing a – sign is denoted as q, - sign represents the negative abnormal return), i.e. H0: p=q=0.5. The relationship between p and q consists with binomial distribution because the possibility of observing a + sign plus that of observing a – sign is equal to 1, i.e. p+q=1. Therefore we can employ the Equation of binomial distribution to calculate the p-value of each probability of observing + signs (x, x=n, n-1,…,0) in this sample:

$$p\{x\} = \frac{x!}{x!(n-x)} p^x q^{n-x}. \tag{20}$$

We choose a certain p_1 which makes $p\{x \geq p_1\}$, i.e. $p\{n\}+p\{n\text{-}1\}+\cdots+p\{p_1\}$, the closest probability to 5 percent level(degree of significance). If the p-value of real number of + signs in the sample ($p\{x \geq p\}$) falls in the critical region, i.e. $p\{x \geq p\} < p\{x \geq p_1\}$ (or <5%), we reject the null hypothesis. Otherwise, if $p\{x \geq p\} \geq p\{x \geq p_1\}$ (or ≥5%) the null hypothesis will be accepted.

Wilcoxon test takes account of not only the signs but also the magnitude of each sign through calculating the rank sums. Thereby, it is regarded as a more sensitive test than sign test. Moreover, it is more sensitive than t-test for small samples with unknown distributions [13] as it does not require estimating the parameters of the values (such as the standard deviation of the population) and the distribution of the sample.

In Wilcoxon test, the elements are ranked according to their absolute values (ascending sort). Then the ranks of the positive elements are summed (the sum is denoted by V). The null hypothesis (H0: u=0) here indicates that there is no difference between V and the rank sum of the negative elements (W), i.e. $V = W = \frac{1}{2}\sum_{n=1}^{N} n$ (N is the sample size). The mean (u_v) and standard deviation (σ_v) of V are calculated by the following Equations:

$$u_v = \frac{1}{2}\sum_{n=1}^{N} n = \frac{N(N+1)}{4}, \tag{21}$$

$$\sigma_v = \sqrt{\frac{N(N+1)(2N+1)}{24}}. \tag{22}$$

The z-value is computed by the Equation below:

$$z = \frac{V - u_v}{\sigma_v}. \tag{23}$$

Compared the z-value with the critical values under the condition of 5 percent significance level and 37, (38-1), degrees of freedom, if the z-value falls in the critical region the null hypothesis will be rejected, otherwise we accept it. The p-value is available from the table of Rank-Sum Critical Values, and its precise value can be calculated by the same method as that in t-test (Equation (19)). In this study, Stata-8 will calculate the corresponding p-value of each z-value. We will compare it with 5 percent significance degree: if p≥5%, we will accept the null hypothesis; Otherwise, if p<5%, the null hypothesis will be rejected.

According to the hypothesis testing assisted by t-test, sign test and Wilcoxon signed rank test, the mean of the cumulative abnormal returns will be justified to be acceptable or not as well as at what significance level. These three methods are all used for testing small samples. However, the nonparametric statistics sign test and Wilcoxon signed rank test relax the normality assumption of the t-test. Moreover, the Wilcoxon signed rank test take the magnitude of the signs into account and thereby can further confirm the result of sign test.

3 Empirical analysis of US bank M&A

3.1 SAMPLE MEAN

Through the operations based on the Equations (1-7) and assisted by Microsoft Excel, the cumulative abnormal returns and combined cumulative abnormal returns are computed from the collected data about the sampled 38 transactions. The results of the cumulative abnormal returns of the bidders (CAR(b)) and targets (CAR(t)) and their CCARs are summarized and illustrated by the following Figure 1.

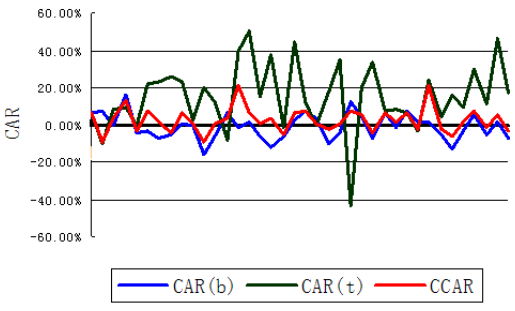

FIGURE 1 CAR Distributions

Figure 1 shows that most of the sampled mergers provide positive cumulative abnormal returns to the targets. There are two outstanding exceptions that characterised by negative target returns but positive bidder returns. One is No. 13---NationsBank (CAR: 6.34%) acquires Boatmen's Bancshares (CAR: -8.44%); the other is No. 24---Wells Fargo & Company (CAR: 12.04%) acquires First Security Corporation (CAR:-43.62%). However, their combined cumulative returns maintain positive.

The average cumulative abnormal returns are listed in the following Table 2.

TABLE 2 Means of CAR and CCAR

	CAR(b)	CAR(t)	CCAR
Mean	-0.99%	15.07%	2.57%

Therefore, within the chosen 38-transaction sample, the observed value effect of the US bank mergers on the bidders is negative (-0.99%) but positive on targets (15.07%) and combined banks (2.57%). Using Stata-8, the statistical significance of the above results can be tested by t-test, sign test and Wilcoxon signed rank test respectively.

3.2 RESULTS OF SIGNIFICANCE TESTING

The process of Stata-8 based significance testing is recorded and analyzed in this part. The following analysis interprets the result of the significance testing.

3.2.1 t-test

As explained in Methodology, the null hypothesis of t-test is that the population mean of the cumulative abnormal returns is zero ($H_{0:\,u}$=0). The result of t-test is demonstrated by the Table 3 below.

TABLE 3 t-test

	t	p	Accept H_0?
CARb	-0.863	0.394	Yes
CARt	5.181	0.000	No
CCAR	2.334	0.025	No

On the bidder side, its t-vale (-0.863) corresponds to a p-value of 39.4%, which is much bigger than the selected degree of significance, 5%. Thereby, this t-vale is located in the acceptance region that means the null hypothesis cannot be rejected. Under this circumstance, the negative sample mean is insignificant for the population. Based on the result of t-test, it is concluded that the value effect of the US bank mergers on bidders is negative, but insignificantly.

In contrast to the situation of the bidder, both the t-statistics of target (5.181) and combined bank (2.334) fall in the critical region, as their p-values, 0.0% and 2.5% respectively, are smaller than 5%. The H0 for the target and combined firm are therefore rejected. As the conclusion, the value effects of the US bank mergers on target and combined firm are significantly positive.

3.2.2 Sign test

There are 17 bidders with observed positive cumulative abnormal returns whilst 21 targets with negative ones. The null hypothesis here is p=q=0.5, i.e. the probabilities of observing a positive and a negative cumulative abnormal return are equivalent. According to the results of sign test shown in Table 4, $p\{x\geq 21\}$ is 62.7% which is much larger than 5%, which means that the null hypothesis should not be rejected. Consists with that of t-test, the corresponding conclusion is that the value effect on bidder is insignificant negative.

TABLE 4 sign-test

	P	Accept Ho?
CARb	0.627	Yes
CARt	0.000	No
CCAR	0.034	No

As for targets, the number of observed + signs is 31 while that of - signs is 7. $p\{x\geq 31\}$=0.0% which is smaller than 5% and H0 therefore can be reject even at 1% level. Similarly, there are 26 pluses and 12 minuses observed within combined banks. In this case, $p\{x\geq 26\}$=3.4% that is also smaller than 5%. The H0 is therefore can be rejected at 5% significance level. Based on the couple of rejections of H0, the sign test obtains the same results as t-test: the positive value effects on targets and combine firms are both significant.

3.2.3 Wilcoxon signed rank test

The result of Wilcoxon test is demonstrated by the Table 5 below.

TABLE 5 Wilcoxon signed rank testt

	z	p	Accept H_0?
CARb	-0.812	0.417	Yes
CARt	4.343	0.000	No
CCAR	2.110	0.035	No

According to the result attained by Stata-8, the z-values of the CAR's rank sums of the bidder, target and combined firm are –0.812, 4.343 and 2.110 respectively. Their corresponding p-values are 41.7%, 0.0% and 3.5%. Therefore, the z-value of the bidder is located in acceptance region while that of the other two fall in critical region. It indicates that the null hypothesis, H0: $V = W = \frac{1}{2}\sum_{n=1}^{N} n$, should be accepted for the bidder while rejected for both the target and the combined firms. As the conclusion, the same as that of t-test and sign test, the negative CAR of bidders is insignificant while the positive CAR of targets and combined firms are both significant.

4 Research finding

The significance testing through t-test, sign test and Wilcoxon signed rank test thus draw the same conclusion, that is, over a 36-day event window the US bank mergers occurring between 1994 and 2003 create insignificantly negative gains for bidders, and significant positive value for target banks and their combinations.

This conclusion firstly supports the previous studies that find positive gains for targets. Such studies include

those conducted by Becher (2000), Houston and Ryngaert (1994), Zhang (1995) and other six studies quoted by Becher (2000) [14], which calculate 20.48% of target bank gains on average. However, although a negative bidder gain is observed (-0.99%) in the 38-transaction sample, it is insignificantly different from zero. This is different from most of the previous studies. Two-third of studies conducted before 1994, found significant negative gains of acquiring banks. Through analysing the bank mergers in the 1990s, Becher (2000) calculate significantly positive bidder returns over a 36-day event window that is similar as what has been used by this study, while significant negative bidder returns are found over an 11-day event window. As for the combined firms, this study documents a significant positive return which supports the conclusion of Becher (2000). Nevertheless, more previous studies suggest the insignificant effect of bank mergers on combined firms due to the offset of negative bidder returns against the positive targets gains. Such studies include those conducted by Hannan and Wolken (1989) and Houston and Ryngaert (1994) [15].

According to Becher's (2000) criteria of clarifying merger motivations, the results of the event study consist with the characteristics of mixed hypotheses of hubris and synergy--- positive target returns, negative bidder returns and positive combined returns. However, the negative bidder return is insignificant, therefore, its attribute is much closer to synergy hypothesis, which is characterised by non-negative bidder returns compared to the mixed hypothesis which implies negative bidder returns. In this case, the US bank mergers occurring between 1994 and 2003 are incline to be motivated by synergy, rather than hubris.

5 Conclusions

As a popular business strategy, M&A has significant merits, including enabling companies to enter new markets more efficiently and smoothly compared to establishing new subsidiaries, as well as requiring only managerial skills in stead of entrepreneurial ones. However, in practice, merger activities are motivated by a variety of factors based on practical situations.

This Paper applies event study methodology with a 36-day event window (30 trading days before and 5 trading days after the announcement date). A 38-transaction sample is chosen from the top fifty US bank mergers (according to the assets of targets) occurred during the period from 1994 to 2003. Through the calculations based on the collected data, this study finds that the average cumulative abnormal return of the bidders in the chosen sample is negative (-0.99%), while that of the targets and combined firms are both positive (15.07% and 2.57% respectively). With the assistance of significance testing, including t-test, sign test and Wilcoxon signed rank test, the negative bidder return is confirmed to be insignificant, whilst the positive return of the target and combined firm are both significant. It indicates that the 3,517 US bank mergers occurred between 1994 and 2003 create insignificantly negative value for bidders, whilst benefit the target and the integrated banks with significant positive gains. Combining with the criteria of the couple of hypothesizes concerning bank merger motives, the conclusion is incline to support the synergy hypothesis, which claims that the US bank mergers occurring from 1994 to 2003 are more likely driven by synergy motive.

Structural equation model of college foreign language writing and classroom teaching quality from perspective of teacher evaluation

Fumeng Gao*

School of Foreign Languages, Fuyang Teachers' College, Fuyang City, Anhui Province, China, 236037

Received 8 September2014, www.cmnt.lv

Abstract

Existing teaching quality evaluation systems have insufficient comprehensive indices reflecting teaching quality: index repetition, complication, quantification difficulty, and difficulty in judging the relationship. To make classroom teaching quality evaluation consistent with teaching effect, element weight is confirmed based on a structural equation model. The present paper takes a college foreign language writing class as the object of study and sets up a structural equation model for classroom teaching quality evaluation. Effect coefficients of each variable are calculated, and the weight of each element of classroom teaching quality evaluation is then obtained. Such method avoids artificially scoring elements during the confirmation of element weight, reduces evaluation subjectivity, and makes the evaluation results more accurate, rational, and credible.

Keywords: structural equation model, teacher evaluation, classroom teaching, teaching quality

1 Introduction

The structural equation model originated from the path analysis concept introduced by Swell Wright in the 1920s. Structural equation model is also called simultaneous equation model and causal model etc. A great breakthrough in the development process of the structural equation model is the development of the concept of latent variable. It is the result of the joint development of latent variable and economics, etc. [4]. The structural equation model in this paper uses the latent variable. Traditional multivariate analysis method can only test the relationship between single independent variable and independent variable at the same time. Factor analysis can reflect the relationship among variables, but cannot further analyze causal relationships among variables. Although path analysis can analyze causal relationships among variables, complying with the following fundamental assumptions is difficult: zero fundamental assumption, unrelated residual error, and single-way causal relationship. A composite model which can synthesize these models is urgently needed. Structural equation model integrates path analysis, confirmatory factor analysis, and general statistical test method, and can analyze mutual causal relationship among variables. It contains advantages of factor analysis and path analysis. Meanwhile, it makes up for disadvantages of factor analysis, considers the error factor, and is not limited to assumed conditions of path analysis.

At present, the enrollment scale of Chinese higher education expands continuously. Problems caused by sharp expansion of enrollment scale include scarcity of teaching resources and reduction of teaching quality. College classroom teaching quality thus becomes a social problem. No stable student pool under the condition where talent cultivation quality receives increasing attention without efficient classroom teaching quality. Thus, colleges will lose core competitiveness. Teaching quality is a multi-layer concept and a vital problem in the development of colleges. Since teaching quality involves the input, process, and results of teaching activities, as well as diversified public, teaching quality is a multi-dimensional evaluation index. Teaching quality refers to students' growth in knowledge, ability, and values, and is the result of comprehensive function of the whole teaching system. Scientific and effective classroom teaching quality evaluation is significant in achieving total teaching quality management and quality monitoring, and plays an irreplaceable role in improving teaching quality. On the other hand, in recent years, English writing ability of college students have received great attention. Unsatisfied employers noted that only 5% of college students have good writing and expression ability, whereas 37% of college students fail to reach the standards and are even poor in terms of writing ability. Thus, many colleges pay more and more attention to foreign language study and with a focus on writing training and cultivation. Many schools now strive to explore other methods and improve the evaluation of foreign language writing teaching results. During course teaching quality evaluation, students are the evaluation subjects, as they know whether the teaching method is effective. However, college course teaching is academically dependent, and final evaluation of teaching quality by students cannot really reflect actual situations.

* ***Corresponding author's*** e-mail: gaofumeng@yeah.net

On the contrary, if students grasp the evaluation of course quality based on interaction between students and teachers this will have direct negative impacts on constructing harmonious student-teacher relationships. Thus, other subjects must be chosen. Teachers participate in evaluation index design, which reflects colleges respect for teachers' autonomous right. In this way, teachers can be aware of teaching evaluation significance and evaluation scheme bases, mentally accept evaluation indices, and provide professional evaluation from an objective perspective. Therefore, teacher evaluation is significant in classroom quality evaluation.

The features of structural equation model are as follows: many research variables cannot be directly be observed and measured like teaching quality. The concept of latent variable is applied when we need to study such variables, and corresponding dominant variables for a research are selected. For example, when we study classroom teaching quality, teaching quality is, to a great extent, reflected in final scores, which can ce measured. Thus, structural equation model with latent variables is applied to classroom teaching quality. Structural equation model with latent variables have two basic modes: structure pattern and measurement pattern. Computational formula system approach is used to verify college foreign language writing teaching. Latent variable factors and their mutual causal relations can be explored through measuring and forming the system. The present paper sets up the structural equation model for college classroom teaching quality evaluation, expands research perspectives and research methods for college teaching quality on the basis of teacher evaluation, and establishes proper teaching quality evaluation indices to estimate teaching quality of foreign language writing class in a college.

2 Theory summary

2.1 STRUCTURAL PATTERN

Structural pattern states causal relationship between latent exogenous variables and latent endogenous variables. The structural equation is expressed as:

$$\eta=B\eta+\Gamma\xi+\zeta, \quad (1)$$

where ξ is the latent exogenous variable (latent independent variable) matrix, η is the latent endogenous variable (latent dependent variable) matrix. Γ is the structure coefficient matrix that represents the effects of ξ on η in the structural model. B is structure coefficient matrix that represents the mutual effects of component factors of η in the structural model, and ζ is the residual error matrix of the structural equation.

2.2 MEASUREMENT PATTERN

Measurement pattern explains the relationship between latent variables η and ξ, and measured variables y and x.

The measurement equation in terms of X is $X=\Lambda X\xi+\delta$, where X is the measured variable matrix of ξ, ΛX is the measurement coefficient matrix that represents the relationship between η and measured variable X and δ is residual error matrix of the measurement equation.

The measurement equation in terms of Y is $Y=\Lambda Y\eta+\varepsilon$, where Y is the measured variable matrix of η; ΛY is measurement coefficient matrix that represents the relationship between η and measured variable Y, and ε is the residual error matrix of the measurement equation.

3 Construction of structural equation model of college foreign language writing classroom teaching quality from perspective of teacher evaluation

3.1 THEORETICAL MODEL FOR TEACHING QUALITY

The structural equation model does not offer the general pattern to set up the theoretical model. Theoretical model construction is based on the research each relevant field and the study of index system establishment. The present paper starts from the perspective of teacher evaluation. Given that teachers tend to be more processional and objective when evaluating course quality, 4 latent variables and 16 observed variables are set (Table 1) The structural model is composed of 3 exogenous latent variables (teaching attitude, teaching content and teaching method) and 1 endogenous latent variable (teaching effect).

Teaching attitude. Teaching attitude involves strictly following teaching discipline, putting sufficient time and energy to prepare lessons and improving teaching methods after class, actively shortening distance with students, communicating with students freely and creating harmonious student-teacher relationship. Teaching attitude reflects the teachers' degree of valuing classroom teaching. Teachers' teaching attitude can directly impact teaching quality as the first key index. Teaching attitude is reflected through 4 indices, i.e. I11, U12, U13 and U14 (Table 1).

Teaching content. Teaching content is the core of classroom teaching, the basic link of knowledge hierarchy construction by students, and the core of classroom teaching quality evaluation. Only when teaching content is correctly planned can the accuracy of classroom teaching quality evaluation be guaranteed. Teaching content refers to the knowledge imparted to students by teachers in the knowledge hierarchy. For most colleges, course teaching content has no absolute uniform requirement. Each college can order teaching materials as needed, and teachers can expand the scope of knowledge on the basis of the teaching material. Evaluation should include indices U21, U22, U23, and U24 (Table 1).

Teaching method. Teaching method refers to the method and process used by teachers to impart knowledge to students. Teaching methods mainly include tools and methods, which directly affect the improvement of teaching quality. Teaching method mainly consists of indices U31, U32, U33, and U34 (Table 1).

TABLE 1 Latent variables and observed variables in the structure

Type of latent variable	Latent variable	Type of observed variable	Observed variable
	Teaching attitude		U11: carefully and responsibly prepare lessons; teaching documents are complete U12: serve as a model for students; impart knowledge and educate students U13: carefully teach; strong enthusiasm for teaching U14: pursue studies rigorously; give strict requirements
Exogenous latent variable (ζ)	Teaching content	Exogenous observed variable	U21: familiar with teaching materials and teaching plans; proficient in teaching U22: concepts are correct; highlight key points and difficult points; demonstration is precise and expression is correct U23: link theory and practice; reflect cutting-edge knowledge of the subject U24: teaching progress is moderate; class period is allocated rationally
	Teaching method		U31: vivid and concise language; logical; accurate examples U32: flexible and diversified teaching methods; pay attention to ability and quality cultivation U33: properly apply various modern teaching supplementary means U34: rational blackboard-writing layout; clear and tidy writing
Endogenous latent variable (η)	Teaching effect	Endogenous observed variable	U41: teaching is attractive; lively classroom atmosphere U42: point out reference materials, arrange after-class review; good classroom discipline U43: students have strong learning interest U44: students' mastery of basic knowledge, theory and skills

Teaching effect. Teaching effect directly reflects classroom teaching quality and classroom teaching quality evaluation indices. It means the approval of course necessity. Teaching effect is mainly reflected by indices U41, U42, U43, and U44 (Table 1).

3.2 DETAILED MODEL OF FOREIGN LANGUAGE WRITING CLASS

3.2.1 Identification of structural equation

For foreign language writing class in particular, exogenous latent variables in Table 1 also contain "teacher quality." Teacher quality is mainly reflected in two aspects: "teachers' pronunciation is standard" and "teachers have strong listening, speaking, and comprehension skills." These are two corresponding exogenous observed variables. Aside from this, endogenous s latent variable (i.e. teaching effect) can be divided into "students' ability to listen to and comprehend a foreign language" and "students' ability to speak and express a foreign language." Thus, the parameters (t) that need to be estimated include 22 path coefficients $\lambda(x)$ and $\lambda(y)$ from latent variables to dominant variables. A total of 18 residual errors δ and ε of dominant variables, 8 path coefficients $\lambda(\zeta)$ and $\lambda(\eta)$ among latent variables, 14 exogenous dominant variables (p), and 4 endogenous dominant variables (q) exist. The freedom degree of the path diagram of the model can be expressed as:

$$df = [(p+q)(p+q+1)/2] - t = 149 > 0.$$

Thus, the model can be identified.

3.2.2 Fitting of structural equation model

The present paper utilizes AMOS software, selects CMIN/DF, RMSEA, GFI, AGFI and NFI) as evaluation indices, and calculates the fitting degree [8]. Table 2 shows the calculation results.

TABLE 2 List of fitting coefficients

Index	CMIN/DF	RMSEA	GFI	AGFI	NFI
Data	2.702	0.077	0.836	0.891	0.854

Bain et al., considering CMIN/DF < 3, show that the overall effect of the model is good. Lyle et al. note that if RMSEA < 0.08 and the value of GFI, AGFI and NFI is between 0.8 and 0.9, then the mode exhibits a good fit. According to Table 2, the explanatory ability of structural equation model for foreign language writing teaching quality evaluation is strong.

3.2.3 Parameter estimation and test

This paper adopts maximum likelihood method and applies AMOS software to analyze factor loading and path coefficient of each dominant variable, then normalization processing is carried out. Finally, normalized factor loading and normalized path coefficient are obtained.

In accordance with the principle of maximum likelihood method, when factor loading exceeds 0.4, the mode has a good explanatory ability. The normalized factor loading of the above dominant variables exceeds 0.4, which indicates that each factor has strong explanatory ability for measurement model. For the first exogenous latent variable teaching attitude $\xi 1$, the loading of the observed variable X_1 "U11" is the largest. This shows the first exogenous latent variable has the greatest contribution, followed by X_2, X_3 and X_4. Similarly, dominant variable X_6 "U22", X_{10} "U32", X_{14} "teachers have strong ability in listening, speaking and comprehension", Y_1 "U41", and Y_3 "U43" have the greatest contribution to the exogenous latent variables "teaching content", "teaching method", "teaching quality", "students' ability to listen to and comprehend a foreign language", and "students' ability to speak and express a foreign language", respectively.

TABLE 3 Normalized factor loading

Dominant variable	Normalized factor loading	Dominant variable	Normalized factor loading
$X_1(\xi_1)$	0.6023	$X_{12}(\xi_3)$	0.4936
$X_2(\xi_1)$	0.4877	$X_{13}(\xi_4)$	0.5824
$X_3(\xi_1)$	0.4721	$X_{14}(\xi_4)$	0.6305
$X_4(\xi_1)$	0.5862	$Y_1(\eta_1)$	0.7082
$X_5(\xi_2)$	0.6417	$Y_2(\eta_1)$	0.5399
$X_6(\xi_2)$	0.7135	$Y_3(\eta_1)$	0.4768
$X_7(\xi_2)$	0.6628	$Y_4(\eta_1)$	0.4693
$X_8(\xi_2)$	0.4176	$Y_1(\eta_2)$	0.6270
$X_9(\xi_3)$	0.5034	$Y_2(\eta_2)$	0.5345
$X_{10}(\xi_3)$	0.6209	$Y_3(\eta_2)$	0.6547
$X_{11}(\xi_3)$	0.5470	$Y_4(\eta_2)$	0.5384

TABLE 4 Normalized path coefficients

Latent variable path	Normalized path coefficient	Significance at 0.0001 level	Verification result of Hypothesis
$\xi_1 \cdots \rightarrow \eta_1$	0.6288	Significant	Support H_1
$\xi_2 \cdots \rightarrow \eta_1$	0.8406	Significant	Support H_2
$\xi_3 \cdots \rightarrow \eta_1$	0.8073	Significant	Support H_3
$\xi_4 \cdots \rightarrow \eta_1$	0.7592	Significant	Support H_4
$\xi_1 \cdots \rightarrow \eta_2$	0.6317	Significant	Support H_5
$\xi_2 \cdots \rightarrow \eta_2$	0.8129	Significant	Support H_6
$\xi_3 \cdots \rightarrow \eta_2$	0.7965	Significant	Support H_7
$\xi_4 \cdots \rightarrow \eta_2$	0.8248	Significant	Support H_8

According to path coefficients of latent variables in the table, overall effects of exogenous latent variables ξ_1, ξ_2, ξ_3 and ξ_4 on endogenous latent variable η_1 are 0.688, 0.8406, 0.8073 and 0.7592, respectively, and their effects on endogenous latent variable η_2 are 0.6317, 0.8129, 0.7965 and 0.8248, respectively. This implies that if teaching attitude, teaching content, teaching method and teacher quality improve one standard unit, students' ability to write and comprehend a foreign language will increase by 0.688, 0.8406, 0.8073, and 0.7592 standard units, respectively, and students' ability to speak sand express a foreign language will increase by 0.6317, 0.8129, 0.7965, and 0.8248 standard units, respectively.

Table 3 and Table 4 show that teaching attitude, teaching content, teaching method, and teacher quality have significant effects on two indices of foreign language writing teaching quality: "students' ability to write and comprehend a foreign language" and "students' ability to speak and express a foreign language". Thus, they can estimate teaching quality. Observed variables X_1 "U11", X_6 "U22", X_{10} "U32", X_{14} "teachers have strong ability in listening, speaking and comprehension", Y_1 "U41", and Y_3 "U43" have the greatest contributions to each latent variable, with each contribution signify-cantly different from the others.

Therefore, the structural equation model forms a reliable quantification measurement scale with certain reliability and validity, and provides a weight coefficient and good theoretical support for displaying foreign language writing teaching quality.

4 Conclusions

Based on the perspective of teacher evaluation, the present paper investigates foreign language writing teaching quality of a college and presents a structural equation model for classroom teaching quality through analyzing and testing sample data. The application of structural equation model strengthens the objectivity of the weight of each element of teaching quality evaluation, and overcomes the subjectivity of scoring by experts using existing point-factor method. Its application on classroom teaching enhances the comparability of teaching quality and keeps evaluation results consistent. The model addresses the difficulty in directly measuring teaching attitude, teaching content, teaching method, and teacher quality, which have direct positive effects on teaching, and promotes studies on the cause and effect influencing foreign language writing teaching. Nowadays, colleges should improve teaching content and approach to enhance education and encourage the continuous improvement of colleges.

Abstract

Developing the rural areas with the aid of the urban areas, which was summarized through the long practice in China, is a new mode of promoting the coordinated development of urban-rural areas. The evaluation of the impact of this mode on promoting the coordinated development of urban-rural areas has great significance for reference for the urbanization development in other countries around the world. This paper takes Chenggong New District in Yunnan, China as an example, calculates the coordination degree of its urban and rural development in 1999, 2004 and 2009 with the use of urban and rural development coordination degree model, then makes clustering analysis of the urban and rural development coordination degree in various districts in Chenggong New District in 2009 with the use of Ward's method. Results indicate that a) the urban and rural development coordination degree of Chenggong New District is 0.359 in 1999, 0.545 in 2004, and 0.504 in 2009. The increase in the coordination degree year by year shows the mode of developing the rural areas with the aid of the urban areas has obvious effects on the coordinated development of urban-rural areas; b)the mode of developing the rural areas with the aid of the urban areas has obvious coordination impact on the aspects of infrastructure construction and basic livelihood guarantee, but has not enough coordination impact on the aspects of environmental governance, medical treatment and education; c) when the mode of developing the rural areas with the aid of the urban areas is applied, the coordinated development of industries and especially the agricultural industrialization development should be paid attention to.

Keywords: the mode of developing the rural areas with the aid of the urban areas, the coordinated development of urban-rural areas, Chenggong New District, China

1 Introduction

With the impetus of economic globalization and the rapid economic development, China has summarized the urban-rural integration mode of developing the rural areas with the aid of the urban areas under the guidance of scientific development concept [1]. The mode of developing the rural areas with the aid of the urban areas, which means the integration of urban and rural areas and aims at developing the rural economy with the help of the urban economic development and promoting the urban development by the potential development of rural areas at the same time, is a virtuous cycle development mode that urban and rural areas, as important resources and markets to each other, serve each other and commonly share modern civilization. China has made developing the rural areas with the aid of the urban areas as a national strategy for the integrated development of urban and rural areas since 2001, but there are now still huge differences in inf*rast*ructures and incomes between rural and urban areas [2]. Therefore, the mode of developing the rural areas with the aid of the urban areas requires scientific understanding and evaluation.

The researches on urban-rural integration have a long history, the much more famous of which are the Urban-rural Fusion Theory from Marx and Engels [3], Urban and Rural Development Theory from Theodore W. Schultz [4] and Central Place Theory proposed by W. Christaller and A. Lsch [5]. The 1957 Nobel Laureate Karl Gunnar Myrdal proposed Geographical Dual Economy Theory, making up for the flaw of the Growth Pole Theory [6]. Research on the coordination of urban and rural development evaluation focused on two aspects [7,8]. The first is the studies on the construction of the index evaluation of the urban and rural coordinated development. (Yang Zhenning (2008), Li Qin, Zhang Yuanhong, Zhang Jun et al (2009)) [9,10], the second is the empirical coordination evaluation research (Deng Ling, Wang Binbin (2008), Xue Hongxia, Liu Juxian, Luo Weiling (2010), Xiao Shien, Li Xianshi (2009), Zhang Deliang, Jiang Yue (2008)) [11-14]. It can be seen that scholars have conducted quite a few researches on the urban-rural integration, which provide related

[*] ***Corresponding author's*** e-mail: lannan7534@163.com

theoretic basis for this paper. In China, there are mature index system and corresponding model for the evaluation of the coordinated development of urban and rural areas, but quantitative evaluation of the mode of developing the rural areas with the aid of the urban areas is rarely involved in. Based on this situation, this paper takes Chenggong New District in Yunnan, China as an example, calculates the coordination degree of its urban and rural development in 1999, 2004 and 2009 with the use of urban and rural development coordination degree model, then makes clustering analysis with the use of Ward's method. The aim is to show the effectiveness and limited factors of promoting the urban-rural integration by the mode of developing the rural areas with the aid of the urban areas, and then come up with some policy suggestions when the mode is undertaken.

TABLE 1 The process of the urban-rural integration in China

Period	Stage	Characteristic
1949-1957	Infancy stage of urbanization	Urban-rural morphological characteristics: Unequal agricultural trade, the restrictive flow of urban-rural labor force, unequal rights between urban residents and farmers, enforceability, promoting urban areas with rural areas
1958-1965	Ups and downs stage of urbanization	
1966-1978	Stagnation stage of urbanization	
1979-1984	Recovery of urbanization	Weakened enforceability, the relatively flow of production factors, capital and interest groups oriented marketization
1985-1992	Stable development of urbanization	
1993-2000	Rapid development of urbanization	
2001 to ---	Scientific Development	Developing the rural areas with the aid of the urban areas under the guidance of the scientific development concept, the strategy understanding of urban and rural areas has been changed from "divide and conquer", "vigorously promote urbanization" to " developing the rural areas with the aid of the urban areas", the urban-rural policy has extended from the economic aspect to political, economic, social, cultural and other aspects

2 The study area

Chenggong New District locates at the southeast the main city of Kunming in Yunnan province. Formerly it was named Chenggong Town, which included Quan County, Longcheng Town, Luoyang Town, Dounan Town, Dayu Village, Majinpu Village, Wujiaying Village and Qidian Village and was famous for its location near Tian Lake. On May 30, 2003, Yunnan government made the strategy of constructing "modern new Kunming". The construction of "Modern New Kunming" firstly started in Chenggong New District. In 2007-2008, Chenggong New District was under administrative redivision, and it has been divided into seven districts (see Figure 1). From the perspective of its development process, Chenggong New District has experienced the development from township to the new district. Before 2003, it was a town; after 2003, it was planned to be a new district, forming the mode of developing the rural areas with the aid of the urban areas. In addition, Chenggong New District borders Tian Lake which coupled with the increasingly serious pollution problems, and its main characteristic industry is the flower industry. Combining these three aspects, it is obvious that Chenggong New District is a typical area to evaluate the effectiveness and the limiting factors for the mode of developing the rural areas with the aid of the urban areas.

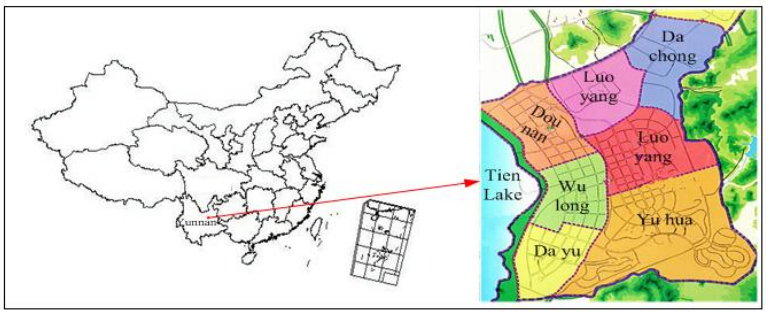

FIGURE 1 Chenggong New District location and zoning

3 Method and data

3.1 THE EVALUATION INDEX

Combining the indexes designed by previous scholars [15] and following the index selecting principles of comprehensiveness, representativeness, operability and comparability, this paper divides the coordinate development index system of urban-rural areas into four layers: A is the target layer, mainly reflecting the comprehensive coordinated development of urban and rural areas; B is the systematic layer, mainly reflecting the coordinated development of the three subsystems of economy, society, environment and space, which refines the target layer; C is the control layer, which further refines the system level indicators; D is the operating index layer, which can be used to measure the specific data to reflect the indicating level of the control layer. Those four index layers have formed a complete hierarchical structure of urban and rural coordinated development evaluation system (as shown in Table 2).

TABLE 2 The evaluation index system of the urban and rural coordinated development

Layer A	Layer B	Layer C	Layer D	Indicator variables
Integrated and Coordinated development of urban and rural areas	Urban and rural economy	Living standards	Per capita GDP (yuan)	X1
		Economic structure	The proportion of agricultural output accounted for the three industries output (%)	X2
		Revenue	Revenue (million)	X3
		Balanced economic benefits	Engel coefficient	X4
	Urban and rural society	Health	Number of beds (sheets) per thousand people	X5
			Number of doctors per thousand (people)	X6
			Financial health care expenditures (yuan)	X7
		Social Security	Minimum living security coverage (%)	X8
		Culture and Education	Educational services expense ratio (%)	X9
		Changes in population	Natural growth rate (‰)	X10
	Urban and rural environment and space	Ecological Construction and Environmental Governance	Urban forest coverage rate (%)	X11
			Sewage treatment rate (%)	X12
		Infrastructure	Car increasing ratio (%)	X13
			Villages traffic rate (%)	X14
			Fixed telephone penetration rate (%)	X15

3.2 MODEL

3.2.1 The evaluation model of the coordination degree of the urban and rural development

Existing studies have shown that the coordination degree models all make the coordinated evaluation on the basis of the comprehensive evaluation of the urban and rural areas. So the evaluation model of the integrated development of urban and rural areas should be determined firstly. To simplify the analysis of the problem and prevent the contained information overlap or cross, this paper uses the principal component analysis to reduce the dimension of the variables and classifies the highly linear original indicators related as a class, turning the original 15 indicators into a few mutual independent main ingredients, which reflect most of the information of the original variables. Principal component analysis takes advantage of the idea of using the least squares estimation to estimate the score of each principal component, which is to express the principal component as a linear combination of indicator variables, namely:

$$F_{ij} = b_{i1} \cdot X_1 + b_{i2} \cdot_{X2} + \cdots b_{in} \cdot X_n \quad (i = 1,2,3\cdots), \tag{1}$$

where F_{ij} is the principal component of the i-th, j-th region, b_{i1} is the sub-factor of the i-th principal component, X_n (n=1,2,...,15) is the nth indicator variables. And then summarize the weight αij of each principal component (the proportion of variance contribution rate of the principal component counting the total variance contribution rate) and come up with the comprehensive score of each urban and rural area in Chenggong New District. Normalize the score F_j and then we can get the score F of each urban and rural integrated development degree, which shows that the higher the score is, the higher the development level will be. The model of urban and rural comprehensive development degree is as follows:

$$F_j = \sum_{i=1}^{m} a_{ij} F_{ij}, \tag{2}$$

$$F = \frac{F_j - F_{j\,min}}{F_{j\,max} - F_{j\,min}} (i = 1,2,3\cdots). \tag{3}$$

After determining the integrated development model of urban and rural areas, we can come up with the coordination degree model of the urban and rural development. Through summarizing current research methods on coordination degree, we can classify them into two categories:

the distance coordination degree and the change coordination degree. Distance coordination degree aims at evaluating the degree primarily through measuring the static distance between each system and the concentration or dispersion degree of coordination between the systems; while change coordination degree aims at evaluating the degree primarily through measuring the consistency of relative changing degree between the systems [16]. According to the actual urban-rural integration development of Chenggong New District, the distance degree coordination is more suitable for its characteristics, so the paper selected this method to determine the urban-rural coordination development degree of Chenggong New District.

At present, the model of distance degree coordination contains two main types. One is to build the coordination degree model based on the dispersion degree between urban and rural development, namely:

$$B = 1 - \frac{S}{\overline{F}}, \tag{4}$$

where B ($0 \le B \le 1$) is the coordination degree of the urban and rural development; $\overline{F}$ is the average of the urban and rural integrated development degree; S is the standard deviation of development degree. The larger the value of B is, the better the degree the coordinated development between the various urban and rural areas will be, and vice versa.

The other is to build the model based on the overall and composite efficiency between urban and rural areas, the theoretical basis of which is the balance theory and utility theory. The balance theory means to maintain a balanced relationship between urban and rural areas, that is to increase A's efficiency without decreasing B's. The utility theory refers to the simultaneous development of urban and rural areas, making the maximum overall benefit [11]. The model is as follows:

$$B = \left\{ \frac{F_1 \cdot F_2}{\left(\frac{F_1 + F_2}{2} \right)^2} \right\}^k, \tag{5}$$

where B is the coordination degree, $0 \le B \le 1$; F_1 and F_2 represent the integrated development degree of the urban and rural areas; K is the adjustment coefficient, $K \ge 2$. Theoretically speaking, the smaller the deviation between F_1 and F_2 becomes, the higher the coordination degree between urban and rural areas will be, and vice versa.

Model (4) is applicable to evaluating multiple (two or more) urban and rural development coordination degrees. Based on this model, we can evaluate the coordination degree between the comprehensive development of each urban area and that of the rural area. Besides, we can also further determine the coordination degree of various subsystems including economic development level, the social status, the environment and space in urban and rural areas. In the end, we can find out the factors limiting the coordinated development of urban and rural areas and provide an important reference for the strategic decisions for the urban and rural coordinated development. Model (5) is applicable to the coordination evaluation between two subsystems, namely, the urban subsystem and the rural subsystem, which uses a whole to represent the development of different rural areas. This may lead to the question whether the development index of the rural area selected is typical and comprehensive. Therefore, the paper selects model (4) as the coordination degree model.

In summary, Equations (1), (2), (3), (4) constitute the evaluation model of the coordination degree of the urban and rural development.

According to previous studies on the coordination degree [12,13], and combining practice, the criteria of the coordination degree of the urban and rural development in this paper is shown in Table 3.

TABLE 3 The criteria of the coordination degree of the urban and rural development

Coordination degree	Very coordinated	Coordinated	Primary coordinated	Less coordinated	Not coordinated
B' value	B≥0.8	0.6≤B≤0.8	0.4≤B≤0.6	0.2≤B≤0.4	B≤0.2

3.2.2 Ward's method

This method was proposed by Ward. Divide n samples into k categories: $G_1, G_2 \ldots G_k$, $X_i^{(t)}$ represents the i-th sample in G_t, n_t represents the sample number of in G_t, $\overline{X}_i^{(t)}$ is the gravity of G_t, and then the sum of squared deviations of the samples in G_t is as follows:

$$S_t = \sum_{i=1}^{n_t} (X_i^{(t)} - \overline{X}_i^{(t)})'(X_i^{(t)} - \overline{X}_i^{(t)}), \tag{6}$$

The sum of squared deviations of the samples in k categories is as follows:

$$S = \sum_{t=1}^{k} S_t = \sum_{t=1}^{k} \sum_{i=1}^{n_t} (X_i^{(t)} - \overline{X}_i^{(t)})'(X_i^{(t)} - \overline{X}_i^{(t)}). \tag{7}$$

3.3 DATA SOURCES

The units of measurement are changeable and the levels of the variable values are very different from each other. In order to eliminate its effects on the analysis of development and coordination degrees of urban and rural areas, the paper uses the statistical analysis software SPSS16.0, and applies dimensionless method to the raw data in 1999, 2004, 2009 from Chenggong New Town Statistical Year-

book and Yunnan Provincial Statistical Yearbook with the use of *Z*-score method, namely

$$Z = \frac{x_i - \bar{x}}{S}. \quad (8)$$

4 Results

4.1 EXTRACTION OF PRINCIPAL COMPONENTS AND WEIGHTS

From the output results of the principal component analysis of the index data of Chenggong New District in 2009 by the software SPSS16.0, it is obvious that there is a high correlation between the 15 indicator variables, indicating that it is very necessary to reduce the dimension of the data and take the principal components out. (as shown in Table 4) in accordance with the principle that the eigenvalue is greater than 1. The paper extracted four principal components respectively represented by F_{1j}, F_{2j}, F_{3j} and F_{4j}. After calculating, the accumulated variance contribution rate of the four principal components reached 91.236%, which can reflect most of the information of the 15 indicators used in this paper. According to the above calculations, we can get the weights of the four principal components as follows: 28.5%, 26.47%, 25.58% and 19.45% respectively.

TABLE 4 Total variance explained

Serial number	The initial eigenvalue			Square load rotation sum		
	Total	Variance %	Cumulative%	Total	Variance %	Cumulative %
1	7.203	48.019	48.019	3.902	26.014	26.014
2	2.962	19.750	67.768	3.623	24.151	50.165
3	2.096	13.972	81.740	3.500	23.335	73.500
4	1.424	9.496	91.236	2.660	17.736	91.236
5	.931	6.207	97.443			
6	.308	2.052	99.495			
7	.076	.505	100.000			
8	5.287E-16	3.525E-15	100.000			
9	3.337E-16	2.225E-15	100.000			
10	2.291E-16	1.527E-15	100.000			
11	1.751E-16	1.167E-15	100.000			
12	8.875E-17	5.917E-16	100.000			
13	6.764E-18	4.509E-17	100.000			
14	-2.216E-16	-1.477E-15	100.000			
15	-3.985E-16	-2.657E-15	100.000			

4.2 DETERMINING PRINCIPAL COMPONENT FACTORS

From Table 5 it can be seen that the load value of the first principal component is relatively large in sewage treatment (X12), Engel's coefficient (X4), the number of one thousand people owning beds (X5) and the number of one thousand people having doctors (X6), as a result F1 mainly reflects the environmental and healthy level; The second principal component is relatively large in the forest coverage in urban and rural areas (X11), villages traffic rate (X14), car increasing ratio (X13) and per capita GDP (X1), so F2 mainly reflects the infrastructure and environmental indicators; The load value of the third principal component is larger in the natural growth rate (X10), fiscal health care expenditure (X7), fixed telephone penetration rate (X15), and minimum living security coverage (X8), and they are all positive correlations, so F3 mainly reflects the social development indicators of the urban and rural areas; The load value of the fourth principal component is larger in the educational services expense ratio (X9) and revenue (X3), so F4 mainly reflects the urban and rural economic and educational development.

TABLE 5 Rotated component matrix

4.3 EVALUATION OF URBAN AND RURAL INTEGRATED DEVELOPMENT

According to Equations (1), (2), (3) and the data in Table 4 and 5, the integrated development degree can be calculated for each urban and rural area in Chenggong New District in 2009 (as shown in Table 6).

TABLE 6 Urban and rural development degree of Chenggong New District in 2009

	F1	F2	F3	F4	F
Quan District	0.165	0.624	1.000	1.000	1.000
Longcheng Street	1.000	0.791	0.495	0.224	1.000
DounanStreet	0.361	0.714	0.000	0.776	0.547
Wujiaying Street	0.660	0.476	0.905	0.074	0.823
Luolong Street	0.102	0.842	0.618	0.270	0.639
Wulong Street	0.000	1.000	0.612	0.023	0.589
Yuhua Street	0.119	0.955	0.520	0.000	0.570
QidianStreet	0.063	0.000	0.403	0.062	0.000

Based on the above methods, this paper makes the principal component analysis to the indicator data in 2004 and 1999 respectively, and ultimately gets the comprehensive development degree of Chenggong New District in 2004 and 1999 (see Table 7), which is used as the calculation basis of urban and rural coordination degree.

TABLE 7 Urban and rural development degree of Chenggong New District in 1999 and 2004

	The whole county	**Longcheng town**	**Luoyang Town**	**Dounan Town**	**Dayu Village**	**Majinpu Village**	**Wujiaying Village**	**Qidian Village**
F1999	1.000	0.878	0.550	0.608	0.228	0.503	0.339	0.000
F2004	1.000	0.892	0.838	0.832	0.581	0.587	0.777	0.000

4.4 ANALYSIS OF URBAN AND RURAL INTEGRATED DEVELOPMENT

According to Equation (5), a comprehensive calculation of the coordinated development of urban and rural areas in 1999, 2004 and 2009 is conducted, and the results are shown in Table 8.

TABLE 8 The coordination degree of Chenggong New District in 1999,2004,2009

Year	**1999**	**2004**	**2009**
Coordination degree	0.359	0.545	0.504
Coordination phase	Less coordinated	Primarily coordinated	Primarily coordinated

Meanwhile, the author calculated the coordination degrees of the four principal components of Chenggong New District based on the scores of each principal component of urban and rural areas in 2009. And then we got the coordination degree of the principal components in sequence (see Table 9). That the development of urban areas and the development of rural areas are uncoordinated in the first and the fourth principal components is the major factor for limiting the coordinated development of urban and rural areas in Chenggong New District.

TABLE 9 Coordination degree of four principal components

Principal component category	F1	F2	F3	F4
Coordination degree	-0.13	0.52	0.46	-0.24
Coordination phase	Uncoordination phase	Primary coordination phase	Primary coordination phase	Uncoordination phase

To analyze the integrated development of each urban and rural area in 2009 more directly, the paper chooses four principal components as the indicator variables of the cluster analysis and classifies various urban and rural levels. The cluster analysis tree is as follows.

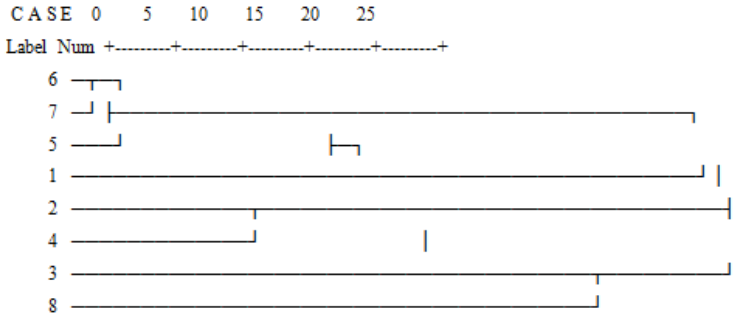

FIGURE 2 Cluster analysis tree

Note: 1:Quan District; 2:Longcheng Street; 3:Dounan Street; 4:Wujiaying Street; 5:Luolong Street; 6:Wulong Street; 7:Yuhua Sreet; 8 Qidian Street

5 Discussion and results

The mode of developing the rural areas with the aid of the urban areas is valid. The coordination degrees of urban and rural development of chenggong new district in 1999, 2004 and 2009 are respectively 0.359, 0.545, and 0.504. So it shows that the urban and rural areas developed rapidly and coordinately from 1999 to 2004, and the urban areas drove the development of rural areas in this short time. The result matches the year 2003 when the Provincial Party Committee and Yunnan government determined the overall strategy of "Modern New Kunming", with Chenggong as a key development area, and the development strategy of "developing the rural areas with the aid of the urban areas" through re-planning. The implementation time consistency of the mode of developing the rural areas with the aid of the urban areas indicates the development strategy mode is valid.

The mode of developing the rural areas with the aid of the urban areas has obvious coordination impact on the aspects of infrastructure construction and basic livelihood guarantee, but has not enough coordination impact on the aspects of environmental governance, medical treatment and education. According to Table 5, the first principal component reflects the level of environmental management and health care, the second represents the infrastructure, the third represents the basic livelihood guarantee, and the fourth reflects the development index of economy and education of urban and rural areas. According to Table 7, the second and the third principal components are coordinated while the first and fourth principal components are uncoordinated. The mode of developing the rural areas with the aid of the urban areas has obvious coordination impact on the aspects of infrastructure construction and basic livelihood guarantee, but has not enough coordination impact on the aspects of environmental governance, medical treatment and education.

Based on the results from Cluster analysis in Figure 3, it can be seen that Dounan Street and Qidian Street are in the last category. Dounan District locates in the northwest of the New District, which mainly relies on Dounan international flower auction trading center and is a flower industry dominated district. Qidian Street is dominated by agriculture and doesn't combine well with the industrialization and urbanization. Besides, each development index is still relatively backward. As a result, developing the rural areas with the aid of the urban areas means that urban areas should service the rural areas well. In addition, the coordinated development of industries and especially the agricultural industrialization development should be paid attention to. Only in this way can it play a better role.

Abstract

This paper proposes a novel method for solving the two-sided matching problem, in which the preferences provided by agents are ordinal numbers, and the preferences provided by intermediary is the expense standard on ordinal numbers. In this paper, the description of the considered two-sided matching problem is given. Then the concepts of satisfaction degrees and expense are introduced. Furthermore, a multi-objective optimization model can be set up consider satisfaction degrees of agents and expense of intermediary. The method of weighted sums based on membership function is used to convert the multi-objective optimization model into a single-objective model. The matching result is obtained by solving the model.

Keywords: two-sided matching, ordinal number, satisfaction degree, expense

1 Introduction

There are plenty of two-sided matching problems in many fields of real life, such as marriage assignment [1], college admission [2], employee selection [3], personnel assignment [4] and trading partner selection [5]. Therefore two-sided matching is a research topic with extensive application backgrounds.

Study on the two-sided matching problem originates from the problem of college admission and marriage assignment [6]. Gale and Shapley initially investigate the concept, existence, optimality and solution algorithm of stable assignment [7]. Then, Roth explicitly proposes the concept of two-sided matching [3]. Following that, various methods, techniques and algorithms have been proposed for solving the two-sided matching problem with different forms of information. For example, Teo et al. derive the optimal cheating strategy in Gale-Shapley stable marriage model, and then apply it to Singapore school admissions problem [8]. Ehlers studies truncation strategies in matching markets using the deferred acceptance algorithm (i.e., Gale-Shapley algorithm), and show that truncation strategies are also applicable to all priority mechanisms and all linear programming mechanisms [9]. Azevedo gives a simple equilibrium model of an imperfectly competitive matching market, in which an infinite number of firms is matched to a continuum of workers [10]. Teo and Sethuraman study the classical stable marriage and stable roommate problems using a polyhedral approach [11]. Fleiner gives a linear characterization of the bipartite stable b-matching polytope [12]. Manlove et al. give a 2-approximation algorithm for the stable marriage problem with incomplete lists and ties of finding a stable matching of maximum or minimum size [13]. Iwama et al. give a $(2-c/\sqrt{N})$ -approximation algorithm to solve the stable marriage problem of finding a stable matching of maximum size when both ties and unacceptable partners are allowed in preference lists, where c is an arbitrary positive constant that satisfies $c \le 1/4\sqrt{6}$, and N is the instance size [14].

Prior studies have made significant contributions to solving the two-sided matching problems. However, on the one hand, most of the existing studies focus on obtaining stability matching(s). However, in some cases, comparing with stability matching, each agent is more concerned about his/her own satisfaction degree over his/her partner. On the other hand, in real world problems, the determination of the stability matching(s) is usually suggested by intermediary [5, 15, 16]. The intermediary could also be the type of pursuing the benefit, and yet the existing studies seldom consider this type of intermediary. Therefore, how to consider the satisfaction degree of agents and the profit of intermediary in the two-sided matching problem is a valuable research topic. These are the motivation of this paper.

The purpose of this paper is to propose a novel method for solving the two-sided matching problem considering the preferences of agents and intermediary. In the method, the concepts of satisfaction degree and expense are introduced. Furthermore, a multi-objective optimization model is built, where the considered sub-objectives are to maximize the satisfaction degree of each agent and expense of intermediary. By solving the multi-objective optimization model, the matching result can be determined.

The rest of this paper is provided as follows: Section 2 describes the two-sided matching problem considering the preferences of agents and intermediary. Section 3 gives the concepts of satisfaction degrees and expense. Section 4 builds a multi-objective optimization model considering satisfaction degrees and expense. Section 5 develops an

* ***Corresponding author's*** e-mail: liyuhuajx@sina.com

algorithm for solving the model. Section 6 summarizes and highlights the main features of the proposed method.

2 The problem

The related concept and notation on two-sided matching can be found in [17, 18]. The two-sided matching problem considering the preferences of agents and intermediary is described below.

For convenience, let $M=\{1,2,\ldots,m\}$, $N=\{1,2,\ldots,n\}$, and suppose $m\le n$. Let $A=\{A_1,A_2,\ldots,A_m\}$ be the set of agents of side A, where A_i denotes the i-th agent of side A, $i\in M$; $B=\{B_1,B_2,\ldots,B_n\}$ be the set of agents of side B, where B_j denotes the j-th agent of side B, $j\in N$. Let $R_i=(r_{i1},r_{i2},\ldots,r_{in})$ be the ordinal number vector provided by agent A_i over the agents of side B, where r_{ij} denotes that agent A_i ranks B_j in the r_{ij}-th position, $r_{ij}\in N$. Let $T_j=(t_{1j},t_{2j},\ldots,t_{mj})^T$ be the ordinal number vector provided by agent B_j over the agents of side A, where t_{ij} denotes that agent B_j ranks A_i in the t_{ij}-th position, $t_{ij}\in M$. The expense standard of agents is usually determined by intermediary. Here, the intermediary refers to a single person, an organization or a decision system that makes a matching between agents of sides A and B.

The problem concerned in this paper is how to obtain the reasonable matching result based on ordinal number vectors $R_i\ (i\in M)$ and $T_j\ (j\in N)$ such that the satisfaction degrees of each agents and the profit of intermediary are as large as possible.

3 The satisfaction degrees and expense

In the two-sided matching problem, without loss of generality, if agent A_i ranks B_j in the first position, then the satisfaction degree of agent A_i over B_j is the highest; if agent A_i ranks B_k in the last position, then the satisfaction degree of agent A_i over B_k is the lowest. Usually, satisfaction degrees of one agent over potential partners are in interval [0, 1]. Hence, we give the following definitions of satisfaction degrees.

Definition 1. Let $r_{ij}\in N$ be the ordinal number provided by agent A_i over B_j. Then the function l_i used to obtain the satisfaction degree of agent A_i over B_j (noted as α_{ij}) is defined as:

$$l_i: N\to[0,1],$$

$$l_i(r_{ij})=\alpha_{ij},$$

where l_i is a monotone decreasing function and satisfies $0\le l_i(n)$, $l_i(1)\le 1$.

Definition 2. Let $t_{ij}\in M$ be the ordinal number provided by agent B_j over A_i. Then the function g_j used to obtain the satisfaction degree of agent B_j over A_i (noted as β_{ij}) is defined as:

$$g_j: M\to[0,1],$$

$$g_j(t_{ij})=\beta_{ij},$$

where g_j is a monotone decreasing function and satisfies $0\le g_j(m)$, $g_j(1)\le 1$.

The expressions of functions l_i and g_j could be different due to the different consideration of agents. The typical expressions of functions l_i and g_j are expressed by:

$$l_i(r_{ij})=\left[\frac{n+1-r_{ij}}{n}\right]^2,\ i\in M \tag{1}$$

and

$$g_j(t_{ij})=\left[\frac{m+1-t_{ij}}{m}\right]^2,\ j\in N. \tag{2}$$

By Equations (1) and (2), the satisfaction degree matrices $\tilde{\mathrm{A}}=[\alpha_{ij}]_{m\times n}$ and $\tilde{\mathrm{B}}=[\beta_{ij}]_{m\times n}$ are constructed, respectively.

Definition 3. Let $r_{ij}\in N$ be the ordinal number provided by agent A_i over B_j. Then the function $y_A(r)$ used to obtain the expense that agent A_i provides to the intermediary if agent A_i is matched with agent B_j (noted as λ_{ij}) is defined as:

$$y_A(r): N\to R,$$

$$y_A(r_{ij})=\lambda_{ij},$$

where $y_A(r)$ is a monotone decreasing function and satisfies $y_A(n)>0$.

Definition 4. Let $t_{ij}\in M$ be the ordinal number provided by agent B_j over A_i. Then the function $y_B(t)$ used to obtain the expense that agent B_j provides to the intermediary if agent B_j is matched with agent A_i (noted as π_{ij}) is defined as:

$$y_B(t): M\to R,$$

$$y_B(t_{ij})=\pi_{ij},$$

where $y_B(t)$ is a monotone decreasing function and satisfies $y_B(m)>0$.

Usually, the expressions of function $y_A(r)$ and $y_B(t)$ are various. In this paper, we consider the following formats:

$$y_A(r)=\begin{cases} p_1, & r=1, \\ p_2, & r=2, \\ \ldots, & \\ p_n, & r=n, \end{cases}, \tag{3}$$

$$y_B(t)=\begin{cases} q_1, & t=1, \\ q_2, & t=2, \\ \ldots, & \\ q_m, & t=m, \end{cases}, \tag{4}$$

where $p_1, p_2, \ldots, p_n$ are the expense values and satisfy $p_1 > p_2 > \ldots > p_n > 0$, and $q_1, q_2, \ldots, q_m$ are also the expense values and satisfy $q_1 > q_2 > \ldots > q_m > 0$. By Equations (3) and (4), expense matrices $\Gamma=[\lambda_{ij}]_{m\times n}$ and $\Pi=[\pi_{ij}]_{m\times n}$ are constructed, respectively.

4 The two-sided matching model

Let x_{ij} be an 0-1 variable, where $x_{ij}=0$ denotes $\mu(A_i)\neq B_j$, $x_{ij}=1$ denotes $\mu(A_i)=B_j$. To maximize the satisfaction degrees of agents and the expense of intermediary, a multi-objective optimization model (5) can be established as follows:

$$\max \quad Z(A_i)=\sum_{j=1}^{n}\alpha_{ij}x_{ij},\ i\in M, \tag{5a}$$

$$\max \quad Z(B_j)=\sum_{i=1}^{m}\beta_{ij}x_{ij},\ j\in N, \tag{5b}$$

$$\max \quad Z(T)=\sum_{i=1}^{m}\sum_{j=1}^{n}(\lambda_{ij}+\pi_{ij})x_{ij}, \tag{5c}$$

$$\text{s.t.} \quad \sum_{j=1}^{n}x_{ij}=1,\ i\in M, \tag{5d}$$

$$\sum_{i=1}^{m}x_{ij}\le 1,\ j\in N, \tag{5e}$$

$$x_{ij}=0 \text{ or } 1,\ i\in M,\ j\in N. \tag{5f}$$

In the model (5), the meaning of Equation (5d) is that agent A_i must match only one agent of side B. The meaning of Equation (5e) is that agent B_j matches at most one agent of side A.

Generally, each agent of one side has equal priority, thus model (5) can be further transformed into the following optimization model (6):

$$\max \quad Z(A)=\sum_{i=1}^{m}\sum_{j=1}^{n}\alpha_{ij}x_{ij}, \tag{6a}$$

$$\max \quad Z(B)=\sum_{i=1}^{m}\sum_{j=1}^{n}\beta_{ij}x_{ij}, \tag{6b}$$

$$\max \quad Z(T)=\sum_{i=1}^{m}\sum_{j=1}^{n}(\lambda_{ij}+\pi_{ij})x_{ij}, \tag{6c}$$

$$\text{s.t.} \quad \sum_{j=1}^{n}x_{ij}=1,\ i\in M, \tag{6d}$$

$$\sum_{i=1}^{m}x_{ij}\le 1,\ j\in N, \tag{6e}$$

$$x_{ij}=0 \text{ or } 1,\ i\in M,\ j\in N. \tag{6f}$$

5 The algorithm

In order to solve model (6), the method of weighted sums based on membership function is adopted [19]. In the followings, we give the detailed analysis on the solution of model (6). Firstly, let $Z_{\min}(A)$ and $Z_{\max}(A)$ be the minimum value and the maximum value for objective function $Z(A)$. Let $Z_{\min}(B)$ and $Z_{\max}(B)$ be the minimum value and the maximum value for objective function $Z(B)$. Let $Z_{\min}(T)$ and $Z_{\max}(T)$ be the minimum value and the maximum value for objective function $Z(T)$. Then, three membership functions can be respectively described with the followings:

$$\mu(Z(A))=\frac{Z(A)-Z_{\min}(A)}{Z_{\max}(A)-Z_{\min}(A)}, \tag{7}$$

$$\mu(Z(B))=\frac{Z(B)-Z_{\min}(B)}{Z_{\max}(B)-Z_{\min}(B)}, \tag{8}$$

$$\mu(Z(T))=\frac{Z(T)-Z_{\min}(T)}{Z_{\max}(T)-Z_{\min}(T)}, \tag{9}$$

obviously, $0\le\mu(Z(A))\le 1$, $0\le\mu(Z(B))\le 1$ and $0\le\mu(Z(T))\le 1$.

Let w_A, w_B and w_T be the weight of objectives functions $Z(A)$, $Z(B)$ and $Z(T)$, respectively, such that $w_A+w_B+w_T=1$, $0<w_A, w_B, w_T<1$, then model (6) is transformed into the single-objective optimization model (10):

$$\max \quad Z=w_A\mu(Z(A))+w_B\mu(Z(B))+w_T\mu(Z(T)), \tag{10a}$$

$$\text{s.t.} \quad \sum_{j=1}^{n}x_{ij}=1,\ i\in M, \tag{10b}$$

$$\sum_{i=1}^{m}x_{ij}\le 1,\ j\in N, \tag{10c}$$

$$x_{ij}=0 \text{ or } 1,\ i\in M,\ j\in N, \tag{10d}$$

where weight w_D $(D=A,B,T)$ reflects the importance

degree of objective function $Z(D)$ in practical decision problems. Usually, to guarantee the fairness of the agents of sides A and B, we have $w_A = w_B$.

Model (10) the can be solved using the existing mathematical optimization software. Then the matching result is determined based on the obtained optimal solution.

In sum, we give an algorithm for solving the two-sided matching problem and its steps are presented as follows:

Step 1: Set up the satisfaction degree matrices $\tilde{\mathrm{A}} = [\alpha_{ij}]_{m\times n}$ and $\tilde{\mathrm{B}} = [\beta_{ij}]_{m\times n}$ by Equations (1) and (2).

Step 2: Set up the expense matrices $\Gamma = [\lambda_{ij}]_{m\times n}$ and $\Pi = [\pi_{ij}]_{m\times n}$ by Eqs. (3) and (4).

Step 3: Set up the multiple-objective optimization model (5) based on satisfaction degree matrices $\tilde{\mathrm{A}}$ and $\tilde{\mathrm{B}}$, and expense matrices Γ and Π.

Step 4: Determine $Z_{\min}(D)$ and $Z_{\max}(D)$, $D = A, B, T$.

Step 5: Transform model (6) into model (10) by Eqs. (7)-(9).

Step 6: Determine the matching result by solving model (10).

6 Conclusion

The two-sided matching problem arises from a wide range of real-world situations. Although many researchers have paid attention to the two-sided matching problem, there are few methods considering the satisfaction degrees of agents and the profit of intermediary. This paper has presented a novel method for solving the two-sided matching problem with ordinal numbers.

Comparing with the existing methods, the proposed method has two characteristics as discussed below. Firstly, the agents' satisfaction degrees and intermediary's profit are considered. This is usually absent in the existing methods. Secondly, the proposed method is simple and is a supplement or extension of the existing methods. In terms of future research, the proposed method can be extended to support situations in which the information data are in other formats.

Abstract

Based on the vector autoregression model, this paper focuses on Zhengzhou and uses the 1994–2013 population structural variables and relevant data on commercial and residential land price to analyze the dynamic relationship between population structure and residential land price through impulse response function and variance decomposition. Results show a co-integration between Zhengzhou residential land price and three variables, namely, urbanization rate, per capita disposable income, and household size. The short-term variation in land price is mainly caused by the residential land price itself, and the three population substructural variables show long-term effects on the land price with a certain time lag. Among these variables, per capita disposable income has the shortest positive effect on residential land price, whereas urbanization rate has the longest and most remarkable positive effect.

Keywords: population, land price, VAR model, Zhengzhou

1 Introduction

All sectors of society have expressed great concern about the increasing land price in large and medium-sized cities of China. In recent years, scholars have attempted to explain the increase from different angles, such as economic growth, social policy, monetary supply, speculative demand and motivation, and housing price. Population is an intrinsic factor that influences housing demand and is less vulnerable to business cycles than other factors, and thus it is more likely to influence housing and land price. However, the influence of population structure on the variation of residential land price has not been studied enough.

Foreign scholars have studied the relationship between population structural variable and housing price and arrived at varied findings. For instance, David [1] examined the Dutch commercial housing price from the aspect of household disposable income and found that disposable income is positively related to and significantly affects housing price. Wolfgang Maennig [2] studied the relationship between the population fluctuation of 98 major German cities and housing price and suggested that population decline in large cities exerts a more significant effect on housing price than population growth. Vansteenkiste and Hiebert [3] studied seven European countries using the vector autoregression (VAR) model to determine the relationship between real per capita income and housing price and found that real per capita income contributes to the rise of real housing price. Ramesh Kumar Jain [4] examined relevant data on major Indian cities and found that the deepening urbanization and urban population accretion promote local economic development and increase regional housing price. Bischoff and Oliver [5] studied the regional difference in the relationship between housing price and income in Germany and found a positive interactive effect between income and housing price. Based on these studies, population development is the most important factor that causes the disparity between housing price and income in all regions.

Most of the literature published by Chinese scholars about the relationship between population and housing price focus on the influence on housing price caused by four factors: population age structure, per capita disposable income, urbanization, and population migration. The consistently drawn conclusion is that per capita disposable income, which signifies a lower correlation index than other influencing factors, is not the primary factor affecting housing price; rather, the ongoing process of urbanization improves urban housing demand and subsequently leads to the fluctuation of housing price. Ha Jiming [6] showed that urbanization and changes in population structure promote economic growth and affect housing price, and that population structure directly affects housing price. Wu Tao [7] demonstrated that gross domestic product and per capita disposable income indirectly affect housing price by influencing CPI. Kuang Weida [8] showed that cities with a higher population growth rate exhibit more volatile housing prices than cities with a relatively small population. Xue Liwei et al. [9] analyzed the data on Beijing, Wuhan, and Xi'an and found a positive correlation between population structural

Corresponding author's e-mail: sizhaoxia@hpu.edu.cn

variables and housing price income. Guo Jian[10] analyzed the influence of the urbanization of the Jiangsu population on commercial housing price and concluded that the extent of population aggregation is the primary factor that affects urban housing price. Conversely, Xun Fang [11] studied Jiangxi and found that level of urbanization could significantly influence housing price. He Fan [12] examined the dependency ratio of population and housing price data of 19 countries and found a negative correlation between dependency ratio of population and housing price fluctuation in most countries; however, the proportionate rise in the aging population of China, rather than a price fall, causes an active demand for commercial housing. Du Benfeng and Zhang Yu [13] used the grey relational degree to study the correlation between the Chinese comprehensive demographic factor and home sales price index and found that population is highly correlated with home sales price index.

The literature review shows that foreign scholars have conducted extensive research about the influence of population structure on housing price fluctuation. Their studies, although recent, have covered a wide range of concerns about theoretical exploration and used the econometrical approach for a quantitative analysis of the correlation between population structure and price fluctuation. By contrast, Chinese scholars have used foreign research methods and the true state of China to focus on typical Chinese regions and found that population structural variables affect the volatility of housing price. Studies involving the correlation between population structure and urban residential land price are rarely conducted. This paper benefits from the method used to study the influence of population structure on the volatility of housing price. It analyzes the dynamic influence of Zhengzhou's population structural variables on residential land price. The findings provide reference for similar research on other regions and contribute to the government's decision making in the development of diverse regulatory policies for local residential land price.

2 Data resource and research method

This paper takes the urban residential land price indexes and population structural variables of Zhengzhou as analysis data. Without affecting the results, price indexes lower data heteroscedasticity while increasing sequence stationarity. The data selected covered the period of 1994–2013 and were taken from the China Urban Land Price Dynamic Monitoring Network, Henan Statistical Network, and Zhengzhou Statistical Network.

This study mainly discusses the extent of influence of Zhengzhou's population structural variables on the fluctuation of residential land price. Analysis software Eviews 6.0 was used for building the VAR model. Co-integration analysis, impulse response function, variance decomposition, and other approaches were used to analyze the correlative mechanism between Zhengzhou population structural variables and land prices.

The AR model is a simultaneous form of the autoregression model. If y_{1t} is related to y_{2t} and the two autoregression models are built separately, the relationship between these two variables will not be captured:

$$y_{1t} = f\left(y_{1,t-1}, y_{1,t-2}, \ldots\right), \tag{1}$$

$$y_{2t} = f\left(y_{2,t-1}, y_{2,t-2}, \ldots\right). \tag{2}$$

Once the simultaneous form is taken, the relationship between the two variables can be determined. Taking the VAR model of one-period lagged variables y_{1t} and y_{2t} as an example, the VAR model can be expressed as:

$$y_{1t} = c_1 + \pi_{11.1} y_{1,t-1} + \pi_{12.1} y_{2,t-1} + u_{1t}, \tag{3}$$

$$y_{2t} = c_2 + \pi_{21.1} y_{1,t-1} + \pi_{22.1} y_{2,t-1} + u_{2t}. \tag{4}$$

3 Empirical analysis

3.1 VARIABLE SCLECTION

Based on demography, population structure generally covers the natural population structure, the socio-economic structural features of the population, and the regional structure of the population. This approach is adopted in this study on population structural variables. By selecting the variables according to the three aspects, this study attempts to discuss Zhengzhou's residential land price from the perspective of population structure.

On the basis of the literature review, this study tentatively selects seven population structural variables: sex ratio (*XB*), labor resource structure (*LP*), dependency ratio (*FY*), household size (*JG*), employment structure (JY), per capita disposable income (*SR*), and urbanization rate (*CZ*).

3.2 DATA STATIONARY TEST

Stationarity was the first variable to be tested. Time series stationarity indicates that statistical laws on time series do not change with time; i.e., the features of the stochastic process during which the variable time series data are generated are time-invariant. Logarithm operation was conducted on these time series variables to reduce heteroscedasticity. The ADF approach was adopted for the unit root test of the same variables. The results indicate that variables do not form a stationary series, that urbanization rate is the only stationary series after the first-order difference, and that the rest of the variables are stationary series after the second-order difference (Table1).

TABLE 1 Unit root test on the time series of land price and population structure variable in Zhengzhou City

Variate	Test Type (c,t,n)	ADF statistical magnitude	5% critical value	Inspection results	Variate	Test Type (c,t,n)	ADF statistical magnitude	5% critical value	Inspection results

Notes: (c, t, n) are the constant term, trend term, and lag order, respectively, in the unit root test.

3.3 JOHANSEN CO-INTEGRATION RELATIONSHIP TEST

The Johansen test is used to determine the existence of several non-zero characteristic roots for the vector matrix of co-integration test, which suggests a co-integration among various time series. The test was conducted with Trace Statistic and Max-Eigen Statistic. The data generation test proved that the system shows no linear trend and that the co-integration equation is a random walk with drift. The Trace Statistic and Max-Eigen Statistic approaches used by the Johansen co-integration relationship test indicate that, below the level of 5%, no non-zero characteristic root exists between Zhengzhou residential land price and dependency ratio, labor resource, employment proportion, and sex ratio, thus indicating the absence of co-integration. Moreover, no non-zero characteristic root exists between Zhengzhou residential land price and urbanization rate, per capita disposable income, and household size, thus indicating a co-integration relationship. Table 2 shows the results of the co-integration relationship test.

TABLE 2 Johansen test between land price and population structure variables in Zhengzhou City

	Original hypothesis co-integration equation	Eigenvalue	Trace Test	Trace Test C.V.	Maximum Eigenvalue	Maximum Eigenvalue C.V.
ln *HP* and ln *CZ*	None*	0.98	35.11	15.49	34.50	14.26

	At most 1	0.49	5.34	3.84	5.34	3.84
ln *HP* and ln *SR*	None*	0.83	16.62	15.49	14.21	14.26
	At most 1	0.26	2.40	3.84	2.39	3.84

Notes: "*" is that refused to the original assumption under the 0.05% significant level

3.4 VAR MODEL ESTIMATION

The co-integration relationship test suggests a long-term equilibrium relationship between Zhengzhou residential land price and urbanization rate, per capita disposable income, and household size. The VAR model, which is used to analyze the correlation between variables, is an unstructured equation model based on data statistics and is completely built on endogenous variables.

Lagged orders, which significantly influenced the test results, need to be set to build the VAR model. Low orders disregard some important variables, whereas high orders lower the freedom of the model, lead to a considerable standard deviation of parameter estimation, and reduce accuracy. This study determines the lag period according to the lag length criteria. As shown in Table 3, the smallest lag periods of the five evaluation indexes are represented by "*". According to the minimum AIC and SC criteria, the optimal lag period is set to 2 and a VAR (2) model is determined for building.

TABLE 3 Criteria to determine VAR lag length and appropriate lag order number

Lag	LogL	LR	FPE	AIC	SC	HQ
0	–321.67	NA	6.10e+10	36.18	36.38	36.21
1	–211.70	15.72	15637203	27.52	29.30	27.76
2	–227.42	136.14*	10850357*	27.49*	28.48*	27.62*

Eviews 6.0 was used to build the four-variable VAR model of Zhengzhou urbanization rate, per capita disposable income, household size, and residential land price. The model estimation results are as follows:

$$\begin{bmatrix}\ln CZ\\ \ln DJ\\ \ln JG\\ \ln SR\end{bmatrix}=\begin{bmatrix}-4.52\\ 124.14\\ 6.24\\ 188339.77\end{bmatrix}+\begin{bmatrix}1.06 & -0.06 & 4.12 & -6.11\\ 2.54 & 1.55 & -60.67 & 5.43\\ 0.05 & 0.02 & -0.32 & 1.42\\ 17274.21 & -1278.27 & 84524.99 & -0.54\end{bmatrix}\begin{bmatrix}\ln CZ(-1)\\ \ln DJ(-1)\\ \ln JG(-1)\\ \ln SR(-1)\end{bmatrix}+\begin{bmatrix}0.09 & 0.04 & -4.06 & -3.45\\ -2.96 & -0.40 & 31.04 & 6.59\\ -0.12 & -0.01 & 0.36 & 1.80\\ -15478.00 & 1274.89 & 150190.05 & -0.22\end{bmatrix}\begin{bmatrix}\ln CZ(-2)\\ \ln DJ(-2)\\ \ln JG(-2)\\ \ln SR(-2)\end{bmatrix}.$$

The stationary test for the model, all characteristic roots in the model shown in Figure1 are in the unit cycle; therefore, the VAR model has a stable system. After the test for the residuals of the VAR (2) model, the model residuals were found to follow a normal distribution and

to have no autocorrelation or heteroscedasticity. Estimation results also suggest that the joint parameter survey is significant. The model determination coefficient R is between 0.955 and 0.996; therefore, the statistical property of VAR (2) is favorable.

of Zhengzhou residential land price and population structural variables
(AR characteristic polynomial root diagram)

3.5 IMPULSE RESPONSE ANALYSIS AND CONTRIBUTION ANALYSIS

The conduct of impulse response analysis and variance decomposition for the VAR model was necessary to study the change rule of the long-term equilibrium relationship within a certain period after the influence.

3.5.1 Impulse response analysis

Impulse response analysis is usually carried out on the basis of the graph observation of the impulse response function, which describes the response of error change. The random disturbance term is assumed to be affected by a standard deviation, and the variables would be affected both in the current and later years; i.e., the change in each endogenous variable can influence itself and all other endogenous variables. Figure 2 shows the disturbance when one standard deviation is given. The response route, which revealed the influence of variables on land price within 10 predictive periods, was observed. The full line denotes the change orbit of land price after the effects, and the dotted line indicates the resulting value of land price plus or minus the double standard deviation, thus showing the maximum range of possible effects, i.e., the upper and lower limits to be reached.

As shown in Figure 3, when a random disturbance of one standard deviation is observed from the household size against the residential land price, a strong influence appears immediately. The current impulse curve falls gradually after going up by approximately five grades; at the eighth period approaching zero, the influence gradually disappears. This trend shows that the development of land price is stable and that short-term variations of household size can cause fluctuations in residential land price. However, the fluctuation range reduces with time. Land price increases immediately when a positive effect of one standard deviation is exerted on itself, but the increase range shrinks gradually and immediately, and the price begins to fall by the second period until the final recovery. When a positive effect of one standard deviation from the urbanization rate is exerted on the residential land price, the effect is gradually seen. The price begins to gradually decline after reaching the second grade by the second predictive period, falls to first grade by the third predictive period, begins to gradually increase by the fourth predictive period, and remains at the third grade. No significant response is shown in land price when a disturbance of one standard deviation from the per capita disposable income is exerted on the residential land price. Based on the effect of population structural variables, the per capita disposable income has the shortest positive effect on residential land price. Given the high price of residential land, income increases may have no significant influence on the increasing land price. By contrast, the positive effect of urbanization rate on residential land price is the longest and strongest. Therefore, new housing demands caused by urbanization can actively promote the residential land price market of Zhengzhou and significantly improve the land price of this region.

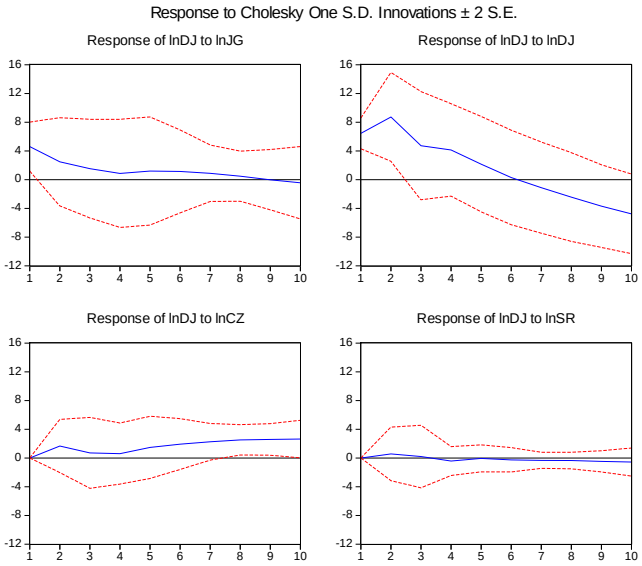

FIGURE 2 Impulse response analysis of Zhengzhou residential land price

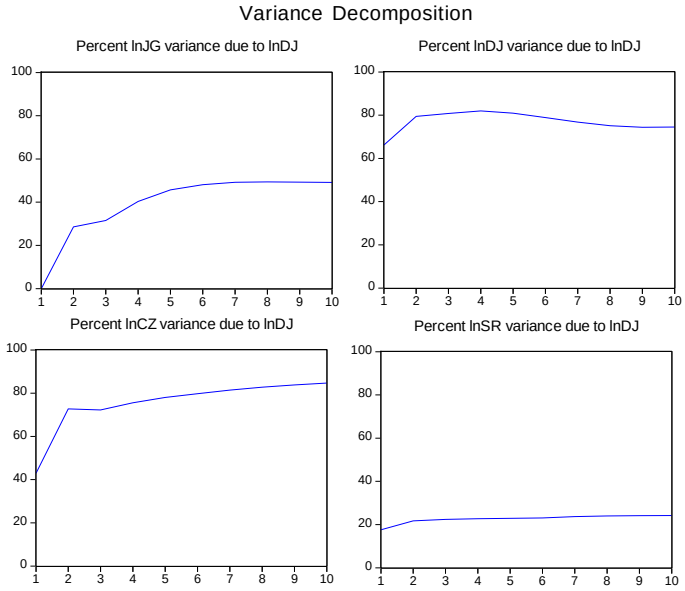

FIGURE 3 Variance decomposition of population structural variables against residential land price in Zhengzhou

3.5.2 Contribution analysis

Variance decomposition means that interactions between variables can be expressed by percentages of predication error variances after a variable in the system suffers one unit of effect. Variance decomposition reflects the relative importance of random information. That is, the variation of each endogenous variable in the system is decomposed into all constituent parts relevant to random disturbance terms to determine the relative importance of innovation to the endogenous variables of the model. Variance decomposition analysis was conducted to study the influence of the Zhengzhou population structural variables on the fluctuation of residential land price.

In Figure 3, the horizontal axis represents the periods after various effects, and the vertical axis represents the contribution of the four variables (including land price itself) to the increase in land price. As shown in Figures 3 and Table 4, land price has an effect on itself. The contribution rate reaches 66.22% by the first predictive period and increases gradually. It reaches approximately 80.91% by the fifth period, declines, and then tends to stabilize until it is maintained at 75%. Household size (lnJG) has no contribution to Zhengzhou land price by the first period. However, the contribution rate increases to 28.58% by the second predictive period, escalates, reaches 48.09% by the sixth predictive period, and then stabilizes. The contribution rate of urbanization rate (InCZ) to Zhengzhou residential land price is only 42.99% by the first predictive period and increases fast thereafter. It reaches 72.75% by the second predictive period and escalates until the 10th predictive period when the contribution rate reaches 84.66%. The contribution rate of per capita disposable income to Zhengzhou residential land price is maintained at a low level all the time at around 23.00%.

TABLE 4 Variance decomposition of population structural variables against residential land price in Zhengzhou

Period	Percent LNDJ variance due to LNDJ (%)	Percent LNSR variance due to LNDJ (%)	Percent LNCZ variance due to LNDJ (%)	Percent LNJG variance due to LNDJ (%)
1	66.22	17.58	42.99	0.00
2	79.47	21.70	72.75	28.58
3	80.81	22.38	72.26	31.52
4	81.97	22.69	75.59	40.34
5	80.91	22.89	78.01	45.66
6	78.92	23.07	79.79	48.09
7	76.83	23.66	81.39	49.19
8	75.15	23.97	82.76	49.38
9	74.42	24.09	83.82	49.26
10	74.53	24.17	84.66	49.15

The contribution analysis shows that different population structural variables have varied effects on the fluctuation of residential land price. Among all the variables, urbanization rate causes the greatest effect, followed by household size. Per capita disposable income causes the smallest effect. In the short term, land price fluctuation is mainly caused by its own influence. Nevertheless, as the predictive period progresses, the effect of population

structural variables on Zhengzhou residential land price becomes stronger and gradually becomes the leading influencing factor. This result suggests that the effect of population structure factors on land price is long standing and stable.

4 Results and discussion

4.1 RESULTS ANALYSIS

This study examines the correlation between the 1994–2013 land prices of Zhengzhou and its population structural variables. Co-integration test, impulse response function, variance decomposition, and other approaches are used to analyze the influence of population structural variables on land price. The findings are as follows:

1) Co-integration test results show that no co-integration relationship exists between Zhengzhou land price and the population structural variables of dependency ratio, labor resource, employment proportion, and sex ratio. However, urbanization rate, per capita disposable income, and household size show significant effects on Zhengzhou land price.
2) The positive effect of Zhengzhou's per capita disposable income on residential land price is the shortest. As income increase may have no significant effect on the increase in residential land price, it is not the primary influential factor on land price. The positive effect of urbanization rate on residential land price is the longest and strongest. Therefore, new housing demands caused by urbanization can actively promote the residential land price market of Zhengzhou and significantly improve the land price of this region.
3) Different population structural variables exert various effects on residential land price fluctuation. Among all the variables, urbanization rate causes the greatest influence, followed by household size. Per capita disposable income causes the smallest effect.
4) In the short term, land price fluctuation is mainly caused by its own influence. Nevertheless, as the predictive period progresses, the effect of population structural variables on Zhengzhou residential land price becomes stronger and gradually becomes the leading influencing factor. This finding suggests that the effect of population structure factors on land price is long-standing and stable.

4.2 DISCUSSION

Through a correlation study between Zhengzhou population structural variables and urban residential land price, this paper examines the impact degree of population structural variables on residential price. Two policy suggestions are suggested:

1) Taking measures to increase resident income should be continued. The empirical tests conducted by this study show that per capita disposable income is not significantly related to residential price. Income growth does not necessarily mean that it can remarkably promote commercial residential land price. The real estate market shows a trend of excessive speculation. Therefore, the basic solution to the housing problem is to increase resident income.
2) Conducting rational control over urbanization should be maintained. Data analysis shows that the increase in and the concentration of urban population are principal factors that increase the price of Zhengzhou commercial residential land. Urbanization, an inevitable process in urban development, greatly influences the development prospect of the real estate market. However, excessively rapid growth can accelerate the increase in urban residential land price, and it will be further promoted under the market force. Therefore, the government should conduct rational control over it. fluctuation in Tianjin caused by a land price fluctuation in Beijing is lower than that in Beijing caused by a land price fluctuation in Tianjin city. This is consistent with the quantitative analysis on the land price fluctuation of the two cities.

Research on the application of ARMA model in China's trade economic development

Xue Wu*

Business Administration College, Chongqing University of Science and Technology, Chongqing city, China, 401331

Received 20 October 2014, www.cmnt.lv

Abstract

The slowing down development of China's foreign trade brings significant impact to its regional economy, which makes many middle and small-sized export enterprises facing with business crisis and even bankruptcy. In this paper, a deep analysis on the development status of China's trade economy was conducted with ARMA model. The short-term development trend and causes of China's trade economy were predicted and analyzed. Results demonstrated that China's imports will decrease while export will keep increasing. The balance of trade in China will decrease and the total volume of foreign trade will decline. This indicates the depression of China's trade economy, which is against China's economic development. To improve the export structure and facilitate the rapid development of trade economy, China is suggested to adopt various measures, such as optimizing fiscal policy, promoting technology upgrading, enhancing export management and perfect import-export infrastructures. Meanwhile, China shall expand domestic demand vigorously to offset impact of trade economic slowdown on regional economy.

Keywords: ARMA model, trade economy, application research, decision reference

1 Introduction

Although the world economy recovers after the financial crisis, the international trade market still remains in downturn with grim situation. Trade economy not only is an important goal of opening to the outside world, but also can facilitate economic development and increase production level of China. With a big population but few land resources, China is in severe shortage of many resources, such as energy which is the basis of economic development. Therefore, developing trade economy is an important measure to offset China's resources and economic deficiencies. In 2013, the total volume of imports and exports of China reached 4,160 billion dollars, ranking the first in goods export in the world. It accounted for 45.39% of GDP. Among them, 24.11% was contributed by goods export. This reflects that trade economy has become very important to China's economy. It is of important practical significance to study the trade economic development.

2 Development status of China's trade economy

Although the world economy recovered gradually in 2013, the international market still remains in downturn, thus resulting in the difficult foreign trade development. In 2013, the total volume of imports and exports in China was 4,160 billion dollars, with 7.6% growth. China became the first trade power in the world. As the first country whose total volume of goods trade exceeds 4,000 billion dollars, China is the miracle in the world trade development history. The exports were 2,210 billion dollars, showing 7.9% growth. It accounted for 11.8% of global exports and was 0.7% higher than that in 2012. China's exports ranked first for five successive years in the world. The imports valued 1,950 billion dollars, showing 7.3% growth. It accounted for 10.3% of global imports and was 0.5% higher than that in 2012. China's imports ranked second for five successive years in the world. The trade surplus was 259.75 billion dollars, occupying 2.8% of GDP. Moreover, the general foreign trade of China in 2013 increased by 9.3% to 2,200 billion dollars, 52.8% of the total volume of foreign trade and 0.8% higher than that in 2012. The processing foreign trade was increased by only 1.1% to 1,360 billion dollars, 32.6% of total the total volume of foreign trade and 2.2% lower than that in 2012. This implies that China's guidance on attention shift from processing trade to technology trade achieved positive progress. Among the processing foreign trade, 11.9% was contributed by middle and west China, showing 2.1% growth than that in 2012 and 8.9% growth than that in 2008. Other foreign trade increased by 18.3% to 610 billion dollars, taking up 14.5% of the total volume of foreign trade.

Facing with the tightening demand and fierce market competition, import and export enterprises adopt transformation actively. They increase investment to technology R&D, brand building and quality management. This further increases technology content and value added of export commodities, thus providing strong support to the stable export growth of commodities. Exports of 7 kinds of labor-intensive products, including textile, clothing, bag, footwear, toy, furniture and plastic products, reached 461.8 billion dollars, increasing by 10.3% (2.4% higher than the overall export growth). Exports of mechanical and elec-

* ***Corresponding author's*** e-mail: wuxue400020@163.com

trical products were 1,265.5 billion dollars, increasing by 7.3% and accounting for 57.3% of the total exports. Viewed from the internal export structure of mechanical and electrical products, automatic data processing equipment (ADPE) export reduced slightly, but appliance export increased slowly and some mechanical equipment export increased quickly, becoming a new growth point of mechanical and electrical products export. Specifically, aircraft exports increased by 76.1%, accompanied with 13.5% growth in mechanical handling equipment and parts as well as 12.4% growth in textile machinery and parts. High-tech product exports increased by 9.8% to 660.3 billion dollars, 29.9% of the total exports and 0.5% up compared to that in 2012.

Generally, China's foreign trade with developed countries increases slowly. In 2013, China's foreign trade with America, EU and Japan increased by 2.1% to 1,392.6 billion dollars, which was equal to 33.5% of the total foreign trade volume, 1.7% lower compared to that in 2012. To be more specifically, China's foreign trades with America and EU were 559.1 billion dollars and 521 billion dollars, increasing by 2.1% and 7.5%, respectively. China's foreign trade with Japan was 312.6 billion dollars, decreasing by 5.1%. On the contrary, China's foreign trade with emerging economies generally maintained a quick growth. However, China's foreign trade with some emerging economies declined to a certain extent after August and September. This is caused by the financial market turmoil and economic slowdown of these emerging economies. In 2013, China's foreign trade with ASEAN, South Africa, Brazil and Russia increased by 10.9%, 8.6%5.3% and 1.1% respectively, but China's foreign trade with India decreased by 1.5%.

Middle and west China plays an increasing important role in trade economy. In 2013, middle and west China contributed 562,6 billion dollars of the total foreign trade volume, increasing by 14.3% (6.7% higher than the growth of total foreign trade volume). Its proportion in the total foreign trade volume increased to 13.5% from 12.7% in 2012. The exports of middle and west China increased by 17.1%, 9.2% higher than the total exports. Yunnan, Ningxia, Guizhou, Gansu, Chongqing and Henan achieved more than 20% growth in exports. Export growth of Yunnan and Ningxia even reached as high as 59.3% and 55.5%. The foreign trade of East China was 3,597.7 billion dollars, increasing by 6.6%. Exports of east China achieved 6.9% growth.

3 Application of ARMA model in China's trade economic development

3.1 THEORY OF ARMA MODEL

ARMA model, or called as autoregression moving average model, was a precise time series forecasting method established by BOX and Jenkins. It believes that some time series are a group of random variables depending on time. Although a single variable composing time series is uncertain, the whole series vary according to certain law. As a result, the future development of such time series can be forecasted. Due to the forecast error, it is impossible to forecast continuously based on the predicted value, but only can make short-term forecast.

1) Autoregression model (AR model): if the time series y_t is the function about its former time series and stochastic term:

$$y_t = \varphi_1 y_{t-1} + \varphi_2 y_{t-2} + ... + \varphi_p y_{t-p} + \mu_t ,$$

y_t is the *p*-order autoregression sequence. φ_1, φ_2 ,…, φ_p are autoregression coefficients. Let B^k to be the lag operator and then:

$$B^k y_t = y_{t-k} .$$

Then, the AR model can be rewritten as:

$$y_t = \varphi_1 B y_t + \varphi_2 B^2 y_t + ... + \varphi_p B^p y_t ,$$

$$\varphi(B) = \varphi_1 B + \varphi_2 B^2 + ... + \varphi_p B^p .$$

It can be further simplified into:

$$\varphi(B) y_t = \mu_t .$$

2) Moving average model (MA model): if y_t is the linear function of its former series and former error term:

$$y_t = \mu_t - \theta_1 \mu_{t-1} - \theta_2 \mu_{t-2} - ... - \theta_q \mu_{t-q} ,$$

y_t is called as *q*-order moving average model. θ_1, θ_2 , , θ_q are moving average coefficients. Similarly, let B^k to be the lag operator and then:

$$\theta(B) = 1 - \theta_1 B - \theta_2 B^2 - ... - \theta_q B^q .$$

It can be further simplified into:

3) ARMA model: if y_t is the function of the error of its current and former stochastic terms as well as former series:

$$y_t = \varphi_1 y_{t-1} + \varphi_2 y_{t-2} + ... + \varphi_p y_{t-p} + \mu_t - \theta_1 \mu_{t-1} - \theta_2 \mu_{t-2} - ... - \theta_q \mu_{t-q} .$$

y_t is called as the (*p*, *q*)-order ARMA model.

3.2 APPLICATION OF ARMA MODEL

Firstly, ARMA model has to analyze its lag orders to get *p* and *q* (Table 1). AR (7) MA (2) can be implemented to variables. Secondly, the least square method is implemented by taking variables as dependent variables and AR(1), AR(2), AR(3), AR(4), AR(5), AR(6), AR(7), MA(1) and MA(2) as independent variables. The calculated parameters are listed in Table 2. ARMA has no strict requirements on *T* and tail probability (*P*). Therefore, there are only three main parameters, namely,

correlation coefficient, AIC and SC. Finally, dependent variables are forecasted by the ARMA model. Results are shown in Figures 1-4.

TABLE 1 *p* and *q* for model analysis

Orders	Imports & Exports	Exports	Imports	Balance
p	7	7	7	6
q	2	2	2	2

TABLE 2 Basic parameters for model forecast

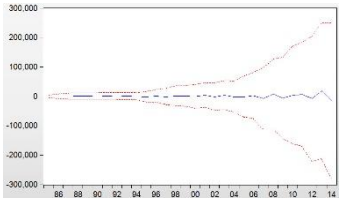

FIGURE 1 Balance of trade forecast in 2014

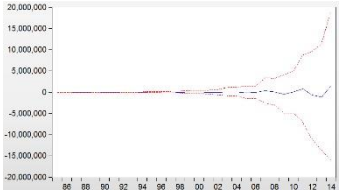

FIGURE 2 Export forecast in 2014

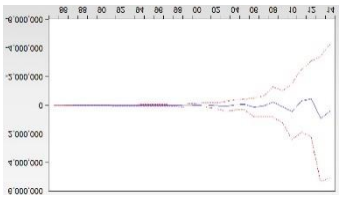

FIGURE 3 Import forecast in 2014

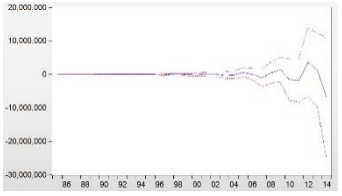

FIGURE 4 Foreign trade forecast in 2014

In Figure 1, the center line represents the forecasted balance of trade, which indicates that the balance of trade will decline in 2014. This agrees with China's trade economic development logic. China has maintained trade surplus for a long time, which brought a lot of trade conflicts with many developed countries. Main causes of balance reduction of trade are analyzed. Firstly, Chinese government is committed to coordination to eliminate trade conflicts and adopts various measures to reduce balance of trade and inhibit the increasing trade deficit. Secondly, China's economy has experienced rapid development and now enters into stable development. This will slow down the trade economic development, thus decreasing balance of trade. Thirdly, the chronic trade deficit intensifies the trade conflicts between China and developed countries. Developed countries will take various measures against China's export development, thus influencing the balance of trade finally.

China's export forecast is shown in Figure 2. The center line reflects that China's export shows a growth trend. There are three causes of China's export growth trend. Firstly, although China's economy enters into stable development, its growth rate is still higher compared to the world economic development. The rapid development of production speed can facilitate export to a certain extent. Secondly, although China pays close attentions on trade balance, it still seems partial to export development, because export can drive region economic development significantly and China still faces with excess capacity in many industries. Thirdly, China is improving the pattern of production continuously. It takes a certain time to transform from labor-intensive product export to technology-intensive product export. Therefore, export will increase continuously.

China's import forecast is shown in Figure 3, which presents a declining trend. There are four main causes of import reduction. Firstly, the world economic slowdown decreases the world's production capacity, thus weakening export capacity of other countries. Secondly, China depends less on import with the enriching production. Thirdly, China, though has entered into the WTO, still has various protection policies to domestic enterprises, which are great barriers for the entry of foreign products. Fourthly, China's policy of promoting domestic demand goes against import. China's subsidy program for rural purchases is only available to domestic products, which is against marketing of foreign products in China.

China's foreign trade forecast is shown in Figure 4, which presents a declining trend. This indicates the gap between China's export growth and import reduction. This is the reason of the reduced balance of trade in China. Such declining trend of China's foreign trade reflects that China's trade economy will face with recession caused by three reasons:

1) the world economic recession;
2) effect of China's economic development strategies;
3) China's economic development trend.

4 Conclusions and suggestions

Based on above analysis, China's import will decline, while export will keep increasing. The balance of trade in China will decrease and the total volume of foreign trade will decline, indicating China's trade economy downturn.

This is against China's economic development. Favorable trade economic development shall include rapid development both import and export, reduced balance of trade, but continuous growth of total foreign trade volume. To achieve this goal, China shall:

1) Facilitate import development through financial policy adjustment. Firstly, import tariff of some commodities shall be adjusted. According to China's current economic development need, provisional tax rates can be adopted to reduce import tariff of energy sources. This can facilitate imports and offset our energy shortage. Additionally, import tariff of rare living goods in China but closely related to people life shall be lowered appropriately. This can improve the living standard in China and increase imports. To improve China's production level and product quality, import tariff of some advanced equipments and parts shall be adjusted appropriately. Key attentions shall be paid to lower import tariff of some products which are needed in primary energy sources and emerging industries but couldn't be produced in China or poor quality of domestic-made ones. China is encouraged to give certain tariff preference to commodities importing from underdeveloped countries. This not only can win their economic and political supports, but also can facilitate import and improve our balance of trade. Tariff reduction to underdeveloped countries shall be accelerated and expanded. Meanwhile, imports from members of free trade zone can be accepted according to practical situations of the free trade zone. Secondly, China can promote imports through financial support. China has set special funds for foreign trade. To promote imports, Chinese government is suggested to increase financial support, provide subsidies on interest payment to encouraged imports, and expand or adjust supports appropriately. Moreover, government shall guide and establish various business platforms with expanded import function, encourage to providing public services (e.g. import communication meeting), and continuously increase support to imports from developing countries.

2) Promote product upgrading and improve export structure. Firstly, China shall propel transformation and upgrading of processing trade. Government shall keep stable policies for processing trade, improve macro environment for technology and industrial transformation, increase confidence of investors, control trade companies with high energy consumption, high pollution but low value added, and guide transformation and derivation of processing toward high-end industries. These can improve China's trade structure comprehensively and help to produce high-quality products. Secondly, China shall establish and perfect domestic trading platform, cultivate enterprises with good reputation and conditions, encourage enterprises to building self-owned brands, and create good domestic marketing channels. Actually, government also can improve export structure and promote product upgrading through tax policies. On one hand, favorable tax treatment shall be offered to high-tech products. On the other hand, additional taxes shall be collected from enterprises with low technology level and value added as well as high pollution risks. Thirdly, China shall attach high attention on service and technology export development. According to experiences of foreign countries, technology and service export can increase value added of exports, protect our resources and prevent drain of our rare resources.

3) Enhance foreign trade management. Firstly, China shall optimize import management, including:

- **a.** eliminating unreasonable restrictions and measures;
- **b.** lowering trade cost, reducing catalogues concerning automatic import licensing commodity management;
- **c.** promoting online application actively;
- **d.** accelerating online verification between electronic data of automatic import licensing and the customs;
- **e.** increasing online verification efficiency, and implementing scientific and effective regulation.

Secondly, China shall impel smooth connection between imports-exports and domestic goods, including:

- i encouraging domestic circulation enterprises to participate in international trade;
- ii supporting qualified enterprise to integrate imports and domestic circulation business;
- iii encouraging domestic commercial enterprises to sell foreign brand articles of consumption as agencies and develop platforms for below-the-line promotional activities to break monopoly and realize full competition;
- iv following standard international practices to perfect relevant laws and regulations, and support development of departure business enjoying tax exemption;
- v increasing import ports to special commodities (e.g. medicine) appropriately and expanding related product export;
- vi accepting imported commodities with inspection and quarantine certificates completely without needing additional test after entered into the Chinese market.

4) Improve infrastructure and improve clearance efficiency. China shall:

- **a.** further improve infrastructures in border ports, check and supervision facilities as well as infrastructures in border economic cooperation zones, establish a modern logistics system integrating cargo transportation, storage and processing, and increase handling capacity of ports;
- **b.** improve supporting facilities in border trade places, fully implement polices about promoting economic and trade development in border

regions, intensify economic and trade contacts with surrounding countries and regions;

c. propel the "Construction Engineering for Improving Work Efficiency of Ports" continuously and accelerate construction of electronic ports;

d. accelerate standardization and electronization of trade documents greatly, facilitate sharing of trade documents and supervision information among different departments, and realize "integrated input but independent declarations" of exports and imports;

e. perfect consulting service platform of technical regulations and conformity assessment of import commodities;

f. make full use of the leading role of local people's government and support to establish local information service platforms.

Transmission power control strategy based on partially observable Markov processes for IEEE802.11 WLAN

Yanpeng Feng*, Hongyan Zheng, Bo Wu

Education Technology and Information Center, Liuxian Road, Shenzhen Polytechnic, Shenzhen, China

Received 1 November 2014, www.cmnt.lv

Abstract

With the limitation of independent channels in IEEE802.11 WLAN, co-channel AP interferes with each other in repeat coverage area. As traditional AP launched a fixed power in sending data packages, which ignores the differences and mobility of STA. According to the mobility of STA and the partially observable feature of AP-STA link, this paper analyses the internal relations among the link state, transmission power and channel interference of co-channel AP, and proposes a single-link transmission power control (TPC) algorithm based on the Partially Observable Markov Decision Processes (POMDP). Firstly, the single AP-STA link POMDP-TPC model is constructed, and the neural network learning model is established to describe the observation function of POMDP-TPC. Secondly, the algorithm constructs reachable belief searching trees to obtain the approximate optimization, which implements the dynamic creating and on-line updating of the power consumption policy. Finally, under the experiment environment in OPNET and IEEE802.11b, the results demonstrate the algorithm can reduce the AP power consumption efficiently and improve the network throughput greatly.

Keywords: wireless local area networks, access point, POMDP, transmission power control, anti-interference

1 Introduction

The rapid rise of wireless LAN makes the deployment of wireless access point (AP) become increasingly intensive; however, WLAN has limited non-interfering channels, especially the 2.4GHz band only uses three non-overlapping channels (1, 6 & 11). Same channel used by different APs may cause hidden nodes, making channel interference and transmission conflict become the main issues that limit network throughput [1,2]. Thus, the link transmission power control (TPC) is becoming one of the key technologies to solve this problem [3]. It ensures AP coverage, reduces the channel interference and improves the network throughput.

Accordingly, Javier del Prado Pavon took 802.11b as the object of study and proposed a link-based power control algorithm, which calculated packet loss rate through SNR and BER, increased AP throughput [4] and lowered energy consumption. However, the algorithm involved changes in protocols and physical layer, so that it is difficult to promote in large scale. Daji Qiao took 802.11a/h as the object of study, and proposed an optimal energy transfer policy (miser strategy) [5]. This method can effectively conserve AP power, but it is difficult to handle changes in STA position. Wei Li proposed a PCAP (Power Control for AP Performance enhancement) algorithm [6], which used heuristic method to achieve balance between network throughput and AP proportional fairness. Jing Nie proposed a pccf protocol [7]. RTS transmission power is based on the carrier sensing threshold, reception threshold and the maximum transmission power, and the data transmission power is calculated according to the SINR (signal to interference noise ratio) threshold. The above-mentioned algorithms have effectively promoted the development of TPC algorithm, but still have the following problems:

1) The existing algorithms mainly take AP reference transmission power as the control object, and control AP coverage by adjusting the transmission power of beacon frame to achieve the purpose of reducing interference; however, the differences between STA position and performance are not considered. It is like "talking with many people in a place". If talking with all persons with the same volume, the objects far away or with weak hearing could not hear clearly, while the objects in near place or with good hearing will feel deafening.

2) The existing algorithms lack consideration of uncertainty in wireless environment. Most algorithms assume that the environment is known and unchanging, but the transmission environment has a great deal of uncertainty in practice due to multiple-operator deployment and illegal AP structure.

To solve the above-mentioned problems, this paper introduces the thinking of probability theory, proposes Partly Observable Markov [8] Decision Processing – Transmission Power Control (POMDP-TPC), takes single-link data packet transmission power as the control object and builds POMDP six-tuple model to analyze the correlation of the strength, SNR, BER and link status of received signals, establish the observation function learning model based on neural network and use reachable belief state online search to achieve dynamic planning and real-time decision-making of strategies, and achieve the

* ***Corresponding author's*** e-mail: ypfeng@szpt.edu.cn

purposes of reducing AP energy consumption and improving network throughput.

2 TPC model based on partly observable Markov

2.1 SYSTEM MODEL

WLAN operating frequencies are 2.4GHz and 5GHz. At present, most operators only support 2.4GHz. For large WLAN network of high-density, although the channels are arranged alternately, the same channel still needs to be used by different APs, and an AP of the same channel can't detect the AP of the opposite end; however, STA in overlapping coverage areas will encounter the risk of conflict (i.e. hidden nodes) in the process of data transmission and reception. Therefore, the link transmission power should be controlled to ensure AP coverage, reduce channel interference and improve the network throughput.

In this paper, co-channel AP interference is the object of study, and the following assumptions are made:

1) AP physical layout and channel planning are basically reasonable, and there is no complete coverage or blind zone;

2) STA has been connected to AP, and this algorithm only controls data transmission power.

If AP and STA can exchange data at a high rate after connecting, they have better wireless channel. Under the premise of high-speed transmission, AP should gradually reduce the transmission power of STA to reduce energy consumption and reduce the interference range of other transmission links. Conversely, if the wireless channel becomes worse and results in speed reduction or packet loss, AP should increase its transmission power. Therefore, the power control algorithm should be specific to each AP-STA link, adjust transmission power in real-time according to the link status and achieve the optimal balance between transfer rate and transmission power.

2.2 SYSTEM FRAMEWORK

The wireless transmission environment has randomness and uncertainty. On the one hand, there are differences between different STAs, including the location of AP from STA and STA sensitivity; on the other hand, the same STA has mobility. Therefore, the transmission power control requires link status observation and assessment for each AP-STA link and then selecting the optimal power adjustment strategy. Its essence is the optimal decision in a random environment. POMDP is an ideal mathematical model to solve such problems. The structure of single link POMDP-TPC is shown in Figure 1.

POMDP allows describing $< S, A, T, R, Z, O >$ with a six-tuple. *S*, *A* and *E* represent state set, action set and observation set respectively; $T: S \times A \to \prod(S)$ is state transition function, which represents the probability of executing a under the state s to state s', recorded as $T(s, a, s')$; $R: S \times A \to R$ represents the strategy evaluation function; $O: S \times A \to \prod(Z)$ is an observation function, which represents the probability of getting observation z when executing a to state s', recorded as $O(s', a, z)$. Evaluate the current link status through six-tuple to get the belief state b. Due to the partial observability and randomness of the link, belief state is actually a probability distribution of state set. The belief state search and value iteration method are used to obtain the optimal strategy, i.e. the optimal transmission power of single link.

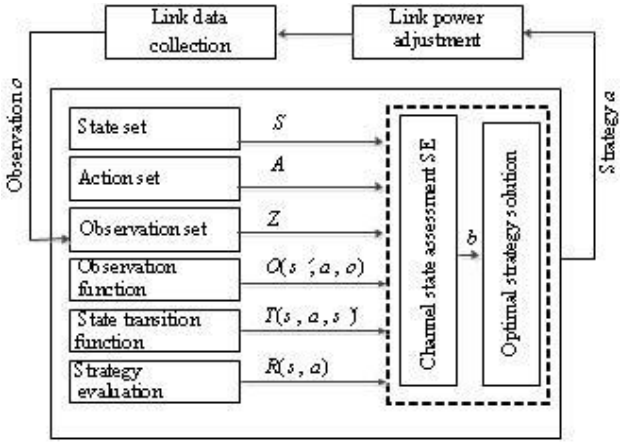

FIGURE 1 POMDP-TPC system framework

POMDP-TPC controller is the core of the system. It takes single AP-STA link as the object. To achieve self-adaption of AP to STA in the data transmission process, a POMDP decision model should be established for each link to obtain the optimal transmission power of the link in real-time and achieve high throughput and low power consumption of the AP.

3 Establishment of POMDP-TPC model

3.1 DEFINITION OF STATE SET, ACTION SET AND OBSERVATION SET

In POMDP-TPC model, the settings of state set, action set and observation set directly affect the effectiveness of control strategies and the complexity of strategy solution. In this paper, the state set, action set and observation set are set as follows through a large number of experiments and correlation analysis:

1) Single AP-STA link status $S_l = S_{ack} \times S_p \times S_{sta}$. S_{ack} indicates whether the message is sent successfully. In IEEE802.11, each packet transmission requires ACK response, and therefore, whether correct ACK packet is received indicates whether the message is sent successfully. S_p indicates the transmission power of the link, $s_p = p_{link} \cdot S_{sta}$ includes STA state, which includes two factors: the distance of the region from AP and whether there is interference in the region. Therefore, the AP transmission power is increased in increments of 0.5 dBm, and its coverage is divided into m regions. Assume that

the maximum transmission power and minimum transmission power of AP are $P_{\max}$ and $P_{\min}$ respectively, then $m = (P_{\max} - P_{\min})/0.5$. In an unknown environment, each region has the possibilities of interference and non-interference, and therefore AP coverage area contains 2m cases, and STA state can be expressed by a two-tuple: $\{(s_{sta\_area}, s_{sta\_inter}) \mid s_{sta\_area} \in (1,m), s_{sta\_inter} \in (0,1)\}$, of which s_{sta_area} indicates the region that STA locates and s_{sta_inter} indicates whether there is interference in this region.

2) The action set A represents a set of power adjustment actions that can be executed by AP. Theoretically, the power adjustment may be any value within the limited range. In fact, AP power adjustment needs to be able to quickly respond to the real time changes in the wireless environment, and should meet the adaptation of opposite end STA to the changes in transmission power. Therefore, the adjustment of transmission power is set to four levels: $\{0.5dBm, 1dBm, 2dBm, 4dBm\}$, so that the power is adjusted to variable step size, which can respond quickly to changes in the environment and can be tuned according to the link status. Depending on the STA, AP transmission power can be increased, reduced or remained unchanged.

3) Observation set Z represents the set of link parameters that can be obtained by AP. STA varies in sensitivity and position and is variable in real time, S_{link} can't be obtained directly, and thus should be inferred by measurable link parameters. The selected parameters should reflect the environment of the reaction medium and the link quality and analyze the association of each parameter and the link state. The calculation is as shown in Equation (1).

$$Correl(X,Y) = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 (y_i - \bar{y})^2}}; i, j = 1,2,...,10, \quad (1)$$

where *n* represents the number of samples, $\bar{x}$ and $\bar{y}$ represent the sample mean.

By analyzing the correlation of wireless communication data in January of a district of Shenzhen, Guangdong Province, the strength *q*, signal-to-noise ratio (SNR), bit error rate *b* and transmission rate (DTR) of the signals of the correlation coefficient greater than 0.7 are selected as the members of observation set.

3.2 STATE TRANSITION FUNCTION

For each AP-STA link, the state transition function represents the changes of link status in two adjacent time slices. Status *s* includes s_{ack}, s_p and s_l, which are independent of the conditions, and therefore the state transition function can be written in the form of conditional probability:

$$T(s,a,s') = Pr(s'_{ack}, s'_p, s'_l \mid a, s) = Pr(s'_{ack} \mid a, s) Pr(s'_p \mid a, s) Pr(s'_l \mid a, s), \quad (2)$$

s_l only associates with the transmission medium and STA position, and doesn't change with the AP transmission power, so that the Equation (2) can be rewritten as:

$$T(s,a,s') = \begin{cases} 0 & s'_l \neq s_l \\ 0 & s'_p \neq s_p + \Delta p \\ Pr(s'_{ack} \mid a, s_{ack}, s_l, s_p) & \text{others} \end{cases}, \quad (3)$$

$Pr(s'_{ack} \mid a, s_{ack}, s_l, s_p)$ is obtained from historical data.

3.3 OBSERVATION MODEL

Under different link status, executing different power adjustment strategies will obtain different observations, namely to observe the model in different states, the possibility of obtaining the corresponding observation under different statuses and policies, which is expressed as follows with probability:

$$O(s',a,o) = Pr(o \mid s', a). \quad (4)$$

It is inferred from Bayesian rule that:

$$Pr(o \mid s', a) = \frac{Pr(s' \mid o, a) Pr(o \mid a)}{Pr(s' \mid a)} = \frac{Pr(s' \mid o, a) Pr(o \mid a)}{Pr(s' \mid a, s)} = \frac{Pr(s' \mid o, a) Pr(o \mid a)}{T(s,a,s')}, \quad (5)$$

where the denominator is the state transition function, which is obtained from Equation (3); in the numerator, $Pr(o \mid a)$ can be regarded as a normalization factor; $Pr(s' \mid o, a)$ represents the probability to obtain status s_{ack} by executing policy a under current observation. As s_{ack}, s_p and s_l are independent of the conditions, so that:

$$Pr(s' \mid o, a) = Pr(s'_{ack} \mid o, a) Pr(s'_p \mid o, a) Pr(s'_l \mid o, a). \quad (6)$$

Obtain $Pr(s'_{ack} \mid o, a)$, $Pr(s'_p \mid o, a)$ and $Pr(s'_l \mid o, a)$ as follows:

1) For $Pr(s'_{ack} \mid o, a)$, whether each data packet is transmitted successfully is determined by whether ACK packet is received. Therefore, the probability of successful transmission of a single packet = probability of data transmission failure * probability of ACK packet transmission failure, as shown below:

$$Pr(s'_{ack}=1|o,a)=(1-Pr(e\_data|o,a))\times(1-Pr(e\_ack|o,a)) \quad (7)$$

The study of the [3] shows that the probability of packet transmission failure can be calculated through BER, SNR and transmission rate:

$$Pr(e\_data|o,a)=1-(1-Pr(b|snr,dtr))^{8L}, \quad (8)$$

where L indicates the packet length. The length of ACK packet is fixed at 14bytes, so

$$Pr(e\_ack|o,a)=1-(1-Pr(b|snr,dtr))^{112}. \quad (9)$$

2) For $Pr(s'_p|o,a)$, assume that the AP power transmitting module always can specify the transmission power, that is, $Pr(s'_p|o,a)$ is independent of the observation and strategies. For all observations, $Pr(s'_p|o,a)=1$.

3) For $Pr(s'_l|o,a)$, link status is strongly correlated to signal strength, SNR, bit error rate and transmission rate strongly correlated. However, the parameters have complex nonlinear relationship, and it is difficult to derive through a simple mathematical model. In this paper, we propose a link status inference model based on BP neural networks, and obtain s' of corresponding observation and strategies through network training and inference.

With three layers BPNN structure, the neurons of input layer and output layer are 4 and 2 respectively. Through the correlation analysis in section 3.1, the link status neural network model inputs are determined as follows: signal strength *q*, SNR, DTR and transmission power *p*. The model output is link status s_l. The number of neurons in the hidden layer calculated in accordance with the empirical equation is identified as 10, and the inference model neural network structure:

$$s_l=\sum_{i=1}^{10} w_{i,o}^{ack}\,\text{tansig}(w_{i,1}^{ack}q+w_{i,2}^{ack}snr+w_{i,3}^{ack}lt+w_{i,4}^{ack}dtr), \quad (10)$$

$w_{i,o}^{ack}$ is the corresponding weight of the *i*-th neuron of the hidden layer to the output neuron, $w_{i,j}^{ack}$ is the corresponding weight of the *j*-th neuron of the input layer to the *i*-th neuron of the hidden layer, and tansig(·) nonlinear Sigmoid activation function is used.

3.4 POLICY-RETURN FUNCTION

If the current link is free of interference and the packet transmission is successful in the process of AP packet transmission, the transmission power should be reduced to the power of STA minimum coverage as soon as possible, which can not only ensure successful data transmission, but also reduce energy consumption of AP; conversely, if the current link is free of interference but the packet isn't sent successfully, the transmission power should be increased to be equal to or slightly greater than the minimum coverage power of STA as soon as possible to increase the probability of success and avoid repeated failures and retransmission:

$$R(s,a)=\begin{cases}\dfrac{1}{|s_p+\Delta p-s_{l\_area}*0.5|} & s_{l\_inter}=0, s_{ack}=1\\ \dfrac{1}{|s_p+\Delta p-s_{l\_area}*0.5-\eta|} & s_{l\_inter}=0, s_{ack}=0\\ \dfrac{1}{|\Delta p|} & s_{l\_inter}=1, s_{ack}=1\\ \dfrac{1}{|s_p+\Delta p-s_{l\_area}*0.5-\mu|} & s_{l\_inter}=1, s_{ack}=0\end{cases}, \quad (11)$$

where Δp is the amount of power change, η and μ are anti-interference margin set according to experience. In particular, when the denominator is zero, $R(s,a)=2(1/0.5)=4$.

4 Optimal control strategy solution of single link POMDP-TPC

4.1 ALGORITHM PROCESS

Traditional Markov solution algorithms usually use offline planning. With the increase in the number of iterations, the complexity of algorithm time and space expands rapidly, which is a typical NP-hard problem. To ensure real-time and dynamic adaptability of TPC algorithm, online algorithm [9] is used to divide the entire strategic planning and policy execution into several small plans and executions, start from the current belief state to build reachable belief status search tree, control the spatial scale of reachable belief state and achieve fast solution, as shown in Figure 2.

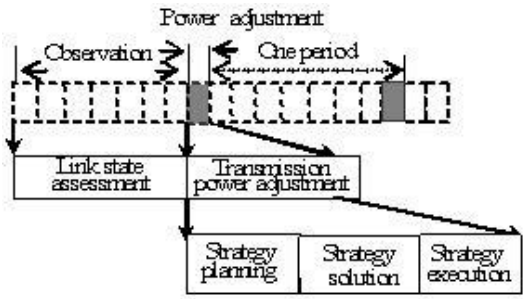

FIGURE 2 Online Solution of AP Link Power Control Algorithm

During system operation, the entire process is run at a fixed period, each period is divided into several small time slices, the former time slices are the observation phase for data collection, filtering and link status assessment, and the power calculation and adjustment are carried out in the last time slice, including strategic planning, strategy solution and strategy execution. After the power is adjusted, repeat observation, assessment of link status and adjustment of

transmission power in the new cycle, and thus ensure that the link transmission power can dynamically adapt to the changes in STA and the environment.

4.2 OPTIMAL STRATEGY SOLUTION

The TPC algorithm of the entire link can be divided into off-line training, online strategy planning, online strategy solution, and strategy execution. The objective of offline training is to obtain the corresponding weight of each neuron of the neural network in gradient descent method. The steps of online strategy planning and online strategy solution are as shown in Table 1.

TABLE 1 TPC online planning and solution algorithm

Algorithm: TPC online planning and solution algorithm
Definition: b_c , current belief state; *T*, belief state search tree;
//Online strategic planning
1): Obtain the current belief state b_t according to observation;
2): Build belief state search tree T with current belief point b_t as the root;
// Online strategy solution 3): Calculate the iterative return value function of belief point in *T* through edge node upward propagation algorithm;
4): Obtain the optimal power control strategy a^* under b_t ;
// Online strategy execution 5): Adjust the packet transmission power according to the power control strategy;
6): Collect the link data, and update belief state b_c according to a^* and *z*;
7): Return to 1) and reconstruct belief state search tree;

Here the belief state b is an assessment by observing the current link status. Due to the partial observability and uncertainty of link, it is the probability distribution on a real state set, determined by the action and observation at the moment of 0-t and described:

$$b_t = Pr(s_t \mid a_t, z_t, a_{t-1}, z_{t-1}, ..., a_0, z_0, s_0). \quad (12)$$

To effectively prevent strategy jitter, it is necessary to consider the long-term effects of the current strategy, that is, to construct the reachable belief state search tree according to the current belief state. The root node of the search tree is the current belief state, and the leaf node is the reachable belief state point after one or several steps of power adjustment. Assume that $b(s')$ is the new belief state point, and $b(s')$ can be obtained from the father belief point, observation function and state transition function:

$$b_t(s') = \frac{\sum_{s' \in S} O(s', a^{t-1}, z^t) T(s, a^{t-1}, s') b^{t-1}(s)}{P(z^t \mid b^{t-1}, a^{t-1})}. \quad (13)$$

Assume that the depth of search tree is *D*, and obtain to reachable belief state search tree through iteration, which indicates all possible intermediate states and end states starting from the current belief state after power adjustment for *D* times.

Convert partly observable Markov strategy solution process into belief state based Markov solution and strategy evaluation function $\rho(b,a) = \sum_{s \in S} b(s) R(s,a)$. Calculate the function *V* with Bellman equation; as shown in Equation (15), γ is the discount factor.

$$V^{t+1}(b) = \max_{a \in A} \left[\sum_{s \in S} b(s) R(s,a) + \gamma \sum_{z \in Z} P(z \mid b,a) V^t(b') \right], \quad (14)$$

$$\pi^{t+1}(b) = \arg\max_{a \in A} \left[\sum_{s \in S} b(s) R(s,a) + \gamma \sum_{z \in Z} P(z \mid b,a) V^t(b') \right]. \quad (15)$$

Effectively estimate the long-term impact of different power control strategies on future link status through constructing belief state search tree and value iteration, select the strategy π with the maximum cumulative return value as the optimal strategy to achieve the balance among AP energy consumption, minimum interference and packet transmission success rate, and avoid jitter of control strategies effectively.

5 Experiments and results analysis

Use OPNET simulation platform to build IEEE802.11b wireless network test environment. The simulation parameters are shown in Table 2. FTP traffic flow of normally distributed packet length is used to simulate the STA business environment of each site.

TABLE 2 Parameters of simulation environment

Parameter	Value
Region size	300m*300m
AP number	Four, evenly distributed arrays
STA number	20, randomly and uniformly distributed
AP channel	1
P_{max}	27dBm
P_{min}	5dBm
P_{beacon}	21dBm

The network is shown in Figure 3. Four APs are recorded as AP1-AP4, and 20 STAs are randomly distributed, of which 9 can detect SSID of two or more APs. All STAs establish a connection with AP1, AP2, AP3 and AP4 respectively, of which AP1 has the heaviest load and AP4 is relatively light.

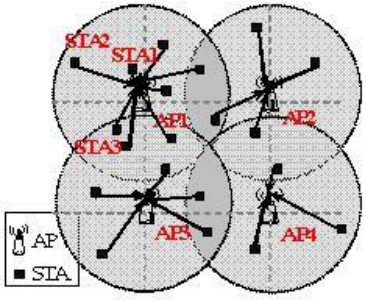

FIGURE 3 Experimental environment network structure

5.1 AP THROUGHPUT AND ENERGY CONSUMPTION

Keep the STA position, and transmission power unchanged and carry out the experiments in three groups: none AP runs this algorithm, AP1 and AP2 run this algorithm, and all APs run this algorithm. Repeat each group of experiments 10 times and evaluate the average. Run each experiment 30 minutes, and compare the average throughput and average energy consumption of AP1, AP2, AP3 and AP4, as shown in Figures 4a and 4b.

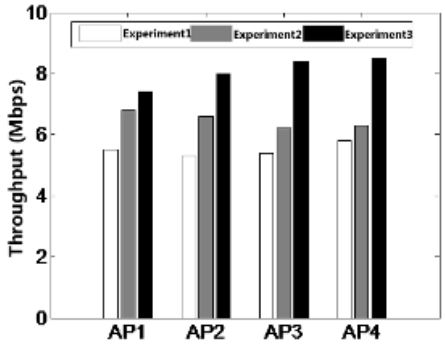

FIGURE 4a Throughput comparison chart

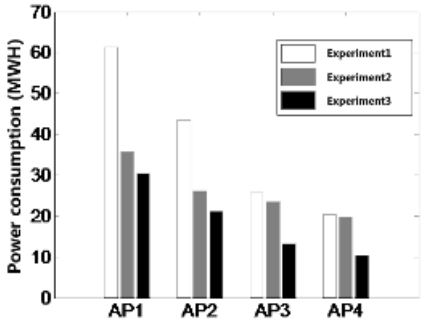

FIGURE 4b Power consumption comparison

Figure 4a shows that the throughputs of four APs have increased when AP1 and AP2 run this algorithm, and AP1 and AP2 are superior to AP3 and AP4, which fully shows that the algorithm can effectively transmit conflict. Although AP3 and AP4 didn't run this algorithm, the throughput was significantly improved because the transmission conflict in repeated coverage region was reduced, and thus the throughput of the entire network was improved effectively; when none AP run the algorithm, all the throughputs were significantly improved, but AP throughputs were the smallest, indicating that although the proposed algorithm can reduce the transmission conflict to some extent, it can't eliminate the conflict. AP1 had the maximum load, so that the possibility of transmission conflict was still greater than other APs, and therefore the throughput was the smallest. Figure 4b well verifies the effectiveness of the algorithm in energy saving. The power consumption of AP is reduced significantly because the algorithm enables AP transmitting data in appropriate power in accordance with the link state.

5.2 DYNAMIC ADAPT ABILITY

Move STA1 position away from 1m from AP1, and move STA2 position close gradually at a distance 80m from AP1. Keep the speed at 5m/s, STA3 position unchanged, and test the transmission power and packet loss rate of these three AP-STA links.

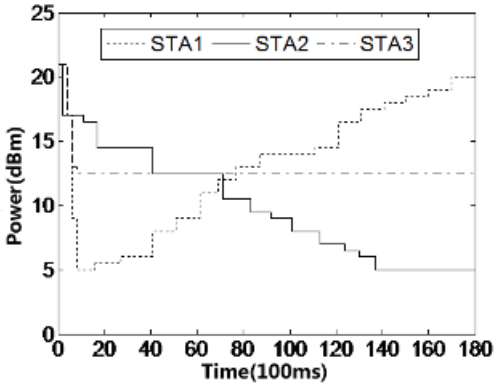

FIGURE 5a Transmission power changes with time

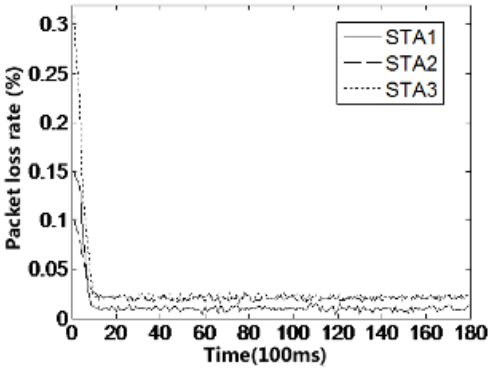

FIGURE 5b Packet loss rate changes with time

Figures 5a and 5b show the relationship of the changes in AP transmission power and packet loss rate. It is known that the adjustment frequency of transmission power is faster in the initial 10 control periods, and the packet loss rate also decreases rapidly. If STA position is unchanged, the transmission power tends to be stabilized and the packet loss rate is reduced to a minimum in the 10^{th} control period; if STA position changes, AP transmission power gradually increases or decreases with the change of STA position, and the packet loss rate can be maintained at a lower level, which fully illustrates that POMDP-TPC has excellent dynamic adaptability.

6 Conclusion

A single link transmission power control method is proposed according to the characteristics that STA position and transmission environment have differences in the control of transmission power. By introducing partly observable Markov theory, establish six-tuple model of single AP-STA link TPC optimal control, construct the

observation function and state transition function of link state, obtain the optimal strategy through belief state search and value iteration, achieve maximized expected value of reward function and achieve the objective of reducing power consumption and co-channel interference. The results of OPNET based simulation experiment show that the algorithm can better optimize AP energy consumption and throughput online, and reduce the interference between co-channel APs effectively. At present, the strategy reward function is set according to expert experience, and machine learning method will be studied to optimize the reward strategy function and correct experience setting.

An analysis framework for building commodity futures market simulation model based on heterogeneous traders

Tan Li, Weiwei Wu*

[1]*School of Management, Harbin Institute of Technology, 13 Fa Yuan Street, Harbin, China*

Received 6 June 2014, www.cmnt.lv

Abstract

Futures price volatility is always the hot topic for academic researchers and traders in futures market. For exploring the rules of futures price fluctuation, we try to develop a new analysing framework from the angle of the heterogeneous traders. We describe heterogeneous traders as four respects: trading motive, predict styles, risk-return preference, reaction speed, which can accurately describe the heterogeneous traders in futures market. According to the categories of heterogeneous traders, we construct traders' internal model, which is used in a commodity futures market simulation model to verify the framework, and the results show the framework is useful.

Keywords: bounded rationality, commodity futures markets, simulation model, heterogeneous traders

1 Introduction

The rules of futures prices movement has been the hot topic that academic researchers and traders have been interested in all the time. The deep understanding of this question not merely facilitates the futures price forecasts, but also favourable to the formulation of the futures market supervision rule, guarantee the market runs effectively. About the rules of futures prices volatility academic writing and actual operators have totally different understanding. In futures market, it is numerous traders that do a deal according to individual decision, forms market price. Studying actual operators' behaviour in futures market is a feasible route to understand price dynamic.

We make analysis to trader's behaviours in the market, and form a dynamic framework to analyse futures market price volatility. Then this framework is used for building a commodity futures market simulation model. The simulation results can be adopted to verify the validity of this analysis framework.

2 Review of commodity futures price theory

There are three main kinds of theoretical research of futures price volatility: (i) all these kinds of research beginning with 1930 of Keynes, he regarded the futures price as the function of the storage cost. The central idea of theory of price of storage is to analyse the composition of the futures price. Inherit the Keynes futures price theory, Working and Hicks developed the cost-of-carry theory to explain the relationship between spot price and futures price. (ii) the second kind of theoretical research mainly relate to core of the Capital Asset Pricing Model, risk premium problem, and think hedgers group in commodity futures market must pay risk premium to speculators group to make them enter position on the contrary to total hedgers group. (iii) Because of remarkable development in econometrics in recent years, almost each new technology in econometrics is rapidly applied to research price fluctuates in various financial markets. A lot of econometrics models are developed to analyse the relationship between spot price and futures price. The results through these models generally show the lead-lag relationship and the long-term forecast result is better, but short-term forecast is relatively bad.

The above (i) and (ii) items can partly explain futures price phenomenon, such as backwardation and contango. Many econometrics models which describe the spot price and futures price relationship can be used to predict the futures price, though the short-time forecast result is not satisfied. But the intrinsic character of the futures price dynamic is still not clear. The key problem is hypothesis of rationality. Many researchers generally used the hypothesis that traders in the market are completely rational and homogeneous. Since the presence of Simon's bounded rationality theory, this hypothesis is constantly questioned by many scholars.

Since 1980s', two representative schools' opinion about bounded rationality have been appeared. First is financial behaviour. The representatives are Robert Shiller and Daniel Kahneman. They have inherited Simon's bounded rationality theory partly. Based on the results got from psychological and human subjective experiments, they studied the relationship between traders' bounded rational behaviour and price dynamics. They developed theories including prospect theory, noise trading model, etc. Behaviour finance theory broke the traditional assumption about rational traders which was dominated in academic cycles in the past, and studied trader's decision under the uncertain conditions, and offered a feasible road for exploring the intrinsic characters of price dynamics in the financial market. But behavioural finance cannot build a unified

* ***Corresponding author's*** e-mail: hit_wu@126.com

frame to explain all the price anonyms appeared in the financial market. It is an obstacle to further develops for behavioural finance. Actual traders always adopt fundamental or technical analysis as their forecasting approaches. In the noise trading model, the traders of technical analysis generally are viewed as noise traders or call as speculators. Noise is defined as a process leading to shadow information, i.e. market mechanisms which blur observations of the market [1]. Noise traders, however, do not transcend the categories of fundamentalists and chartists. Recently, some scholars adopted the questionnaire among the traders in foreign exchange market, and find the majority of traders adopt the technical analysis method for short-term forecasting. As the extension of time horizon changes, these traders take fundamental analysis as the main method gradually.

Other scholars take the method of experimental economics, simulate financial market through the computer program, study traders' strategies and the influence to financial market price, and call it agent-based computational finance. Santa Fe of USA is famous in this field, their artificial financial market can really recur the statistics characteristic of the data on real financial markets. In their artificial financial market model, traders are heterogeneous. Agent-based computational finance so is a feasible road to study the financial market price dynamic characteristic. Studies of Behaviour finance and agent-based computational finance have one important common characteristic to think traders of financial market are bounded and heterogeneous. But in agent-based computational finance field, the empirical study on heterogeneous traders is still lack. In this field, traders are classified as fundamental and chartist / technical ones according to perception, not to first-hand data. Several results from investigations about heterogeneous expectations are not analysed systematically. Just like what Goodhart said, Economists cannot just rely on assumptions and hypotheses about how speculators and other market agents may operate in theory, but should examine how they work in practice, by first-hand study of such market [2]. Some researchers used questionnaire and interview to study foreign exchange market traders' expectation. The further work is to use these methods for the research of the commodity futures markets, and use the results of investigations to construct artificial futures markets simulation model. The following part of the paper is arranged like this, section two will analyse the meaning of trader's heterogeneity, and evidence for it. Section four will describe all kinds of traders' heterogeneity in the market carefully, and construct the internal model of the traders used in the artificial futures markets simulation model. Section five analyses the futures market price dynamic based on the hypothesis of heterogeneous traders. In the last section, summarize the futures market price dynamic analysis frame of heterogeneous traders and propose the future research work.

3 Definition of heterogeneity of traders and evidences

3.1 DEFINITION OF HETEROGENEOUS TRADERS

One of the reasons to explore trader's heterogeneity is to explain anomies in financial market. These anomies generally include aggregational Gaussianity, clustered volatility, fat-tailed return distributions, and long-term memory. Before define traders' heterogeneity, we will first discuss traders' rationality in financial market.

The bounded rationality theory first appears in Simon's "Management Behaviour". Simon thought, in broad sense, "rationality" refers to a behavioural manner: (i) Suitable for realizing the goal; (ii) And within the designated constraints. Economists use the word "rationality" to describe the attribution of action plans, not of decision process [3]. Kahneman and Tversky thought that people pay more attention to the amount of changes in their wealth, instead of their wealth final quantity. People incline to take the risk of gambling while facing the losses with suitable terms, and while facing the profit with suitable condition, incline to accept the determinacy and make profits. The happiness of making profits brings less than the agony that equal amount of losses. Yang Xiao-Kai summarizes Simon's bounded rationality theory to 3 main points: non-complete information cost of process information and some non-traditional goal function of decision makers. But Yang thought the 3 points of Simon' bounded rationality mentioned did not touch the nature of bounded rationality conception. Knight pointed out the foundation of bounded rationality lay in fundamental uncertainty, and this cannot be equal to non-complete information.

In this paper, traders' bounded rationality is the description of the decision-making process attribute. Traders' bounded rationality means two respects: (i) What traders faced is a complicated, uncertain market environment, this kind of uncertainty includes endogenous and exogenous uncertainty, endogenous uncertainty is caused by numerous trader's decision, endogenous uncertainty still exists even in such situation that not exogenous uncertainty; Exogenous uncertainty causes the uncertainty of the external factor of the financial market of various influence. So traders do not have complete information, have information asymmetry; (ii) Trader's computing capability and cognitive ability to the environment are limited, this one that includes to understanding that has already acquired knowledge and computing capability is limited.

Financial economics and new classical economics usually view individual traders as homogeneity, there are common risk preferences and beliefs between traders, or further assume traders have common knowledge. Under market equilibrium frame, several researchers study non-homogeneous traders' influence to market equilibrium. These researchers described heterogeneity of traders as heterogeneous beliefs or heterogeneous risk preferences, or both of them. According behavioural decision theory, a robust discovery is that the individual traders are heterogeneous in beliefs and risk-preferences [4-7].

The traders in the real financial market are bounded rational, and have different risk preferences, beliefs and information sets. According to the above-mentioned analysis, In this paper, trader heterogeneity of futures market refers to, the bounded rational traders, because the individual's risk preference, computing capability, information quantity and quality hold, difference level of affections by other traders, form different beliefs on futures price.

3.2 EVIDENCES FOR HETEROGENEITY OF TRADERS

Tests for heterogeneous traders mainly concentrate on the test for heterogeneous expectations in the futures market, and generally have two kinds of methods. One is "indirect test", while being so-called, because the method to estimate, receive through parameter trader have among the distribution or market that heterogeneity it is expected on the basis of constructing all kinds of and expecting the model heterogeneously Only allow reason to expect the proportion that traders account for verifies the existence of anticipated heterogeneity. Baak added bounded rational traders in the linear programming model that the standard reason of a financial market expects. In the model, bounded rational traders think the price obeys the AR(1) process. Finding market trend and traders' anticipated form in the market have close relations [8]. According to the calculation, when bounded rational traders' proportion "n" value exceeds a certain critical value in the market, the price can't converge to the equilibrium state. Frechette has adopted "indirect test" to examine heterogeneous expectations too, use the time series data of the commodity futures to test method validity [9]. One common point of the method is to divide traders into two or three groups, including fundamental and technical analysis traders, or rational expectation traders and bounded rational expectation traders, or is divided into naive traders, quasi-rational expectation traders and rational trader according to forecasting methods [10,11]. In addition, Hommes and Sorger assumed bounded rational traders form expectation according to the observed value of price time series, and this is similar to the traders who adopt the technical analysis to forecast in real market. Results of these research support market have heterogeneous expectations, but this kind of traders' categorized method is according to the general consciousness, not empirical investigation and statistical analysis, does not have convincingness, the accuracy of the result is queried.

Another test method for heterogeneous expectations can call "direct test". Oberlechner adopted questionnaire and interview method, studied the forecasting approaches used by European exchange market practical traders and financial journalists. His results confirm that most traders use both forecasting approaches (fundamental and technical analysis method), and that the shorter the forecasting horizon, the more important chartist/technical analysis is. In the past dozens of years, the importance of technical analysis in the foreign exchange market rises remarkably [12]. In addition, Lui studied the Hong Kong foreign exchange market dealers, and found technical analysis is considered slightly more useful in forecasting trends than fundamental analysis, but significantly more useful in predicting turning points and move average or other trend follow system is the most useful technical analysis method [13]. Cheung investigated traders' views on determination of exchange rate [14]. Cheung found a large part of traders thought that purchasing power parity (PPP) can be used to measure an foreign exchange rate's the fundamental value, however a much smaller percentage of traders would trade in such a way as to move exchange rates closer to PPP levels. It means the fundamental value criterion of exchange rate that traders admit is inconsistent with their standards of estimating adopted at the time of real trade. Cheung mentions, he has experienced the divergence between academic writing and traders' views. The above researchers' questionnaire investigation result s are enough to prove traders are not homogeneous in the foreign exchange market, including forecasting approaches at different forecasting horizon, the admitted factors of fundamental values, traders' reaction speed, traders' motivations, etc.. The difference between traders is so huge, and homogeneity and rationality are unable to describe all traders. Have not found that carry on the studying of this kind of investtigation to commodity futures markets traders, according to the materials collected at present, but believe that will get the similar result.

4 Developing heterogeneous traders' internal model

According to above-mentioned researches, there are sufficient evidences to support traders' heterogeneity, how to accurately describe traders' heterogeneity in constructing the artificial market simulation model is very important. De la Maza and Yuret first researches artificial futures market price dynamic, put forward information set, algorithm set, model set, constraint set to describe heterogeneity, but they fixed algorithm set and model set in the model [15]. This kind of 4 sets of de la Maza and Yuret describes constructs a rough frame for trader's internal model. According to the reasons, describe and affection for traders' heterogeneous, this paper constructs heterogeneous traders' internal model.

4.1 REASONS FOR HETEROGENEITY OF TRADERS

Researchers hold different views on what lead to trader's heterogeneity. Chavas' opinion was there were fundamental analysis traders (rational) and technical analysis traders (bounded rational) and different traders received and different experience caused trader's difference in knowledge [16]. Frechette attributed traders' heterogeneity to different traders' priori beliefs and filtration way in information, regarded individual's expectations difference as the expression of trader's heterogeneity. Oberlechner found trader's different prediction styles were related to individual background (such as age, gender, professional rank, years of work experience), but have no relations with trading locations. Author thought this because of in will obtain more information and training, etc. close to global transaction place of banking centre. We divide reasons into the internal factors and external factors. Internal factor refers to trader's education and training experience, individual risk-preference, predict style, etc. which are determined by individual characteristic. External factors refer to the differences between individual caused by individual trading motivation. According to the differences, we can divide traders group into several sub-groups.

According to the external factors, traders can be divided into hedgers, risk management traders, speculators.

1) Hedgers generally hold stock for production, or themselves are stock manufacturers. The aim of hedgers is just to hedge the position of the stock using futures contracts. In theory, hedgers will not adjustment position frequently, so they might not intraday traders. Hedgers including every industry's manufacturers, such as Jiangxi copper industry group in China.

2) Risk management traders refer to futures broker who engage agency business and clear their position in a day for risk avoidance need, they deal in order to guarantee their own position minimum risk in market. Three domestic futures exchanges (not including Hong Kong and Taiwan areas) implement the member system at present. There are two kinds of members, self-operation member, managers, and no comprehensive type. Therefore, in our country at present there is no market maker whose purpose is to minimize the risk by adjusting intraday position.

3) Speculators refer to who do not need to hold the stock for production, may hold stock for speculation, trading purely with the purpose of making a profit in speculation among futures market. This kind of traders can adjust their position for maximizing profit at any time. All hedge funds which invest in derivative markets belong to this kind of traders. Some domestic funds raised privately belong to this group at present.

According to the internal factors, individual traders can be distinguished as hedgers, risk management traders, speculators. Each trader among his group, because internal factor cause individual difference trade behaviour of the course reflect according to heterogeneous traders' behaviour.

4.2 REPRESENTATION OF HETEROGENEITY OF TRADERS

Sager and Taylor researched on foreign exchange market and got the results that heterogeneity of traders included information asymmetries, different reaction speed to information innovations, diverse trading opportunity sets and risk-return expectations [17]. Klitgaard and Weir used private information and public information to distinguish heterogeneous traders [18]. The private information here is analogous to traders and form all contents included price expectations. De la Maza and Yuret's research adopted information set, algorithm set, model set, constraint set, to describe traders' heterogeneity. We use forecast style, risk-return preference, and reaction speeds, totally three respects to describe traders' heterogeneity.

1) Forecast style. Oberlechner adopted clustering analysis method to obtain four forecast styles: chartist, ascending (technical analysis method is more popular in short-term, as time horizon is lengthened, change direction and fundamental analysis gradually becomes more popular when time horizon become longer than one year), fundamental, ascending (adopt the basic analytical method more than the technical analysis of rising in short-term, as the time horizon is lengthened, change direction and rely mainly on the fact that the foundation is analysed gradually, level become extreme foundation analysis trader longer than one year, in time), constant chartist (no matter time level grow section, pay attention to technical analysis even more, does not change much, this and Cheung, Chinn and Marsh, 2004 research conclusion the same), inverse middle (adopt the foundation to analyse more in a short time, but turn in long-term forecast to and adopt the technical analysis method finally). Through interview traders, Oberlechner found traders view the charts as "visual representations of mass psychology".

2) Risk-return preference. Generally speaking, hedgers should carry on the middle or long-term trading in the futures market, and belong to risk neutral traders, because their trading motive lies in hedging stock value, but not in order to earn the great amount of profit through futures trading. Risk management traders generally do intraday transaction, and the purpose is for voiding business risk. It is generally acknowledged, speculators do short-term transaction, and their purpose to buy or sell futures contracts is just for earning great amount of profit. According to modern finance theory, more return with more risk, congenial profit-making traders, just traders have offered flow ability in order to hedge. But Haigh, Hranaiova and Overdahl studied speculators in futures market. They found the original common consensus that speculators do short-term transaction was not true, such as hedge fund mostly did middle or long-term transaction, but hedgers more frequently changed their positions than speculators did [19].

TABLE 1 Risk preference of three groups

Time Level	Hedgers	Risk Manager	Speculators
Short	RISK AVERSION	RISK AVERSION	RISK AVERSION
Middle or Long	RISK NEUTER	–	RISK APPETITE

Cheung, Chinn and Mars investigated traders in foreign exchange market and found that traders in market thought the predictability of price movement increased with time horizon extended. They also found the next day or intraday trade has little predictability. This result proved these traders thought next day or intraday trade was very risky, but interview results showed these traders felt little risk in the next day or intraday. These results appear to contradict each other, and the reason may be that at least for part of traders, the risk measurement index may not be the variance, but the changes of assets. Because intraday or next day transaction even though makes loss, change percentage is very small for total amount of assets. Although it have more predictability for a long-time horizon, for an exact time level, traders think the predictability is extremely limited too. So we should adopt a new risk measurement method for descripting trader's risk-return preference, which is different from the past to adopt price variance of change estimate the risk. And what traders think is too risky to bring the higher income maybe not higher income. Such as risk management traders do intraday transaction, but they are risk-aversion. Three groups of risk management traders, hed-

gers and speculators are divided according to time horizons (see Table 1).

3) Reaction speed. Sager and Taylor thought some hedge funds had the fastest reaction speed to information innovations. But in Haigh, Hranaiova, and Overdahl's research hedge funds adjusted their positions after hedgers' position changed, that was to say hedgers have a faster reaction speed than hedge funds. It is still unclear what causes this each other contradictory result, but the fact is that traders really have different reaction speeds to new information. So reaction speed can become one aspect of trader's heterogeneity.

The traders are influenced by market sentiment mentioned in some literatures, and this is a kind of behaviour of heterogeneity too. Find through interview trader think "chart masses psychology but view ", can think traders adopt the technical analysis method to include his receiving the mood effect of the market while predicting. Using trading motive, predict styles, risk-return preference, reaction speed, totally four respects to describe heterogeneous traders.

4.3 IMPLICATIONS OF TRADERS' HETEROGENEITY

Trader's heterogeneity influence is divided into two parts, including the influence on producing between traders, i.e. the interaction between traders, and trader's overall influence on producing dynamically at the market price.

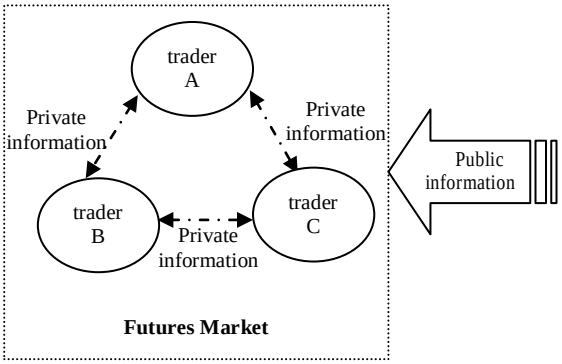

FIGURE 1 Relationship between internal model and outside environment

Because of difference predict style, deal motivation, risk-return preference, reaction speed, heterogeneous traders constantly influence each other. Traders who adopt technical analysis experience the mood in market by chart, influenced indirectly by mood in market. But as for individual, the influence received is the common influence which other heterogeneity traders produce in the market, traders react in the market price according to the decision that technical analysis is made, thus have an influence on other traders. So the heterogeneity traders in the market are the interaction, influence each other. Because of traders' heterogeneity, individual traders' decision exerts an influence on the price commonly at the same moment.

The reasons, representation and influence, totally three respects form commodity futures market trader internal model of artificial model of heterogeneity. The internal model exists in the whole market system, there is exchange of information and energy with the whole market, influence each other (Figure 1).

5 Commodity futures markets simulation

Since middle period of the 1990s last century, a lot of scholars have adopted the heterogeneous actor to suppose the research of carrying on artificial modelling to the financial market trend already. For instance Hommes, Le Baron, Lux, et al. adopt agent-based financial markets model to study a lot of market prices which accord with the result of study of experience count the characteristic. Carry on to commodity futures market price artificial research still relatively getting little dynamically[20], futures market and stock market are in the trade mechanism, the participant in the market, the structure of market, and the decision of basic value has a lot of difference. In the research of de la Maza and Yuret, adopt and fix model collecting and algorithm collection on two scholar's treatment to trader's internal model, observe trader information set restrain situation to collect change from, evolution trends of the market. Discover the traders with fund advantage and relative information advantage are easier to obtain in the market, two scholar in propose, should break through to some extent in constructing the more careful model of participant in the market to the further investigation of field here in their article.

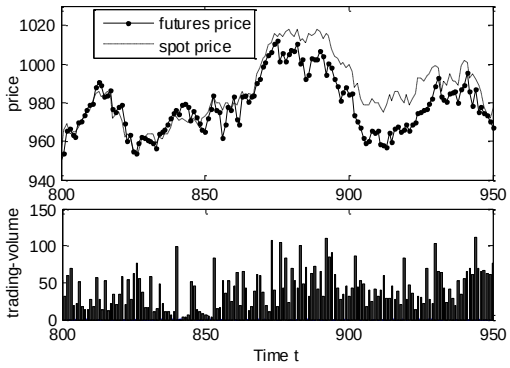

FIGURE 2 Market price and trading-volume in simulation

We apply the above framework to construct a simulation model to certificate the framework is useful. The software of Matlab is used for simulation analysis in the paper and Figure 2 shows the output. We use the actual spot price and simulation, and then we get the futures price series. Finally, we use the futures price series to test whether or not the framework can explain the anomies in futures market.

In the simulation, we choose real wheat spot price and the data can be obtained from wheat database on the website http://www.czce.com.cn.

From the simulation, we got the futures price and trading-volume which is showed in Figure 2. The test results have listed in Table 2. The simulation generates the futures price series have these characters: aggregational Gaussianity, clustered volatility, fat-tailed return distributions, and long-term memory. These results can partly verify the framework which is constructed in this paper (see Table 2).

TABLE 2 Futures prices series tests results

Statistics index	Futures price	Spot price
Sample size	960	960
Max (Min)	0.05(-0.04)	0.07(-0.04)
Standard variance	0.01	0.01
Skewness	0.60	3.76
Kurtosis	12.28	51.16
JB statistic	3477.86 [0.00]	94521.02 [0.00]
Q-statistic	98.62 [0.00]	52.66 [0.00]
Q^*-statistic	185.27 [0.00]	29.31 [0.00]
Hurst	0.69	0.64
Hurst*	0.50	0.52
LM test	6.76 [0.009]	0.12 [0.73]

In Table 2, Hurst index can be calculated by R/S analysis. Hurst* can be calculated by R/S analysis with using rearranged original sequence; Q is Box-Pierce Q-statistic used for autocorrelation test, Q* is Box-Pierce Q-statistic with using absolute return; LM test is a test for heteroskedastic in time series. All the values in square brackets are the probability of relevant test.

6 Conclusion

This paper summarizes the current literature about heterogeneous expectation test in financial markets and about financial market price dynamics simulation based on heterogeneous behaviour hypothesis, and analyses the reasons for heterogeneity, the representation of heterogeneous traders, as well as the influence of heterogeneity on the market, put forward the analysis framework of commodity futures market price dynamics based on heterogeneous traders.

We will further adopt direct examine method, use questionnaire and interview method to investigate traders' heterogeneity in the commodity futures market. The investigation may include all kinds of traders' risk preferences, forecasting technology, trade level, judgment of contract value, reaction speed, learning capability, etc. The results will be used for representation of heterogeneous traders in commodity futures market simulation model. Using artificial method to study micro pricing mechanism in futures market will be an effective route. This is the content that we will study further.

Abstract

Enterprise cluster development can improve development capacity of enterprises and industrial competitiveness by lowering cost, stimulating innovations, increasing efficiency and intensifying competition. It is one key industrial development trend in the future and an important consideration of enterprises in choosing regions. Recently, industrial cluster in China has achieved primary development. Provinces and cities are putting great efforts to creating industrial parks of Industrial Cluster. This plays an important role in promoting regional economic development and regional industrial competitiveness. In this paper, a competitiveness evaluation model of enterprise cluster was established using the GEM model. It was applied to the furniture enterprise cluster in Guangdong Province. Accuracy, time effectiveness, advantages and disadvantages of the model was analyzed through the case study. Advantages and disadvantages of regional enterprise cluster can be identified from competitiveness analysis of the model. Countermeasures to these disadvantages were suggested.

Keywords: GEM model cluster competitiveness

1 Introduction

Industrial cluster is a spatial aggregate of enterprises of an industry with different scales and levels as well as behavioral agents related to their development (e.g. institutions and organizations) within a certain region. They have clear division of labor and are closely connected through a complicated network. Industrial cluster represents a new form of economic organization between enterprise and market. Enterprise cluster development is overwhelming in the world, thus attractting great attentions from economists and managerialists. Facing with economic globalization and regional economic integration, enterprise cluster development has become a new organizational pattern and development trend of regional economy. It enables enterprises to make full use of their advantages and achieve scale economies effect at a small scale, improving competitiveness of both enterprises and enterprise cluster. Currently, research attentions are paid to evaluation of competitiveness, advantages and disadvantages of enterprise cluster as well as analysis of measures to improve competitiveness. Industrial cluster development in China just starts. Scholars focus on qualitative research of enterprise cluster, but reported few model-based researches on the competitiveness of enterprise cluster. This paper established a competitiveness evaluation model of enterprise cluster based on GEM model, which was used to analyze competitiveness of the furniture enterprise cluster in Guangdong Province.

2 Competitiveness evaluation model of enterprise cluster

2.1 MEDEL CONSTRUCTION

GEM model is improved from the diamond model by Tim Padmore and Hervey Gibon, which can be used for quantification. It determines 6 major influencing factors of cluster competitiveness: resources, facilities, suppliers and relative assistance industries, enterprise strategies and competition, local market and external market. They can be divided into three groups: 1) fundamental factors: resources and facilities; 2) enterprise factors: suppliers and relative assistance industries as well as enterprise strategies and competition; 3) market factors: local market and external market. Compared to the diamond model, GEM model is superior for factor quantification. Factor quantification includes three steps:

Step 1: Assignments. These 6 influencing factors are level-1 evaluation indexes. To evaluate them, level-2 indexes will be generated and assigned with value. Suppose these 6 influencing factors are *A, B, C, D, E* and *F*, and their level-2 indexes are $A\left(a_1, a_2, ..., a_i\right)$, $B\left(b_1, b_2, ..., b_j\right)$, $C\left(c_1, c_2, ..., c_l\right)$, $D\left(d_1, d_2, ..., d_n\right)$, $E\left(e_1, e_2, ..., e_m\right)$, $F\left(f_1, f_2, ..., f_u\right)$ and, respectively. Score these level-2 indexes from 0-5. The higher the better and 3 is the mean level or pass line.

Step 2: Calculation. Assignments are often implemented by several experts or senior management of the industry. Mean of their assignments shall be calculated.

[*] ***Corresponding author's*** e-mail: zht@bnu.edu.cn

Moreover, different level-2 indexes have different weights because of their different influences. Scores of level-1 indexes shall be calculated according to weights of corresponding level-2 indexes:

$$\left\{\begin{array}{l} a_1=\dfrac{\sum_{q=1}^{N}a_{1q}}{N} \\ a_2=\dfrac{\sum_{q=1}^{N}a_{2q}}{N} \\ \cdots \\ a_i=\dfrac{\sum_{q=1}^{N}a_{iq}}{N} \end{array}\right\}\left\{\begin{array}{l} b_1=\dfrac{\sum_{q=1}^{N}b_{1q}}{N} \\ b_2=\dfrac{\sum_{q=1}^{N}b_{2q}}{N} \\ \cdots \\ b_j=\dfrac{\sum_{q=1}^{N}b_{iq}}{N} \end{array}\right\}\left\{\begin{array}{l} c_1=\dfrac{\sum_{q=1}^{N}c_{1q}}{N} \\ c_2=\dfrac{\sum_{q=1}^{N}c_{2q}}{N} \\ \cdots \\ c_l=\dfrac{\sum_{q=1}^{N}c_{iq}}{N} \end{array}\right\}\left\{\begin{array}{l} d_1=\dfrac{\sum_{q=1}^{N}d_{1q}}{N} \\ d_2=\dfrac{\sum_{q=1}^{N}d_{2q}}{N} \\ \cdots \\ d_n=\dfrac{\sum_{q=1}^{N}d_{iq}}{N} \end{array}\right\}\left\{\begin{array}{l} e_1=\dfrac{\sum_{q=1}^{N}e_{1q}}{N} \\ e_2=\dfrac{\sum_{q=1}^{N}e_{2q}}{N} \\ \cdots \\ e_m=\dfrac{\sum_{q=1}^{N}e_{iq}}{N} \end{array}\right\}\left\{\begin{array}{l} f_1=\dfrac{\sum_{q=1}^{N}f_{1q}}{N} \\ f_2=\dfrac{\sum_{q=1}^{N}f_{2q}}{N} \\ \cdots \\ f_u=\dfrac{\sum_{q=1}^{N}f_{iq}}{N} \end{array}\right\}. \quad (1)$$

N is number of people participated in the assignments.

$$A=\sum_{p=1}^{p=i}\alpha_p a_p, B=\sum_{p=1}^{p=j}\beta_p b_p$$
$$C=\sum_{p=1}^{p=l}\gamma_p c_p, D=\sum_{p=1}^{p=n}\phi_p d_p \ , \quad (2)$$
$$E=\sum_{p=1}^{p=m}\varphi_p e_p, F=\sum_{p=1}^{p=u}\theta_p f_p$$

where $(\alpha,\beta,\gamma,\phi,\varphi,\theta)$ is weight of level-2 indexes, respectively.

Step 3: Calculate and convert factor groups, and calculate the final results:

$$P_1=\frac{A+B}{2},\ P_2=\frac{C+D}{2},\ P_3=\frac{E+F}{2} \quad (3)$$

$$DEM=2.5\left[\prod\nolimits_{i=1.2.3}P_i\right]^{2/3}. \quad (4)$$

2.2 MODEL APPLICATION

The established model was used to evaluate competitiveness of furniture enterprise cluster in Guangdong Province. Beijing Forestry University investigated furniture enterprise cluster in Guangdong Province in 2012. Level-2 indexes of resources include labor supply, technician supply, raw material supply and fund supply. Level-2 indexes of facilities are facilities of industrial park, transportation conditions, public R&D institutions, support of industry association and business environment. Level-2 indexes of assistance industries include professional level of local suppliers, local device supply and cooperation & communication with local associated enterprises. Level-2 indexes of enterprise strategies and competition are goal orientation of enterprise development strategies, property right structure, competition and ambition of senior executives. Level-2 indexes of local market are domestic market share, influence of domestic market and domestic market prospect. Level-2 indexes of external market include international market share, influence of international market, entry barriers of international market and international market prospect. Assignments of 6 level-1 indexes are listed in Table 1.

TABLE 1 The value of the variable

A	B	C	D	E	F
3.40	3.82	3.96	3.97	3.77	3.59

According to the Table 1, competitiveness of the furniture enterprise cluster in Guangdong Province can be calculated:

$$P_1=\frac{A+B}{2}=3.61$$
$$P_2=\frac{C+D}{2}=3.97,$$
$$P_3=\frac{E+F}{2}=3.68$$

$$DEM=2.5\left[\prod\nolimits_{i=1.2.3}P_i\right]^{2/3}=$$
$$2.5\left[3.61\cdot 3.97\cdot 3.68\right]^{2/3}=35.15.$$

Above analysis data reveal that the furniture enterprise cluster in Guangdong Province has limited competitive edges.

Firstly, resources and external market are inferior. Resources are calculated 3.40, the lowest one and least competitive of 6 influencing factors. The external market is calculated 3.59. Although it is higher than resources, its competitiveness is still unsatisfying and needs further improvement. They are against the overall competitiveness of enterprise cluster. Specifically, labor shortage is a common problem in furniture industry. Some enterprises even suffer collective strikes for low wage level. Although China's furniture industry is facing with raw materials shortage, especially imported timbers, the raw material supply in Guangdong Province is strongly

supported by its geographical advantages and stable import channels built for years. Moreover, Guangdong Province is one of wealthy regions in China, which intensifies support to furniture industrial development. The furniture industry in Guangdong Province depends on external markets significantly. The furniture industry in Guangdong Province developed from processing trade-oriented joint ventures with Hong Kong and Taiwan investment. Later, supported by geographical advantages and the reform and open up, it shows stronger export preference than other regions in China. However, its furniture products enter into the international market as original equipment manufacturer (OEM) products and have no real influence in international market. This determines the high susceptibility of Guangdong furniture export to international market fluctuations. Viewed from international market prospect, with rich export experiences and advantages, furniture industry in Guangdong Province has stronger market penetration than rest regions in China.

Secondly, enterprise strategies and assistance industries have a distinct advantage. In Table 1, enterprise strategies get the highest scores, indicating the strongest competitiveness than other factors. For assistance Industries, the furniture industrial cluster in Guangdong Province is poorer than those in other regions. It is characteristic of "big cluster-small enterprise". According to level-2 indexes, most furniture enterprises in Guangdong haven't made long-term strategic development plan yet. Vicious competition among similar enterprises is universal, such as mutual imitation and race to keep the prices down. Most executives didn't receive high education and have no ambitions and entrepreneur spirit. On the contrary, support of suppliers and relative assistance industries in Guangdong furniture industry ranks the top in China. Since furniture industrial cluster began early in Guangdong Province, it has established a developed division of labor within the industry, leading to the high professional level of suppliers and strong local device supply. However, limited by traditional competition concept between enterprises, cooperation and communication of furniture enterprises in Guangdong Province with local associated enterprises still has a great development space.

Thirdly, facilities and local market are not so competitive. Facilities of industrial park are evaluated less competitive. This is because the furniture enterprise cluster in Guangdong Province is formed spontaneously under the drive of market economy, without government leading and normal planning. In transportation, Guangdong possesses well-developed highways, railways and ports, which improve logistics efficiency of local furniture industry significantly. Furniture enterprise cluster in Guangdong province has cutting edges in public R&D institutions, support of industrial association and business environment. Guangdong Province, the earliest region developing market economy in China, has standard business environment and clear orientation of industry association. These can provide favorable services and supports for industrial development. Furniture enterprise cluster in Guangdong province occupies at least 30% domestic market share, the highest in China. Influenced by traditional regional brands and promoted by furniture exhibition, it takes the dominant role in domestic market. However, its development prospect in domestic market is gloomy. This is caused by its attention on labor-intensive products with low value added, intensifying competition with other domestic regions and higher production cost than Chinese mainland.

2.3 MODEL ANANLYSIS

Accuracy. Model accuracy is mainly determined by the reasonability of level-2 indexes, that is, whether level-2 indexes can reflect conditions of level-1 indexes comprehensively. If yes, the model has high accuracy and the calculated results can reflect the real competitiveness of level-1 indexes; otherwise, the evaluation results will deviates from real performance of level-1 indexes.

Time effectiveness. Given fixed settings, any model can only provide short-term time effectiveness, because any condition change of industry cluster will change the corresponding environment accordingly. As a result, the time effectiveness of mode is limited. However, this can be solved by using same calculation method but changeable indexes (both level-1 and level-2 indexes). Actually, environment keeps stable in a short period. For long-term evaluation, level-2 indexes shall be changed accordingly, followed by level-1 indexes. If there's great environmental change, level-1 and level-2 indexes shall be changed simultaneously.

Advantages and disadvantages. Model advantages can be analyzed quickly from data collected through a simple survey. Since 6 level-1 indexes involve both internal and external environmental changes and the level-2 indexes can be updated as needed, the model can reflect competitiveness of enterprise cluster comprehensively. However, it still has some disadvantages. Firstly, it requires professional surveys. The number of people participated in assignments is proportional to the model accuracy. Secondly, its calculation is simple. Indexes couldn't represent all aspects of enterprise clusters.

3 Suggestions

The model is used to evaluate competitiveness of regional enterprise cluster, but its ultimate goal is to improve competitiveness of regional enterprise cluster. In view of the involved six influencing factors, it is suggested to:

Enhance policy support and perfect soft and hard environments. Policy support includes direct support and indirect support. Direct support refers to financial assistance and preferential policies to enterprises within the cluster. Indirect support refers to governmental supports through optimizing infrastructures and market order. In China hard environmental improvement refers

to perfect infrastructures in places of enterprise cluster, such as transportation, water, electricity, shopping, school, hospital, entertainment, fitness centers, etc. Soft environmental improvement including optimizing market order, enhance market supervision and management, improving unreasonable market provisions, promoting high-efficient market operation, building talent management and training system, as well as establishing channels for communication and cooperation between enterprises.

Increase talent recruitment, strengthen independent innovation, and improve continuous competitiveness of industrial cluster. Entrepreneurs shall bring new ideas to management and system, including reform and innovation of organizational system, management system and human resource system. They shall focus on creating an enterprise cultural atmosphere to train, attract and retain talents. Enterprises shall pay more attentions on vocational education to improve knowledge and quality of workers. Meanwhile, great efforts in implementing talent strategies and introducing advanced talents and management experiences are needed, so that talents can be trained and retained permanently. Furthermore, enterprises can enhance technological innovation through various ways, for example, increasing investment to technological development, establishing technological development institutes with universities and scientific research institutes, etc.

Implement regional information share and reinforce enterprise competition and cooperation. Disordered and vicious competition is a big problem of industrial cluster. Accelerating the construction of resource share and public service platform is the only one solution to this problem. It can overcome transaction difficulties caused by incomplete information and lower information search cost to a certain extent. Nowadays, Chinese enterprises in a region pay more attention to competition rather than harmonious development and copy from each other instead of create new products. Such vicious competition is distressing. Therefore, enterprises focus on mutual cooperation (e.g. Joint-funded R&D center, enterprise cluster or enterprise alliance) when compete with each other. A regional coordination development mechanism shall be established to create a multi-win structure.

Research on contract management evaluation of construction company based on fuzzy comprehensive evaluation model

Yuejun Liu*, Fang Fang, Yali Zhang

College of Economics and Management, Hebei Institute of Architectural and Civil Engineering, Zhangjiakou, Hebei Province, China, 075000

Received 28 October 2014, www.cmnt.lv

Abstract

Contract management is the core of project management of construction companies. Establishing a perfect contract management evaluation system of construction companies is of important significance to enhance their contract signing and performance as well as competitiveness in international market. Based on the overall contract management of construction companies, this paper discussed how to establish an evaluation system. Combined with fuzzy comprehensive evaluation, the established evaluation system was verified by an empirical analysis.

Keywords: contract management capability, evaluation model, fuzzy comprehensive evaluation, empirical analysis

1 Research significance

Contract management is the core of project management of construction companies and runs through the whole implementation of engineering project. It is of more significance to some large construction companies in China who attempt to step into the international market.

Contract management capability of project management personnel can be evaluated through some way, which enables us to become aware of shortcomings, differences and potential causes of low-efficient project implementation, and give early warnings.

2 Content of contract management of construction companies

Contract management of construction companies is the generic term of a series of legal behaviors on involved contract, including formation, performance, modification, dissolution, assignment, termination, review, supervision and control of contracts. Formation, performance, modification, dissolution, assignment, termination of contracts are the content of contract management, while the rest three are means of contract management [4].

Contract management of construction companies is the most complicated, painstaking and important work, which has significant impact on the whole engineering project.

3 Contract management evaluation model of construction companies

To evaluate contract management capability of China's construction companies, this paper deems that an evaluation model shall be established under the guidance of both domestic and foreign theories of contract management and combining with practical situations of China's construction companies as well as evaluation methods for project management.

3.1 LEVEL-1 EVALUATION INDEXES OF THE MODEL

Three level-1 evaluation indexes for contract management capability were concluded from review of existing associated research results.

1) Support of organizational system. Contract management is implemented through personnel, system and procedure set by the management organization of enterprises. The organizational management is important to contract management. The management organization of enterprises determines division of collaboration and function of departments, providing strong support to contract management.

2) Bidding and contracting management. Offer and commitment are two stages before the conclusion of contracts. Bidding is the offer of construction companies. The bid price not only can influence performance of enterprises directly, but also the key of winning the bidding. After winning the bidding, a "win-win" contract shall be signed by all means. These pave the way for contract performance.

3) Contract performance management. Contract performance is the core of whole contract management. Executives, project department, contract management department and other relevant departments are asked to perform contractual obligations in agreed time, cost and quality by all control means and win agreed rights. Since contract management is very complicated, it has high requirement on capabilities of related personnel.

The above three aspects are the key of the contract

management capability evaluation model of construction companies (hereinafter referred as CMC model, Figure 1. They are level-1 evaluation indexes of the CMC model and the key domain indexes of contract management capability.

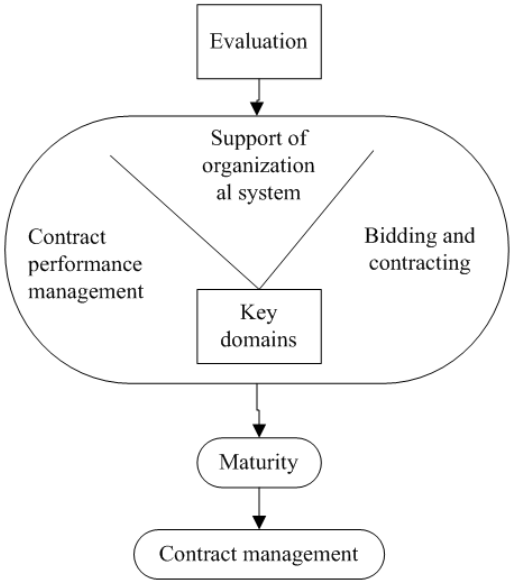

FIGURE 1 CMC model

3.2 LEVEL-2 EVALUATION INDEXES

OF THE MODEL

Due to the inadequate understanding of China's construction staff on contract management and their great differences of education background, opinions of relatively independent experts with rich experiences were used in this paper in order to establish a more scientific and reasonable evaluation system for engineering contract management. The experts mainly include scholars, enterprise managers and project managers in construction field. To get more comprehensive level-2 evaluation indexes, open-ended questionnaire survey was conducted. Firstly, experts were asked to list key indexes of three key domains through face-to-face interview or E-mail. After three questionnaire surveys, a total of 12 level-2 evaluation indexes were concluded under the assistance of experts. These indexes are, in accordance with the design principle of indexes, have certain scientific and independence and can reflect practical capabilities of key domains (Table 1).

3.3 WEIGHT DETEMINATION OF EVALUATION INDEXES

To reflect effect of evaluation indexes in the evaluation system, this paper analyzed significance of evaluation indexes through analytic hierarchy process (AHP). Based on experts' opinions and yaahp0.4.1 AHP software, weights of evaluation indexes were determined (Table 1).

TABLE 1 General situation of contract management evaluation indexes of the construction

goal	Level-1 indexes	Weight	Level-2 indexes	Weight	Maturity grades				
					Chaotic management	*Simple management*	*Standard management*	*Lean management*	*Strategic management*
Contract management capability (C)	Support of Organizational system (C_1.)	0.2972	Completeness of contract management system (C11)	0.2780	0/6	1/6	4/6	1/6	0/6
			Effectiveness of incentives(C_{12})	0.1361	0/6	1/6	3/6	2/6	0/6
			Adaptability of organizational structure (C_{13})	0.0875	0/6	1/6	3/6	2/6	0/6
			Competency of contract management personnel (C_{14})	0.4987	0/6	1/6	4/6	1/6	0/6
	Bidding and Contracting Management (C_2.)	0.1284	Bidding capacity (C_{21})	0.3522	0/6	0/6	3/6	3/6	0/6
			Contract risk management (C_{22})	0.3486	0/6	1/6	3/6	2/6	0/6
			Contract negotiation ability (C_{23})	0.2991	0/6	1/6	4/6	1/6	0/6
	Contract Performance Management (C_3)	0.5744	Contract claim management (C_{31})	0.3202	0/6	2/6	4/6	0/6	0/6
			Contract modification management (C_{32})	0.0584	0/6	0/6	3/6	2/6	1/6
			Contract cost, schedule and quality control (C_{33})	0.3856	0/6	2/6	3/6	1/6	0/6
			Contract analysis and presentation capability (C_{34})	0.0908	0/6	0/6	2/6	3/6	1/6
			Contract information management (C_{35})	0.1450	0/6	1/6	3/6	2/6	0/6

4 An empirical study about fuzzy evaluation on maturity of contract management capability of a construction company

4.1 DETERMINATION OF EVALUTION SET

Similar project management, maturity of contract management was also divided into five grades. Grade 1 represents the poorest contract management, while Grade 5 represents the highest contract management. Therefore, the grade evaluation set of contract management is:

C={chaotic management, simple management, standard management, lean management and strategic management}.

4.2 EVALUATION PREPARATION

4.2.1 Test Projects of the construction company

This paper tried to make a comprehensive evaluation on the contract management of the construction company through its projects under construction, finished projects, domestic and international projects, industrial construction project, civil construction projects and municipal construction projects. Its contract management capability was evaluated based on four domestic and foreign typical projects.

4.2.2 Composition of evaluation personnel

Evaluation personnel includes deputy manager and experts from headquarter, external experts, manager of UAE department, manager of project department, and manager of contract estimation department. The deputy manager from headquarter is the leader of this evaluation group.

4.3 WEIGHT DETERMINNATION OF EVALUATION INDEX

4.3.1 Build AHP structure

Social, economic and scientific management problems were analyzed by AHP. Firstly, problems shall be systematized and layered to build an AHP structure.

The established AHP structure built based on the index system of the CMC model is shown in Figure 2.

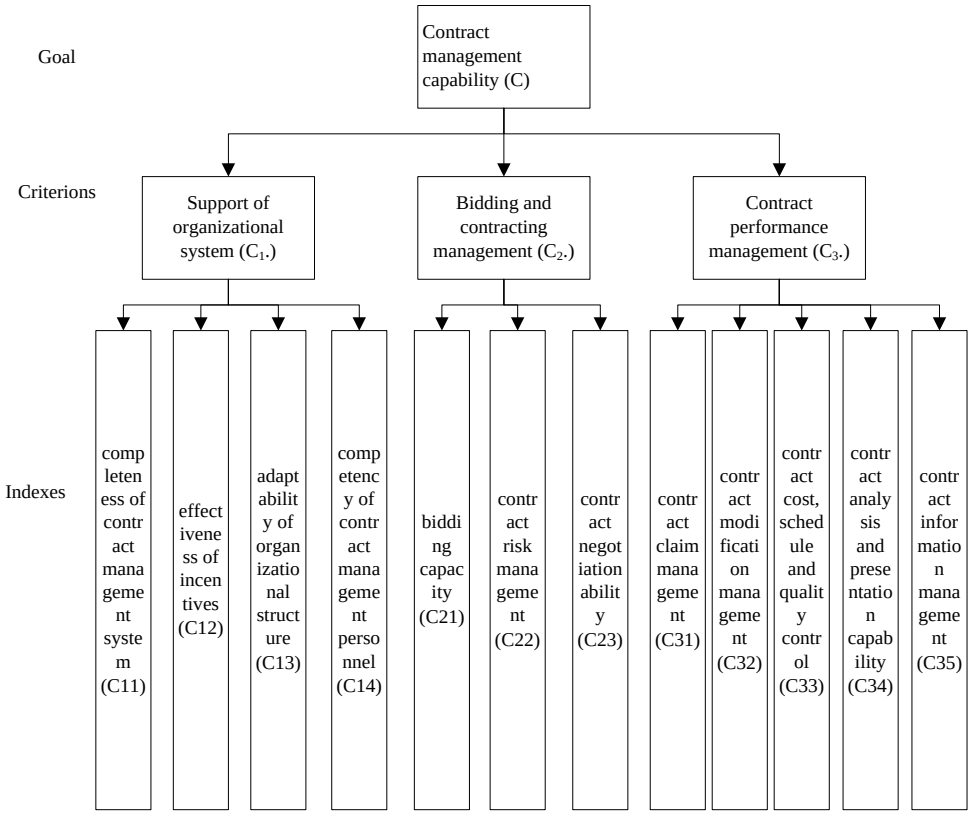

FIGURE 2 The level structure of contract management

4.3.2 Build judgment matrix

Suppose factors of previous layer (*C*) are criteria, which control factors of lower layer $(C_1, C_2, ...C_n)$. Our goal is to give weight of, $(C_1, C_2, ...C_n)$ according to their significance under the criterion Bk. For *n* factors, the judgment matrix of two factors is $C = (C_{ij})n*n$, where C_{ij} is the significance of *i* and *j* to the goal.
The built judgment matrix is:

	C_1	C_2	...	C_n
C_1	C_{11}	C_{12}	...	C_{1n}
C_2	C_{21}	C_{22}	...	C_{2n}
...	...	...	...	...
C_n	C_{n1}	C_{12}	...	C_{nn}

This judgment matrix is characteristic of:

1) $C_{ij} > 0$.

2) $C_{ij} = 1/C_{ji} (i \neq j)$.

3) $C_{ij} = 1 (i, j = 1, 2, ..., n)$.

Next, significance of C_i and C_j in criterion *C* was compared. "Significance" shall be given with certain numerical value, which uses 1-9 scale in this paper [25].

Then, evaluation personnel implemented the pairwise comparison of relevant factors by using their knowledge and experiences, filling in the weight evaluation table of contract management.

Weights of criteria are Criteria include Support of Organizational System, Bidding and Contracting Management as well as Contract Performance Management. Different evaluators got different judgment matrixes of criteria.

The judgment matrix of Evaluator 1 is:

	C_1	C_2	C_3
C_1	1	1/3	1/7
C_2	3	1	1/5
C_3	7	5	1

1) Calculate the product of each row of factors (M_i)

$$M_i = \prod C_{ij},\ i = 1, 2, ..., n,\ j = 1.$$

Therefore, $M = (0.0476, 0.6, 35)^T$.

2) Normalize $M_i (W_i)$

$$W_i = \sqrt[n]{M_i}.$$

Therefore, $W = (0.3625, 0.8434, 3.2711)^T$.

3) Normalize W_i

$$W_i = \frac{\overline{W_i}}{\sum_{j=1}^{n} \overline{W}_j}.$$

The eigenvector is: $W = (0.081, 0.1884, 0.7306)^T$.

4) Calculate the largest eigenvalue of the judgment matrix (λ_{max}). Therefore, $\lambda_{max} = 3.0649$.

$$CI = \frac{\lambda_{max} - n}{n-1} = \frac{3.0649 - 3}{3-1} = 0.0324.$$

5) Calculate the consistency ratio (CR): when $n = 3$, $RI = 0.58$.

$$CR = CI / RI = 0.0324 / 0.58 = 0.0559 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 2 is:

	C_1	C_2	C_3
C_1	1	5	1/5
C_2	1/3	1	1/9
C_3	5	9	1

Similarly, its eigenvectors can be calculated:

$$W = (0.1782, 0.0704, 0.7514)^T$$

$$\lambda_{max} = 3.0291, CI = 0.0145, RI = 0.58, CR = 0.0251 < 0.1$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 3 is:

	C_1	C_2	C_3
C_1	1	7	1/3
C_2	1/7	1	1/9
C_3	3	9	1

Its eigenvectors can be calculated:

$$W = (0.2897, 0.0549, 0.6554)^T$$

$$\lambda_{max} = 3.0803, CI = 0.0401, RI = 0.58, CR = 0.0692 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 4 is:

	C_1	C_2	C_3
C_1	1	3	1
C_2	1/3	1	1/5
C_3	1	5	1

Its eigenvectors can be calculated:

$$W = (0.4054, 0.1140, 0.4806)^T$$

$$\lambda_{max} = 3.0291, CI = 0.0145, RI = 0.58, CR = 0.0251 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 5 is:

	C_1	C_2	C_3
C_1	1	2	1
C_2	1/2	1	1/2
C_3	2	2	1

Its eigenvectors can be calculated:

$$W=(0.4,0.2,0.4)^T$$
$$\lambda_{\max}=3.0, CI=0, RI=0.58, CR=0<0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 6 is:

	C_1	C_2	C_3
C_1	1	3	1
C_2	1/3	1	1/3
C_3	1	3	1

Its eigenvectors can be calculated:

$$W=(0.4286,0.1429,0.4286)^T$$
$$\lambda_{\max}=3.0, CI=0, RI=0.58, CR=0<0.1$$

Therefore, this judgment matrix has satisfying consistency.

As a result, weights of three criteria are:

$$\begin{cases} a_1=(0.081+0.1782+0.2897+0.405+0.4+0.4286)/6=0.2971 \\ a_2=(0.1884+0.0704+0.0549+0.114+0.2+0.1429)/6=0.1284 \\ a_3=(0.7306+0.7514+0.6554+0.4806+0.4+0.4286)/6=0.5744 \end{cases}$$

The weight set of evaluation indexes is $C=(0.2971,0.1284,0.5744)$, representing the weights of Support of Organization System, Bidding and Contracting Management as well as Contract Performance Management, respectively.

Similarly, weight of the goal can be evaluated. Different evaluators got different judgment matrixes of Support of Organization System.

The judgment matrix of Evaluator 1 is:

	C_1	C_2	C_3	C_4
C_1	1	2	5	1/7
C_2	1/2	1	1	1/9
C_3	1/5	1	1	1/8
C_4	7	9	8	1

Then, its eigenvectors can be calculated:

$$W=(0.1628,0.0723,0.0592,0.7057)^T$$
$$\lambda_{\max}=4.2061, CI=0.0687, RI=0.90, CR=0.0763<0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 2 is:

	C_1	C_2	C_3	C_4
C_1	1	3	2	1/3
C_2	1/3	1	1/3	1/9
C_3	1/2	3	1	1/5
C_4	3	7	5	1

Then, its eigenvectors can be calculated:

$$W=(0.2186,0.0647,0.1349,0.5836)^T$$
$$\lambda_{\max}=4.0729, CI=0.0243, RI=0.90, CR=0.0270<0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 3 is:

	C_1	C_2	C_3	C_4
C_1	1	1	3	1/3
C_2	1	1	2	1/9
C_3	1/3	1/2	1	1/9
C_4	5	7	5	1

Then, its eigenvectors can be calculated:

$$W=(0.1421,0.1181,0.0596,0.6803)^T$$
$$\lambda_{\max}=4.0460, CI=0.0153, RI=0.90, CR=0.0171<0.1$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 4 is:

	C_1	C_2	C_3	C_4
C_1	1	5	7	1
C_2	1/5	1	4	1/5
C_3	1/7	1/4	1	1/7
C_4	1	5	7	1

Then, its eigenvectors can be calculated:

$$W=(0.4220,0.1097,0.0464,0.4220)^T$$
$$\lambda_{\max}=4.1398, CI=0.0466, RI=0.90, CR=0.0518<0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 5 is:

	C_1	C_2	C_3	C_4
C_1	1	1	3	1
C_2	1	1	5	1
C_3	1/3	1/5	1	1/7
C_4	1/3	1	3	1

Then, its eigenvectors can be calculated. Therefore, this judgment matrix has satisfying consistency. The judgment matrix of Evaluator 6 is:

	C_1	C_2	C_3	C_4
C_1	1	3	2	1/3
C_2	1/3	1	1	1/3
C_3	1/2	1	1	1/3
C_4	1	3	3	1

Then, its eigenvectors can be calculated:

$$W = (0.3468, 0.1279, 0.1416, 0.3838)^T$$
$$\lambda_{\max} = 4.0206, CI = 0.0069, RI = 0.90, CR = 0.0076 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.
As a result, weights of four indexes of Support of Organizational System are:

$$\begin{cases} a_{11} = (0.1628 + 0.2186 + 0.1421 + 0.4220.0.3754 + 0.3468)/6 = 0.2780 \\ a_{12} = (0.0723 + 0.0647 + 0.1181 + 0.1097 + 0.3241 + 0.1279)/6 = 0.1361 \\ a_{13} = (0.0592 + 0.1349 + 0.0596 + 0.0464 + 0.0834 + 0.1416)/6 = 0.0875 \\ a_{14} = (0.7057 + 0.5836 + 0.6803 + 0.4420 + 0.2168 + 0.3838)/6 = 0.4987 \end{cases}.$$

The weight set of Support of Organizational System is $A_1 = (0.2780, 0.1361, 0.0875, 0.4987)$, representing completeness of contract management system, effectiveness of incentives, adaptability of organizational structure and competency of contract management personnel, respectively.

Different evaluators got different judgment matrixes of Bidding and Contracting Management.

The judgment matrix of Evaluator 1 is:

	C_1	C_2	C_3
C_1	1	3	1/2
C_2	1/3	1	1/3
C_3	2	3	1

Then, its eigenvectors can be calculated:

$$W = (0.3325, 0.1396, 0.5278)^T$$
$$\lambda_{\max} = 3.0536, CI = 0.0268, RI = 0.58, CR = 0.0462 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 2 is:

	C_1	C_2	C_3
C_1	1	2	2
C_2	1/2	1	1
C_3	1/2	1	1

Then, its eigenvectors can be calculated:

$$W = (0.5, 0.25, 0.25)^T$$
$$\lambda_{\max} = 3.0, CI = 0, RI = 0.58, CR = 0 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 4 is:

	C_1	C_2	C_3
C_1	1	1	1
C_2	1	1	1
C_3	1	1	1

Then, its eigenvectors can be calculated:

$$W = (0.3333, 0.3333, 0.3333)^T$$
$$\lambda_{\max} = 3.0, CI = 0, RI = 0.58, CR = 0 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 5 is:

	C_1	C_2	C_3
C_1	1	3	5
C_2	1/3	1	2
C_3	1/5	1/2	1

Then, its eigenvectors can be calculated:

$$W = (0.6483, 0.2297, 0.1220)^T$$
$$\lambda_{\max} = 3.0037, CI = 0.00018, RI = 0.58, CR = 0.0032 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 6 is:

	C_1	C_2	C_3
C_1	1	1/5	1/3
C_2	5	1	1
C_3	1/5	1/2	1

Then, its eigenvectors can be calculated:

$$W = (0.1140, 0.4806, 0.4054)^T$$
$$\lambda_{\max} = 3.0291, CI = 0.0145, RI = 0.58, CR = 0.0251 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.
As a result,

$$\begin{cases} a_{11} = (0.3325 + 0.1852 + 0.5 + 0.3333 + 0.6483 + 0.1140)/6 = 0.3522 \\ a_{22} = (0.1396 + 0.6586 + 0.25 + 0.3333 + 0.2297 + 0.4806)/6 = 0.3486 \\ a_{23} = (0.5278 + 0.1562 + 0.25 + 0.3333 + 0.1220 + 0.4054)/6 = 0.2991 \end{cases}$$

The weight set of Bidding and Contract Management is $A_2 = (0.3522, 0.3486, 0.2991)$, representing bidding capacity, contract risk management and contract negotiation ability, respectively.

Different evaluators got different judgment matrixes of Contract Performance Management.

The judgment matrix of Evaluator 1 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	7	1/3	3	5
C_2	1/7	1	1/9	1/3	1
C_3	7	9	1	5	9
C_4	1/3	3	1/5	1	3
C_5	1/5	1	1/9	1/3	1

Then, its eigenvectors can be calculated:

$$W = (0.2609, 0.0449, 0.5304, 0.1157, 0.0480)^T$$

$$\lambda_{\max} = 5.0954, CI = 0.0239, RI = 1.12, CR = 0.0213 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 2 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	7	3	5	7
C_2	1/7	1	1/5	1/3	1/2
C_3	1/3	5	1	3	7
C_4	1/5	3	1/3	1	3
C_5	1/7	1	1/9	1/3	1

Then, its eigenvectors can be calculated:

$$W = (0.5009, 0.0537, 0.2460, 0.1292, 0.0703)^T$$

$$\lambda_{\max} = 5.4323, CI = 0.1081, RI = 1.12, CR = 0.0965 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 3 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	3	1/3	3	2
C_2	1/3	1	1/5	1/3	1/3
C_3	3	5	1	5	3
C_4	1/3	1	1/5	1	1/3
C_5	1/7	3	1/3	3	1

Then, its eigenvectors can be calculated:

$$W = (0.2235, 0.0729, 0.4613, 0.0729, 0.1694)^T$$

$$\lambda_{\max} = 5.1140, CI = 0.0285, RI = 1.12, CR = 0.0254 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 4 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	7	1	5	3
C_2	1/7	1	1/5	1	1/5
C_3	1	5	1	5	3
C_4	1/5	1	1/5	1	1/3
C_5	1/3	5	1/3	3	1

Then, its eigenvectors can be calculated:

$$W = (0.3734, 0.0524, 0.3491, 0.0621, 0.1630)^T$$

$$\lambda_{\max} = 5.12, CI = 0.0300, RI = 1.12, CR = 0.0268 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 5 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	8	1/2	5	2
C_2	1/8	1	1/9	1/3	1/4
C_3	2	9	1	7	3
C_4	1/5	3	1/7	1	1/2
C_5	1/2	4	1/3	3	1

Then, its eigenvectors can be calculated:

$$W = (0.2897, 0.0358, 0.4540, 0.0738, 0.1467)^T$$

$$\lambda_{\max} = 5.0797, CI = 0.0199, RI = 1.12, CR = 0.0178 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

The judgment matrix of Evaluator 6 is:

	C_1	C_2	C_3	C_4	C_5
C_1	1	3	1	3	1
C_2	1/3	1	1/3	1	1/3
C_3	1	3	1	3	1
C_4	1/3	1	1/3	1	1/3
C_5	1	3	1	3	1

Then, its eigenvectors can be calculated:

$$W = (0.2727, 0.0909, 0.2727, 0.0909, 0.2727)^T$$

$$\lambda_{\max} = 5.0, CI = 0, RI = 1.12, CR = 0 < 0.1.$$

Therefore, this judgment matrix has satisfying consistency.

As a result, weights of five indexes of Contract Performance Management are:

$$\begin{cases} a_{31} = (0.2609 + 0.5009 + 0.2235 + 0.3734 + 0.2897 + 0.2727)/6 = 0.3202 \\ a_{32} = (0.0449 + 0.0537 + 0.0729 + 0.0524 + 0.0358 + 0.0909)/6 = 0.0584 \\ a_{33} = (0.5304 + 0.2460 + 0.4613 + 0.3491 + 0.4540 + 0.2727)/6 = 0.3856 \\ a_{34} = (0.1157 + 0.1292 + 0.0729 + 0.0621 + 0.0738 + 0.0909)/6 = 0.0908 \\ a_{35} = (0.0480 + 0.0703 + 0.1694 + 0.1630 + 0.1467 + 0.2727)/6 = 0.0908 \end{cases}.$$

The weight set of Contract Performance Management is $A_3 = (0.3202, 0.0584, 0.3856, 0.0908, 0.1450)$, representing contract claim management, contract modification management, contract cost, schedule and quality control, contract analysis and presentation capability as well as contract information management, respectively.

4.4 FUZZY EVALUATION OF MATURITY

4.4.1 Fuzzy membership

The fuzzy memberships of level-2 indexes were evaluated by evaluators according to project situations (Table 1).

4.4.2 Fuzzy evaluation matrix

1. Fuzzy evaluation matrix of single factor.

According to Table 1, evaluation matrixes of single factor are:

Support of Organizational System:

$$R_1 = \begin{bmatrix} 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \end{bmatrix}.$$

Bidding and Contract Management:

$$R_2 = \begin{bmatrix} 0/6 & 0/6 & 3/6 & 3/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \end{bmatrix}.$$

Contract Performance Management:

$$R_3 = \begin{bmatrix} 0/6 & 2/6 & 4/6 & 0/6 & 0/6 \\ 0/6 & 0/6 & 3/6 & 2/6 & 1/6 \\ 0/6 & 2/6 & 3/6 & 1/6 & 0/6 \\ 0/6 & 0/6 & 2/6 & 3/6 & 1/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \end{bmatrix}.$$

Then, the judgment vectors of Support of Organizational System (B_1), Bidding and Contract Management (B_2) as well as Contract Performance Management (B_3) can be calculated from $B = A_i * R_i$:

$$B_1 = (0.2780, 0.1361, 0.0875, 0.4987) * \begin{bmatrix} 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \end{bmatrix} = (0, 0.1667, 0.6296, 0.204, 0),$$

$$B_2 = (0.3522, 0.3486, 0.2991) * \begin{bmatrix} 0/6 & 0/6 & 3/6 & 3/6 & 0/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \\ 0/6 & 1/6 & 4/6 & 1/6 & 0/6 \end{bmatrix} = (1080, 0.5498, 0.3422, 0),$$

$$B_3 = (0.3202, 0.0584, 0.3856, 0.0908, 0.1450) * \begin{bmatrix} 0/6 & 2/6 & 4/6 & 0/6 & 0/6 \\ 0/6 & 0/6 & 3/6 & 2/6 & 1/6 \\ 0/6 & 2/6 & 3/6 & 1/6 & 0/6 \\ 0/6 & 0/6 & 2/6 & 3/6 & 1/6 \\ 0/6 & 1/6 & 3/6 & 2/6 & 0/6 \end{bmatrix} = (0, 0.2594, 0.5382, 0.1775, 0.0249).$$

2. The judgment matrix of multiple factors is:

$$B = (0.2971, 0.1284, 0.5744) * \begin{bmatrix} 0 & 0.1667 & 0.6296 & 0.2040 & 0 \\ 0 & 0.1080 & 0.5498 & 0.3422 & 0 \\ 0 & 0.2594 & 0.5382 & 0.1775 & 0.0249 \end{bmatrix} = (0, 0.2124, 0.5668, 0.2065, 0.0143).$$

4.4.3 Evaluation on the maturity of contract management

Evaluation set for the maturity of contract management is $C = (C_1, C_2, C_3) =$ (Support of Organizational System, Bidding and Contract Management, Contract Performance Management). The evaluation standard is divided into five grades: $U(1, 2, 3, 4, 5)$, representing chaotic management, simple management, standard management, lean management and strategic management, respectively.

1. Single factor evaluation

$$C_1 = B_1 * U^T = (0, 0.1667, 0.6296, 0.204, 0) * \begin{vmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{vmatrix} = 3.0382.$$

This indicates that the maturity of Support of Organizational System is 3.0382, close to standard management. The construction company shall enhance support of organizational system.

$$C_2 = B_2 * U^T = (0, 0.1080, 0.5498, 0.3422, 0) * \begin{vmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{vmatrix} = 3.2342.$$

This reveals that the maturity of Bidding and Contract Management is 3.2342, between standard and lean management, close to standard management. The construction company still shall enhance its bidding and contract management.

$$C_3 = B_3 * U^T = (0, 0.2594, 0.5382, 0.1775, 0.0249) * \begin{vmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{vmatrix} = 2.9679 \cdot$$

This demonstrates that the maturity of Contract Performance Management is 2.9679, between simple and standard management, close to standard management. The construction company shall further standardize implementation of contract management and improve contract performance management continuously.

2. Multi-factor evaluation

$$C = B * U^T = (0, 0.2124, 0.5668, 0.2065, 0.0143) * \begin{vmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{vmatrix} = 3.0227 .$$

This shows that the maturity of contract management capability is 3.0227, close to standard management. The construction company has basically achieved effective contract management and control, but still has to further improve its contract management capability.

5 Conclusions

The evaluation group attempts to make a comprehensive evaluation on the contract management of the construction company through its projects under construction, finished projects, domestic and international projects, industrial construction project, civil construction projects and municipal construction projects. The evaluation reflects that the construction company has standard contract management, far from the lean management. If it wants to get an invincible position in international competition and win more economic benefits, the contract management capability still needs further improvement. Its maturity of Bidding and Contract Management is the highest, while that of Contract Performance Management is the lowest. However, both of them are close to standard management.

Abstract

After the economic crisis in Wall Street in 2008, the risks of financial derivatives and risk control have received great attention from countries in the world. The research on the risks of financial derivatives and risk control can effectively prevent the financial crisis. Through the extraction of the characteristics of risks of financial derivatives, the paper expounds the application of sensitivity analysis and in the risk measurement financial derivatives. The result shows that despite certain achievements of China's financial derivatives in the development process, there is still much room for improvement. Based on the result and with reference to the practice of the UK, US and Japan in the risk prevention and control of financial derivatives, the paper proposes some suggestions.

Keywords: financial derivatives, risk prevention and control, VAR model, financial crisis

1 Introduction

The economic crisis in the world financial center Wall Street in 2008 resulted in the global economic depression. After analysis, researchers believed that the lack of control of the investment in financial derivatives was the main factor. At the same time, as shown in Figure 1, some state-owned enterprises in China like China Railway and China Eastern Airlines also suffered serious losses due to the investment in financial derivatives. In order to effectively limit the investment in financial derivatives, two investment channels were added in the Chinese financial market in 2010 and the new two kinds of investment channels, Several Opinions on Further Doing a Good Job in the Utilization of Foreign Investment was released.

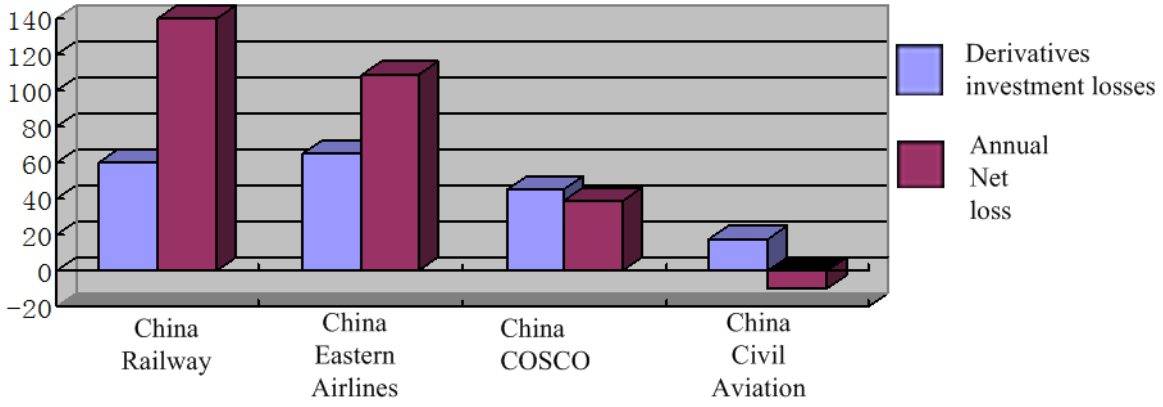

FIGURE 1 The Losses of the investment in financial derivatives in China

The emergence of inflation also let China's economic market face the shock from the development of financial derivatives, which is reflected by the US's economic pressure on China. In addition, financial derivatives are bound to affect China's economy. Many researchers believe that China's market economy will be affected by the development of global financial derivatives and the development orientation of financial derivatives is a common issue concerned by all countries at present. At the same time, whether some derivatives really conforms to our national situation is open to question.

2 Risk types and characteristics of financial derivatives

ISDA explains the industry of financial derivatives as follow: "financial derivative is a financial instrument used for swapping cash flow, transferring risks, etc. After the trade, the debt is determined by the market stock and index futures. It's also a way of securities trading used to reduce risks". This instrument has many characteristics and owns the basic characteristics of some financial products. As a derivative, its income comes from the gains of other financial products. The slight fluctuations in the financial market can also cause the great changes in its gains, so it's very sensitive to the financial market. Futures and risk contract are the typical types.

2.1 RISK TYPE OF FINACIAL DERIVATIVES

The Group of Thirty (G30) is an authority of studying the risk type of financial derivatives which is mainly composed of professional talents in economy, law, banking, financial academics and other fields with the wide and deep research, because the product function determines its risk characteristics. It's found in the process of research that practice and principle are the important reference for risks. In the trading process, the trading market risk is the main source of risk. Then, the performance degree of other risks is different in different periods. There are other standards for classification. For example, the risk analysis by the IOSCO is more specific than the analysis report of G30. It adds the risk analysis of market liquidity, financial operation and transaction settlement. Here, the analysis report of G30 will be discussed.

2.1.1 Market risk

Affected by the price, the trading market risk has great uncertainty. Price change is the source of risk, such as stock, securities, conversion rate, transacting rate and interest rate. According to the trading characteristics, G30 divides the trading market risk into four types such as interest rate risk. Both bank rate and monetary exchange rate can lead to price changes and then result in losses. Equity risk like the change of securities and stock index may cause losses.

2.1.2 Credit risk

Credit risk cite in the paper mainly refers to the risk caused because the other party does not fulfill the stipulated obligations under the contract spirit. In other words, the fiduciary cannot pay principal and interest in the promising time in accordance with the contract conditions, which will lead to the obvious difference between the actual and expected earnings of the accredited party. It's also the main component of the financial risk under the current market economic environment.

2.1.3 Operation risk

Relative to credit risk, operation risk also has great influence on financial derivatives in the market. Operation risk mainly refers to the possibility of being unable to achieve the expected operation goal due to the environmental factors objectively and the insufficient cognition of the influence of environment subjectively. On one hand, operation risk comes from the systematic vulnerabilities caused by poor operation structure, low operation efficiency and unreasonable internal work arrangement; on the other hand, it comes from the external force majeure, such as the unavoidable losses caused by some things which can't be predicted in advance or by natural disasters.

2.1.4 Legal risk

The daily business activities or all kinds of transaction of commercial banks should abide by the relevant business norms and legal principles. In this process, the commercial banks may fail to fulfill the contract because they cannot meet or violate the legal requirements, leading to issues, lawsuits or other disputes and thus causing the risk of economic loss, which is known as the legal risk.

2.2 RISK CHARATERISITICS OF FINACIAL DERIVATIVES

2.2.1 Suddenness

As a product of the development of financial market in a certain period, financial derivative usually refers to the innovation of the financial instruments appeared on the basis of the original assets. It's characterized by completing the trade in full with the corresponding deposit without the problem of principal transfer. Thus, the trading of financial derivatives has the leverage effect. The less the deposit is, the greater the leverage effect is and the greater the risk is. Because of the low threshold, it is difficult to realize the effective control. Therefore, the risks of financial derivatives have certain suddenness.

2.2.2 Strong infection

Due to the characteristic of linkage of financial derivatives, the value of financial instruments is closely linked to basic products or basic variables. Several financial crises in the history were caused due to the spread of the risks of financial derivatives in the market, such as Mexico's financial crisis.

2.2.3 Huge harmfulness

Under the market economy environment, the harmfulness caused by the risks of financial derivatives is huge. It not only brings serious damage to monomer, but also causes the chain harm. For example, due to the bad financial environment, LTcM in the US suffered the crisis of bankruptcy. However, because the financial derivatives of its assets occupy a large share, its influence in the market is huge. Once LTcM sells its assets, the companies buying the financial derivatives of LTcM will also suffer great losses. If LTcM declares bankruptcy, those accreditors will also face dangerous situation. This thing reflects the serious harmfulness of financial derivatives.

3 Methods of risk measurement of financial derivatives

At present, the expansion of financial accessories raises higher requirements on the existing risk prevention system. The specific measures for risk prevention include sensitivity test and VAR. The former is to test the sensitivity of the relevant elements on the basis of multiple financial accessories. It mainly reflects the trading measures through the sensitivity of risks under some simple trading environments. The latter is to show all risks in the numerical value. The value also means the concealed loss of the trade.

3.1 SENSITIVITY ANALYSISI

The maximum advantage of the sensitivity test is that it allows the user to intuitively observe the sensitivity of the accessories and their values in the transaction. Due to its simple operation, it's favored by the users. After getting the change of elements in the market and the correlation of the produced values, the change of values can be obtained through certain calculation. John C Hull proposed the method of the sensitivity test. The values brought by the derivatives are set to be *F*. It's the function of *S*, α and *t* and is expanded with Taylor:

$$\Delta f = \frac{af}{aS}\Delta S + \frac{af}{a\alpha}\Delta\alpha + \frac{af}{at}\Delta t + \frac{1}{2}\frac{af}{aS^2}\Delta S^2 + \ldots,$$

where *f* is the value of the derivatives; *S* is the standard assets; *a* is the changing probability of the assets price; *t* is the time; Δt is the change of time; Δf is the change of *f*; ΔS is the change of *S*; and, $\Delta\alpha$ is the change of *a*.

In fact, Deltas is the first order function and Gamma is the second order function. In the above equation, Delta means the price change of the derivatives in a small scope in a short period of time on the premise of no any explanation. Gamma means the change in a large scope without sensitivity to the assets on the premise of nearly no explanation. These two derivatives symbolize the linear and nonlinear risk test of the derivatives on the change of assets.

Evga represents the effectiveness degree of the instrument value in reflecting the price change in the market environment. Theta and Rho represent the reflection ability of the derivatives in the risk level.

3.2 VAR ANALYSIS

VAR analysis is also known as Value at Risk. It provides an overall guiding value for the existing risks in the market. Value risk is based on the fixed time and the determined proportion, because the market value risk means the possible harm to the enterprises due to the market interest rate change in certain time and at certain probability.

Risk model establishment and risk calculation measure can be included into two aspects: the first is to get the partial calculation result and the second is to get the global calculation result. Those two different aspects in essence are reflected by the different treating methods of the profits brought by different assets.

3.2.1 Delta-the normal method

The following formula shows the profit earned by an investment portfolio in a certain period of time:

$$R_{P^{t+1}} = \sum_{i=1}^{n} W_{i,t} P_{i,t+1},$$

$$VaR = E(\omega) - \omega^* = W_0[1+E(R)] - W_0(1+R^*) = W_0[E(R)-R^*] = -W_0[E(R)-R^*] = W_0 R^*,$$

(setting $E(R)=0$),

where $W_{i,t}$ refers to the ratio of change of different assets based on the change of time. The change of time can show the development form of an investment portfolio. In the actual application, Delta –normal method first acquiesces the extensive existence of the normal distribution in the profit rate. Represented by $R_{i,t+1}$, the profit rate shows the obvious characteristics of the normal distribution variable in the calculation process. Thus, it can be assumed like that. The variance calculation formula of the investment portfolio is:

$$V(R_{p,t+1}) = {}_{\alpha\sigma\rho}\, W = \alpha\sqrt{x\sum x}.$$

3.2.2 Historical data simulation method

As a common method in the current comprehensive valuation, historical data simulation method can provide the valuation result more conveniently and quickly. In the specific application process, the current weight and the

portfolio composed of historical asset profit rates are its core content.

$$R_{p,t+1} = \sum_{i=1}^{n} W_{i,t} R_{i,t+1} .$$

The complete price data is the basis of the successful application of the method. The price in the t[th] period of time can be calculated with the current price and the historical price changes.

$$R^*_{j-\tau} = P_{j-\mu} + \Delta P_{j,\tau} .$$

With the complete virtual price, the key data in the above formula can be solved. In the process, the non-linear relationship can be verified. Then, the virtual profit ratio corresponding to *r* can be obtained:

$$P_{p.t} = \frac{P_{p,t+1} - P_{p,0}}{P_{p,0}} .$$

On this basis, VAR value can be obtained.

3.2.3 Parameter method

It's also known as the variance-covariance method in some literate with the core of estimating the variance-covariance matrix of the return on assets. It sets the current assumption and the normal distribution assumption to make calculation, namely, $X - \mu / \sigma \sim N(0,1)$ and setting $\mu = 0$, then $X \sim N(0, \sigma^2)$. In the process of solving the σ variance, the equal weight formula can be adopted according to the actual situation. It tests the unconditional volatility in the financial derivative market, that is:

$$\sigma = \sqrt{\frac{1}{n-1} \sum_{t=1}^{n} (R_t - \mu)^2} .$$

The application of the index weight formula can provide us with the conditional volatility, that is:

$$\sigma = \sqrt{(1-\lambda) \sum_{t=1}^{n} \lambda^{n-t} (R_t - \mu)^2} .$$

The equation above can effectively express the volatility of the financial time series in the current market.

4 Empirical Analysis of Risk Measurement with the VAR Model

4.1 NORMAL VAR SINGLE RISK FACTOR δ

The simple statistical processing was done on the trading data in 1308 days with the relevant statistical tools to get the geometric profit rate level in a single period of time. On this basis, the specialized software was adopted to analyze the data statistically and get the daily standard deviation of 0.00142 of the national debt. The data of securities investment funds, stocks and bank deposits were 0.0032, 0.00753, and 0.00097, respectively. In the actual calculation process, we could think that the calculation formula of the maximum level of the negative change of the national debt in a single period of time could be simplified as $0.00142 \times 1.65 \times 1 = 0.00234$ under 95% confidence level. In the same calculation method, the data of securities funds, stocks and band deposits could be calculated to be 0.00528, 0.00753 and 0.0016, respectively.

Thus, the single factor
VAR of the national debt was $27.1 \times 0.00234 = 0.0634$;
VAR of securities was $VaR = 19.4 \times 0.058 = 0.1024$;
VAR of stocks was $VdR = 10.2 \times 0.00753 = 0.1268$
and
VAR of band deposits was $VaR = 43.3 \times 0.0016 = 0.06925$.

After calculation of the total VAR with the factor promoting method, the sum of the absolute values was 0.3618. In the actual application process, the method did not give full consideration to the correlation among four kinds of assets above but made the simple superposition. Thus, from the perspective of historical data, we could get the VAR invested by the insurance company was 0.3618 hundred billion yuan at the confidence level of 95%. In fact, the data proved that in the current market economy environment, more than 95% of people held that the total losses of the insurance company were less than 0.3618 hundred billion yuan in the unit period of time.

4.2 NORMAL VAR OF MULTI-RISK FACTOR δ

Next, on the premise of considering the correlation of assets, the normal VAR of double risk factors was calculated.

$$VaR_{ALL} = \sqrt{VaR_1^2 + VaR_1^2 + 2\rho_{12} VaR_1 VaR_2} .$$

In the equation above, ρ_{12} represented the correlation coefficient of two risk factors participating in the calculation.

The calculation of VAR depending on three risk factors could be expressed as:

$$VaR_{ALL} = \sqrt{VaR_1^2 + VaR_1^2 + VaR_3^2 + 2\rho_{12} VaR_1 VaR_2 + 2\rho_{13} VaR_1 VaR_3} .$$

The calculation formation of VAR of n risk factors could be expressed as:

$$VaR_{ALL} = \sqrt{\left(\sum_i \sum_j \rho_{ij} VaR_i VaR_j \right)^{12}} .$$

The application of matrix sign was the necessary choice in the case of many risk factors. Its basic formula could be simply expressed as:

$$VaR_{ALL} = \sqrt{VCV^T},$$

where V represented the row vector of VAR of n single factors; C was the $n \times n$ correlation matrix between factors; T was the matrix transposition calculation sign.

Through the statistical analysis of four kinds of assets above, the following matrix could be obtained:

$$\begin{bmatrix} 1 & -0.0267 & 0.00716 & 0.54653 \\ -0.0267 & 1 & 0.08848 & 0.05440 \\ 0.00716 & 0.008848 & 1 & 0.00260 \\ 0.54653 & 0.05440 & 0.00260 & 1 \end{bmatrix}.$$

Then, the corresponding normal VAR of δ was:

$$VaR_{ALL} = \sqrt{(0.0634, 0.1024, 0.1268, 0.0693) \begin{bmatrix} 1 & -0.0267 & 0.00716 & 0.54653 \\ -0.0267 & 1 & 0.08848 & 0.05440 \\ 0.00716 & 0.008848 & 1 & 0.00260 \\ 0.54653 & 0.05440 & 0.00260 & 1 \end{bmatrix} (0.0634, 0.1024, 0.1268, 0.0693)^T} \approx 0.19681.$$

The historical market prices of all subjects at the current stage can be known according to the above empirical analysis results. Through the matrix analysis and calculation, the VAR value under 95% confidence level is 0.19681 hundred million yuan, which actually proves that the probability that the company may lose less than 0.19681 hundred million yuan on the current day in the current market economy environment was 95%.

At the same time, the above calculation results also prove that the total VAR of δ is 0.19681 hundred million yuan, which is greater than any single factor VAR obtained above but not greater than the VAR value promoted by total factors. Objectively, the differential investment objects provided in the asset portfolio process are closely correlated. For this reason, the result obtained with the matrix method can ensure the normal VAR of δ is more consistent with the actual situation. Similarly, on this basis, the insurance company can obtain the total VAR and then determine the ultimate loss amount under the extreme situation of 5%, so as to withdraw the reserves in advance and take measures to control the investment risks.

5 Conclusion and Suggestions

Through the above research, despite certain achievements of China's financial derivatives in the development process, there is still much room for improvement. In order to control the risks of financial derivatives in the market economy more effectively, the following aspects must be done:

The first is to strengthen legislation, so as to create a good institutional environment for the development of financial derivatives. The government's laws, regulations and systems on the financial derivative industry are very important for the development of the financial market. Thus, China needs to improve the relevant regulations and systems, make the comprehensive supervision and management of the specific trading processes in the industry, create the reasonable and orderly trading environment for the futures market, protect the interests of both parties to the maximum and realize the good development of the financial derivatives.

The second is to strengthen the external supervision of the finance supervision institutions and ensure the standard development of the financial derivative market. The financial derivative industry in Europe, the US and Japan develops in a good environment, in which the governments play an important role despite their different supervision ways. The strong supervision of the governments ensures the orderly and reasonable development of the market and the bright prospects of the financial derivatives.

The third is to strengthen the supervision on the financial derivative transaction and ensure the fair trading in the exchange. As the important sector managing the financial market and the main place for the financial derivative trading, on one hand, the exchange supervises and manages the orderly development of the financial derivatives; on the other hand, it creates the open and equal environment for the development of the financial market. Considering that the exchange is a sector of investment operation, it should also be fully supervised.

The fourth is to give full play to the role of the self-regulation organization in supervising the financial derivatives. China should draw lessons from the foreign self-regulation organizations of finance to make ours more complete and play the supervision role.

The last is to build the risk measurement model of the financial derivative trading. In order to more accurately predict the potential risks in the financial transactions, the financial enterprises adopt the risk measurement model. The VAR model which is widely used in the foreign countries is an obvious example. VAR model makes precise prediction of the risks in transaction and prevents risks timely or reduce the losses to the minimum when the risks occur in the process of financial derivative transaction, which is conductive to the successful development of the financial derivative market.

A study on the relationship between the developments of China's trading economy and environmental factors

Xueying Zheng*

Economic and Trade College, Zhejiang Business College, Hangzhou, Zhejiang Province, China, 310053

Received 28 October 2014, www.cmnt.lv

Abstract

Trade environment refers to the social and economic environment facing trading economy, and it can directly affect the pace of trade development and trade structure. Establishing a good trade development environment can optimize trade structure, and promote the sustained and healthy economic development. This paper firstly analyzes the current environment of China's trade development with relevant theories, then analyzes the relationship between environmental factors and the development of trading economy based on indexes, builds error correction model, and uses the model to make in-depth analysis on the impacts of environment on the development of trading economy. According to the study results, the ratio of trade dependency over trade surplus exerts side effects on the development of trading economy, while trade openness exerts positive effects on the development of trading economy. In terms of import, the development of China's trading economy shows excessive dependence on foreign energy and other resource-based products, this seriously affects the stable development of economy. In terms of export, some Chinese companies that have overcapacity show over-reliance on international markets, thus reducing the competitiveness of export products, and leading to the situation where China's trading economy is vulnerable to fluctuations of international markets. Based on this, a method is proposed in the paper to improve China's trade environment.

Keywords: error correction model, trading economy, environment; impact

1 Introduction

The economic relations between countries have shifted from simple import and export trading relationship to various forms of economic relations; import and export of goods has evolved into multiple forms, including labor input and output, commodity trade, technology trade and service trade. From commodities that can meet material enjoyment to tourism that can meet the spiritual enjoyment, trade structure and trade patterns have undergone great changes [1,2]. Trade has a very important position in international economic relations. All the world's developed countries are inward-looking, they are interdependent with other countries in terms of economy, so are the United States, Japan, European countries and other developed countries, these countries exert economic impacts on other countries while being under the influence of other countries, and this mutual influence phenomenon is caused by the "transfer" channel named foreign trade [3-5]. Since the 1990s, the rapid development of foreign trade to has made great contributions to China's economic growth. The breadth, depth and speed of China's foreign trading economy have surpassed any other period in history. Dynamic benefits generated from foreign trade enable economic sectors at all levels to have economic growth, thus boosting the overall growth of the national economy [4-6]. Meanwhile, the development of foreign trade has effectively promoted China's diplomatic work, and made significant contributions to the establishment of favorable international environment for China's modernization construction. At present, China has become the world's largest trading nation; China's foreign trade has exerted significant influences on the world trade environment, while China's foreign trade can also be affected by the external environment. Based on the connotation of Kuznets Curve model [7-9], the paper presents an in-depth analysis of the internal and external environmental factors that affect China's foreign trade, and explores the countermeasures for China's trading economy, in order to promote the rapid and healthy development of China's foreign trade [10,11].

2 Analysis of China's current trade environment

First, China has increasing dependence on some foreign resources, especially energy and resource-based commodities. With the continuous development of China's economy, China has become a large energy consumption country. It is estimated that the degree of dependence on foreign energy is more than 80%, while some energy resources are almost 100% imported from other count-

* ***Corresponding author's*** e-mail: ysgao218@163.com

ries. Therefore, with the rapid economic development, China has increasing dependence on soybeans, iron ores, fish meal and other resource-based commodities. With increasing import quantum, China will be one of the world's major importers of energy and resource-based commodities. At present, the degree of China's dependence on imported crude oil, iron ore, aluminum and copper ores has reached 90%, with an increase of 40%. However, China is often forced to accept price increases in international trading of energy and resource-based commodities, and is subject to the external environment. In recent years, the price of various resources including fuel has constantly risen, resulting in the overall increase of China's domestic price level. This situation will be worsened with the development of China's economy.

Secondly, China's economic dependence on international markets is gradually increasing. In recent years, China's labor-intensive goods are basically saturated in the domestic market, this is mainly due to the international market. Therefore, if they are unsalable in the international market, foreign trade enterprises will suffer lethal blow, China's economy will also suffer huge damages, and the damages will increase with the increase of our export value. In addition to transferring excess capacity, China's dependence on the international market environment has also increased significantly in terms of import and export of goods and services, labor and employment. According to statistics, about 100 million people directly work for China's export trade, including 20 million in the textile industry with severe overcapacity of about 20 million, and more than 60 million in electronic product industry. It is estimated that China's output of shoes accounts for 60% of the world's total sales, the output of DVD accounts for 50% of the world's total sales. It can be seen that many China's sectors have over-dependence on the international market.

Thirdly, China still has great dependence on foreign product patents and core technologies. Due to lack of digestion and absorption ability of technologies and lack of innovative capacity, although China is the largest producing country of color TV, computers, mobile phones, stereos and other electronic equipment. China does not have the core production technology of these products, and has to import some key components and equipment. According to statistics, foreign enterprises control 85% of China's integrated circuits, more than 85% of pharmaceutical products, over 80% of chips, more than 70% of CNC machine tools and textile machinery, and more than 90% of automobile patents. This means that China's domestic industrial development and export trade are hollow. As China needs to pay expensive royalties to foreign countries, production costs are increasing, China's technology innovation and development is vulnerable to pressure from foreign companies, forcing many state-owned enterprises and private enterprises to withdraw from the international market competition, thus affecting the core competitiveness of China's foreign trade.

Fourthly, China's foreign trade frictions are increasing, the scope of trade barriers is expanding. China has maintained the trend of trade surplus since the 1990s, and the scale has been increasing; this exerts varying degrees of impacts on related industries of developed countries and developing countries. With China's rapid economic development, China not only seized the international share of developing countries' competitive industries, but also occupied the domestic market, seriously affecting and even marginalizing their competitive industries and pillar industries. Therefore, some countries and regions constantly set various barriers on China's products in order to protect their own industries, and even cause trade disputes. Since 1979, foreign countries have launched a total of more than 1000 cases of trade disputes, involving 4000 kinds of products exported from China, and affected China's exports of nearly $ 20 billion. According to WTO statistics, China's trade disputes have accounted for 15% of WTO anti-dumping cases since 1995, and these trade frictions are mainly caused by Chinese labor-intensive products that have competitive edges.

3 The construction and analysis of error correction model

3.1 MODEL

Based on the above analyses, indexes including the ratio of total export-import volume over gross domestic product (GDP) (JZ), export dependence (YN), the ratio of trade surplus (MY) and the growth rate of total export-import volume (ZZ) are set, in order to analyze the relevance and establish an error correction model. The data are collect from statistical yearbook of 1979 to 2012 on China Statistical Information Network, they are sorted as shown in Table 1.

TABLE 1 Index data

Index	JZ	YN	MY	ZZ	Index	JZ	YN	MY	ZZ
1979	0.1119	0.0521	-0.1284	0.2806	1996	0.3391	0.1767	0.0882	0.0270

1993	0.3190	0.1496	-0.1172	0.2359	2010	0.5024	0.2665	0.1301	`0.3390
1994	0.4229	0.2162	0.0464	0.8083	2011	0.4997	0.2605	0.0891	0.1719
1995	0.3866	0.2048	0.1271	0.1530	2012	0.4700	0.2490	0.1268	0.0328

Firstly, unit root test is carried out. ADF test is adopted, it is found that under the condition of no difference, they both have unit root; while after difference of first order, unit root is removed, and the sequences begins to be stable. For details, please see Table 2. Thus, an error correction model is established.

TABLE 2 The ADF test results of variables

Variable	t-Statistic	Prob.*
JZ	-4.6538	0.0007
MY	-5.0222	0.0003
YN	-4.9718	0.0003
ZZ	-6.5761	0.0000
1% level	-3.6537	
5% level	-2.9571	
10% level	-2.6174	

Then, the growth rate of total export-import volume (ZZ) is taken as the dependent variable, while the ratio of total export-import volume over gross domestic product (JZ), export dependence (YN) and the ratio of trade surplus (MY) are taken as independent variables, the least square method is adopted for correlation analysis. Related technologies are -3.4624, -0.5088 and 2.1755, then the error correction term can be established, it is Equation (1).

$$\begin{aligned}&\text{ECM=ZZ(-1)+3.4624*YN(-1)+}\\&\text{0.5088*MY(-1)-2.1755*JZ(-1)}\end{aligned}. \quad (1)$$

Then, the growth rate of total export-import volume (ZZ) is taken as the dependent variable, while the ratio of total export-import volume over gross domestic product (JZ), export dependence (YN) and the ratio of trade surplus (MY) are taken as independent variables for correlation analysis, the results are shown in Table 3. As can be seen from the data in Table 2, the tail probability of all variables is less than 0.01, therefore it meets the requirements at a confidence level of 1%, and the relevant probability is 0.6457, the degree of correlation is very high. Therefore, the fitting degree of dependent variable and independent variables is very good, the model construction is very successful.

TABLE 3 The error correction model parameter estimation

Variable	Coefficient	Std. Error	t-Statistic	Prob.
YN(-1)	-5.6146	3.93E-13	-8.82E+12	0.0000
MY(-1)	-0.2551	2.97E-14	-1.71E+13	0.0000
JZ(-1)	5.8537	2.06E-13	1.05E+13	0.0000
ECM	-0.9841	8.99E-15	1.11E+14	0.0000
C	0.0896	4.52E-15	-2.726609	0.0109
R-squared	0.6457	Mean dependent var		0.2303
Adjusted R-squared	0.6213	S.D. dependent var		0.1842

According to Table 2, the data model can be constructed as follows:

$$\begin{aligned}&D(ZZ)=-5.6146\cdot \mathrm{D(YN)}-0.2551\cdot \mathrm{D(MY)}+\\&5.8537\cdot \mathrm{D(JZ)}-0.9841\cdot \mathrm{ECM}+0.0896+\mu\end{aligned}. \quad (2)$$

In which:

$$\begin{cases}D(ZZ)=ZZ-ZZ(-1)\\D(YN)=YN-YN(-1)\\D(MY)=MY-MY(-1)\\D(JZ)=JZ-JZ(-1)\end{cases}. \quad (3)$$

If Equation (1) and for Equation (3) are put into Equation (2), then:

$$\begin{aligned} &ZZ - ZZ(-1) = \\ &\text{-}5.6146 \cdot [YN - YN(-1)] - \\ &0.2551 \cdot [MY - MY(-1)] + \\ &5.8537 \cdot [JZ - JZ(-1)] - \\ &0.9841 \cdot [\text{ZZ(-1)} + 3.4624 \cdot \text{YN(-1)} + \\ &0.5088 \cdot \text{MY(-1)} - 2.1755 \cdot \text{JZ(-1)}] \end{aligned} \quad . \quad (4)$$

After sorting Equation (4), then:

$$\begin{aligned} &ZZ = 0.0159 \cdot ZZ(-1) - 0.6146 \cdot YN + \\ &2.5140 \cdot YN(-1) - 0.2551 \cdot MY - \\ &0.2456 \cdot MY(-1) + 5.8538 \cdot JZ - \\ &3.7127 \cdot JZ(-1) \end{aligned} \quad . \quad (5)$$

3.2 MODEL ANALYSIS

According to the error correction model, the following points can be seen:

Firstly, the development speed of trading economy has positive correlation with the ratio of total import-export volume over gross domestic product (GDP). The total import-export volume can reflect China's domestic overcapacity. When overcapacity becomes more serious, the development of trading economy can also address capacity issues, thus promoting the growth of trading economy to some extent. However, with overcapacity and excessive development of trading economy, if the ratio of trade economy over the total domestic economy increase, trading economy will exert more impacts on the growth of national economy, China's economy is more vulnerable to the impacts of estimated markets. Meanwhile, the larger the proportion of import-export volume in GDP, the greater the degree of China's opening up, and this can also promote the development of trading economy.

Secondly, the development speed of trading economy has positive correlation with export dependence, but is negatively correlated with the current period export dependence. It is in proportional with export dependence, because current exports are an important part of the current trade economy, therefore the larger the proportion is, the more the volume of trading economy. It is in inversely proportional to previous exports, overall speaking, it is in inversely proportional to export dependence, this indicates that the pace of development speed of trading economy is negatively correlated with trade dependence. This negative correlation indicates that export dependence will exert side effects on the development of trading economy, the greater the export dependence is, the more side effects will be exerted on trading economy. This is mainly because that great export dependence will put China's economy and foreign trade under the influences of fluctuations in international markets, and be short of bargaining power.

Thirdly, the development speed of trading economy has positive correlation with the ratio of trade surplus. This is mainly because that trade surplus will bring more resistances, such as trade friction, deteriorated international trade relations, thus impeding the development of trading economy. This is also the main reason for increasing trade disputes and trade tensions over the years when China maintained trade surplus. Other countries will inevitably take various measures to protect their products, such as preparing various high-specification provisions to limit the entry of Chinese products, or using of a variety of national trade laws to hamper the entry of Chinese products.

4 Measures to improve the trading environment

It can be seen from above analyses that the ratio of trade dependency over trade surplus has side effects on the development of trading economy, and openness degree of trade has positive effects on the development of trading economy. Based on this, in order to promote the growth of China's trading economy and promote economic growth, it is recommended to improve the trade environment from the following perspectives:

Firstly, the construction of international trade environment should be enhanced. This is not only an economic task, but also a political mission. Trade surplus is an inevitable part in the development of China's trading economy. Completing the shift from trade surplus to trade deficit is the basic task of strengthening the construction of international trading environment. Therefore, emphasis should be attached to the maintenance and construction of China's trade environment, promoting the development of foreign trade and construction of international trade environment. A good international trade environment is essential for us to seize strategic opportunities and realize more strategic goals, and it is also a necessary external condition to construct China's harmonious society and achieve peaceful development.

Secondly, to constantly balance the development of China's industries, improve the technical level and reduce some industries' dependence on international trade. Over dependency on international markets, technologies and resources will exert adverse effects on the development of China's trading economy, and affect the domestic economy; this also reflects the imperfections of China's industrial development. The current imbalance in China's industrial development is very serious, the over dependency on imports leads to the increasing price of imported products, and unstable domestic economy. Technology is indeed the vital dilemma in China's economic development, the trade pattern can only be improved when great technological breakthroughs are made.

Thirdly, to actively participate in the competition in international market, and keep the balanced development of foreign and domestic trades. Trading economy is very important, so great attention should be paid to it. However, China, as a major consumer market in the

world, is also China's economic center. Therefore, when promoting the development of trading economy, domestic market should be protected and occupied, the balanced development of domestic and foreign trades should be constantly promoted. In fact, establishing a stable domestic market is the first step of establishing a stable trade environment, and the basic measure to promote the development of foreign trade and trading economy.

Empirical analysis of Chinese cultural products trade based on the gravity model

Pingping Qiao*

Department of Economy and Management, Henan Polytechnic Institute, Nanyang, Henan Province, China, 47300, China

Received 28 October 2014, www.cmnt.lv

Abstract

Based on date of bilateral cultural trades between China and 26 other countries (regions), the paper uses a gravity model to perform an empirical test on the influencing factors and export potential of cultural products. The research shows that Chinese economic size, importing country's economic scale, GDP per capital, trade openness and preferential trade arrangements have a positive effect on the export of Chinese cultural products. Spatial distance and cultural distance from China have a negative effect on exports of Chinese cultural products. The effect of cultural distance is bigger than that of spatial distance. It is very important for promoting the exports of Chinese cultural products to strengthen communication and overcome "cultural discount". In the 26 samples, the trades of cultural products between China and 7 countries (regions) are sufficient, and the trades of cultural products between China and other 19 countries (regions) are insufficient. China has a great potential for cultural products trades, but China should develop it targeted.

Keywords: gravity model, cultural products trade, influencing factors, export potential

1 Introduction

The cultural products have the following features of low consumption, low pollution and high added value, therefore, it becomes a strategic pillar industry which is an important path for many countries to develop and enhance their "soft power". According to international experience, when the ratio of output value in a certain industry and GDP is more than 5%, the industry can be called a pillar industry. In 2010, the cultural industry accounted for 2.75% of GDP in China, and there is still a large gap to reach the target of 5%. As a result, it's imperative to develop the cultural industry in China.

Accelerating the development of cultural trade and expanding the scale of foreign trade of cultural products, which is an important means to promote the cultural industry to be the pillar industry of China. Therefore, we need to research the factors that determine the scale and direction of China's cultural trade, and explore the export potential of cultural products. This paper analyzes the influence factors and export potential of China's cultural products trade based on the gravity model.

The gravity model is used in various social sciences to predict and describe certain behaviors that mimic gravitational interaction as described in Isaac Newton's law of gravity. Gravity model has been widely used in areas of traditional trade. With the continuous expansion of global cultural trade, gravity model has gradually been studied in the field of culture trade. Schulze introduced the gravity model to the field of culture trade first, and he found that the trade flow of artistic products is proportional to the economy scale of the countries, and inversely proportional to the distance [1]. Disdier et al added dummy variable such as common language and colonial relationship to the original gravity model, and he found that, compared with non-cultural products, cultural products trade used to happen in countries that have a short distance [2]. The empirical research from Ferreira & Waldfogel shows that the scale of cultural trade between the close countries that have the same language will be large [3]. They also noted that, with the development of transport and communication technology, the spatial distance between the countries will be shorten, but the spatial distance will be one of the main factors that influence the cultural products trade.

Cultural products that are different from the traditional products will have the phenomenon of "cultural discount" in international trade. "Cultural discount" refers to the value of the cultural products that will be discount in another country because of the cultural differences. The experts usually use the cultural distance to measure the possibility of cultural discount. The research from Disdier et al shows that the more similar the culture of the two countries is, the greater the scale of bilateral trade will be [4]. The paper calculates the export potential of China's cultural products trade with major trading partners on the base of the empirical analysis of the factors affecting Chinese cultural products trade.

2 Application of gravity model

2.1 CONSTRUCTION OF GRAVITY MODEL

The gravity model is a basic law in physics, which pointed out that the gravitational force between two objects is directly proportional to the product of their quality, and inversely proportional to the square of the distance between them.

* ***Corresponding author's*** e-mail: 59103214@qq.com

The gravity model was applied first by Tinbergen (1962) to the study of international trade, introducing GDP of the both sides and geographic distance as explanatory variables to the analysis of bilateral trade volume. The basic form is as follows:

$$T_{ij} = \frac{AY_iY_i}{D_{ij}},$$

T_{ij} represents the bilateral trade volume between country i and country j, A is a constant, Y_i represents GDP of country i, Y_i represents GDP of country j, D_{ij} represents the geographic distance between country i and country j.

According to the characteristics of cultural products trade, the paper added a new explanatory variable in the original gravity model to extend and modify the model, and established the model for the export of Chinese cultural products. Meanwhile, in order to overcome the heteroskedasticity of gravity model, take the natural logarithm on both sides of gravity model, and the final econometric model is as follows:

$$LnEX_{ijt} = A_{ijt} + \beta_1 LnGDP_{it} + \beta_2 LnGDP_{jt} + \beta_3 LnY_{jt} + \beta_4 LnSD_{ij} + \beta_5 LnCD_{ij} + \beta_6 LnOpen_{jt} + \beta_7 FTA_{ijt} + \varepsilon_{ijt}.$$

The subscript i represents China, t represents the time. A_{ijt} represents constant term. EX_{ijt} represents the export of Chinese cultural products to j country(region). GDP_{it} represents China's GDP, and GDP_{jt} represents the GDP of j country (region) as importer. Y_{jt} represents the per capita GDP of j country (region). SD_{ij} represents the spatial distance between China and j country (region). CD_{ij} represents the cultural distance between China and j country (region). $Open_{jt}$ represents the degree of opening in j country (region). FTA_{ijt} is a virtual variable that represents the situation whether China and the importing country (region) j are belong to a trade group. When the two countries are both in the same trade group, the trade flows between them will increase due to preferential trade arrangements. Therefore, FTA_{ijt} was used to investigate the effect of the national or regional economic cooperation on cultural trade. ε_{ijt} represents deviation item.

2.2 SELETION OD DATA

At present, the popular standard of cultural trade statistics is the "Framework for Cultural Statistics" (FCS for short) issued by UNESCO. "2009 Framework for Cultural Statistics of UNESCO" (2009FCS for short) is the new framework for cultural statistics issued by UNESCO in 2011.

Generalized fields of culture are divided into the narrow field of culture (the field of culture) and related fields. The field of culture represents a series of cultural production, activities and practices, which can be classified into the following categories: cultural and natural heritage (coded as A); performances and celebrations (coded as B); visual arts and handicrafts (coded as C); books and newspapers (coded as D); audio-visual and interactive media (coded as E); design and creative Services (coded as F). In addition, it also includes four horizontal fields: non-material cultural heritage, archiving and protection, education and training, equipping and supporting material. The related fields include sports, recreation and tourism. Due to some difficulties in the statistics of horizontal field and related field, the research does not include horizontal field and related field, but only six categories A-F of cultural field (called as culture products by UNESCO), which represent the most core culture field.

UNESCO also encourages countries to collect comparable data at least in these areas. "2009FCS" not only delineate the width of the culture field, but also provides SITC code that is accurate to 5 digits in A-F of cultural field.

According to the SITC code of "2009FCS", the bilateral trade data of cultural products have been obtained from the United Nations' commodity trade database (comrade database). The paper selects 16 developed countries and 10 developing countries (regions) as the sample. In 2010, the export of Chinese cultural products to the 26 countries (regions) accounted for 83.91% of China's total export of cultural products; therefore, the sample is representative. GDP and per capita GDP are from WEO database of the IMF site. The spatial distance between China and the importing country (region), indicated by the distance between the capitals of whom, is from the "distance calculator" of www.indo.com. The trade openness index $Open_{jt}$ is the ratio of total goods trade and GDP of the importing country. The total goods trade is from the official website of WTO. The paper takes the Asia Pacific Economic Cooperation (APEC) as the trade group. If China and the importing country (region) are both in APEC, $FTA_{ijt} = 1$, otherwise, $FTA_{ijt} = 0$.

Cultural distance (CD_{ij}) is used to measure the cultural differences between China and the importing country (region). The paper takes Hofstedes research method of five cultural dimensions for reference, the formula of that is as follows:

$$CD_{ij} = \frac{1}{5}\left[\sum_{k=1}^{5} I_{kj} - I_{ki}\right]^2 / V_k,$$

I_{kj} represents the score of country (region) j in the cultural dimension of k, I_{ki} represents the score of China in the cultural dimension of k, V_k represents the variance of cultural dimension k. The five cultural dimensions are power distance, uncertainty avoidance, individuallism/collectivism, degree of male/female, and the orientation of long/short term. The scores of China and its 26 trading partners in 5 cultural dimensions are all from the Hofstede website. The greater CD_{ij} is, the larger cultural distance will be, which indicates the cultural difference between China and its importing country (region).

The period of sample is 1992-2010. The paper makes an empirical analysis with panel data. The econometric method of panel data combines advantages of time series data and cross-section data, which is more comprehensive to reflect the individual characteristics of the research objects, and makes the regression model more persuasive

than pure time series model and cross section model due to the expansion of the sample capacity.

3 The regression results of the gravity model

In order to test the robustness of the gravity model, the paper uses the method of stepwise regression, and gets the regression results in Table 1.With the gradual adding of independent variables. The goodness of fit (R^2) for the model is improved. The goodness of fit reaches 0.85, and the explanatory power of the independent variables on the equation reaches 85%. The independent variables are stable, and the statistic values (t) of the independent variable pass the significance test, which shows that the model has good robustness.

TABLE 1 regression results of gravity model

	Equation1	Equation2	Equation3	Equation4	Equation5	Equation6	Equation7
constant	8.686 (10.140)	5.020 (5.694)	4.591 (6.385)	5.814 (6.235)	5.672 (8.125)	1.618 (2.587)	1.503 (2.539)
$LnGDP_{it}$	1.369*** (11.164)	1.141*** (9.906)	0.874*** (9.139)	0.332*** (6.541)	0.529*** (13.406)	0.268*** (7.379)	0.303*** (8.744)
$LnGDP_{jt}$		0.546*** (9.166)	0.331*** (6.520)	0.888*** (9.262)	0.773*** (10.738)	0.546*** (9.067)	0.541*** (9.495)
LnY_{jt}			0.698*** (14.585)	0.699*** (14.608)	0.789*** (21.829)	1.215*** (29.954)	1.194*** (31.007)
$LnSD_{ij}$				–0.164** (–2.059)	–0.165*** (–2.779)	–0.117** (–2.417)	–0.120*** (–2.620)
$LnCD_{ij}$					–1.252*** (–18.540)	–0.786*** (–12.547)	–0.718*** (–11.948)
$LnOpen_{jt}$						1.128*** (15.175)	1.037*** (14.511)
FTA_{ijt}							0.234*** (7.292)
R^2	0.220	0.346	0.556	0.560	0.751	0.835	0.852
Adjust–R^2	0.219	0.343	0.553	0.557	0.748	0.833	0.850

Notes: ***, **,* represent 1%, 5%,10% of significant level, The value in brackets is the value of t.

In the gravity model of Chinese cultural products export the elastic coefficient of the independent variable $LnGDP_{it}$ is 0.303, which indicates that when China's GDP increases by 1%, the export of Chinese cultural products will increase by 0.303%. The expanding of China's economy scale will promote the export of cultural products. The elastic coefficient of the independent variable $LnGDP_{jt}$ is 0.541, which indicates that when GDP of the importing country (region) increases by 1%, the export of Chinese cultural products to it will increase by 0.541%. The rising economic might will be conducive to China's cultural products export.

The elastic coefficient of the independent variable LnY_{jt} is 1.194, and its absolute value is the largest in that of all elastic coefficients with the most significant t, which indicates that when per capita GDP of the importing country (region) increases by 1%, the export of Chinese cultural products to it will increase by 1.194%. The per capita GDP of the importing country (region) has great effect on the export of Chinese cultural products.

The elastic coefficient of the independent variable $LnSD_{ij}$ is -0.120, which indicates that when the spatial distance between China and the importing country (region) increases by 1%, the trade flows of the cultural products will reduce by 0.12%. There is a negative correlation between the spatial distance and the export of Chinese cultural products. The spatial distance is still one of the main factors influencing China's cultural products export. The elastic coefficient of the independent variable $LnCD_{ij}$ is -0.718, which indicates that when the cultural distance between China and the importing country (region) increases by 1%, the trade flows of the cultural products will reduce by 0.718%. China tends to export the cultural products to the countries (regions) with the similar culture, which is consistent with the conclusion of Disdier et al (2010) [5,6]. From the absolute value of the elastic coefficient, elastic coefficient of cultural distance is far greater than the elastic coefficient of spatial distance, therefore, the effect of cultural distance on the export of Chinese cultural products is much greater than that of spatial distance.

The elastic coefficient of importing country's (region's) trade openness ($LnOpen_{jt}$) is 1.037, which indicates that when the trade openness of the importing country (region) increases by 1%, the export of Chinese cultural products to it will increase by 1.037%. The liberalization of global cultural trade would promote China's export. The elastic coefficient of FTA_{ijt} is 0.234, which indicates that preferential trade policy would promote China's export of cultural products, if the importing country (region) is the member of APEC.

4 The export potential calculation of Chinese cultural products

The calculation of export potential compares the actual export value with the simulate export value, applying potential export value of product in "theory" or "natural" state of the gravity model.

If actual value / simulate value>1, the actual trade value between the two countries is greater than the simulated values, which indicates "excessive trade"; if actual value / simulate value<1, the actual trade value between the two countries is less than the simulated values,

which indicates "insufficient trade" and the trade potential. Taking 2010 as an example, the paper calculates the export potential of Chinese cultural products. The results are shown in Table 2.

TABLE 2 Export potential of Chinese cultural products in 2010 (Unit: million dollars)

Country (region)	Trade volume (actual value)	Trade volume (simulate value)	Actual value/Simulate value
Australia	408.290	402.352	0.985
Brazil	145.312	321.388	2.212
Britain	1471.281	1081.288	0.735
Canada	683.725	397.160	0.581
Denmark	744.094	50.655	0.068
Philippines	51.854	106.540	2.055
Finland	106.043	65.844	0.621
France	1810.142	418.791	0.231
Germany	3147.851	1526.109	0.485
Hong Kong of China	875.983	7589.268	8.664
India	195.644	297.329	1.520
Italy	549.314	486.593	0.886
Japan	3814.819	1085.347	0.285
South Korea	869.123	346.982	0.399
Malaysia	187.661	196.129	1.045
Mexico	326.426	111.397	0.341
Holland	593.046	718.851	1.212
New Zealand	39.273	33.629	0.856
Portugal	36.466	30.449	0.835
Russia	469.033	319.456	0.681
Singapore	527.868	260.250	0.493
Spain	333.325	275.972	0.828
Sweden	172.977	81.253	0.470
Switzerland	322.573	32.584	0.101
Thailand	167.646	129.896	0.775
America	4591.946	8240.661	1.795

In the calculation of China's export potential to 26 countries, 7countries (regions) who are America, Holland, Hong Kong, Brazil, India, Philippines and Malaysia show "excessive trade", while 19 countries (regions) who are Japan, Italy, France, Germany, South Korea, Mexico, Russia, Singapore, Thailand and so on, show "insufficient trade". Ranking first is Hong Kong of China (8.644), and the last is Denmark (0.068), which shows that the potential of China's export to Denmark is huge. In addition, the ratio of actual value and simulate value in 7 countries, who are France, Germany, Japan, South Korea, Mexico Sweden and Switzerland, is less than 0.5. It indicates that the potential of China's export to the 7 countries above is relatively large. Overall, China's export of cultural products to its main trading partners is in the situation of "insufficient trade".

5 Conclusions and suggestions

The paper selected the panel data of China's cultural products export trade with other 26 countries (regions) in 1992~2010, using the gravity model to empirically analyze the influence factors of Chinese cultural products export trade [7]. On this basis, the paper calculated China's potential of cultural products export. According to the results of empirical analysis, the paper obtained the following conclusions:

First, the traditional factors are still the main factors affecting China's cultural products export. GDP and per capita GDP of China and import country (region) have the positive effect on China's cultural products export, while the spatial distance has the negative correlation with China's cultural products export.

Second, China's cultural products export has its own features. Compared with the space distance, the cultural distance has much more negative influence on China's cultural products export. The trade openness of importing country (region) and whether the trade partners belong to a free trade area, which have a positive effect on China's cultural products export.

Third, Chinese cultural products have great export potential. The relevant research shows that, the export of China to the major trading partners is on the situation of "insufficient trade", the ratio of the actual value to the simulation value is 0.740. In China's 26 major trading partners, only 7 countries' (regions') cultural products trade with China show "excessive trade", and 19 countries (regions) belong to the "insufficient trade".

Based on the research conclusions above, the paper believes that the following measures should be taken to expand the export scale of Chinese cultural product, to promote the development of China's cultural industry.

5.1 TO DEVELOP THE REAL ECONOMY VIGOROUSLY

GDP of the exporting country (region) is one of the important influence factors which influent the cultural products export. The sustained growth of China's GDP is conductive to improve the export capacity of cultural products. The enhancement of cultural products' export capacity, will not only further stimulate China's GDP growth in return, but also promote the upgrading of the national completive structure. However, for a long time, China focused on traditional goods export and ignored the cultural products' export [8]. Therefore, China should not only strive to develop the real economy, but also actively promote the export of cultural industry and make the strategic policy of culture trade:

1) To encourage the establishment of cultural industry organizations (or association), in order to strengthen the development and protection of traditional culture resources;

2) To increase the financial support on the culture industry, for example, supplying export credit subsidy and export credit insurance for the relevant cultural enterprises;

3) To promote the cooperation between cultural enterprises;

4) to promote implementation of the strategy that is "going out" of the domestic cultural enterprises.

5.2 TO STRENGTHEN THE CULTURAL COMMUNICATION AND SHORTEN THE CULTURAL DISTANCE IN ORDER TO AVOID "CULTURAL DISCOUNT"

The cultural distance between import and export country (region) is a very important factor influencing the export of Chinese cultural products. Shortening the cultural dis-

tance to overcome the "cultural discount", which will promote China's export of cultural products. The government should:

1) Strengthen international cultural communication, positive publicize and spread Chinese cultural products;

2) Hold high level cultural communications to promote the understanding of Chinese culture in the world and make Chinese elements melt into the world;

3) Vigorously develop the business of teaching foreigner Chinese through the Kong Zi College;

4) Spread China's language and culture philosophy in the world;

5) Export China's rich cultural goods through the Chinese bridge to all over the world. The export enterprises should make market research fully. The cultural products should not only embody Chinese characteristics, but also meet the foreign consumers' demand and aesthetic habits, in order to avoid "cultural discount" and open the overseas market as soon as possible.

5.3 TO PARTICIPATE IN THE GLOBAL OR REGIONAL ECONOMIC COOPERATION ACTIVELY

Preferential trade arrangement plays an important role in promoting the cultural products export of a country or an area. On one hand, as the member of WTO, China should actively participate in the formulation of world trade rules, as far as possible to reduce trade barriers and unfair treatment which hinder the export of Chinese cultural products; on the other hand, China should actively participate in various organizations of trade cooperation and regional economic integration, and establish close relations of economy and trade with trading partners to create a good international environment for the export of culture enterprise.

5.4 TO DEVELOP TARGETED CULTURAL TRADE

China should actively develop cultural trade with the countries, which have insufficient trade or the export potential, such as Denmark, France, Germany, etc. In addition, GDP, per capita GDP and trade openness of import country (region) have the positive effect on cultural products export. Therefore, China should focus on developing cultural products export with the developed countries which are rich and relatively open. As for the countries "excessive trade" (such as Brazil), China should adjust the export structure of cultural products and improve the grade of export products, in order to avoid the tendency of "excessive trade".

Research on the influential factors of China's logistics demand based on the econometric model

Xuewen Jin*

College of management, Jiangxi University of Technology, Jiangxi Province, China, 330029

Received 28 October 2014, www.cmnt.lv

Abstract

Logistics demand reflects the pace of economic development, and the pace of economic development also affects the change of logistics demand in turn. In fact, logistics demand is affected by many factors. Through the theoretical analysis, the paper points out that the influential factors on logistics demand mainly include four aspects, namely, economic development level, regional industrial structure, macro-economic policy and economic system, and consumption level and concept. Then, the econometric model is established with the data in different periods of time based on those four aspects to make an in-depth analysis of the application of the model. At the same time, in order to promote the development of the logistics industry, improve logistics demand and meet the development demand of the regional economy, it puts forward reasonable suggestions.

Keywords: logistics demand, econometric model, influential factors

1 Introduction

With the continuous development of market economy and information economy, the logistics industry has grown from the end industry to the important one with a great impact on the economy and a role of guiding and promoting the development of other industries, and even the forerunner industry of other industries. Modern logistics industry is a comprehensive industry which integrates systematization, informatization and warehousing modernization together with IT information technology as the support and the transportation industry as the core. The development of the logistics industry plays a huge role in optimizing the industrial structure, enhancing the development of enterprises and improving the quality of economic operation. [1] In recent years, China's logistics industry has been growing rapidly. Various types of logistics enterprises have grown up and distribution center, logistics base, cargo loading center and other logistics related infrastructure facilities have been improved. Both the central and local governments attach great importance to the development of the logistics industry. The State Economic and Trade Commission, the State Planning Commission and the State Council Development Research Center all have made in-depth research and exploration on the problems and developed a series of necessary policies to promote the development of the logistics industry and create a good external environment for the application of logistics by enterprises and for the development of the logistics industry. [2] At present, some cities, especially those with rapid economic development like Shenzhen, Guangzhou and Beijing, provide support to the development of the logistics development from the level of the local government by developing a series of supporting policies. Many cities have listed promoting the development of the logistics industry into the 10th Five-year Plan. Therefore, predictably, the logistics industry will become an important industry and a new economic growth point in China in the 21st century. The development and expansion of the logistics industry is of great significance to realizing the sustainable development of the Chinese economy, improving the quality of economic operation, optimizing the allocation of resources, and promoting the reform and development. [3] This paper makes an in-depth analysis on the influential factors on logistics demand with the empirical method and establishes the econometric model, which can provide the important method and reference for the governments and the enterprises related to the logistics industry to make logistics planning and analyze logistics demand. Thus, this research has important practical significance.

2 Analysis of the influential factors on logistics demand

Logistics demand refers to the demand for space, time and cost generated due to the distribution and circulation of some goods in the social and economic activities in a certain period of time. As an important part of the social and economic activities, logistics demand runs through the whole social and economic activities of production, circulation and consumption and has close relationship with the status and speed of the social and economic development. Thus, the status and speed of the social and economic development is the main factor affecting logistics demand. The factors affecting the status and speed of the social and economic development will inevitably affect the development of the logistics industry and logistics demand. Logistics demand can be reflected

* ***Corresponding author's*** e-mail: 1418758482@qq.com

through the freight turnover rate and freight volume. Figure 1 presents the annual growth trend of China's logistics industry. According to the Figure, China's logistics quantity has been maintaining an average annual growth rate of 8% since 1986, lower than the growth rate of China's economy, which indicates the imbalance between supply and demand of logistics in China. Generally speaking, the growth rate of logistics is positively correlated with that of economy. At the same time, it can be known from the figure that the annual growth rates of freight volume and turnover are very unstable. The figures fell down very sharply particularly in recent years: the growth rate of freight volume was 14% in 2011, 11% in 2012 and still about 11% in 2013; the growth rate of freight turnover was 12% in 2011, 9% in 2012 and -3% in 2013. The change of logistics demand can reflect the development status of China's economy. Meanwhile, it's affected by many factors as follows:

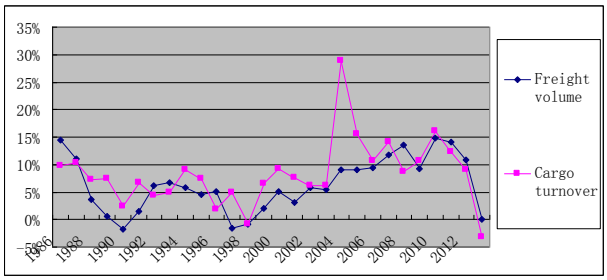

FIGURE 1 The changing trend of China's logistics demand

Note: the data are from www.tjcn.org.com

The first is the level of economic development. The level of economic development determines the level of output and consumption, that is, the regional economic aggregate. In the short term, it's the determinant and basic drive of logistics demand. This is because the object of logistics is always the basic output and consumption of regional economy. If the regional output and consumption level is high, the economic aggregate is big and the logistics demand must be great. If the output and consumption level is low, the economic aggregate is small and the object of logistics will not be virtually high. [4,5]. Thus, the high economic development level leads to the high logistics demand. For example, after comparison between the central and west China and the east China, the relative per capita logistics demand in the central and west China is low and that in the east China is high.

The second is the industrial structure. Different industrial structures have a significant impact on the logistics demand function, logistics level and logistics demand structure. The logistics demand of agriculture, forestry and animal husbandry in the primary industry is extensive with large quantity but low value. Manufacturing and mining in the secondary industry provide the products with physical substance which are reliant on logistics from production and consumption, so they have great logistics demand. The tertiary industry is given priority to the service industry which is less dependent on the logistics activity but needs more the modern logistics service based on the information technology [6]. Thus, different industries have obviously different degrees of logistics demand. In the regional industrial structure, if the primary and secondary industries occupy a large proportion, under given conditions, its logistics demand is large; but if the proportion of the tertiary industry is high, its logistics demand is small.

The third is the macro economic policy and management system. Due to the derivation of logistics demand, the macro economic policy directly affects the logistics quantity. First of all, if the policy can promote the economic development, the economic aggregate will increase, which will promote the development of the logistics industry and increase the logistics demand. If the macro economic policy fails to keep up with the development requirements of regional economy, leading to the economic stagnation or impossibility of recovery, it will affect the increase of the logistics demand [7]. Since the logistics service is strictly dependent on the infrastructure, the management system exerts a direct impact on the construction of the logistics infrastructure. For example, the increase of the investment in the logistics industry by the governments at all levels provides good conditions for the rapid development of the logistics industry. The investment scale in railways, highways and waterways directly affects the density and level of the transport network and further exerts the corresponding impact on logistics demand.

The fourth is the consumption level and concept. The ultimate purpose of circulation is consumption, so like the economic aggregate the consumption level can also reflect the regional logistics demand. If the regional consumption level increases, the demand for the products will be large. In other words, the local products cannot meet the consumption. Then, the products produced by other places will enter through logistics. The consumption concept will also affect the demand of products [8]. The circulation of different products needs different logistics demands. This is because the weight, volume and basic requirement for logistics which are important factors affecting logistics demand are different. In fact, the consumption concept directly affects the enterprises' management decision, production, sales and further the logistics size. New products and service always need the high-level logistics service for support.

The fifth is other factors. Market environment and technological advance also affect logistics demand. The logistics activity serves production and life. The change of the market environment affects the development speed of the regional economy, the residents' consumption expectations and thus the regional logistics quantity [9]. At the same time, different macro environmental conditions in different regions have different influence on the regional economy, which will also affect the flow direction and service way of logistics goods as well as the quality and quantity of service. The technological advance including the logistics technology will also affect the demand. For example, the Internet technology will increase the logistics demand. In fact, the domestic and foreign trading ways, economic globalization and other market environment all affect logistics demand.

3 Empirical analysis

3.1 MODEL ESTABLISHMENT AND PREDCTION

According to the theoretical analysis, the factors affecting the model include economic development level, regional industrial structure, macro economic policy and economic system, and consumption level and concept. The following indicators can be set: the added value of the primary industry (DY), the added value of the secondary industry (DE), the added value of the tertiary industry (DS) and the consumer level (XF). The development among industries can not only reflect the economic development level, but also the proportion change of the tertiary industry. At the same time, the logistics industry is also affected by its own development. Thus, the model can be established as follow:

$$WL = a_1 \cdot DY + a_2 \cdot DE + a_3 \cdot DS + a_4 \cdot XF + a_5 \cdot WL(-1) + u_t \quad (1)$$

The data are from China Statistical Yearbook from 1980 to 2013. To verify the model, it's necessary to test the unit root. It's found through the ADF test that the sequence is in the unstable state under both no difference and the first order difference, but it's in the stable state after the second order difference. The specific results are shown in Table 1.

TABLE 1 Augmented dickey-fuller test statistic

Variable	t-Statistic	Prob.*	Variable	t-Statistic	Prob.*
DE	-8.6250	0.0000	XF	-4.6302	0.0134
DS	-8.1326	0.0017	1% level	-3.6702	
DY	-8.2647	0.0000	5% level	-2.9640	
WL	-3.2338	0.0285	10% level	-2.6210	

Thus, it can be seen that the model can be used for the correlation analysis. When WL(-1) is listed in the influential factors for analysis according to the expectation, the result is not significant, so it should be excluded. Here, the analysis is made from four directions. The sequence coefficients of the correlation analysis are shown in Table 2 and the model is as shown in Equation (2):

$$\begin{cases} WL_{1980-2013} = 205.9716 \cdot XF + 11.8296 \cdot DY + 9.5704 \cdot DS + 1.0517 \cdot DE + u_t \\ WL_{1980-1990} = 520.4910 \cdot XF + 4.4747 \cdot DY + 8.6536 \cdot DS + 13.2296 \cdot DE + u_t \\ WL_{1990-2000} = 201.7310 \cdot XF + 9.2186 \cdot DY + 2.0680 \cdot DS + 9.2289 \cdot DE + u_t \\ WL_{2000-2014} = 273.3543 \cdot XF + 2.5861 \cdot DY + 2.2714 \cdot DS + 9.9887 \cdot DE + u_t \end{cases} \quad (2)$$

TABLE 2 Technical Drawing of the Econometric Model

Time	XF	DY	DS	DE
1980-2013	205.9761	11.8296	9.5704	1.0517
1980-1990	520.4910	4.4747	8.6536	13.2296
1990-2000	201.7310	9.2186	2.0680	9.2289
2000-2014	273.3543	2.5861	2.2714	9.9887

3.2 THE PREDICTION RESULT

Figure 2 makes prediction with the data from 1980 to 2013. According to the figure, the difference between the budget line and the balance error line is small, which indicates that the prediction value is about 42 billion tons in 2014 according to the prediction. Figure 3 makes prediction with the data from 1980 to 1990. The prediction value is greatly different from the actual one, but the trends are consistent. The prediction value of the latter is greater than that of the former. Figure 4 makes prediction with the data from 1990 and 2000. It can be seen from the figure that the difference between the error and the actual value is the largest and the prediction value is small, which indicates that the data growth area during 1990 and 2000 is significantly different from that in other years and its growth rate is smaller than that of others. Figure 5 makes prediction with the data from 2000 to 2013. According to the figure, the prediction value is closer to the actual one and the difference between the balance error line and the prediction line is better than that of Figure 1, indicating that the model is more accurate.

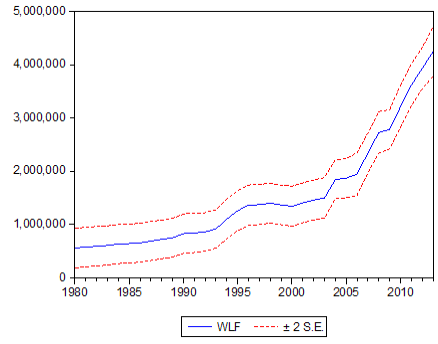

FIGURE 2 The prediction diagram based on the data from 1980 to 2013

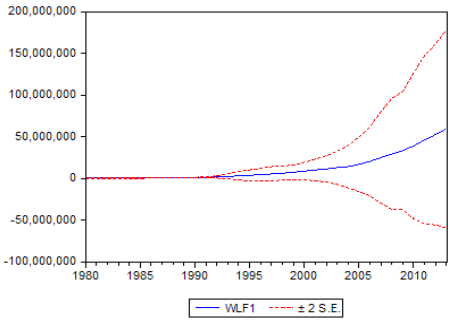

FIGURE 3 The prediction diagram based on the data from 1980 to 1990

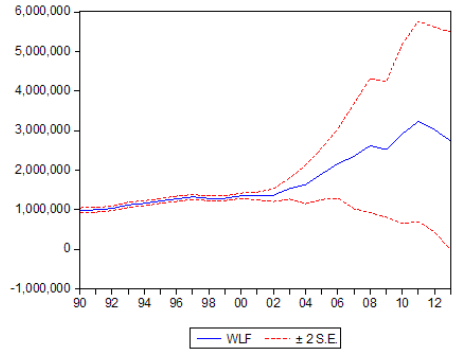

FIGURE 4 The prediction diagram based on the data from 1990 to 2000

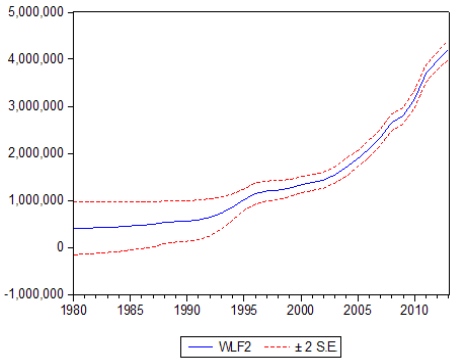

FIGURE 5 The prediction diagram based on the data from 2000 to 2013

3.3 APPLICATION ANALYSIS OF THE MODEL

First of all, the accuracy of the model can be verified through the model. The comparison among the parameters of four prediction models and four prediction diagrams indicates the accuracy of the model. It can be found that more cited data does not mean the more accurate model. The estimation should be based on the data in recent years. Thus, Figure 5 with the data in the past 13 years is more accurate than Figure 1 with the data in the past 34 years. This is mainly because the environment is always changing, so is the parameters of the model.

Secondly, the coefficients of the model change greatly, which indicates the great change of the model. Generally speaking, the greater the coefficient is, the greater the influence is. The great change of the coefficient is mainly because it's dependent on the environment. For example, the coefficient of the secondary industry changes greatly, indicating that its influence on logistics demand is small due to the development environments of different regional economies. When the trade volume of the regional goods is large, the demand for logistics will be huge; when the regions tend to satisfy the current scale of the industry, the trade volume is small and the demand for logistics will be small.

Thirdly, attention should be paid to the timeliness in the application of the model. In the current period, the model is affected by four influential factors. However, with the changes of the environment, the influential factors and the degree of influence, the model will also change, which is the timeliness of the model. To ensure the long-term practical application of the model, it's necessary to update the influential factors according to the change of the environment, get rid of those with little influence or no influence and add some new ones. Thus, the empirical analysis should be made often to estimate the model with the data in the past dozen years to predict the future data.

4 Conclusion and suggestion

Analysis of the influential factors on logistics demand and prediction of the demand is to analyze the development of the logistics industry according to the changing trend of the influential factors and better satisfy the development requirements. This is because if the supply of the logistics industry can't meet the future development of logistics demand, it will limit the development of the regional industry and even the whole regional economy and affect the economic efficiency; if the supply exceeds the demand, it will waste the logistics resources and affect the economic efficiency, too. Therefore, in order to balance the relationship between the logistics demand and supply, ensure the moderate development of the logistics industry, meet the demand of economic development and promote the upgrading and transformation of the logistics industry at the same time, the following aspects should be improved.

The first is to cultivate the concept of modern logistics, grasp its development trend and develop the development plan of modern logistics based on the full consideration of regional development, economic structure, transportation information, city planning and logistics demand. The government should avoid the excessive interference in the logistics market and establish the socialized and specialized modern logistics system with the market as the orientation and the logistics enterprises as the main players.

The second is to integrate the logistics resources and cultivate the main players in the logistics market. In the large area of China, it should break the regional block, promote advantages and abolish disadvantages of each region. In addition, it should guide the manufacturing and trade enterprises to promote the recombination of enterprise logistics management and enterprise logistics orderly based on their own development requirements and establish the logistics model to meet their special requirements.

The third is to accelerate the construction of the informatized and standard logistics enterprises and comprehensively improve the logistics service and technical level. Informatization is the soul of modern logistics. Modern information technology realizes the information communication and sharing in different economic sectors and enterprises and thus achieves the purpose of effecttively coordinating, managing and integrating the logistics elements and functions. It should promote the application of modern information management technology like ERP and MRP in logistics enterprises and logistics management of business enterprises, make great efforts to promote the construction of the public information platform, establish the sound e-commerce certification system, on-line payment system and logistics distribution management system, so as to create conditions for the smooth and efficient communication of logistics information.

Abstract

Agile methodology has getting wide recognition within the software industry due to its flexibility and ability to cope with rapid changes in the software development environments. It is however comes with a number of demands that must be complied with. This paper presents a pilot systematic literature review (SLR) study on the limitations of Agile methods in the industry based on primary research. In this study, conference and journal papers in the IEEE, published between 2007 and 2012 were investigated. 29 papers were found as the most relevant. While the SLR findings have brought to both limitations in the implementation and in the Agile methods, the former becomes the most addressed issues. The result revealed that high dependency on people/personnel, organizational dependency, as well as high impact on organizational structure and culture as the three most repeatedly addressed factors. While these three factors are mutually related, people factor especially upper level management strong involvement and support can be regarded as a primary necessity in the Agile implementation. In spite of apparent emphasis on people critical function stated in the Agile principles, plus the excellent rules in the gist of the principles, the problem still arose when it comes to the implementation part. This indicates the need for future work on proper guidelines for management, given that existing guidelines for Agile adoptions and implementations are general and less focus given to upper level managers.

Keywords: Agile, limitation, human factor, pilot management, systematic review

1 Introduction

Agile methods are now becoming the mainstream and extensively being adopted outside of its initial intended scope of small and collocated project teams. They are now being implemented in all project sizes (small, medium and large), in both distributed (locally and globally) and non-distributed project environments, as well as in various project domains such as engineering, manufacturing, banking and medical. As a result, new versions of Agile methodology have been developed, Agile methods have been enhanced or being integrated with other models to support the increasing demands of different project environments. The initial intention was to integrate Agile method (AM) with an existing framework originated from non-software industry to enhance the AM adoption coverage. To further explore the limitations of Agile practices before deciding their suitability for integration, a pilot systematic literature review (SLR) study has been conducted.

While the limitations of AM in the industry have been aimed at, the limitations in adopting and implementing the AM were identified more during the reviewing. The Agile Manifesto that was addressed as too informal [5] and embraced "abstract principles" [1] raised a lot of issues in the implementation and adaptation of the Agile practices. Regardless of abundance suggestions and recommendations from existing experiences, the flexibility and generality of AM open for various interpretations and therefore, inviting issues in the way to effectively perform AM in practice notably for early adopters.

Agile methodology is an iterative and evolutionary approach for software project development. Initiated by seventeen experts of organizational anarchists in February 2001, it operates under four core values and twelve principles, namely Agile Manifesto [7]. This widely known people-centric process model is inspired among which by sentiments, working with people who shared compatible goals and values based on mutual trust and respect, promoting collaborative, people-focused organizational models and building the types of professional communities in which we would want to work [7]. There are different types of AM. For example, Dynamic Systems Development Method.

(DSDM), Extreme programming (XP), Scrum, Crystal Clear, Feature-Driven Development and Lean Software Development. Each of the different types of Agile methods such as Scrum and XP have their own practices which are based on different concentrations. While XP concentrates on the project level activities of software deployment, Scrum "concentrates on the management aspects of software development" [8].

In this paper, we firstly highlight the background of this pilot SLR study which encompasses a brief introduction on Agile methodology, previous related studies as well as motivation behind the study. Then, the

* ***Corresponding author's*** e-mail: 408569488@qq.com

review method or the steps taken in performing the SLR is elucidated. Subsequently, the result consisting of the overview of the study and the compiled limitations is presented. Last but not least, we conclude our SLR study together with our future work.

2 Background

Agile methods are getting wider attention and widely used at present. However, early investigation (end of 2011) finds their usage are limited (i.e. more suitable for experienced and skilled software engineers, and less appropriate for large and complex projects) despite of their ambitious purpose. AM is regarded as an ambitious practice because it allows for changes within rapid software development environment but the anticipated outcome is yet to be stably attained. At the same time, no paper is found to discuss the drawbacks of AM inclusively.

As a result, pilot SLR was conducted to dig out the limitations of Agile practices and prioritized them based on frequencies. The SLR review process was very helpful as the reviewer could clearly understand the situations and issues surrounded the AM practice. This study also brings the reviewer to see different angles in the research area and help her to firmly decide on what direction that should be focused.

First systematic review study on AM done by Dingsøyr and Dyba [6] intends to tackle the issue of anecdotal evidence in the agile adoption success story. The SLR specifically reviews empirical studies of agile software development since beginning up to 2005 with earlier search result of 1996 papers. The benefits and limitations of AM from their finalized 36 empirical studies as well as the strength of evidences were discussed. Their inclusive analysis provides guidance and comparison for industrial readership based on situational applicability. To conclude, the study mainly advocated for further similar study with better quality in the similar area.

This next systematic review of Agile methodology was specific for global software engineering (GSE) environment [9]. The SLR includes papers from five electronic databases between the year 1999 and 2009 where 77 most relevant papers were analysed. The study found that Agile practices in most cases were customized to fit the project environments and requirements. Thus, future work in incorporating existing experiences was pointed as required to aid agile adopters in distributed project settings.

Subsequently, Causevic et al. [4] have conducted a systematic review on factors limiting industrial adoption of test-driven development (TDD), one of the Agile practices. This SLR study examines both mainly focus and non-specific TDD empirical studies covering papers of industrial and academic studies from 2005 to 2009. The study was based on earlier research findings that the TDD practice "is not followed to the extent preferred by industry". Based on the result, the paper addressed the need for guidelines "to overcome these limiting factors for successful industrial adoption of TDD" [4]. While papers from seven electronic databases were investigated, the SLR merely focuses on one basic agile software development practice.

The only paper of similar focus with this SLR study was by Livermore [12]. Nevertheless, it was a worldwide online survey of general focus involving various industrial areas. With a low response rate of 5.76% or 112 survey responses, factors that were found to significantly impact the Agile implementation include; training, management involvement, access to external resources, as well as corporate size. Through this smaller scope of findings (compared to this SLR study), the management was identified as having main influence over most of the other factors.

Lastly, Neves et al. [14] have presented a paper on a thorough analysis and evaluation (empirically) of the benefits and limitations of Agile practices in relation to knowledge formation and transition experienced by Agile teams. In the last phase of evaluation, a SWOT (Strength Weakness Opportunity Threat) analysis was utilized to evaluate Agile contributions toward the productivity of the software development teams. Our SLR findings show a number of similar limitation items with this paper results of weaknesses and threats of Agile processes in knowledge management.

3 Review Method

First and foremost, an informal review is conducted to gain some understanding on the issues surrounded the AM. In the process, the author review articles, journals and conference papers by searching through the "google" and several well-known electronic databases such as ACM portal, IEEE Xplore, ScienceDirect and SpringerLink that pointed out the limitations or constraints of AM. The information obtained from this preliminary search and review is used as a basis to plan the systematic review.

To form an appropriate systematic review, separate search on papers discussing systematic review method is performed. There are two combination of search strings used; "systematic review AND software" and "systematic review AND Agile". In the process, several papers are retrieved based on title where final selection is made based on abstract and recent published date. Here, two systematic review papers on different AM research focus are chosen and referred; Empirical studies in Agile software development [6] and Agile practices in Global Software Engineering [9]. Their review techniques are carefully assessed and combined in building this systematic review plan. In actual, their SLR methods which focus to the AM study based on several SLR guidelines (i.e. [10]) provide a very helpful and clear-cut guidance for the reviewer to work on the SLR.

Basically, the design of this SLR review protocol was closely influenced by the review method presented by Dingsøyr and Dyba [6] and Jalali and Wohlin [9]. The combination of their review techniques resulted to the following construct. In a systematic literature review, research question that is required to be initially built defines the scope of the review study for the paper. In this

review study, the following research question has been formulated with the objective of finding and gathering the limitations of AM.

A lot of previous research reports pointed out the issue of the validity of Agile methods (AM) study, saying most of the reported results were anecdotal. Based on the situation, research community asks for more concrete study on AM where more and more AM study focusing on tangible results were published afterwards. Therefore this SLR study started with searching AM related papers that were based on strong foundation such as empirical or case study as well as survey and industrial experience report with concrete evidences or strong justifications. In the process, a reviewer went through the research method used in each paper to identify their validity.

Since this review study is about finding the limitations of Agile practices, the primary keyword used in the searching process is "agile" meanwhile "limitation" becomes the secondary keyword. For the first keyword, there are different types of AM such as extreme programming (XP), scrum, crystal clear, dynamic systems development method (DSDM), feature-driven development and lean software development. Separate search is conducted to identify the limitations of each of these AM types. Since the second keyword "limitation" is a common noun, similar meaning words are listed. The words are spotted from papers in the earlier informal review process. The formulation of several search strings from the keywords ensures that only related papers are extracted. The searching activity is conducted using IEEE Advanced Search, the sole electronic database used in this pilot SLR. IEEE is one of the general sponsors for Agile Conference annual events since 2003 and the main publisher for papers in the conferences.

Altogether, there were 7 search strings formed and used in the searching process. This is to ensure that all the related papers, according to the research question could be extracted. Basically, there were 2 types of search string as indicated below:

First search string: to extract all Agile practices in software project related papers that having Agile keyword in their abstract. Second to seventh search string: to extract papers that discuss specific Agile practices such as Scrum which is not included in the first searching, where these papers having no Agile keyword in their abstract.

The reviewer went through four stages of searching and filtering to identify relevant papers In the first stage, a total of 306 search results were returned after 7 individual searches in the IEEE Advanced Search. Next stages were a three phase filtering process. While the first filter is mostly quite straightforward (scanning the titles or abstract), there were cases where the reviewer need to go beyond the abstract to further understand and decide. During the last two phases, the reviewer carefully went through each paper where in most of the cases, need to go through the whole paper or study the full-text to identify its relevancy. In all the three phases, intended data as well as potential points were extracted and stored in an excel file. At the final stage, 29 papers are found to be most relevant to the SLR topic. Subsequent process, the data extraction was not straightforward as the process was delayed by the way of the studies/experiences were reported. The limitation elements are most of the time generally pointed or non-transparent (not in the surface). Thus, the intended points could not be easily extracted and require critical reading and understanding. Furthermore, the points to be extracted are not fix or unique whereby keyword search is not possible. To put in a nutshell, the limitations data are extracted based on the reviewer's analysis and conclusion by reading the whole paper normally more than once to understand the cases/experiences reported.

4 Results and Discussions

4.1 OVERVIEW OF THE RESULT

29 studies that addressed limitations in the Agile method implementations have been identified. The constraints of AM are constantly addressed through the year 2007 to 2012 (until 8th of August 2012), though the papers were extracted merely from an electronic database.

14 of them were case studies of either single or multiple case studies, 11 of them were experience reports, 3 were empirical studies, and the remaining 1 paper is a survey. 38% or 11 papers were affirmed as having large projects or large scale Agile adoptions.

Out of the 29 relevant papers, majority of them or 90% were published in conferences while only three papers (10%) were journals. In this review study, Scrum is found as the most adopted Agile techniques (38%), followed by Agile practices in general (28%). The rest are extreme programming (XP) (2 studies), Lean (1 study), Lean and Agile (1 study), Evo (1 study) and a mixture of several AM (1 study). Having single Scrum adoption as the majority, there are also hybrid implementation of Scrum and XP (1 study), Scrum and User Stories as well as Scrum and Lean (1 study). A new approach in practicing Scrum namely Enterprise Scrum was also developed and exercised (1 study). Our result aligns with several earlier reported studies where at present, Scrum is noted as the most favoured approach among other AM [2,3,17,S2,].

More than half or 55% of the reviewed papers implement Agile in collocated or non-distributed project setting, 21% applied Agile in distributed project environment, 14% of the papers discussed globally distributed Agile projects and the remaining three studies (10%) reported Agile implementation in both environments.

There are five Agile transition cases reported where four of them involve large projects and/or large scale Agile adoptions and four of the five cases as well adopted Scrum [S11,S16,S22,S25]. Besides, an experience report also discussed how the Scrum method has been extended to the executive level to effectively handle large scale Scrum implementation [S10]. The final result of this review compilation exhibits a variety of industry have involved in the Agile adoption other than software such as medical, system engineering, and embedded systems.

4.2 LIMITATION FACTORS

The limitations in the Agile implementation are compiled into several categories. High dependency on people/personnel, organizational dependency, as well as high impact on organizational structure and culture are found as the three factors with highest priority that limiting the Agile implementations in the industry. Here, we are going to highlight the issues identified from the related papers on these three elements.

The most addressed element, people or personnel dependency is divided into four groups. The first one that is found to enforce most barriers to the AM implementation is strong reliance on management. Without management support or having no full support, the agile implementations were either reported as facing greater pain and challenges [S1,S1s] or less effective due to so many problems and difficulties arose [S23], and in the worst case, the implementation was terminated [S11]. In one case, the developers felt insecure and threatened with their Agile adoption status due to suspiciousness after there was a change in key management personnel, lead to work impairment [S9]. While a case study reported successful in the Scrum implementation, strong management support has been gained from the beginning and above that, the company has been practicing Scrum for five years [S13].

On the other hand, a company was clearly reported as failed with lacking in management support as the main cause [S11]. In the case, management approval was raised as fundamental towards AM realization. Developer's with experienced and highly skilled was the second most concentrated factor within the people dependency constraint. Adopting AM, using merely product backlog in place of traditional requirements engineering (RE) practices requires for vast expertise to handle huge gap between the user requirements and coding [S22]. Besides, the lack of documentation [S29], the emphasis on working autonomously (both individually and as a team) through the self-organizing approach [S19], having no design work prior to applying user stories technique for requirements elicitation [S3] and doing things in a speedy way without adequate experience lead to technical debt. Technical debt is a term utilized by Kaiser and Royse [S14] that made use of financial debt as parable to refer to code issues where "when a developer cuts a corner (whether they are implicitly asked to do so or not) it is potentially something that the company will pay for down the road. That is because it will generally cost more (sometimes much more) to resolve it later". All of these conditions were addressed as factors contributing to the favorable of highly skilled and experienced developers or project team in exercising AM. The fact that Agile approaches favors skillful personnel has been acknowledged based on Smith and King [S24] experience report on a project adopted XP method stated that, "a clear benefit was the high level of expertise of candidates that applied for positions throughout the project" [S24].

Subsequent dependency concern was on other personnel such as agile/scrum master and product owner (PO). To start, clear specification of each and everyone's role and tasks for Agile project team is a must according to Jakobsen and Poppendieck [S13] based on their multiple case study findings. In one case, clear blueprint of PO's roles to the extent "how the team collaborated with the PO" has been recognized as a key factor for successful project sprints. Nevertheless, no proper guidelines available for either PO's role and job description, agile/scrum master or other main roles in an Agile project until to-date. At the same time few literatures discussed about PO's role regardless of its clear need [S16]. To conclude, the applications of PO or Agile and Scrum master position in the studied literatures are inconsistent and reported in disappointed ways [S11, S14, S16, S20, S26]. They were either inexperienced, inactive, rarely available, unavailable, or inefficient. So to say, those who want to adopt Agile needs to place extra initiative and effort to carefully design main roles job description based on their project requirements and environment.

Last but not least, Agile practices depend highly on intensive communication with customer as customer collaboration is one of the four core values of Agile methodologies. As a result, when there is a lack of trust on the customer side or the customer is unavailable, relevant information and feedback will be in scarce [S7]. The information shortage issue has been identified also in Korkala and Abrahamsson [S15] report that had caused serious problems due to lack of well-defined customer. In their case of distributed agile project, the customer became intermediate between two remotely located teams but inactively held the responsibility and failed to deliver important information between the two teams. While according to Jakobsen and Poppendieck [S13], "many projects struggling with clarifying features in collaboration with the customer. Clarifications from the customer were late, leading to a decrease in flow, which we know causes schedule and cost overrun". In the case, too much expectation was placed on the customer that exceeds the customer's ability and readiness.

Srinivasan and Lundqvist [S26] reported that inappropriate tool has been used to support Agile processes as it was mandated by the company, given a lot of investment has been made on the tool. Meanwhile organizational restructures have obstructed the communication and collaboration between developers and testers as well as with the QA team (the team felt the lack of support from the QA organization) when they are placed separately from each other [S27]. According to Thomas [S27], organizational boundaries such as enterprise policies that exercise separate team for testing and release activity from the development team made agile technique like Test-Driven Development (TDD) inapplicable [S4]. This kind of policies disallow the adoption of testing process like TDD besides impractical to be incorporated in a short release cycle due to longer time taken for testing activity. "Organizational resistance may be the main barrier to other organizations trying it, because top executives and engineers must be willing to give it a serious try" [S10]. It refers to a Scrum practice extension initiative at the executive level. To truly gain the commitment from the people on the changes brought about by the Agile through its values, the effort must come from the highest organi-

zational level [S1]. It has been concluded by Lalsing et al. [11] where it is imperative that before any organization decides to adopt an AM, it needs to assess whether the company culture, operating structure, business processes and projects are suited for the use of an Agile Project Management Methodology.

To adopt AM, there will be a need for changes not only in the working style but also in the organizational structure and culture whenever necessary. For example, Thomas and Baker [S28] stated that there was "an inherent conflict" between the AM and organization operated under legacy processes, mindsets and cultures. While Middleton and Joyce [S17] pointed out the drawback of Lean methods as might be conflicting with current corporate standards. Among the obstacles specified; "Lean does not work well with targets, milestones, Gantt charts and traffic light reporting methods" (the artifacts/requirements demanded in organization with heavy plan driven process), besides the need for changes in the job roles and responsibility such as the manager being a facilitator [S17] instead of a planner and controller [13]. To conclude, organizational changes are necessary in the Agile adoption process [S11,S20], especially for traditional corporate governance [S28]. Nevertheless, culture and mindset among the people within organization were recognized as the most difficult aspects to change [S25].

4.3 SUMMARY

Firstly, recognized AM limitations from the final 29 relevant papers are compiled and grouped through profound analysis made throughout the SLR study. Meanwhile discoveries and inputs from other literature readings (e.g. [14]) contribute to the refinement of the limitation items. Nonetheless, instead of classifying the limitations based on project sizes (small, medium and big) and/or project types (non-distributed and distributed), they are generally itemized.

Secondly, the two factors; organizational dependency as well as high impact on organizational structure and culture are separated from each other. While organizational dependency refers to constraints posed by the decision at the organizational level, the latter factor signifies the required organizational changes that had imposed strong opposition and challenges. To conclude, these two factors are mutually related and can be associated back to the people factor.

To compare, this pilot SLR finding aligns with several earlier research results on the importance of upper level management high commitment and support for better implementations of AM. For instance, Young and Jordan [18] result on multiple case studies on projects "ranged from complete failure to complete success" shows that top management support (TMS) is the most critical determinant for project success or failure. While Livermore [12] through his worldwide online survey found that, "a number of the factors that impact the implementation of an agile development methodology are completely under the control of management". Lastly, recent study on agile deployment in three companies [15] identified management clear vision and support as very significant and thus provided recommendations for management on effective agile deployment plan.

4.4 LIMITATIONS OF THIS REVIEW

The limitation in the SLR is on the electronic database (e-database) used where only papers in IEEE is reviewed (one e-database only). Therefore, this review study can be regarded as pilot SLR to identify and prioritize the factors limiting Agile implementations in the industry. Since the SLR inclusion criteria is broad; includes case study, empirical study, experience report, survey, and expert opinion of all project types (small, medium and large) in both distributed and non-distributed Agile project management and development, using only one e-database has taken considerable time. This is because the whole SLR process is done by a single reviewer through a profound analysis.

This SLR study as well does not specifically include the obstacles of implementing AM in the distributed projects. The reviewer found that other than technology restrictions, the relevant papers do not distinctly stress the limitations concerning distributed environments. In spite of that, the shortcoming of implementing AM in such project setting is an important and a huge area to be focused on its own.

The equation shown below was used to calculate the error rate. It was required to calculate two measures; the number of error patterns and the total number of patterns, which was used to find the error rate in the improved K-means clustering algorithm and the K-means clustering algorithm in all data sets of this study. In next section, it will be seen that the RER-K-means algorithm reduced the error rate and iteration. In this algorithm, additional operations that have a negative effect on the calculation must be avoided. In all the data sets, the K-means clustering and the RER-K-means algorithms implementation were similar and only the data set name and data set coordinates were changed by the algorithms.

6 Conclusion

From 29 most relevant papers identified in the IEEE database, high dependency on people/personnel was found as the most mentioned factor imposing barriers to the Agile implementations in the industry. People dependency encompasses management, developers, customers, and others such as agile master and product owner. This is followed by organizational dependency as well as high impact on the organizational structure and culture as the second and third limitation factor. The SLR demonstrates that the first three limitations with highest frequencies are mainly originated from the people factor where management plays the most important role. While the rest of the limitations exhibit that most of them can be strongly associated back to the people factor (management), they are not highlighted in this paper.

If compared to the Agile principles illustrated in the Agile Manifesto [7], elements such as people dependency and heavy reliance on communication are clearly mentio-

ned and therefore should be mostly expected. To conclude, clear relations between the SLR findings and the Agile principles stated in the Agile Manifesto could be identified. High dependency on people that is supposed to be vastly anticipated during the Agile adoption became the most addressed factor that bring limitations to the Agile adoption and implementation in the industry.

In spite of apparent emphasis on people critical function stated in the Agile principles, plus the excellent rules in the gist of the principles, the problem still arose when it comes to the implementation part. Therefore, future research is to construct a set of guidelines to tackle the identified issue of "lacking in specific guidelines in the practical application of AM" as an approach in preparing the top/senior management with proper direction (on their actual role) in managing people in the practical implementation of AM (aligns with Agile principles).

Received 1 March 2014, www.cmnt.lv

Abstract

Recently a vast amount of geographic information system (GIS) data make road networks around the world as polylines with attributes. In this form, the data are insufficient for applications such as simulation and 3D visualization—tools which will grow in power and demand as sensor data become more pervasive and as governments try to optimize their existing physical infrastructure. With the increased dissemination and computing power of mobile devices, it is now possible to execute distributed artificial intelligence applications for various situations: intelligent routing using algorithms, planning, is tribute optimization of traffic lights. This paper reports on our development of a GIS-based traffic network analysis system, named GIS-based Transport Decision Support System, which provides a graphical analysis platform to transportation planners and researchers for transportation network analysis. The system has the functions of designing traffic networks on digital maps and doing traffic equilibrium analysis, as well as a novel function to integrate local detailed structures of intersections into global networks. The latter is particularly useful for the analysis of large traffic network where the detailed local network structures of some intersections have to be taken into account. The system links great volumes of traffic data and geography information data accumulated for visualization traffic analysis. We added information data on the following: road structure data, zone geography information data and node geography information data. The system also enabled us to extract traffic data by road section and by specific condition.

Keywords: K-means, clustering algorithm, error rate, iteration, reduction, stable

1 Introduction

Traffic simulation describes large numbers of vehicles on a traffic network by taking advantage of the reduced dimensionality typically found on road networks: vehicles follow roads and their motion can be described with few degrees of freedom. Research on techniques for traffic simulation has been carried out since the 1950s; see the survey of Helbing for a good overview of the field. Traffic is an integral component of any virtual environment that attempts to realistically portray the contemporary world, be it a video game, movie, or virtual globe. Traffic is also a global challenge with a direct impact on the economy, energy consumption, and the environment in today's society. Traffic simulation is a key tool to address both the challenges of traffic and its visualization. However, traffic simulation takes place on a complex domain and realistic road networks. The main objective of this work is to create road network representations from polyline data that can be used directly for real-time traffic simulation and visualization in a virtual world.

Traffic simulation presents unique challenges in the acquisition and representation of the underlying simulation domain, namely, the road network. Digital representations of real-world road networks are commonly available, but the level of detail of these data is not immediately usable for many queries related to traffic simulation. Traffic simulations take place on a network of lanes. This network needs to be represented with all its details, including the number of lanes on a road, intersections, merging zones, and ramps.

Optimizing vehicle routes in the context of current road congestions can reduce fuel consumption and transportation time. Maximizing the load of each vehicle in a transport company depending on route, will reduce the amount of trips per goods. Giving the driver information about Point of Interests (POI), such as safe parking spots or resting places, reduces the down time having to search for them manually. Online simulation of trafic can assist existing route guidance systems by predicting problems such as congestion. Accurate predictions require accurate status information about vehicles – the fact that vehicles are distributed over large-scale road infrastructure makes this particularly challenging.

A fundamental problem in transportation network planning and traffic engineering is the evaluation of the impacts of a design plan or some management policy on the distribution of traffic flow on the network, which is solved by the equilibrium network analysis method. The essence of equilibrium network analysis is the consideration of the influence of traffic volumes on travel times, and consequently on route choices of travellers, which then reversely change traffic volumes. There have been developed several software packages in which the equilibrium network analysis algorithms are implemented.

This work entails numerous scientific challenges. First, constructing the intersection, ramp, and road geometries presents numerous special and degenerate cases, typical of geometric computation. Our method is speci-

* ***Corresponding author's*** e-mail: jiandazhusz@163.com

fically designed to automatically handle as many of these cases as possible. Second, GIS data of road networks are not intended to be used for simulation. We reformulate these networks in order to extrapolate a network on which simulation can be done. Third, the data as available require filtering in order to be processed; while this is not the main focus of our work, it is a challenge that we have addressed in this paper. Fourth, these networks are large in scale, and so efficient algorithms and implementations are required. Fifth, the scale of the implementation itself is a challenge as this project is a combination of multiple systems, a road network importer, a road network representation, a simulation system, and a visualization system. Finally, there are algorithmic challenges in capturing details such as over-passes and in defining arc roads, which further address the needs of traffic simulation.

The idea in this study is to consider active vehicles in the traffic as agents, which send traffic reports to a centralized server via wireless internet. A centralized server behaves as an agent which collects data from vehicle agents and estimates average traffic flow speed for each road piece on the map. The vehicles are able to retrieve real-time traffic flow speed of a specific set of road pieces when they wish to plan a route between two points. The purpose of the study is to investigate if route planning based on real-time data is more effective and efficient than route planning based on static and statistical traffic data.

2 Related works

While digital road networks are widely available, the amount of detail varies widely across sources. Data for North America and Europe are freely available from the US Census Bureau's TIGER/Line database [4] and "crowd-sourced" community projects like OpenStreetMaps [5], but these data sets contain polyline roads with minimal attributes–information about lanes and intersection structure is wholly missing. Commercially available data sets, such as those provided by NAVTEQ [6], often contain some further attributes, such as the lane arrangements at intersections, but they are expensive to obtain, the techniques used are not known, and they do not capture all of the desired detail.

Numerous methods have been proposed for automatic and semiautomatic GIS road extraction from aerial and satellite images. Extensive surveys include [7-9]. These methods are complementary to our work: the GIS network we assume as input could be the product of a satellite image extraction method.

Procedural modelling of cities and roads has been an active area of research interest in computer graphics. For example, recent work in [10,11], among a notable body of investigation, has enabled the generation of detailed, realistic urban layouts, and roads for visualization. Commercial procedural city modelling software is also available. For example, consider the intersection geometry generated by CityEngine. Here, the intersection is modelled as a square connected to neighbouring rectangles with narrow triangles. In our work, we construct the geometry for every lane, not just the roads; the lane connections are C1 continuous, and the geometry defines all the needed parameters for vehicle animation, including orientation and steering angle.

Numerous spatial representations of curves have been developed over the years – see the comprehensive books by Farin [13] and Cohen et al. [14]. However, road networks and traffic behaviour have specific requirements: existing curve representations are not the best suited for modelling road networks to support real-time traffic simulations. For example, the popular NURBS formulation [15], despite of its generality of representations, is costly in space and efficiency. In particular, many splines do not readily admit arc-length parameterizations: those must be obtained using relatively expensive numerical integration techniques for establishing vehicle positions and for describing quantities of vehicles on each lane in traffic simulators. Willemsen et al. [16] describe ribbon networks, specifically discussing the need for "fattened" splines to describe road shapes, and our technique is potentially complimentary to the modelling technique for road networks they present. How-ever, they use the representation of Wang et al. [17], which is only approximately arc length parameterized and requires iterative techniques for evaluation. In contrast, our method only needs a simpler and much cheaper direct evaluation. Van den Berg and Overmars [18] proposed a model of road maps for robot motion planning using connected clothed curves. However, their choice of representation is based solely on the need to generate vehicle motion. For both traffic visualization and simulation, the representation must also be suitable for the generation of road surfaces, which are not necessarily clothed curves. Additionally, clothed curves are expensive to compute–requiring the evaluation of Fresnel integrals–whereas our method relies solely on coordinate frames, sins, and cosines. Nieuwenhuisen et al. [19] use circular arcs, as we do, to represent curves, but these arcs are used to smooth the corners of road maps for motion planning as in [18]. Furthermore, neither of these techniques have been investigated for the case of extracting ribbon-like surfaces, as we do, nor is there an established technique for fitting them to multisegment, no planar polylines.

3 The proposed method

3.1 PRELIMINARIES

The common formulations for traffic simulation are lane-based. These lanes are treated as queues of cars, represented either as discrete agents or by continuous density values. For traffic simulation, lane geometry is irrelevant as long as speed limits and distances are available. However, geometry matters for visualization and for localizing data, such as cell phone or GPS transmissions sent to inform about traffic conditions. These lanes are connected in various ways to form a road network, and cars traverse these connected lanes by crossing intersections and merging between adjacent lanes. The principle requirement for simulation is the creation of this network of lanes. This includes the division of roads into lanes, but also the creation of transient "virtual" lanes within

intersections: these virtual lanes exist only during specific states of a traffic signal. The creation of the network of lanes also entails determining the topological relationships be-tween lanes (so that vehicles can change lanes and take on-and off-ramps) and making geometric modifications to the road network to allow the construction of 2D or 3D road geometry.

To efficiently support traffic simulation, there are a number of queries the network needs to be able to answer in a computationally efficient manner. The nature of these queries depends on the simulation technique (i.e., whether the technique is continuum-based or discrete). Additionally, it is desirable that the road network representation abstracts away the details of the queries on the road network to maintain clear separation and software modularity between the traffic simulation and the road network.

3.2 GIS DATA FILTERING

We filter the GIS data we use to remove the most commonly occurring errors. These changes are not meant to change the underlying geometry or topology of the network, only to correct sloppy data creation. The first filter removes points that are coincident, where is a distance argument that is kept on the order of feet. This is done prior to the splitting and joining algorithms, while the remaining filters are applied afterward. The second filter removes collinear points within roads. The third filter ensures that no point added to a road causes it to turn too sharply or double back on itself. This filter calculates the offset, as in Figure 1, that would be required for a circle of minimum turning radius to be inscribed within the polyline segments. If this offset is greater than half the length of either segment, the node is not added. This ensures that when a point is added to the road, the road still satisfies the kinematic constraints of a typical car. Further filtering includes ensuring that one way roads are defined in the correct direction and that roads have been assigned the correct classification.

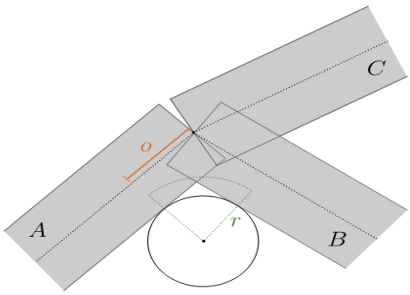

FIGURE 1 A simple intersection with three roads

3.3 THE PROPOSED COMPONENTS

We have implemented the Traffic Map Editor (TME), as a traffic simulator in Java in which infrastructures can be edited easily by using the mouse, and different levels of road usage can be simulated. A large number of fixed and dynamic traffic light controllers have already been tested in the simulator and the resulting average waiting times of cars have been plotted and compared. We will speak about dynamic traffic lights system as the adaptability component of the solution.

1) Application Architecture: Traffic Map Editor (TME) has been divided in several main components that describe the features that come together with the application. The architecture allows developers to not only build on top of TME but also allows them to enrich core features by adding new (or even replace) plug-ins. To the core of the application have been attached several important components as: db, editor, exporter, importer, network view, visualizer, simulation statistic or TmeEventServer.

2) Traffic Data: Traffic data that is aimed to be shared between agents is the speed of the vehicles moving along road segments and average speed of unique road segments. Vehicle agents request traffic data from the server agent by sending a list of road identifiers. Server agent's response to these requests contains the calculated average flow speed of the requested road segments. The reports that vehicle agents send to the server agent contain the momentary movement speed of the vehicle and the unique id of the road segment on which the vehicle is moving. These reports also contain the reporting time and the exact coordinates of the vehicle at that moment. These reports are received by the server agent and the average flow speeds of road segments are calculated.

In our development of GIS-TDSS for traffic road network mapping applications, objectives on geographic processing providing operations for processing or transforming data in a manner determined by user specified data. Through the system, we are able to integrate with other new traffic analysis model, this including road information, data management, and traffic model execution and management. Figure 2 shows the structure of our development of GIS-TDSS system.

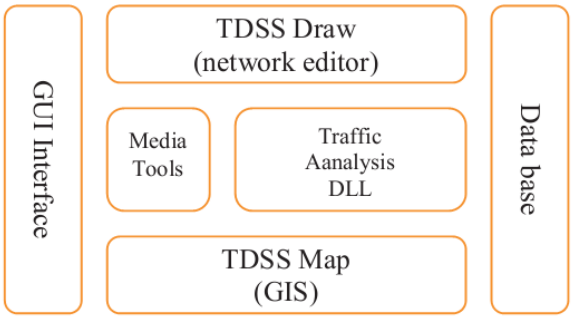

FIGURE 2 Structure of GIS-TDSS system

Similar to other GIS software, geographic information in our development is organized into 6 groups as follows: GUI system, database system, TDSS Map, TDSS Draw, media information tool and traffic network analysis algorithm DLL (Dynamic link library) files. GUI is the basic function group in a graphic interface built using Microsoft GDI (Graphics Device Interface). TDSS Map is the core module for processing digital map.

TDSS Draw is the module for network drawing and editing. The media tools module provides tools for sto-

ring various kind of regional multimedia information, e.g., traffic video at important intersections. The traffic network analysis algorithm DLL is the dynamic link library of network analysis programs. GIS-TDSS uses conventional layer models for storing and editing information. The topological relation between a global network and a local network is described in the data table for the local network data, detailed structure of this is described in the following section.

3.4 DATA STRUCTURE

The characteristics of the geospatial data set are changing. First and foremost, in order to meet users demands effectively, the capacity for the real-time collection, synthesis and access must exist; data import and export is essential. The data should be seamless, without artificial boundaries, and linked to attributes table that has become critical to many applications, for example, traffic flow management, road of disaster, and flood and earthquake traffic.

The GIS-TDSS system project file consists of a workspaces file, multiple geometric files, multiple relational data tables and multiple attribute data tables. The map file is a direct access, variable-record-length file in which each record describes a shape with a list of its vertices. In the index file, each record contains the offset of the corresponding main file record from the beginning of the main file. The data table contains feature attributes with one record per feature. The one-to-one relationship between geometry and attributes is based on record number. Attribute records in the data file must be in the same order as records in the main file. Figure 3 shows the data file structure of GIS-TDSS system and data file flow.

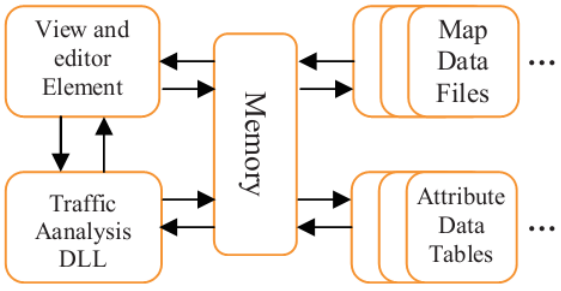

FIGURE 3 Data file structure of GIS-TDSS system

We propose new concepts for the GIS-DSS system: seamless operation of a detailed local network into a global network. As mentioned in the Introduction section, the integration of a detailed local network for an intersection into a global network is necessary to improve traffic analysis accuracy without involving too large a computational burden.

In the general structure of GIS (9), spatial data can be divided into three groups: 1) geometric data – data for describing space characteristics of spatial data, also known as location data, positioning data; 2) attribute data – data for describing attributes of spatial data such as type, grade, name, status, and so on; 3) relational data – data for describing topological relationship between spatial data. These three data groups are stored in separate tables in conventional GIS. In this study, the geometric data and relational data are placed in a unified data management table. In the following an example is given to illustrate our method.

The module for implementing the above data modification in the GIS-TDSS is shown in Figure 4.

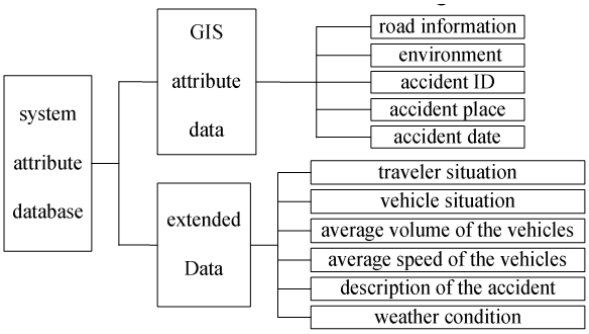

FIGURE 4 Attribute data organization chart of the traffic

The layer manager extracts data from data file in accordance with the requirements of the system, forms a graphic layer with the data of the geometric table, and then loads the required layer attribute data, and loads them into memory to output the required layer. The data manager controls the definition and value assignment of the structure and metadata in the layer-refining table, defines the geometric shapes in network, extracts data, etc.

3.5 DATA PROCESSING

Geographic entities are organized by layers in spatial database, mainly including point, line, and area entity. Geographic entities of map are called graphic element which are display as Feature object. Each geographic entity has its own attribute and is stored in attribute list in the form of one record. Entities with similar attributes or functions are stored in the same layer when needed in practical application. Each layer corresponds with one attribute list, to realize operation and inquiry of attributes of graphic element.

Actually, in the traffic information management and promulgating system based on GIS, the spatial database which storing and managing various spatial information and attribute data of graphic element is a map file of MapInfo in the system, including spatial database of non-related data structure with spatial information and attribute database with related data structure. The files or updated ones can be downloaded when running the GIS viewer. Spatial data mainly include point, line, area entity such as urban road network, urban terrain, traffic facility map, administrative regionalization, road transect and vertical section. Spatial data on the road map are collected and input by electronic map or engineering drawing of AutoCAD format. Then the data are edited and processed by MapInfo. At last, basic layers are integrated by Geoset Manager, in order to link and operate.

4 Experiments

Traffic attribute data in GIS attribute list are applied to inquire and analyse basic information about road traffic by users, not including parameters of traffic flow and all the information of traffic accidents, while they are stored in extended database and defined according to data list field. Entity attribute list of traffic flow and accident is formed by part of extended data list field. Traffic reference point data are from writing and electronic data related to traffic police department, which are processed by manual inputting, scanning, and format changing and so on. At last, the data are inputted into SQL Server 2000 database. The data collected from section detector through the analysis and decision-making module processing, the necessary flow, with an average speed of traffic flow parameters and other important information are archived, stored in SQL Server2000 database, which provide basic data for the future transport planning and road design and transportation research.

Spatial data are the basic loaders to indicate, query, analyse space and construct road network. Since the range of urban road network is large, traffic information is refreshed at any time. The spatial data of different traffic information in road network are on adjusting, which need to maintain and refresh spatial data frequently, in order to ensure integrity, accuracy, and validity of spatial data. Attribute data are stored in a list in the form of database, usually extended database. There are many alternatives here and relation database is often chosen, such as SQL Server, Oracle, Sybase, Access, dBase, Paradox, and so on. Generally, SQL Server and Oracle are used to develop large-scale database, Access and dBase are used to develop medium and small-scale database. The attribute and spatial data are linked by data index mechanism in GIS. Graphs and characters can be checked quickly with each other too. Data index mechanism is a method associating spatial objects with attribute data.

1) When we query spatial information from the attribute information, in the first the corresponding database records should be found in the attribute data file, such as the number N record. You can find the Nth pointer in the cross-index file, the pointer is pointing to a map of an object which is the spatial objects correspond with the database records.

2) When we query attribute information from the spatial information, if you have found a space object from the map, the system read out its spatial information and the corresponding database record number from the spatial data file, according to a database record number, the attribute information of the map object could be query in the attribute database. History data records of traffic information are stored in extended database, which should also be connected with processing module of extended detectors. Besides, there should be index linking attribute data of graphic elements. Related database can be realized on this point.

Suppose that we are interested in the traffic flow crossing a special intersection indicated in the map. For this the detailed network for the intersection is integrated into the global city road network. Due to space restriction, the detailed data for the parameters of the network are omitted here.

Step 1: The Conventional equilibrium analysis result of the common transport network, and the part surrounded by the dotted line. We can find out the traffic volume of the four links (two-way) connected to node intersection.

Step 2: The node intersection is set to be a common intersection (local detailed network), so that new twelve links at the intersection can be inserted into data table and the start point or the end point of four links connected to the node intersection can be revised.

Step 3: A further calculation on the new network obtained in Step 2 is taken to get the new equilibrium analysis results. The traffic volume change on links connected to node happened.

For detailed analysis of the intersection denoted as node Intersection in the network, Intersection is expanded as a local detailed network with twelve new links. It can be seen that some of the traffic volumes have turned onto other links due to the delay impact of the intersection.

Two alternative evaluation procedures were used in testing the accuracy of the road traffic noise prediction model developed in this study. First, grouped data were collected from 85 locations near road segments where sound propagation was not interrupted by barriers. Second, an additional set of grouped data were collected from 148 reception points within housing estates in Beijing, where the noise environment was believed to be much closer to real conditions. Results of these two data collection procedures are presented in Figures 5 and 6.

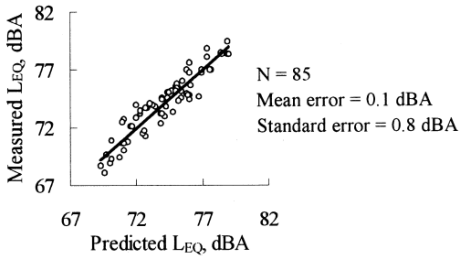

FIGURE 5 Evaluation of accuracy of model by field data

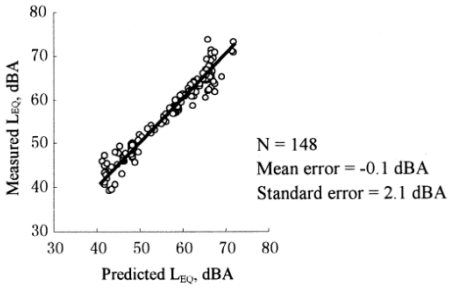

FIGURE 6 Evaluation of accuracy of model.

Evaluation of the modelled results indicates that noise prediction is more accurate at locations closer to the road carriage way where the environment of sound propagation is less complex. The model has an accuracy of 0.8

dBA for traffic noise prediction at locations nearer the road, and was accurate to 2.1 dBA for locations within the housing estate. Further, there were no systematic errors in the prediction results observed for either set of conditions. The accuracy in predictive results of the adjusted model for China is comparable to those of the FHWA model, whose predictive accuracy is 2.0 dBA.

5 Conclusions

We have presented a method for transforming GIS data into a topological and geometric representation suitable for use in traffic simulation. Our geometric representation of roads is visually smooth, including at ramps and intersections. Our method preserves the topological relationships of the GIS road network. We have shown examples of GIS data that have been processed by our method and composed with satellite images. These figures illustrate features of the road networks generated by our method, such as intersection handling and highway ramps, as well as the extensive scale of models that our method can process within a matter of few seconds.

Abstract

Financial management are derived for the profitability analyses of demand-side management (DSM) alternatives. The present value of cost and equivalent uniform annual cost models are selected to determine the least-cost solution, while the net present value, pay back year and benefit/cost ratio models are proposed for the execution of cost–benefit analyses. In a market economy, Market orientation is the only correct choice for economic development strategy, so it is also significant for financial management innovation. While most studies in the past decade focused on the consequences of fund in financial management, few have investigated antecedents to market orientation concept. This paper derives two fuzzy financial profitability models, namely, a least cost solution model and a cost-benefit analysis model, to evaluate the fuzzy financial profitability of load management alternatives. A straightforward vertex parameters' fuzzy mathematics operation using the function principle is de-rived as an alternative to the traditional extension principle and is applied to evaluate a number of different financial decision indexes. The developed models represent readily implemented possibility analysis tools for use in the arena of uncertain financial decision-making.

Keywords: financial management, decision making, finance decision making, big data

1 Introduction

Financial management includes the functions of activities for solution to enterprise funds, costs, capital structure, cash flow, financial risk control, etc. As the innovation of financial in management level, Financial management innovation is the re-combination of elements of financial management to adapt to environmental change, then thereby remodelling and the establishment of their own financial capability. Market orientation has received much attention for its apparent positive effect on organizational performance. In a market economy, Market orientation is the only correct choice for economic development strategy, and the poor or rich of natural resources is the second. Because financial activities are the lifeline of business operations and financial management innovation is an important part of business innovation, so Market orientation is also significant for financial management innovation.

With the advances of information communication technologies, it is critical to improve the efficiency and accuracy of modern data processing techniques. The past decade has witnessed the tremendous technical advances in Sensor Networks, Internet/Web of Things, Cloud Computing, Mobile/Embedded Computing, Spatial/Temporal Data Processing, and Big Data, and these technologies have provided new opportunities and solutions to data processing techniques. Big data is an emerging paradigm applied to datasets whose size is beyond the ability of commonly used software tools to capture, manage, and process the data within a tolerable elapsed time. Such datasets are often from various sources (Variety) yet unstructured such as social media, sensors, scientific applications, surveillance, video and image archives, Internet texts and documents, Internet search indexing, medical records, business transactions and web logs; and are of large size (Volume) with fast data in/out (Velocity). More importantly, big data has to be of high value (Value) and establish trust in it for business decision making (Veracity). Various technologies are being discussed to support the handling of big data such as massively parallel processing databases, scalable storage systems, cloud computing platforms, and MapReduce. Big data is more than simply a matter of size; it is an opportunity to find insights in new and emerging types of data and content, to make business more agile, and to answer questions that were previously considered beyond our reach.

Strategic financial planning, or strategic planning for short, is a common way for organizations to plan to achieve their long-term financial objectives by focusing on where best to invest and allocate resources. Typically, strategic planning starts by establishing a baseline of performance and setting up goals over the planning horizon, including financial objectives. A strategic plan is then developed to map out the path to achieving these goals, along with indicators to track and measure per-

[*] ***Corresponding author's*** e-mail: tinghao_tju@126.com

formance with respect to the plan. While there is extensive agreement among business leaders that strategic planning is essential to enabling the continued success of a company, there are differences in the approaches used. Most of these, at least implicitly, acknowledge the uncertainties associated with the future as well as the existence of risks that may interfere with achieving the planned objectives. However, these approaches have proven not to be effective in reflecting and managing strategic risks. In fact, a recent study finds that over 80% of all cases of significant value loss among Top 1000 companies over the last 10 years are attributable to failure to adequately recognize and manage strategic risks.

Conventional fuzzy mathematical operations using the extension principle are applicable only to normalized fuzzy numbers. However, generalized fuzzy numbers (i.e., normalized and non-normalized fuzzy numbers) have the advantage that the degrees of confidence of a decision-makers' opinions can be rep-resented by their heights. Moreover, fuzzy mathematical operations using the extension principle change the membership function type of the fuzzy number following mathematical manipulation and involve complex and laborious mathematical operations. Accordingly, Chen proposed the function principle, which can be used to perform fuzzy mathematical operations on generalized fuzzy numbers. The authors pointed out that the fuzzy mathematical operations preserve the membership function type of the fuzzy number following mathematical manipulation and reduce the complexity and tediousness of the mathematical operations. Consequently, the present paper develops an easily implemented and conceptually straightforward vertexes operation using the function principle for application to fuzzy mathematics. The developed fuzzy mathematics operations are then applied to evaluate fuzzy financial indexes as part of a decision-making process. The proposed financial decision analysis method is more flexible and more intelligent than other methods since it takes the degree of confidence of the decision-makers' opinions into account.

Following the manipulation of fuzzy financial functions by fuzzy mathematics, the task of comparing or ranking the resultant fuzzy numbers can invoke a further problem since fuzzy numbers do not always yield a totally ordered set in the same way that crisp numbers do. Many authors have investigated the use of different fuzzy set ranking methods. These methods have been reviewed and compared. However, the majority of previous studies focused on the ranking of normalized fuzzy numbers, while relatively few considered the case of non-normalized fuzzy numbers. In this paper, a geometric moment model is derived to rank generalized fuzzy numbers based on the probability measure of fuzzy events. The geometric moments of a fuzzy number comprise the domain moment sand the grade moments.

2 Related works

Over the years, scholars has different opinions and views of what is Market orientation. After years of debates, at present, there are two points of view of Market orientation was generally accepted by marketing strategy literatures: Market orientation concept of culture and behavior. In the two views, formed different definitions and division of content of the Market orientation. Several scholars describe the marketing concept as a form of organizational culture. Deshpande&Webster [1-3] put forward a Market orientation is a kind of organizational culture, which could have the efficiency and effectiveness of the creation of the necessary acts and create outstanding customer value. Narver and Slater [4-6] further defined Market orientation in terms of culture and related it to the fundamental characteristics of the organization, although they asserted. That it is the organization culture that most effectively creates the necessary behaviors for creating superior value for buyers, and thus, continuous superior performance for the business. And it is characterized by:

l) Aim to profit and excellent customer value, whereas taking into account other interests of stakeholders;

2) To provide the behavior of organizational development and reflecting market information.

MO in their structure included elements of the three acts: customer orientation, competitor orientation and intersectoral collaboration, and there have two decision-making criteria: long-term perspective and attention to profits. As two of the components of Market orientation, customer orientation focuses on "the sufficient understanding of one's target buyers," whereas competitor orientation emphasizes the understanding of "the short-term strengths and weaknesses and long-term capabilities and strategies of both the key current and potential competitors" [7-9]. Further, customer and competitive orientations are two primary means that firms employ to interact with environments [10]. Behavior perspective of Market orientation Kohli and Jaworski [11] use the term Market orientation to describe organizational behaviors and activities that manifest the adoption of the marketing concept philosophy. Different from Culture Perspective of MO, Behavior Perspective is more focused on the study of specific behaviors related of MO [12]. Kohli and Jaworski [13-15] define market-oriented behaviors (MOBs) is in terms of three behavioral processes, namely the generation and dissemination of, and responsiveness to, market intelligence [16]. Concepted in the conduct of information infrastructure point of view, evolved several other acts of behavior perspective of MO.

The cash-flow models applied in many financial decision-making problems often involve some degree of uncertainty. In the case of deficient data, most decision-makers tend to rely on an expert's knowledge of financial information when carrying out their financial modelling

activities. Since the nature of this knowledge often tends to be vague rather than random, Dr. Zadehi introduced fuzzy set theory, which aimed to rationalise the uncertainty caused by vagueness or imprecision. However, practical applications of fuzzy set theory in the profitability arena require two laborious tasks, namely fuzzy mathematical operations and the comparison or ranking of the resultant complex fuzzy numbers. Fuzzy mathematics is based on the extended principles presented in [17], in which the traditional addition, subtraction, multiplication, division, power, logarithmic and exponent mathematical operations are applied to fuzzy numbers. Dubois and Prade [18] demonstrated that, when performing the binary manipulation of fuzzy numbers, the resultant increasing (decreasing) part arose from binary operations on the non-decreasing (non-increasing) parts of the two fuzzy numbers. The extended operations ensured that the resultant fuzzy number continuously maintained its fuzzy properties during the arithmetic operating procedure. It is found that fuzzy mathematics tends to be cumbersome for even the m or e straightforward operations such as addition and subtraction. Unfortunately, financial and engineering applications involving fuzzy sets typically require the more complex nonlinear mathematical operations such as product, division, power and logarithmic manipulations [19]. In some cases, fuzzy operations of this type may require an insurmountable computational effort. Consequently, it has been proposed that approximated triangular fuzzy numbers be used to examine the resultant fuzzy profitability indexes [20].

3 Methodology and analysis

3.1 MARKET ORIENTED FINANCIAL MANAGEMENT

The goal of financial management is to maximize stakeholder's value. In broader terms, business stakeholders include shareholders, creditors, and employees, suppliers, senders, the Government and the public. Because multiple targets will draw away financial manager's attention and not been as an action standard, selection the part of stakeholders in many stakeholders and maximizing their value is essential to the target of financial management. According with the foregoing summary, Culture Perspective of MO consider that Market orientation is an organizational culture containing behavior elements. Its characteristic is that let create profit and superior customer value as the supreme principle, while taking into account the interests of other stakeholders. This orientation point out the new standards to ensure financial management objectives.

In accordance with the time the methods of financial management including the operating methods of asset management, cost management, investment and financial management, income distribution methods, can be divided into financial decision-making and budgeting, financial control, financial analysis. As the traditional financial sector usually directly faces to the capital market but not to the product market, therefore, in terms of cost control, investment and financing management and distribution of income, the financial sector obtain corresponding data from the enterprise but not the market to carry out the management activities.

Market orientation has a greater impact on the use of financial management methods in enterprises. Under Market orientation, it requires the financial sector to face directly the product market and capital market at the same time, and access to product market information and capital market information related with financial management, to analysis customer and competitor, let financial activities directly linked to customer value.

Actions of decision-making, budgeting, control and analysis of financial management need to obtain a variety of financial information, including internal and external financial information, and the macro-and micro-financial information. To deal with the financial information cannot be separated from the market. Behavior Perspective of Market orientation hold that MO is the implementation of marketing concepts, as generation, dissemination of and response to market intelligence to the main line. Behavior Perspective of Market orientation can conduct the behavior criterion for financial work and market information response. This behavior criterion requires not only dealing with information on the capital market, but also carrying out customer orientation and competitor orientation to collect information on customers and competitors. In order to fully understand the needs of current and future customers, and competitors strengths, weaknesses and trends, coordinate financial sector functions with other internal departments in the financial management of enterprises, so as to give best to create more customer value than competitors offer, and then come true the purpose of maximizing customer value.

3.2 FINANCIAL MANAGEMENT BASED DECISION MAKING

The value creation mechanism and management of logistics financial management of supply chain system as shown in Figure 1. The external influence factors of the value creation of logistics financial management of supply chain system are macroeconomic environment, market environment, supply chain length and related parties factors, etc. The logistics financial management value of supply chain system mainly influenced by the supply chain cost and profit. The supply chain system value chain contains suppliers, manufacturers, distributors, final customers, reverse logistics and their respective logistics financial management elements such as technology infrastructure investment, financing costs, warehousing costs, supply chain optimization cost, customer service cost, reverse logistics cost, logistics transport cost, etc., respectively constitutes the subsystem's logistics financial management

structure of a supply chain system. Logistics financial management of supply chain system through use of logistics financial planning, organizing, control and other methods. Effect on the role of capital flow, logistics, information flow, and obtain a corresponding logistics financial management performance, optimize suppliers, manufacturers and distributors of their respective logistics financial management activities, so as to create the overall value of logistics financial management of supply chain system.

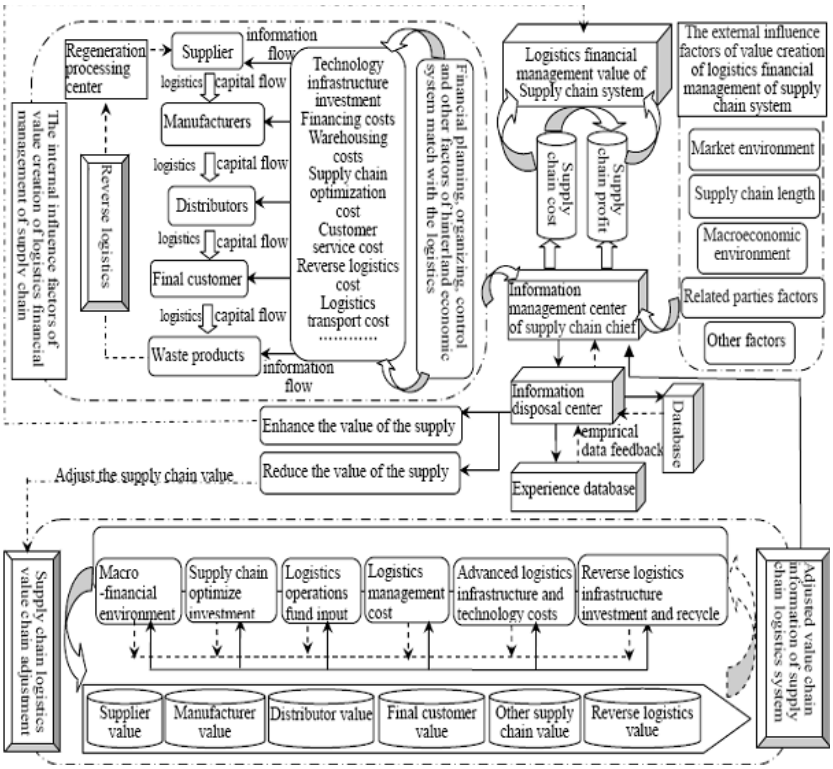

FIGURE 1 Logistics financial management

The status and data of the subsystems of the logistics financial management of supply chain system are changing constantly, and it can collect, dispose and feedback data depending on the information management center, information disposal center, data base and experience data base that built by the chief of supply chain. The advance or reduction of the value of logistics financial management of supply chain system can be measured through making the best of the data proposal function of information management center, receiving the input of information data from every process of supply chain and internal and external environment. The value chain of logistics financial management of supply chain will make adjustment according to the feedback received from information disposal center. Feed back to information management center of the chief, and hammer at the adjustment and improvement of logistics financial management during every part of value chain of logistics financial management of supply chain, so that the systematic value creation level of financial management is improved. As a result every aspect that affects the value improvement of logistics financial management of supply chain shapes the feedback loop of value creation mechanism and management.

Value chain is the process of value increase through the production of final products or services inside and between manufacturers. It covers all phases experienced by the commodities or services in the creation process from raw materials to final consumer goods. Logistics financial management of supply chain can achieve value maximum of the subsystem of every parts through value chain management, increasing combined running efficiency, in order to get competitive advantages through the improvement of market reaction speed, and the value creation efficiency of systematic logistics financial management will be improved finally. During the value chain of logistics financial management of supply chain, every logistics point of suppliers, manufacturers, distributors, final customers, reverse logistics and other stakeholders will be affected by macroscopic financial environment. Supply chain optimize investment, logistic operation fund input, logistic operation management cost, logistic technical investment, and reverse logistic infrastructure investment and recycle, and so forth, so that the efficiency of financial management and even the value creation efficiency of logistics financial management of supply chain will be affected.

3.3 LOGISTICS FINANCIAL MANAGEMENT MECHANISM

Macroscopic financial influencing factors: value creation of logistics financial management of supply chain can be influenced by macroscopic financial environment, and the main influencing factors include unemployment rate, market rate of interest, inflation rate, exchange rate and

international balance of payment, and so on. It is positive correlation with target variable.

Supply chain optimization: the value variable of supply chain optimization is mainly the increase or decrease of logistics points, making the currency of logistics reduced in supply chain system, logistics cost decreased, logistics points more reasonable, and supply chain more smooth. At present, the important problems of supply chain optimization are selecting suppliers, transfer warehouse and distributions, building proper inventory, establishing supplies related to the uncertainty of market demands, and fully displaying storage worth of supply chain. It is also possible to use logistics storage financing of supply chain to avoid financial deposit. Logistics storage financing is supply chain financing points using the document of title to get loan from business bank. Storage logistics finance can be third-party warrantor, avoiding financial risks efficiently, and also can accommodate logistics capital flows to blow up systematic logistics quantity and efficiently use long-standing inventory. Logistics finance/storage financing is one of the approaches of supply chain optimization, positive correlated to target variable.

Logistics operation fund input: under the influence of demand and supply of logistics finance, supply chain forms comparative condition of supply and demand of logistics fund and cost of supply chain. The comparative condition may be that the supply of logistics fund fulfils the demand of logistics fund, reaching the balance, so that the logistics of supply chain runs smoothly. Therefore, this variable is correlated positively to target variable in system.

Logistics operation management cost: relating to the manufacturing cost and quantity during logistics system of supply chain in ports-hinterland, including material cost, transportation, load and unload, transit, inventory, package, process, dispatching, wages and tax and interest and so on. It is correlated negatively to target variable. Backward status of logistics infrastructure and technology: it is necessary to increase investment to keep the advancement of logistics technical infrastructure of supply chain, and it is also good to improve logistics finance management value of supply chain through enhancing technology and consummating infrastructure.

While backward logistics infrastructure and technology block the logistics finance management value of supply chain, mainly incarnating at the aspects of transportation technology, load and unload technology, inventory technology, package technology, containerization technology and logistics information technology and so forth. It is correlated negatively to target variable. Reverse logistics infrastructure investment and recycle value: as a result of the pressure of living environment and law and regulations, and the drive of economic benefit, the reverse logistics is getting more and more attention. It contains reverse logistics in manufacture, reverse logistics in distribution, reverse logistics after distribution, customer B2B business reverse logistics, reverse logistics of customer service, and reverse logistics after use. The investment and recycle value of reverse logistics can improve supply chain value. Almost every parts of supply chain will come down to reverse logistics. So it is correlated positively to target variable

4 Case study

The fuzzy financial decision-making procedures are described briefly. First, the estimated input parameters, such as interest rate, inflation rate, investment, and operating revenue and/or cost, which are needed in financial index calculation, should be provided by the expert in form of fuzzy numbers. The fuzzy financial decision indexes are then calculated according to the models developed in Section III. The fuzzy financial decision is made finally according to the relative ranking of the resultant fuzzy financial indexes, which is performed following the process described in Figure 2.

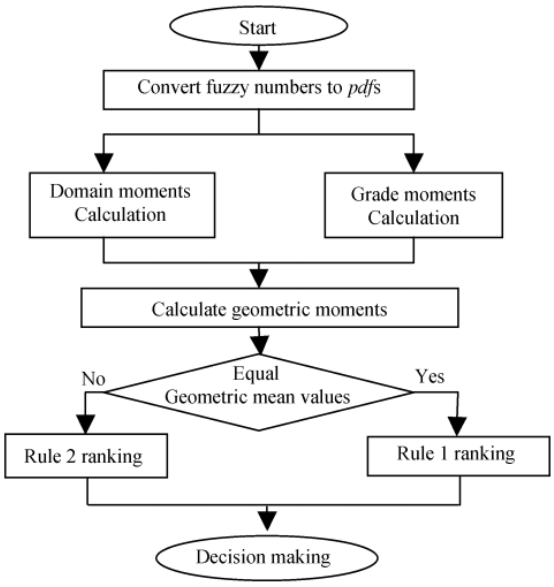

FIGURE 2 Flow chart of fuzzy number ranking process

A Cool Energy Storage air conditioning system (CES-system) functions by removing heat from a thermal storage medium during periods of low cooling demand and then releasing the stored cooling at a later time to meet an air-conditioning or process' cooling load. A CES-system has the advantage that it can meet the same total cooling load in a given period as a non-storage system but with a lower instantaneous cooling capacity. From the perspective of the utilities, a CES-system not only generates a reduction in the electrical demand but also shifts the consumer's energy consumption from peak time to off-peak hours. By decoupling the chiller operation from the instantaneous loads, CES-systems enable a more stable loading on the refrigeration equipment and increase the chiller efficiency due to the lower condensing temperatures associated with night time operation. It has been demonstrated that the use of cheaper off-peak energy and the reduction or elimination of peak-time charges enables CES-systems to pro-vide substantial operating cost savings. Various forms of cool storage

media may be used, including chilled water, ice, or a eutectic salt phase-change material. Depending upon the desired mode of operation, various combinations of these coolant paths can be achieved through the appropriate adjustment of the CES-system control mode.

5 Conclusions

This study contributes to the existing literature in three ways. First, most financial management innovation studies have been conducted at the fund orientation. The present study focuses on the financial management innovation at the MO. Second, this paper takes a first step on researching the impact of culture of Market orientation on financial management. The next Market orientation's three core activities (market information generation, dissemination and responsiveness). Finally, we research financial management innovation across four different aspects of the financial management, and thereby show the consequences of financial management innovation more than previous studies. While most studies in the past decade focused on the consequences of fund in financial management, few have investigated antecedents to Market orientation concept. To our knowledge, no study has investigated several of the antecedents included here. We hope to fill a part of this gap in extant knowledge.

Abstract

In online social networks, opinion dynamics generally lead to different types of collective online behaviour such as consensus, polarization and fragment. Then an open problem arises: how are different typical collective online behaviours emerged from the behavioural decisions of individual and interactions among individuals during the process of opinion dynamics? This work examines the process of opinion dynamic in online social networks and different types of interactions among individuals on this process. An opinion-driven dynamics model, which combines a social network-based opinion dynamics model with generative individual behaviour, is proposed by adding antagonistic responses to the DW model. The proposed model integrates three types of interactions and setting up two thresholds to characterize individual behaviour. The behavioural component utilizes an initiation threshold such that if an individual's opinion exceeds this threshold, the individual will initiate the behaviour. In order to verify the effectiveness of the model, simulations are presented to examine how different typical collective behaviours emerge. As a result, we find that opinion dynamics with different threshold lead to different types of collective online behaviours. The openness of individuals to a differing opinion is the key factors to consensus or fragment.

Keywords: opinion dynamics, consensus, antagonism, fragment, online social network

1 Introduction

Online social networking sites such as Weibo are popular platforms for social interaction which may lead to collective behaviour emerged from local interactions among individuals [1,2]. The interaction can include a broad range of individual decision such as behavioural choices and transitions [3]. Therefore, collective online behaviour is driven by behaviour decisions of individuals in a social network environment, but it is not simply the aggregation of individual behaviours [4-6]. In online social networks, opinion and behaviour are woven into the fabric of individuals' daily life. This naturally leads to opinion and behaviour correlation between connected individuals. Behavioural decisions of individuals are triggered by their opinion and attitudes on a certain topic or events and influenced by the opinion and behaviour of friends or neighbours. Studies have demonstrated that individuals register an immediate and automatic reaction of "good" or "bad" towards everything they encounter in less than a second, even before they are aware of having formed an opinion [7]. Advertising, educational campaigns, and other persuasive media messages are all built on the premise that behaviour follows opinion, and opinion can be influenced with the right message delivered during the process of exchanging [8]. Therefore, there is an unprecedented opportunity to analyze collective online behaviour based on opinion-driven behavioural dynamics model, which assumes that collective online behaviour dynamics combines a social network-based opinion dynamics with generative individual behaviour.

In online environments, there are three typical collective behaviours [9-11]. The first is characterized by the emergence of a global consensus, in which all individuals reach the same state in the long run. Consensus behaviours are driven by opinion agreement and can lead to a movement towards uniformity such as collective condemning. In the consensus behaviours, all individuals have to interact to achieve the same state through changing opinion and behaviour. The second is characterized by the emergency of a bipartite consensus, in which all individuals achieve a double extreme convergence with identical magnitude but opposite sign. Bipartite consensus behaviours are driven by antagonistic opinion and can lead to a polarization phenomenon that often happens in a two-coalition community such that opposite opinions are held by two fractions. The third is characterized by the emergency of a global fragment, in which all individuals hold disagreement in the long run. Fragment is driven by diversity of opinions and lead to an anarchy. In examining three typical collective behaviours, we shall draw heavily on the interactions among individuals and opinions change of individuals. We also need to work on two different levels: the microscopic level, where the

* ***Corresponding author's*** e-mail: xim_wang@163.com

behavioural decisions of the individual occur, and the macroscopic level where collective behaviour can be observed. The greatest promise lies in analysis of linking microscopic opinion change and behavioural decision to macroscopic behaviours [12,13]. Then two open problems arise: how can we describe the behavioural decisions of individual and analyze different typical collective behaviours emerging from both individual interactions and opinion dynamics? Can we change individuals' opinions threshold to influence the behavioural decisions of individual and collective behaviours?

Analysis of social network-based interactions has proven effective and efficient to the understanding of collective behaviour. Recently opinion dynamics modelling has been provided for the analysis of social influences on individual opinions and the emergency of resulting collective behaviour. Several formal mathematical models have been proposed to simulate opinion dynamic, in which interactions between individuals differ from model to model. However, all opinion dynamic models are built on common theoretical roots, and all individuals adjust opinions based on local rules governing the interaction range, which is so-called neighbour-based method. In these models, a set of individuals are used to populate a community, and are seeded with initial opinion value. Each individual adjusts his opinion in the light of interactions with his neighbours. In order to answer those questions aforementioned, a proper choice of the dynamics modelling is the neighbour-based method. Therefore, an opinion-driven behavioural dynamics model is presented in this paper. In the proposed model, behavioural dynamics combines a neighbour-based opinion dynamics with the generative behavioural decision of individual.

Our purpose in this paper is achieved according to the following three aspects:

(i) As collective online behaviours are driven in part by opinions that individuals hold regarding a certain topic, the opinion-driven mechanism is described by opinion-behaviour mapping based on the interaction among individuals, which is the first step to analyze collective online behaviour.

(ii) As collective online behaviours emerged from individuals' opinions and behaviours which are influenced by their personal social network and updated based on neighbour-based method, an opinion-driven behavioural dynamics model is established to analyze three typical collective online behaviours, namely, consensus, polarization or bipartite consensus and fragmentation.

(iii) This study will examine how individuals' opinion dynamics influence the behavioural decisions of individuals and collective behaviours? Interventions to influence collective online behaviour are presented by applying the proposed model.

The following parts of this paper are organized as follows: In Section 2, we review classical opinion dynamic models and explain why an opinion-driven behavioural dynamics can be used to analyze collective online behavioural. In Section 3, opinion-behaviour mapping is established, and an opinion-driven behavioural dynamics model is presented. In Section 4, the proposed model is applied to analyze collective online behaviours using the method of computer simulating. Finally, the paper is concluded in Section 5.

2 Classical opinion dynamics

Consider that online social network is a graph $G=(V,E)$ with $V=\{1,2,\ldots,n\}$ and $E \subset V \times V$, where a node represents an individual and the edges represent the interactions between two individuals. In the graph, the neighbour set of the vertex i is defined by $N_i=\{ j \in V \mid (j, i) \in E \}$.The graph may be directed or undirected. A directed graph is used to model networks where relationships are not symmetric, for example, the follower relationship in Weibo. An undirected graph models a network with symmetric relationships where $(i, j) \in E$ implies $(j, i) \in E$ such as the friend relationship in Wechat. Two individuals i and j are called adjacent if there is an edge connecting them, i.e., $(i, j) \in E$, and individual i is a neighbour of individual j. Although the original work concentrated on mutual exchanges of opinion, interaction relationship in online social network are often regarded as directed edges. In this study, we focus our analysis on directed social networks.

Early works to study opinion dynamics were focused on exploring the patterns of interactions and consensus problem that can explain what kind of interactions will lead to agreement of opinions. There are two classical models including "binary opinions dynamics", where opinions are represented by binary value, and "continuous opinion dynamics", where opinions are represented by real positive numbers. In contrast, the latter deals with the problem of what happens to the probability of choosing one decision over another.

In recent years bounded confidence (BC) models have received significant attention. BC models are genuinely models of continuous opinion dynamics in which individuals have bounded confidence in others opinions. The first version of BC models was developed and investigated by Hegselmann and Krause [14,15], called HK model where agents synchronously update their opinions by averaging all opinions in their confidence bound. The other version was presented by Deffuant and Weisbuch [16,17], called DW model, where a pairwise-sequential updating procedure is employed. Both HK and DW are very similar, and assume that individuals have a continuous opinion and tolerance threshold. The principle of them is that an individual takes into account opinions from others in a limited zone which is defined by the tolerance threshold, around its own opinion. They differ in their update rule. In the DW model agents meet in random pair-wise encounters after which they compromise

or not. In the HK model, each agent moves to the average opinion of all agents which lie in his area of confidence.

This study considers the model of group opinion dynamics within an online social network that was DW model. DW model was initially constructed through randomized interactions among individuals who are assigned a random opinion, resided as a value on the interval [0,1] drawn from a uniform distribution and a threshold which limits the number of interactions that will result in an opinion change. The threshold can also be taken as a measure of uncertainty about a given issue, in which the individual opinion moves closer to his neighbours. If the difference between his opinion and that of his neighbours is considered too far apart (that is, exceeds their threshold), he is not willing to receive his neighbours' opinion, and no adjustment takes place. Each individual i has an opinion $x_i(t) \in [0,1]$ in the round t, which is the representation of the individual's support for a certain topic. Let $w_{ij} \geq 0$ be the weight that individual i places on the opinion of individual j with the normalization requirement that $\sum_{j=1}^{n} w_{ij} = 1$. Let $\varepsilon_i \in (0,1)$ be the threshold that represents the effect tolerance of individual i. In each round, each individual adjusts his opinion based on based on opinions of neighbouring agents and their own tolerance, taking a weighted average of his own opinion and the opinions of his neighbours and ignoring neighbours whose opinion is outside individual's tolerance. Collective behaviours take places in the discrete rounds. Specifically, the individual i updates his opinion as follows:

$$x_i(t+1) = w_{i1}x_1(t) + w_{i2}x_2(t) + w_{i3}x_3(t) + \ldots + w_{in}x_n(t), \quad (1)$$

where $w_{ij} > 0$ only if $(i, j) \in E$, and $|x_i(t) - x_j(t)| < \varepsilon_i$, otherwise, $w_{ij} = 0$.

3 Opinion-driven behavioural dynamics model

3.1 OPINION-BEHAVIOUR MAPPING

Collective online behaviours are emerged from individuals' behaviour decision and interactions among individuals. According to cognitive-behaviour theory, individuals' behaviour decision can be categorized as a behaviour change to the interaction which is triggered by opinion dynamics. In the original definition of DW opinion dynamics, there are two types of potential interactions between two individuals who are neighbours: positive interaction, in which the individuals' opinions and behaviours move closer to one another, and neutral interactions, in which the opinions are considered too far apart so that no adjustment takes place. Although these two possibilities capture a wide range of potential interactions, there is a third possibility in online social network: a negative interaction that drives the opinions of the individuals further apart. The proposed model extends it by adding antagonistic responses in order to enable us to capture a more complete range of interactions between different types of individuals. Besides, we extend opinion dynamics by adding behaviour as illustrated in Figure 1.

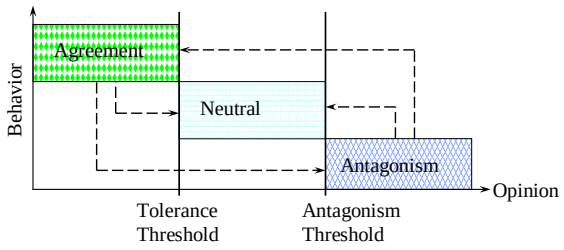

FIGURE 1 Graph illustration of opinion-behaviour mapping in online social network

For purposes of simplicity, a simple step function with the value of the behaviour being either true or false is proposed. The extended model describes the interactions between individuals by postulating that individuals' actions are driven by the objective of maximizing their own expected utilities, which depend on the state of collective behaviours in their own world. Individuals observe the actions of their neighbours, and update their opinions, optimally amalgamating public opinions obtained by observing their neighbours' behaviours. There are two initiation thresholds for every individual, including tolerance threshold and antagonism threshold, especially, the tolerance threshold is less than antagonism threshold. When an individual whose opinion differs from his neighbours by an amount exceeds the antagonism threshold value, he initiates the behaviour to give antagonistic responses to group opinions and collective behaviours. When an individual whose opinion differs from his neighbours by an amount is less than the tolerance threshold value, his opinion and behaviour move closer to group opinions and collective behaviour. When an individual whose opinion differs from his neighbours by an amount is between two thresholds, his opinion and behaviour stay the place. Therefore, addition of antagonistic response and mapping opinions to behaviour to classical DW model enables us to simulate a more complete range of opinion-driven behavioural dynamics among individuals in online social network as follows:

1) Agreement with individuals adjusting new opinions and behaviours closer to their friends whose opinions are similar.
2) Polarization with individuals adopting widely divergent opinions and behaviours when opinion difference exceeds the antagonism threshold.
3) Disagreement with individuals not affected by opinions of their friends where opinion differences are greater than the tolerance threshold.

3.2 THE PROPOSED MODEL

We extend the DW model to directed online social network and interpret the opinion-driven behavioural dynamics to represent overall social influences from all individuals rather than discrete pair-wise interactions. That is, the proposed model considers continuous interactions between individuals rather than the discrete exchanges.

There is a population with N individuals. In the round t each individual i has an opinion $x_i(t) \in [0,1]$ which is the representation of the individual's support for a certain topic, a tolerance threshold determining the latitude of reception $t_i \in (0,1)$ and an antagonism threshold determining the latitude of rejection $a_i \in (0,1)$ with $a_i > t_i$. Let $w_{ij}>0$ be the weight that individual i places on the opinion of individual j with the normalization requirement that $\sum_{j=1}^{n} w_{ij} = 1$. We refer to w_{ij} as the weight of edge (i, j), and $w_i = 1 - \sum_{j \neq i} w_{ij}$. In each round, each individual adjusts his opinion based on based on opinions of neighbouring agents and their own tolerance, taking a weighted average of his own opinion and the opinions of his neighbours and ignoring neighbours whose opinion is outside individual's tolerance. Besides, on account of individuals' different influence in online social network, a parameter is introduced to control for the strength of influence, which is determined by individuals' edges. Collective behaviour takes places in the discrete rounds. More specifically, individual i updates his opinion as follows:

$$x_i(t+1) = w_i x_i(t) + k \sum_{j \in T_i} w_{ij} x_j(t), \tag{2}$$

where T_i is the set of all out-degree neighbours of x_i (t) whose opinions fall out the bounds of antagonism threshold; $w_{ij}>0$ only if $(i, j) \in E$, otherwise, $w_{ij}=0$; k is a coefficient and $k \in \{-1,0,1\}$. If $|x_i(t) - x_j(t)| < t_i$, then $k = 1$, and T_i is the set of all neighbours of $x_i(t)$ whose connecting edge points from $x_i(t)$ and whose opinions fall within the tolerance threshold. The process can be viewed as individuals seeking to gain consensus with their friends in online social network. If $|x_i(t) - x_j(t)| \geq a_i$, then $k = -1$, and T_i is the set of all out-degree neighbours of $x_i(t)$ whose opinions fall out the bounds of antagonism threshold. The process can be viewed as some agents seeking to antagonistic response to polarization. If $t_i \leq |x_i(t) - x_j(t)| \leq a_i$, then $k = 0$, $|T_i|=0$ and $w_i = 1$.

4 Collective online behaviour analysis

The proposed model is applied to analyze three typical collective behaviours, and explore how three typical collective behaviours are driven by opinion dynamics and what will lead to different collective online behaviours. First we examine how adjusting tolerances influences collective online behaviour, which modify individual tolerances at strategic locations in the network. Next we examine how adjusting antagonisms influences collective online behaviour, which modify individual antagonisms at strategic locations in the network. Finally we examine how adjusting both tolerance and antagonisms influences collective online behaviour, which modify individual antagonisms at strategic locations in the network

According to complex network theory, the ability for a node to influence the network via opinion propagation is primarily determined by an individual's centrality. Online social network members who regularly exchange information with many others in the network are represented by nodes having greater centrality. In online social network, there are some opinion leaders with high centrality, who might have greater influence on making other individuals update opinions toward their own opinion. To effect behavioural change across the network, the proposed model allows us to examine the effectiveness of different nodes importance metric such as the betweenness centrality. Therefore, we adjust the tolerance threshold or the antagonism threshold for the 10 percent nodes with highest betweenness ranking and explore how it influences on collective online behaviour.

We simulated collective online behaviour using the proposed model based on *NetLogo*, which is a programmable modelling environment for simulating natural and social phenomena. The conditions in the simulations are the following: the population N indicates that there are N individuals in online social network, and $[w_{ij}]$ is a $n \times n$ matrix obtained from the adjacent matrix of the network graph. In the experiment, the population is setup $N = 1000$. Every agent has an opinion $x_i(t) \in [0,1]$ at time t and has two thresholds, tolerance T and antagonism A. Given a random network, interactions between two agents have been abstracted as equation (2).

4.1 ADJUST TOLERANCE TO INFLUENCE COLLECTIVE ONLINE BEHAVIOUR

Tolerance in the proposed model indicates the openness of an individual to a differing opinion, and is also termed uncertainty about one's own opinion. In the first experiment, we assume that the tolerance threshold for the ten percent nodes with the highest centrality ranking have the same initial opinion, the same tolerance $T \in (0, 1)$, and a constant antagonism $A = 0.8$. In Figure 2, the diagram shows that adjusting tolerance T results in the emergence of different collective online behaviours in case of the same initial opinion for central nodes. In the second experiment, we assume that the tolerance threshold for the ten percent nodes with the highest centrality ranking have opposite initial opinions, the same tolerance $T \in (0, 1)$ and a constant antagonism $A = 0.8$. One half of the ten percent nodes with the highest centrality ranking have initial opinion $x_i(t) \geq 0.9$, the other half of those nodes have initial opinion $x_i(t) \leq 0.1$. In Figure 3, the diagram shows

that adjusting tolerance T results in the emergence of different collective online behaviours in case of having opposite initial opinion for central nodes.

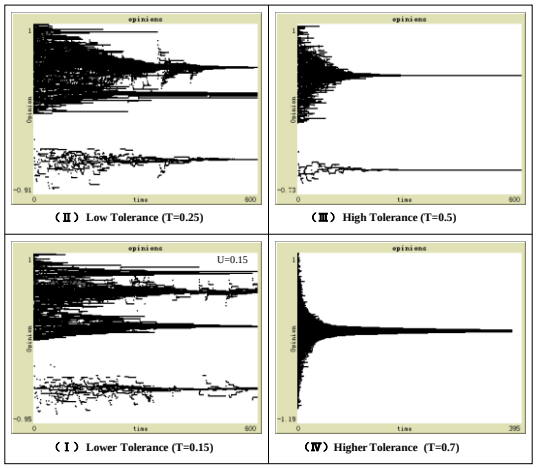

FIGURE 2 The emergency of collective online behaviour in case of different tolerance for central nodes having the same initial opinion and a constant antagonism threshold

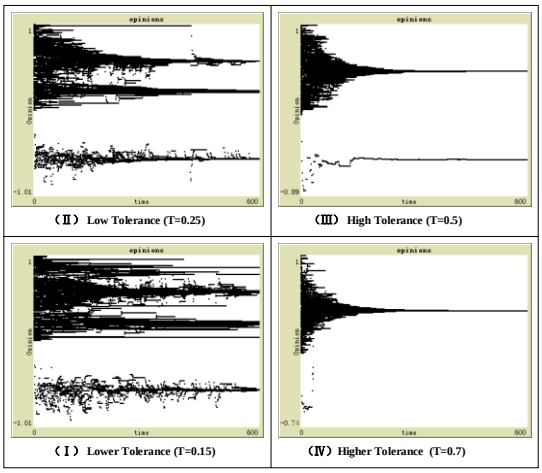

FIGURE 3 The emergency of collective online behaviour in case of different tolerance for central nodes having the opposite initial opinion and a constant antagonism threshold

From the result of simulations, we find that a network composed of individuals with a low tolerance threshold to their neighbours lead to fragment, and a network composed of individuals with a high tolerance typically results in one or bipartite consensus. Our simulations indicate that adjusting the tolerance threshold of the ten percent nodes with the highest centrality can have a dramatic influence on collective online behaviours. Raising the tolerance value of those ten percent nodes above 0.5 resulted in a large increase the possibility of clustering and consensus. Lowering the tolerance value of those 10 percent nodes below 0.5 strongly mitigated the possibility of clustering and consensus, and fragment emerges more easily. Especially, we find that initial opinions of the individuals have no significant impact on collective online behaviour by comparing the results of two experiments. In a word, an online social network composed of nodes with lower tolerance threshold leads to fragment more easily, those networks composed of nodes with lower tolerance threshold result in consensus even if there are three typical interactions including agreement, antagonism and neutrality.

4.2 ADJUST ANTAGONISM TO INFLUENCE COLLECTIVE ONLINE BEHAVIOUR

Antagonism in the proposed model determines the latitude of rejection of an individual to a differing opinion, and is also termed tenacity about one's own opinion. In the third experiment, we assume that the antagonism threshold for the ten percent nodes with the highest centrality ranking have the same initial opinion, the same antagonism $A \in (0,1)$ and $A > T$, and a constant tolerance $T = 0.5$. In Figure 4, the diagram shows that adjusting antagonism A results in the emergence of different collective online behaviours in case of the same initial opinion for central nodes.

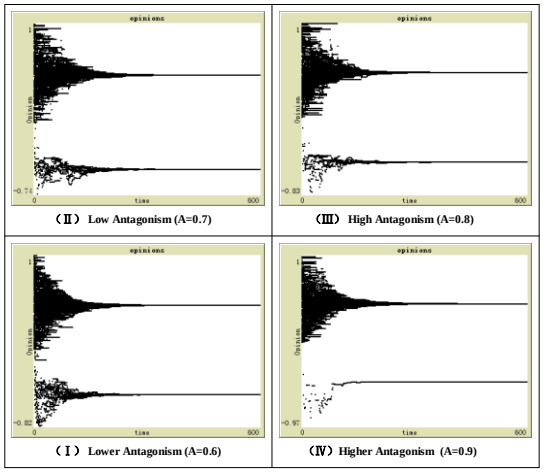

FIGURE 4 The emergency of collective online behaviour in case of different antagonism for central nodes having the same initial opinion and a constant tolerance threshold

In the forth experiment, we assume that the antagonism threshold for the ten percent nodes with the highest centrality ranking have opposite initial opinions, the same antagonism $A \in (0, 1)$, and constant tolerance $T = 0.3$. One half of the ten percent nodes with the highest centrality ranking have initial opinion $x_i(t) \geq 0.9$, the other half of those nodes have initial opinion $x_i(t) \leq 0.1$. In Figure 5, the diagram shows that adjusting antagonism threshold A results in the emergence of different collective online behaviours in case of having opposite initial opinion for central nodes.

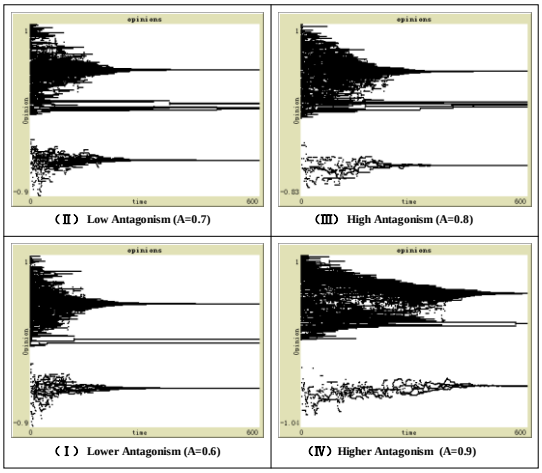

FIGURE 5 The emergency of collective online behaviour in case of different antagonism for central nodes having opposite initial opinion and a constant tolerance threshold

From the result of simulations, we find that a network composed of individuals with both a low and a high antagonism threshold to their neighbours and lead to the same type of collective behaviour, and the difference is only the speed of clustering. A network composed of individuals with a lower antagonism threshold has a higher speed of clustering. Our simulations indicate that adjusting the antagonism threshold of the ten percent nodes with the highest centrality can have a tiny influence on collective online behaviour. With the constant tolerance threshold both raising and lowering the tolerance value of those 10 percent nodes does not change the type of collective online behaviour. Especially, we find that initial opinions of the individuals have no significant impact on collective online behaviour by comparing the results of two experiments.

4.2 ADJUST BOTH TOLERANCE AND ANTAGONISM TO INFLUENCE COLLECTIVE ONLINE BEHAVIOUR

The difference between tolerance and antagonism decides whether an individual takes a neutral interaction with his neighbours. In the last experiment, we assume that individuals are initialized with the same initial opinion, the same antagonism $A \in (0, 1)$ and the same tolerance $T \in (0, 1)$. The values of A and T is varied between 0.1 and the maximum of 1.0 with the constraint of $A > T$.

In Figure 6, the diagram shows that different conditions for the values of T and A result in the emergence of consensus and anarchy. According to the result of simulations, we find that consensus emerges only in case of high uncertainty and high antagonism threshold as (III) shown in Figure 6. In other cases, polarization and fragment emerge as (I), (II) and (IV) shown in Figure 6. Fragment is more notable in case of low uncertainty and high antagonism, while polarization is more notable in case of low antagonism, and bipartite consensus is more notable in case of high uncertainty and low antagonism. As a result, difference between tolerance and antagonism is the key indicator to the emerging of consensus and fragment, and when the difference is smaller, consensus is attained more easily

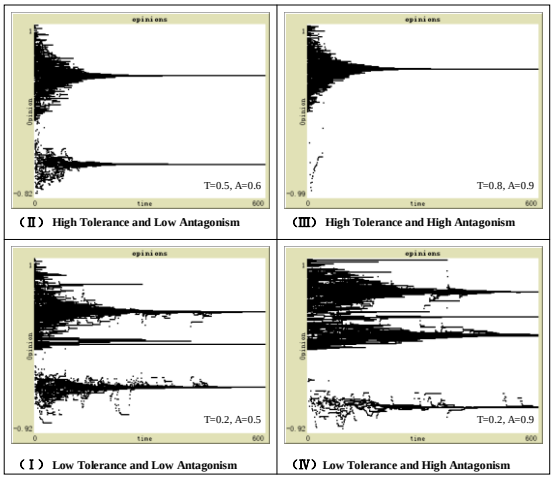

FIGURE 6 The emergency of collective online behaviour in case of a typical opinion trajectory for individuals with different antagonism A and different tolerance threshold T

5 Conclusions

In this paper, we study the process of collective online behaviour triggered by opinion dynamic in online social networks and the influences of different types of interactions among individuals on this process. Our work extended the classical DW model and investigated a possible source of consensus, polarization and fragment by adding antagonistic responses in order to enable us to capture more generative individual behaviours. We consider online social networks as directed graph, and there are three interactions among individuals such as agreement, antagonism and neutrality. The proposed model maps opinion dynamics to collective online behaviour and considers the continuous interactions among individuals. All individuals have a continuous opinion and two thresholds including tolerance and antagonism. We simulated collective online behaviour for the proposed model considered three types of interactions into online social networks based on *NetLogo* to observe the emerging of three typical collective behaviours. As a result, we find that opinion dynamics with different threshold lead to different types of collective online behaviours. The openness of individuals to a differing opinion is the key factors to consensus or fragment. Certainly, our study only focuses on the static social network and simulating for a constructed network. It is a next step to study real and dynamic social networks of collective online behaviour in our future research.

Received 1 March 2014, www.cmnt.lv

Abstract

Many Chinese universities have begun reforms to enhance educational competitiveness in our globalizing economy. This study aims to ascertain the status of English education and English-medium instruction at a Chinese engineering school and to offer workable suggestions for English communication training for Chinese graduate engineering students. Colleges and universities across China are adopting bilingual education to meet the need for well-rounded personnel with sound knowledge in specialized areas and competency in foreign languages. The development and difficulties of current bilingual education in China are discussed. First, the short-term English word context is generated to identify related concepts of the word. Second, the user context is generated based on the click through data of users. Finally, a forgetting factor is introduced to merge the independent user context in a user session, which maintains the evolution of user preferences. It is significant to the reform from teacher-centered to student-centered teaching mode. It is helpful to the cultivation of the students' collaborative ability and spirit, and has important theoretical significance and practical value.

1 Introduction

Under the increasing influence of globalization, many Asian governments have begun university reforms to enhance educational competitiveness and national competence in a globalizing economy. Subsequently, internationalization has impelled the restructuring of higher education institutions in a number of Asian nations, including China, Hong Kong, Japan, Singapore, South Korea, and Taiwan [1]. Individual governments have taken different approaches and measures to enhance the competitiveness of their institutions of higher education. The Chinese government has taken quantitative and qualitative measures such as the massification of higher education and the development of world-class universities since the mid-1990s [2]. With financial support from the government, Chinese universities have actively recruited high-quality academics from around the world to improve their educational quality [2]. The Japanese government has had concerns about the diminishing positions of their universities and has supported international collaborations and exchanges to facilitate the repositioning of Japanese higher education institutions [3]. In the case of Singapore, the government has carried out extensive university reforms with the intention of establishing the island country as a center of education in the Asia-Pacific area. To achieve this goal, the government has promoted the establishment of branch campuses of reputable foreign universities in addition to the reformation of university curricula [4].

The English-Chinese bilingual education in China has two main objectives. The first one is to empower China's elite youths to get advanced sciences and technologies directly from English literatures. Second, it helps students develop bilingual skills for efficient and effective worldwide communication. For these purposes, research has been conducted nationwide to help promote English-Chinese bilingual education, which includes evaluations of the training of bilingual teachers, and revisions of college curriculums for bilingual requirement. However, little research is done on the network aided learning environment for bilingual education. Current e-learning systems in China are mostly focused on continuing education and adult education. They are incapable of providing an original English environment and are often not suitable for bilingual courses.

The extensive use of digital technologies in China has greatly changed the college English teaching methodologies. College English Curriculum Requirements was issued to replace the Syllabus, and from then on it has served as an outline in the transformation effort. Accordingly, The Testing Syllabus for College English Test-Band 4 states, the objective of College English is to develop students ability to use English in a well-rounded way, especially in listening and speaking, so that in their future studies and careers as well as social interactions they will be able to communicate effectively in both oral and written forms. In this sense, CET-4 and CET-6 are aimed at measuring precisely college students' comprehensive employment of English and thus play an active role in realizing the objective of college English teaching." With the new orientation of the test objectives in The Testing Syllabus, college English teaching is expe-

* ***Corresponding author's*** e-mail: missguo168@163.com

riencing a change from the test whether the students have attained the various purposes established in the Teaching Syllabus after they have finished the four-year college learning to test how well the students can use English, which means developing students' all-round English abilities and The Requirements symbolizes that an era demanding a uniform teaching requirement is over, and a new era stressing the individualized and diversified college English teaching starts. After working under the guidance of the Syllabus and its refined version for about a decade and half, CE was found to be less and less up to date because of challenges from globalization, student demands, enrollment expansion, and changes in primary and middle school curricula. Therefore, in the new e-learning environment college English teaching must set up a new teaching system according to the societies' needs, the teachers' strong points and students' interests. In order to meet the students' requirements, some universities already started to offer some enrichment courses for undergraduates who have passed CET Band 4 & 6. College English teaching is changing from fostering English language knowledge to cultivating practical abilities. The main features of the transforming period is that the terms and the hours per week for college English teaching is shortening, while the number of the enrichment courses (the elective or optional courses) which emphasize developing ability is increasing.

In this paper, first, the short-term English word context is generated to identify related concepts of the word. Second, the user context is generated based on the click through data of users. Finally, a forgetting factor is introduced to merge the independent user context in a user session, which maintains the evolution of user preferences. It is significant to the reform from teacher-centered to student-centered teaching mode. It is helpful to the cultivation of the students' collaborative ability and spirit, and has important theoretical significance and practical value.

2 Related Works

As higher education rapidly accepts the notions and practices of e-Learning, the learning and teaching processes are experiencing ever-increasing changes [5-7]. Several universities, including Iranian universities, are currently providing online learning courses and facilities for students' use [8], which have significantly increased the quality of each field of study especially language education including language learning, language pedagogy, and language use [9]. However, the integration of leT tools in language classroom setting offers a broader concept of e-Learning which is defined variously in many studies. The most general educational demotion of e-learning is provided by Urdan and Weggen [l0] as a term for all types of electronic-supported learning and teaching which deliver the knowledge through electronic media such as the Internet, intranets, extranets, satellite broadcast, audio/video tape, interactive TV, CD-ROM. Moreover, sveral studies have compared the traditional language learning to e-learning of language and revealed a number of e-Learning benefits. Fageeh [11], for instance, indicated that e-Learning has effectively reduced the shortcomings of traditional learning including inadequate time devoted in the classroom, limited opportunities for students to discuss freely in the classroom as a result of their shyness or time restraints, lack of well-organized and better interaction with their peers and teachers synchronously or asynchronously. To confirm his comparison, Fageeh [11] carried out a descriptive research, including a survey and in-depth interview, to make out the perceptions of EFL students and their teachers towards e-Learning. The participants declared that e-Learning environment not only decreases the affective obstacles or inhibitors which motivate students to be more active and less silent and shy but also enhance inputs, outputs, and the processes of educational practices. Similarly, Mohammadi, Ghorbani and Hamidi [12] asserted that learning language via ICT resources is a learner centered, self-paced, cooperative, comprehensive, communicative learning which is dynamic and convenient any time and any place. Moreover, e-Learning provides opportunities for language learners to get familiar and interact with target language culture via online videos, chat rooms and videoconferencing [13].

Nevertheless, despite the growing numbers of e-Learning benefits, some studies have focused on the inhibitors in the implementation of e-Learning. One of the major obstacles seems to be related to the characteristics of ICT key users in e-learning settings, namely, language learners. Several research studies indicated that user-related inhibitors include lack of ICT literacy and computer anxiety [2], age and gender [14] as well as lack of readiness to use ICT resources [7].

Since the emergence of ICT tools in education in the 70s, language programs have enjoyed the implementation of these beneficial tools in language classes. It is suggested that ICT with its different forms from educational software to using networking has created a revolution in language teaching and learning [16]. ICT has not only been increasingly used in the practice of the skills of reading, writing, speaking, and listening as well as into corpus linguistics and testing but also provided lots of opportunities for language learners to enhance their communicative abilities [16]. Also, Beatty [17] characterized ICT-based language education as a process in which learners use computers and as a result of that they improve their language proficiency.

In sum, in line with the vital need of e-learning readiness assessment, this study investigated e-learning readiness among EFL students for the implementation of the e-learning language education in Shiraz Azad University. Moreover, the relationship between EFL students' English proficiency and their readiness was investigated.

3 The Proposed User Profile based Method

3.1 THE BASIC FRAMEWORK

An investigation of e-learning products leads to the fact that teaching materials are usually prepared in advance

and then lose flexibility in customer's interests as well as up-to-dateness in contents. On the other hand, abundant online resources (dictionaries, thesaurus, lexicons or encyclopedia etc.) are separated from contexts and becomes hence to some extent to be "big white elephant". The conceptual guideline of the framework here is thus allocated on the pedagogical motivation of "The customers decide what to learn and we help it to be well learned". The concrete technical measures to support this idea consist of three parts:

1) The texts to be processed are supplied or selected by customers;

2) related analytical measures based on web service discovery are introduced in the process of text analysis and teaching explanation generating, including language point determination, looking-up online dictionaries for new words;

3) the output of analytical results can be individually represented according to the specific need of customers both in forms and contents. The schematic framework is illustrated in Figure 1.

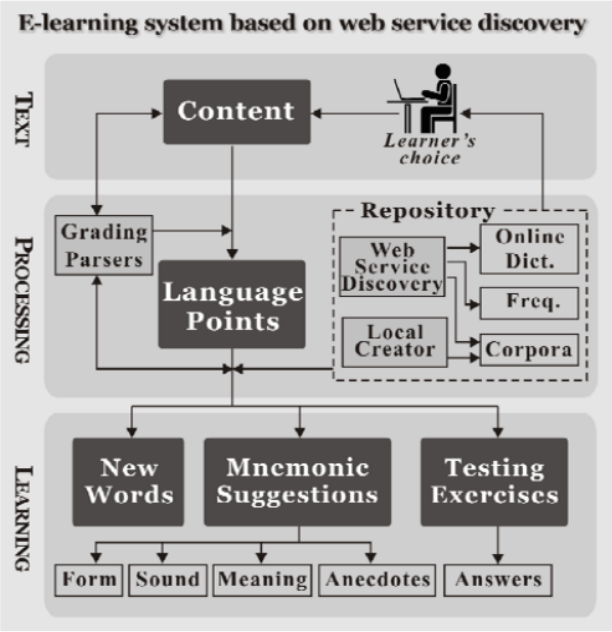

Figure 1 Flowchart of E-learning system

3.2 BUILDING THE WORD CONTEXT

Context, in its general form, refers to any additional information associated with the query [14]. In this paper, we narrow the context to represent a piece of text (e.g., a few words, a sentence, a paragraph) that has been authored by the users. Generally speaking, a word context can be represented as a concept vector. An obvious choice for extracting concepts of the query q is mining the Web pages returned by Web search engines, such as Google which provides the URLof each search result. However, the above choice is impractical. The reasons are given as follows:

1) Time consuming. Though Google provides the URL of each search result, it is time consuming to download these Web pages;
2) Parsing infeasible. Due to the huge number of Web pages and the high growth rate of the Web, it is impractical to analyze each Web search result pages directly and separately. Meanwhile, different Web sites have different HTML format, it is infeasible to parse the different Web sites at the Web scale.

Therefore, the web-snippets of the word are used for extracting concepts instead of the Web pages. Snippets are useful information resources provided by Web search engines, which are brief summaries of Web pages along with the search results. Generally speaking, a snippet contains a brief window of text selected by a Web search-engine around the query *q* in a Web page. Since many stopwords such as preposition, pronoun may occur on the snippets, it is necessary to do some preprocessing steps to reduce noise from the snippets before extracting concepts. Given the real time of building query context, we do not use some time consuming language dependent preprocessing steps such as part-of-speech tagging. Instead, we only remove the stopwords using standard SMART stopword list. After preprocessing the snippets of the query *q*, it is time to extract concepts of the query q. Our concepts extraction method is inspired by the famous problem of finding frequent patterns in data mining. When the query q is submitted to the Web search engine, a set of snippets are obtained for identifying the concepts. According to the theory of cognitive science, if a concept appears frequently in the snippets of the query q, it represents an important concept related to the query q since it coexists in close proximity with the query q in the top Web search results.

Besides the weight of concept ci, the relations between concepts can also be mined from the snippets. A famous formula named Pointwise Mutual Information (PMI) from information theory [20] is used to compute the relation between concepts.

3.3 BUILDING STUDENT PROFILE

The query context reflects the related concept of the query *q* in the Web search result pages, which can be derived without any user click through data. Different from query context which is static, the user context is dynamic and based on the click through data of the users. In other words, the user context is user-oriented. Given the query *q*, the problem of building user context can be viewed as a three-stage process.

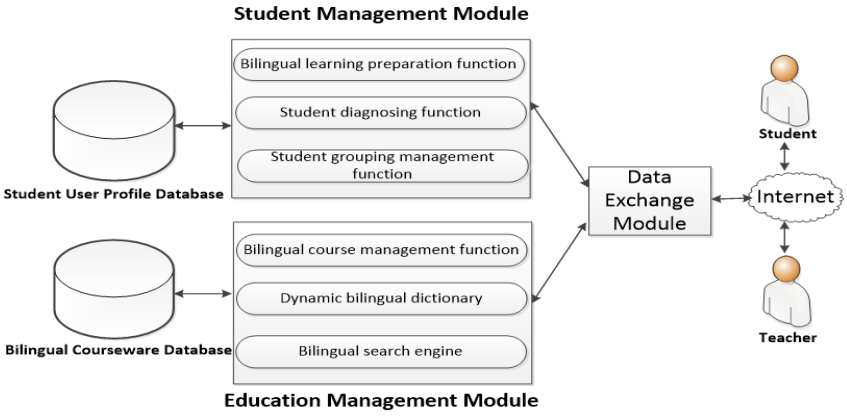

Figure 2 System organization

1) Obtain the explicit concepts of user context. The explicit concepts mean the concepts appear in the click snippets of the users. For example, when the user searches the query "apple," then he/she clicks the snippet which contains the concept "iPhone," thus the concept "iPhone" is the explicit concept of the user.
2) Obtain the implicit concepts of user context. The implicit concepts mean the concepts do not appear in the click snippets but may be interested by the users. For example, if the user is interested in the concept "iPhone," the concepts which are related to the "iPhone" such as "iPod" may be the implicit concepts of the users.
3) Process the sequential click snippets of user context. Each click snippet of users can be used to generate a context, respectively. The merging of these user contexts in a user session should be considered.

Intuitively, the concepts which appear in the user click snippets can be thought as the explicit concepts of the user context. For instance, if a user submits the query "apple," and he/she is interested in the concept "iPhone," then he/she may click the snippet containing the concept "iPhone". In other words, the concepts which appear in the snippets of the Web search result may be interested by the user who clicks it. Besides the concepts which appear in the snippets clicked by the users, other concepts may also be interested by the users. The implicit concepts mean the concepts do not appear in the click snippets but may be interested by the user which is shown in Figure 2.

The concept relationship graph of query context gives us a chance to find the implicit concepts of the user context. If a user is interested in the concept ci, the concepts which are the neighborhood of the concept ci in the concept relationship graph are the implicit concepts of the user context, which means these concepts are more likely interested by the users. For instance, if a user submits the query "apple," and he/she is interested in the concept "iPhone," then he/she may click the snippets containing the concept "iPhone". Obviously, the concepts which are neighborhood of the concept "iPhone" in the concept relationship graph of query "apple" such as "stock" and "store" may be interested by the users. Therefore, we compute not only the weight of the explicit concepts appearing in the click snippet, but also the weight of the implicit concepts which are the neighborhood of the explicit concepts in the concept relationship graph. An intuitive method for computing the weight of the implicit concepts ci is using the strength of the link between the implicit concept ci and the explicit concept cj. Unfortunately, this method is impractical since one implicit concept may relate to many explicit concepts. For example, suppose "iPhone" and "iPod" are two explicit concepts appearing in the click snippet, but the implicit concept "Mac" may link to both "iPhone" and "iPod." In that case, it is difficult to select which link should be the weight of the implicit concept "Mac" to the user context. To address this problem, three strategies are proposed to compute the weight of the implicit concepts of the user context.

3.4 RESEARCH INSTRUMENTS

For the purpose of this study two major instruments were used including e-learning readiness questionnaire and a retired version of Test of English as a Foreign Language (TOEFL). First, EFL students' e-learning readiness was assessed by using e-Learning readiness questionnaire adapted from Watkins, Leigh, and Triner. The privilege of using this scale is to provide practitioners with tools for improving both individual and organizational performance through useful e-learning experiences. The questionnaire has two major sections. The first section includes demographic characteristics such as age, gender, computer use, computer ownership, internet use for academic activities. The second part consists of 27 closed-ended items categorized under six factors in order of:

1) technology access (three items),
2) online skills and relationships (nine items),
3) motivation (three items),
4) online audio/video (three items),
5) internet discussion (four items),
6) importance to one's success (five items).

The participants were asked to rate their readiness in e-learning environment on a 5-point Likert scale based on Strongly Disagree (1 point), Disagree (2 points), Unsure (3 points), Agree (4 points), Strongly Agree(5 points).

The overall reliability for this questionnaire was found by estimating Cronbach's alpha (0.75) making it acceptable in terms of internal consistency. The results of reliability analysis for six components of the scale indicate acceptable levels of internal reliability for all components ranging from 0.63 to 0.87. Secondly, a retired version of TOEFL test was used to investigate the proficiency score of the participants. This test consists of 30 questions in three parts (reading comprehension, structure and written expression).

4 Analysis

Digital technology makes it possible to construct a system of teaching contents, which can combine words, pictures, sounds and visual clips together, and thus content-based and multi dimensional approach of college English enrichment course teaching arises. This teaching mode is based on the digital technology and multimedia teaching environment, so it can embody the principle of combining practicality, interest and knowledge together. It can be realized both in the classroom activities and after-class Internet-based autonomous learning. During the classroom activities, the teachers will concentrate on some role play activities, so as to develop the students' autonomous and initiative learning spirits.

Then how to adopt the content-based teaching mode of CEEC in the e-learning environment? Before class activities: This technology provides a very good environment for both the students and the teachers to finish their tasks before each lesson. With online accessibility, they can read up-to-date English materials on the websites of the BBC or The New York Times, visit English learning websites to complete various after-class assignments online. They can also easily find English-speaking partners through the Internet or participate in online forums in English. After the students collect the materials closely related to the certain theme, they can discuss and communicate in various online ways and make some PPT documents so that they can present group work in class. This process must involve students' autonomous and cooperative learning. Compared with the confinement of the traditional classroom, an e-learning environment gives them many more opportunities to improve their English ability dramatically. Incorporating digital technology to college English enrichment courses is not only effective in improving students' English proficiency, but also offers teachers many more possibilities. At our university, we can teach every multimedia college English class, which means we can incorporate video and other visual aids into classroom work.

The students are enthusiastic about using video clips of English movies for a lesson with the particular theme. In class activities: In the e-learning environment, tasks are more easily assigned to cater to students' needs and interests. The teacher design some pair work, group work role play and imitating activities to improve students' oral expressing abilities. The e-learning environment will surely make it feasible for the students to be immersed in authentic English learning environments, so as to enhance their sense of language and cultivate their culturally communicative abilities. The e-learning environment also makes it possible to combine after-class work with the in-class work, combine the online work with the offline work, and combine the multimedia teaching with the traditional teaching. Thus, the maximum amount of authentic communicative activities make students strongly stimulated by audio video clips, enrich their intellectual functions and train their cooperative and initiative consciousness.

A sectional interface of the online teaching and learning system is illustrated. It is composed of three sections: (1) text display; (2) new word annotation and mnemonic suggestion; and (3) new word association (e.g. synonyms and antonyms). The Gettysburg Address by U.S. President Abraham Lincoln is selected as a demonstrative built-in text in our created repository to illustrate the functionalities of our system. The entire speech consisted of 272 words as Encyclopedia tells. Our system gives exactly the same result and uncovers more facts about it as illustrated in Table II. Of the total 272 words, 138 are distinct. From the results, readers could find that easy texts for primary learners (like B in the table) are with a lower coefficient and a condensed reading text for advance learners (like C) has a higher value. A speech, which is usually composed of colloquial expressions, is often a medium degree of difficulty and medium coverage of new words.

The facts of texts B, C and D in Table II reveal that text B belongs to essential course with easy words and low degree of difficulty; text C advocates an intensive expanding of vocabulary; and text D in the last volume of the series does not have the largest vocabulary coverage but rather tackle with cultural issues as the author designed, as can see from the series names: First Things First, Practice And Progress, Developing Skills, and Fluency in English. Such an arrangement is also introduced in author's pedagogical instructions. The analytical results of the example texts demonstrate the important function of text evaluation for teachers to select a proper text aiming a specific group of students. After the reading text is scanned through above algorithm, new words come out from the distinct words that are equal or higher than the level the customer has assigned. They are marked by bold and blue letters. Once the list of new words is determined, the list is sent to the repository system, where the standing MAS serves for vocabulary data collection and administration in advance and real-time if necessary. It sends back all word information on the list, including vocabulary notes, mnemonic suggestions, learning points, and test questions. Under the category of mnemonic suggestions and learning points, useful learning materials are provided there. Distinction notes on similar words in form, for example "repository" and depository, are compared. Similarly, "sun" and "son" are pronounced the same; both "attain" and "obtain" have a meaning of "to gain or get" etc. They are all served for improving the impressive memory of learners to new words. Some anecdotes about certain words are also recorded in the mnemonic corpus of the repository, for example, "arithmetic" as the acronym of "a rat in Tom's house may eat Tom's ice cream". The webpage frame of test questions shows the test question of corresponding

new word to deliver practice for learners to master new words. After all new words are learned and tested, a score is then fed back to the learners to reminder them the degree of their understanding and digestion.

5 Conclusion

This paper first brings about three problems in the traditional teaching mode of college English interpretation class. They are disconnection between teachers' instruction and students' learning, shortage of interaction between teachers and students, the out-of-date content and the single teaching methods, static instruction and shortage of authentic practice. Then, the author points out that applying E-Learning in college interpretation instruction may help solve the three problems. e-learning, as a new way of education, has many characteristics, such as individuality of the subject, interaction of the learning process, integration of learning content and the opportunity for life-long learning. In the e-learning environment, college English interpretation teaching shows a new development trend. The roles of teachers and students will be changed. Students become the subject of teaching and they have more autonomy. While teachers play the role of monitoring and directing and they become the designer of the learning, the organizer and the attendant of teaching activities, and also the guidance and the consultant of the students' learning. In order to meet the requirements of the modem college English interpretation course, teachers have to learn the computer and network techniques well, or they will encounter some difficulties and problems. Altogether, nowadays e-learning and network learning have become the new trend of education and their advantages must greatly facilitate college English interpretation teaching and learning in the future.

Received 1 March 2014, www.cmnt.lv

Abstract

Recently, new technologies have emerged in industrial automation platforms. A rapid modelling and simulation environment is required to integrate these new technologies with existing devices and platforms to reduce the design effort and time to market. System-level modelling is a popular design technique that provides early simulation, verification, and architectural exploration. However, integration of real devices with system models is quite challenging due to synchronization and hard real-time constraints in industrial automation. Simulations are software tools approximating and predicting the behaviour of real industrial plants. Unlike real plants, the utilization of simulations cannot cause dam-ages and it saves time and costs during series of experiments. A shortcoming of current simulation models is the complicated runtime integration into legacy industrial systems and platforms, as well as ad-hoc design phase, introducing manual and error-prone work. This paper contributes to improve the efficiency of simulation model design and integration. It utilizes a semantic knowledge base, implemented by ontologies and their mappings. The integration uses the Automation Service Bus and the paper explains how to configure the runtime integration level semantically.

Keywords: assembly systems, estimation, part feeding, pose statistics, simulation

1 Introduction

Industrial automation systems are experiencing a paradigm shift due to incorporation of new technologies, such as embedded real-time devices and communication networks. It has been shown that the demand for plug and play mechatronic solutions increases significantly and the investments on automation systems that utilize hardware–software and communication infrastructures cannot be ignored in today's factory systems [1-3]. As the complexity of these systems increase, a rapid modelling and simulation environment is required to reduce the design and verification time. System-level modelling is a very effective way of reducing the development cycle while providing early prototypes and enabling architectural exploration and verification.

The role of simulation models is becoming more essential as industrial systems are being more complex and their structure more sophisticated. Simulation models are necessary for the advanced process control and they are important for optimization or as test-beds to analyze the behavior of both a control system and the whole plant under normal, extreme or testing conditions, when an engineer compares different parameters or control algorithms under various operation scenarios.

A lot of research effort has been invested into problems dealing with mathematical modelling, some effort has been in-vested into the description of models. But only few works have been concerned with the description of the whole automation system including knowledge about the real plant, control system, software tools, and communication interfaces not only on the hardware level, but also on the software level. Such pieces of information should be explicitly conceptualized, interfaces for the integration of sub-systems should be described in a machine-understandable form and the integrated solution has to be consistent and easy to maintain.

System-level modelling also allows reuse of different forms of intellectual properties (IPs), which is a common practice in the industry. Since industrial automation systems are increasingly connected with other IPs or industrial components, they should also benefit from system-level modelling techniques to reduce the development costs. In traditional system-level modelling, all components need to be modelled. However, modelling has no added value for components that are already physically implemented because modelling is an abstraction mechanism and requires human effort. Therefore, techniques have to be developed for incorporating real devices with virtual models. Traditionally, there are communication mechanisms between virtual models. These mechanisms are defined through the constructs of modelling languages. Similarly, real implemented devices communicate with each other through physical mediums with predefined exchange data formats. However, there is no established mechanism that provides communication between real devices and virtual models, and this paper fills this gap. Specifically, we present synchronization mechanisms between virtual models and real devices so as to achieve real-time communication.

The goal of this paper is to introduce an ontology-based approach for the plant description that is focused on both

* ***Corresponding author's*** e-mail: wangjianxuanzz@126.com

complex and flexible automation systems. Although this paper deals especially with simulation models, the approach provides additional support for integration of diverse engineering tools that are involved in the automation system engineering as well. All phases of the automation system life-cycle are based on the description of the real industrial plant. In the early design stage, such a description is needed for optimization of the process structure and parameters, afterwards, it is useful to design a simulation model as a virtual test-bed for the control system design and fine-tuning. Since every industrial process is modified and maintained, the plant description has to reflect the current state. Particularly, modifications of the industrial process bring fundamental benefits of the explicit plant description that is independent on other engineering tools, such as simulators. For example, in approaches used nowadays a simulation expert has to modify the simulation model according to the modified plant, which is usually time-consuming, because he or she has to study principles of the simulation model, meaning of required parameters and often empirically check the results. Using the explicit plant description a process specialist modifies this description according to the real plant and all necessary changes are propagated into the simulation model and other systems in the automated way. Traceability of changes is one of the important features of modern system engineering.

This paper addresses problems related to the integration of automation systems including simulations, human-machine interface (HMI) as a part of SCADA systems (standing for supervisory control and data acquisition), and interaction with real systems solved via OPC UA or OPC classic. Some tools can be legacy, i.e., they had been designed before the need for interoperability emerged. One of the automation system tools are simulations, being the software approximations of the real plant behavior. Since their design phase, reuse and access to historical data pose problems which have not been satisfactorily solved by now, this paper addresses these issues. The presented simulation model design is oriented on structural issues dealing with simulation blocks, their interconnections, and parameters; whereas mathematical equations are not handled.

The proposed approach utilizes ontologies comprising knowledge about design and integration of a real plant, a simulation model, as well as other industrial automation tools. The knowledge base provides the information in a machine-understandable form, hence the computer is able to process and query the knowledge required for the integration and the simulation model design. The presented approach is an application of the semantic integration [4-7]. In contrast to classic integration approaches, the semantic integration is based on utilizing mappings between adequate entities. For example, semantic map-pings relate really measured variables and their simulated approximations, real devices and their equivalents in a simulation model or local tag names used in a particular tool with the global representation of tag names.

2 Related Works

In the last decade, there have been significant studies to develop design platforms for intelligent industrial automation systems [8-10]. These automation systems rely heavily on a distributed computer-based infrastructure, where smart sensors and actuators, intelligent machines, robots, and other automation devices can interact using industrial protocols and take decisions in real time. In these systems, system-level communication, device synchronization, and the integration of new devices to the system are extremely challenging issues. Hence, there is a demand for sophisticated tools for the design of intelligent complex industrial automation systems. In SIMOO-RT [11-13], an object-oriented framework is pro-posed for modelling a real-time industrial automation system. A system model with real devices cannot be developed with SIMOO-RT. OOONEIDA [14-16] complies with IEC 61449 [17], which is a standard to design distributed control systems with intelligent devices. It proposes encapsulation of different types of IPs into reusable portable software modules called as function blocks. To achieve this, interfaces are created between various kinds of automation IPs such as devices, RTOSes, machines, systems, and industrial enterprises. However, in IEC 61499, the real-time properties of applications (e.g., reaction time) and resources (e.g., polling of data by function blocks, communication) are unspecified [18]. In OOONEIDA, real-time properties have to be handled via embedded controllers that are introduced to the system by encapsulation. There has also been a proposal on handling real-time issues in function blocks [19], but it has not been implemented yet. The encapsulation modules are developed in Java for the Eclipse and NetBeans integrated development environments. In RIMACS [20] project, a service-oriented architecture with real-time capabilities is proposed. Temporal behavior of each activity is isolated as much as possible by using dedicated hardware and software [4]. Linux kernel is modified to provide temporal isolation.

On the technical interoperability level, there can be found approaches using general-purpose distribution techniques such as DCOM, CORBA, J233, as well as architectures or frameworks related to the simulation area, such as DIS, SEDRIS, HLA. Especially HLA is used in many approaches, but its shortcomings are the lack of a semantic layer and data source description. The ex-tension of HLA with semantics is proposed in [12]. Ref. [114] proposes the Ontology Driven Simulation Design Tool (ODS). It is based on two ontologies that are mapped: the domain ontology categorizing knowledge including a problem vocabulary, and the modelling ontology used for the simulation model description.

3 Motivation and Formulation

The major challenges for the automation system integration in runtime are expressed in Figure 1. It depicts the typical architecture used in the industrial practice now.

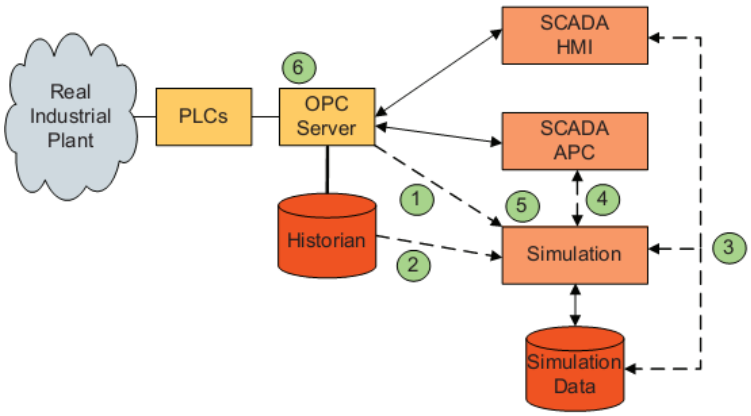

FIGURE 1 Current approach in industrial automation practice and its challenges

The meaning of circled labels refers to the issues as follows:

1. Import of runtime data into simulations.
2. Import of historical data into simulations.
3. Visualization of simulation data in standard HMIs and testing dispatchers' commands entered via HMI on simulation models.
4. Testing of SCADA advanced process control (APC) control actions on simulations.
5. Semi-automated design of simulation models.
6. Semi-automated configuration of OPC tags and other integration interfaces.

Analyzing these major challenges, our approach is based on two integration levels:

1) The technical integration level dealing with the technical transmission of data between particular tools.
2) The semantic integration level, which captures the meaning of the relevant knowledge, mapping common pieces of knowledge, and configuring the technical integration level. The paper addresses especially the semantic level of integration, whose research issues are summarized in the following overview.

The problems, which are investigated in this paper, were summarized into following research issues. Simulation models are hard to design and integrate manually. The goal of this research issue is to design an approach, which is based on explicitly represented engineering knowledge and to support the design of simulations semi-automatically. Since the runtime integration requires the proper structure of data in design time, the knowledge base must respect the integration request and involve it into the design time as well.

Current technical integration approaches require repeating manual work. This research issue is aimed at supporting runtime integration of industrial automation tools with a strong focus on simulations, which is flexible and easy to configure. Since the Simulation Framework is used as the technical integration level in the presented approach, one of the required output of the knowledge base tool is a generated set of configuration files for the Simulation Framework.

4 The Design of simulation based model

Although simulations are becoming widely used in industrial practice, their integration within the remainder of the automation system has not been satisfactorily solved. In addition, the design phase of simulations is usually done ad-hoc, which causes problems when either the real system is modified or some parts of the simulation should be reused. The goal of the presented work is to improve the design phase of simulation models in order to integrate them within the remainder of the automation system easily. We propose to capture the knowledge required for the simulation model design in the knowledge base.

4.1 SEMANTIC DESIGN OF SIMULATION MODELS

The typical engineering workflow [16] starts with the under-standing and summarization of a terminology. In other words, a domain specific language (DSL) is adopted for a particular class of plants, such as for hydraulic systems. DSL includes typical components and possible kinds of their connections, typical parameters and their types, relevant physical variables, definitions of relevant mathematical models, etc. Such pieces of information have to be structured and stored in a real plant ontology.

Plant device classes are represented as ontology classes, their parameters and relationships as ontology proper-ties. The creation of a general plant ontology structure enables to accelerate further project stages and it is done only once for every type of plant.

Having the ontology structure for the real plant, the description of the particular physical plant is created, i.e., there are created individuals of ontology classes. The individuals are labeled with unique names and relations to other individuals are entered. Parameters and their values can be entered, too. Based on the real plant ontology, simulation specialists are able to implement a simulation library, comprising generic simulation blocks. In a basic case, every plant ontology concept corresponds to a simulation block; in a more general case, a real plant element can be modeled by several blocks or vice versa. In the further subsection, this problem is discussed in more details.

The methodology for simulation model design and integration strongly depends on the available knowledge at the initial state of the automation project. In simulation practice, it is usual to utilize libraries containing generic blocks that are parameterized to approximate a specific device. In most cases, engineers are not able to create the library from scratch and afterwards assemble the simulation using these blocks. Usually, they must gain experiences on early versions of the simulations, perform a set of tests and comparisons of measured and simulated data and finally create or finalize the simulation library. Therefore, the first project in a specific area, such as a water distribution network simulation, requires iterative work on the simulation model and on the library. Other simulation projects of such networks reuse the library and even if some blocks must be added or modified, it is a simple task for an experienced simulation expert.

The simulation design phase is strongly influenced by the availability of the simulation library. If the simulation library exists, the semantic knowledge base tool is able to generate the simulation model semi-automatically. If the library is not available at the beginning, the knowledge base tool must be used in a similar way as an expert system, driving the user throughout a workflow collecting relevant pieces of knowledge required for the simulation model design.

In both cases, the general knowledge about the type of a real plant must be captured in the automation ontology. For example, the general knowledge about water distribution networks contains information that plants can have pumps, pipes, tanks, water wells, consumers or some disturbances; pumps have flow and pressure on their input and flow and pressure on their output, real parameters can be length, diameter and elevation, etc. The general knowledge is a kind of knowledge skeleton, which can be filled with real values when describing the specific plant. If needed, it can be extended with other parameters which are device-specific.

If the simulation library is available, the library blocks are annotated in the knowledge base, including their inputs, outputs and parameters. Consequently, the plant description must be formalized, including real plant topology and parameters. Technically, this step means populating the automation ontology with individuals denoting the real devices, their interconnections, tags, etc. Based on those pieces of knowledge, the semantic knowledge base tool is able to generate the simulation model structure automatically. Finally, the simulation expert is required to insert values of simulation block parameters, such as diameters or lengths of pipes.

In the case that the simulation library does not exist, the general knowledge is extended with a particular plant description in a similar way, but afterwards, the simulation model structure cannot be obtained automatically. The process of gathering the expert knowledge starts up with a specification which devices will be simulated. The step includes both grouping devices into complex subsystems (such as the whole plant can be decomposed to several simulation modules or a group of devices can be modeled as one block) and specification of block interfaces (such as the utilization of just one of the variables flow and pressure or both of them, an extension with further signals such as control values for devices). Afterwards, for each simulation block, there must be declared simulation parameters.

4.2 BLOCK-BASED DESIGN OF SIMULATION MODELS

System analysis and synthesis is typically based on the decomposition of problems into sub-problems. Engineering disciplines usually utilize components or blocks for the system design. For example, software engineers use methods as well as classes to encapsulate specific functionalities. In the simulation design area, the behavior of devices is often encapsulated by simulation blocks, which represent for example pumps, pipes, etc. Such blocks are comprised in a (universal) simulation library and the implementation of these blocks is generic in terms of their parameterization for the specific use.

This section addresses the research issue RI-2, i.e., the integration of whole simulations and other tools into the automation system environment. On the semantic level, the proposed solution is based on the representation of knowledge about local tag data models and mapping them to the global tag representation in the ontology. On the technical level, the approach is based on the enterprise service bus (ESB) approach. Although this paper is focused on the semantic level, the following paragraphs provide an overview of the technical layer, which is crucial for under-standing.

The proposed integration architecture, implemented by the Simulation Framework, is depicted in Figure 2. Tools are interconnected via connectors (having domain

specific and tool specific parts) to the ASB. The ASB transfers data according to the defined service bus workflow. This architecture poses a solution to the technical integration, nevertheless, it must be configured via a set of XML files to work properly. The preparation of such configuration files can be solved either manually, bringing short-comings in repeating error-prone manual work, or semi-automatically. We propose the semi-automated approach, which guarantees a consistent solution being flexible and capable to adopt modifications of real plant or software automation tools easily. The proposed solution is based on the structural tag description based on mappings between global tag representations and their local tool names.

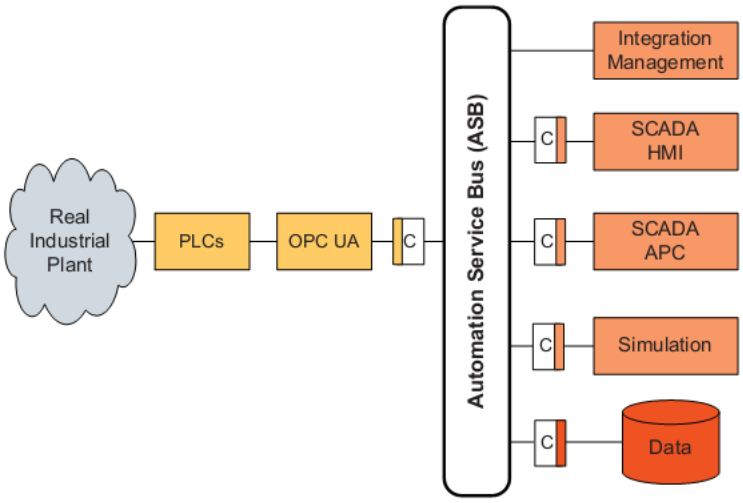

FIGURE 2 Industrial integration based on automation service

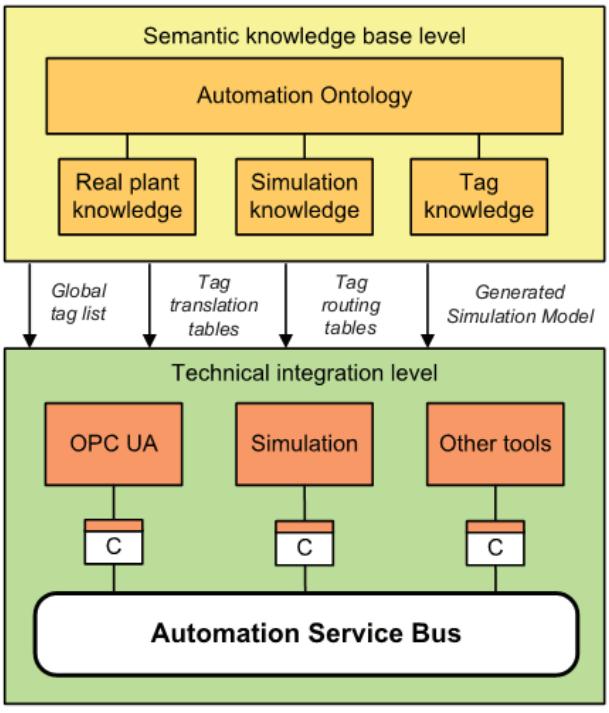

FIGURE 3 Technical layers including their interface

On the top of the Simulation Framework, we utilize the semantic knowledge base tool, which encapsulates the included ontologies, and provides interfaces to access it easily. The conceptual diagram of the proposed layered architecture is depicted in Figure 3. The knowledge base provides configuration XML files for the Simulation Framework, which are responsible for the definition of runtime behavior and furthermore, the knowledge base is able to support the design of particular tool models (such as simulation models in the current version).

4.3 PARAMETER MANAGEMENT OF THE SIMULATION SYSTEM

Since simulation parameters, i.e., parameters required for the parameterization of simulation blocks, can differ from parameters of real plant devices in both count and scale, the descriptive paradigm has to reflect this fact and manage them efficiently.

The presented approach distinguishes 3 classes of parameters. Real system parameters are parameters of devices included in the real system. Simulation model parameters are parameters of simulation modules. Simulation solver parameters are parameters of the simulation solver, such as simulation start time or stop time, required precision, etc.

In order to guarantee the consistency and avoiding errors while the real plant is changed, the presented approach involves the parameters in ontologies: the simulation ontology comprises definitions of required parameters to run the simulation for each block and plant ontology involves especially real plant elements description. A process specialist, for example, is not interested in the model parameters of a pump, which is modeled and simulated as the first-order system. Although he knows

almost everything about the real pump, he does neither know how simulation specialists would model pumps, nor the expected value, that can be calculated even by some algorithm. On the other hand, to reach the consistency in large-scale projects, changes should be automatically propagated between engineering domains and tools, hence these parameters are inter-linked. Mapping corresponding entities, such as real system parameters and simulation model parameters, which depend on them, is very easy to handle in ontologies that is one of the advantages of using them in this area.

The configuration of the Simulation Framework is based on the following XML files: Global tag list, tag translation tables, and tag routing tables. The global tag list file is aimed at setting all existing tags in the ASB environment and their properties (such as type, minimal and maximal values or others, which are useful for a control system). The tag translation tables are related to ASB connectors, which translate tag names between local names (occurring in the particular tool data model scope) and global tag representations, being uniquely available in the ASB. The tag routing tables define how tag values should be distributed between the tools (such as simulation results must be transmitted to HMI, simulation inputs must be entered with an operator-training data-set). Note that the global tag list and tag translation tables are project-specific, whereas routing tables are task-specific. Every project can have several tasks, such as simulation can be used as a soft-sensor to estimate unmeasured states, or as a test-bed to analyse control system behavior and train operators.

5 The real simulation cases

We selected a sample project to test the presented approach and to evaluate its efficiency. Since the complexity of typical industrial systems is very high and too complicated for a conference paper, we selected the simulation of the passive house. The goal is to describe a particular passive house in the unified ontology way and to generate its simulation model automatically. The simulation library with generic blocks is available. It is called Bldsimlib library [22], and it is implemented in MATLAB-Simulink. To create a simulation model of a particular house, the appropriate generic blocks from the library bldsimlib.mdl have to be inserted into a blank simulation model file simulation.mdl. Their names have to be set uniquely, and the blocks have to be interconnected according to the passive house floor plan. As well, the required parameters of the blocks have to be entered into the simulator workspace, in our case MATLAB Workspace.

For the first experiments, a simplified passive house was defined. It offers enough testing possibilities and the obtained results can be easily checked by people. To describe the testing house, a passive house ontology was designed. Its concepts define general elements of passive houses, such as rooms, walls, windows, etc. Afterwards, a description of the testing house was created by making ontology individuals representing the real passive house equipment.

The task for engineers is to design a simulation model for this plant and to integrate it within the remainder of the automation system. According to the workflow presented in Figure 2, the simulation model design requires general knowledge about hydraulic systems at the beginning. The second step is to populate the knowledge base (i.e. the automation ontology) with individuals representing devices in this particular industrial plant. In case of the universal simulation library being available, the simulation model structure can be generated automatically; otherwise, the simulation expert is driven through the process of gathering relevant simulation data. In this case, the simulation expert selects which devices create a simulation module and which blocks will be included in the modules. Since the system does not include repeating segments such as pump-stations, every device will be approximated by one simulation block. Interfaces of the blocks will be input and output flow and pressure; furthermore, tanks will have level sensor variables as outputs. Pumps and valves will have input control signals to distinguish their states. As tags are a subset of variables, there are expected tank level tags and pump flows to be considered as tags. The subsequent step in the methodology is to define simulation parameters. One possible solution is to accord to every device an elevation to the reference point and to define for every tank its height, diameter, and diameters of inlets and outlets. Pipes are expected to have resistances and pumps maximal volumetric flows. In a further step of the design methodology, the simulation library will be derived automatically. Finally, the simulation parameter values must be entered.

6 Conclusion

Industrial plants and processes are becoming very complex and sophisticated. Appropriate control algorithms, being necessary for their efficient operation, can be tested and fine-tuned on simulation models; for advanced process control the models are even necessary. Therefore, the fundamental precondition for control algorithm design is to implement and fine-tune a simulation model. Since plant description methods used nowadays are insufficient for describing modern flexible plants, this paper presents an ontology-based approach to the plant description. The proposed paradigm enables querying and inferring new pieces of knowledge. The solution supports the efficient integration of diverse engineering tools, such as simulators, SCADA systems, or even proprietary software used in particular projects. The proposed approach supports reasoning techniques and efficient utilization of domain specific languages for each engineer or expert. Ontologies comprise explicitly specified knowledge,

enable to interchange it between automation tools and can guarantee consistency of the whole integrated solution. The presented approach can be used for both continuous and discrete systems, especially the large-scale ones. A practical example, describing a passive house with ontology individuals and generating a structure of a simulation model automatically by the implemented tool, is involved in this paper.

Intelligent human resources systems in the information technology era

Jie Guo*

School of Philosophy and Public Administration, Henan University, Kaifeng, Henan, 475001, China

Received 1 March 2014, www.cmnt.lv

Abstract

Effective human resource management facilitates the success of an organization and the progress of a society. We describe an evolutionary computer model that simulates different modes of interaction between people and their environment. A two-level genotype-phenotype structure is used to represent the characteristics of an individual. The environment is modelled as a two-dimensional array of regions in which each region is characterized by a set of regional features and organizational culture (e.g., leadership strategies). Human resource decisions are subject to limitations, because they always depend on human knowledge, judgment and preference. Decision support applications can be used to provide fair and consistent decisions, besides to improve the effectiveness of decision making processes. This study consists of three parts; the first part is to understand the IDSS concepts, applications and related research in human resources decision making application known as HR DSS. The second part is to identify the potential intelligent techniques that can be used in HR DSS application, and the third part is to suggest the HR DSS framework that is related to human resource decisions. Finally, the paper proposed the HR DSS framework and the potential intelligent techniques that can be used to develop the IDSS application in any phases of decision making processes.

Keywords: human resource decision support, human resource management systems, human resource strategy

1 Introduction

At this point, information technology (IT) can play an essential role, providing the tools for the modeling of an integrated system. However, IT is not enough to convert information into knowledge. Appropriate qualitative and quantitative models must be added to analyze the information and produce outputs that support the decision procedure [1]. Operational research (OR) can provide these models. In the rapidly changing knowledge–based economy, organizations that manage knowledge effectively survive and develop through the years. Knowledge is acquired, retrieved and created by people [2]. Thus, high quality human resources (HR) is the determinant factor that can lead to a competitive and inimitable advantage. In that respect, both HR academics and HR professionals have turned their focus to the strategic role of human resource management (HRM) [3]. In order HRM to perform this role, individual HR practices should be engaged in a way to build a coherent HRM system that supports decision making at corporate level.

The vast majority of human beings are genetically distinctive from each other. Furthermore, as we grow physically and develop mentally, each of us becomes unique in the world. There is no single mechanism that can underlie all human behaviour [4]. In some cases, people want to conform, while in others they want to be different. The immediate decisions made by individuals are sometimes unpredictable. The diversity of human beings makes human resource management more of an art than a science. The common approach for studying human resource management problems has involved statistical measurements. Individual behavior has been totally neglected. However, under certain circumstances, a small number of people can cause a system to change drastically. That is, a system might respond unexpectedly when slight turbulence is introduced. In the real world, human resource management problems are extremely complex [5-8]. A fair measure of fitness for people is a very subjective and controversial notion. As we know, an individual might respond differently to the same things at different times or places, or with different people. Schelling wrote, "People are responding to an environment that consists of other people responding to their environment, which consists of people responding to an environment of yet other people's responses."

It is difficult to predict what behavior will emerge from such intensive human interactions. As a consequence, it is not feasible to conduct experiments on people in various environments and with different management strategies, and to study the effect of altering environments and management strategies on human satisfaction. It is becoming increasingly clear that the HR system is one important component that can help an organization become more

* ***Corresponding author's*** e-mail: guoguo@henu.edu.cn

effective and achieve a competitive advantage. However, a larger question remains unanswered: How does HRM contribute to firm performance? Disappointedly, this question has not been answered until now, thus, the relationship between HRM and organizational performance is called a 'black box' problem. Much of the debate over the relationships between HRM and organizational performance has been based on the distinction between two views typically referred to as 'best practice' and 'best fit' [9-11]. The best practice perspective identifies a set of HR practices that is associated with improved performance in all types of organization and, by implication, for all kinds of employees. The best fit approach argues that performance is maximized when the HR policies adopted are consistent with the business strategy. Both of these perspectives assume that the HR policies adopted will be implemented as intended and have the same effect on all employees who work for the organization. Various authors have questioned these assumptions because of the differences between intended HR policies and employees' experience, because complex organizations have different types of employees who may be managed successfully through diverse sets of HR policies.

This paper presents a new modeling platform for human resource management using computer simulation and evolutionary computational techniques. Our objective was to construct a computer model that served as a tool for investigating the phenomena that could occur in a human resource management system. In this model, individual behavior was taken into account. Through computer simulation, we were allowed to perform a variety of experiments in a feasible manner. The application of evolutionary computational techniques to solve real-world problems has received more attention in recent years. Our model, an artificial world simulation system, abstracts the above essential features of human resource management. Likewise, the goal of our model is not to draw every possible aspect of human resource management into the system and then try to optimize it. Instead, it should be pictured as a large relational model better thought of, like an evolutionary ecosystem, as an existential game. Self-organizing dynamics are the essence of this model. The criterion for the success of this model is reproduction of the essential features of human resource management. If we generate a new phenomenon that is unknown, then either something new has been discovered that could come into effect under appropriate circumstances, or there is some universal constraint that is operative that quenches this effect. However, we cannot describe all of the human resource management features in great detail. Simplifying assumptions and compromises are thus unavoidable.

2 Related work

Human resources refers to a production capacity in the human body, it is reflected in workers who, as measured by the quantity and quality of resources of laborers, it play a productive role in economic, the national income growth. It is the most active labor factor of production is the most active, create and accumulate material capital, development and utilization of natural resources, and promote the development of national economy, and promote the social transformation of infinite power [12]. Rural human resources refers to the total rural population has a range of physical and mental, it includes two aspects of quality and quantity, the total is the product of the two. The number of rural human resources, refers to the number of the population of the rural labor range; the quality of rural human resources, rural human resources refers to has the physique, intelligence, knowledge, skills, generally reflected in the rural labor population fitness level and culture level [13,14].

According to the resource – based view of the firm [15], the basis for competitive advantage lies primarily in the resources it possesses. Even though this point of view has received much criticism, it is widely accepted that the way an organization manages its own resources can contribute to a superior or inferior performance. Considering also the fact that HR are an organization's most valuable asset, HRM can indeed plays a significant role to the excellence of a firm. In that respect, the concept of strategic HRM (SHRM) has been developed. SHRM focuses on organizational performance rather than individual performance. It also emphasizes the role of HRM systems rather than individual HR practices in isolation as solutions to business problems [16]. Before proceeding with the concept of this study, it is important to remind the definition of a "system". It is a set of interacting or interdependent entities, each one being described by a number of characteristics, forming an integrated whole that is in constant communication with the external environment. One of the main features of a system is the relationships among the entities. That differentiates a system from a sum / group of entities. So, in particular, we cannot consider a HRM system only as a sum of unrelated HR practices. The interactions among practices lead to what Ichniowski et al. [17] declared: The basic assumption is that the effectiveness of any practice depends on the other practices in place. If all of the practices fit into a coherent system, the effect of that system on performance should be greater than the sum of the individual effects from each practice alone.

According to Tannenbaum [18], HRIS is a systematic procedure to acquire, store, manipulate, analyze, retrieve, and distribute information about an organization's HR. Usually, HRIS is restricted to a transaction processing or record–keeping role. Even though the above mentioned tasks are included in the responsibilities of a HRIS, the important strategic role is neglected. HRIS support an organization's operations in two ways, by facilitating the daily tasks of the personnel and by providing useful outcomes to decision makers.

3 The proposed artificial human resource system

With our understanding of the human resource structure, we built an artificial human resource system that uses an agent-based simulation method to model and simulate human resource dynamics in PM. Using the basic elements that comprise the human resource system, employees are modeled as the main agents. Each agent has its own properties, such as age, gender, working experience, grade, and so on. Accordingly, each agent has five types of behaviors: recruitment, retirement, grade promotion, position promotion, and leaving, which is shown in Figure 1.

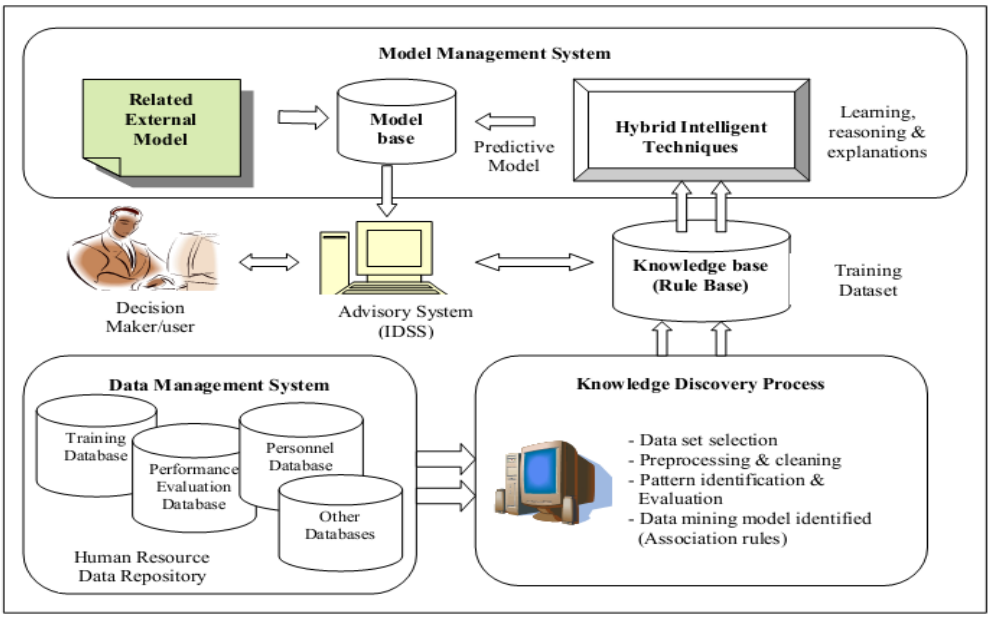

FIGURE 1 The proposed HR system

3.1 SYSTEM LEVEL

Personnel selection is one of the most critical functions of HRM. Apart from the straightforward fact that an organization should be staffed with the right people, a wrong hiring decision can lead to serious consequences. This is more obvious at high level managerial positions (e.g. director of department) where the decision may drive the future overall performance. Extensive literature can be found on selection methods, their validity and reliability [26]. Recently, endeavors from operations research and decision support fields strived to highlight the complexity of the selection function [8,9]. In general, the problem of hiring or promoting the right person should be considered in its multidimensional and incorporate all these parameters that influence the final decision.

An important factor that is linked to long term success and growth of an organization is its capacity to evaluate employees' performance and in addition the capacity to use the relevant information in order to improve employees' as well as organizational performance. Employee appraisal should not be conducted only against the outputs / results but also against behaviors and attitudes come into practice. Employee appraisal is the backbone of the concept called performance management. The latter links the main functions of HRM, aiming at improving the performance of a firm as a whole.

Compensation system has become more and more a really complicated issue for employers. It is not only to determine the base salary, considering the years of experience. Many other rewards do motivate and retain employees and might determine even the organizational performance. Compensation strategy can be used as a motivation and satisfaction incentive and as a recruitment and retain tool. In parallel, it is the mirror of the values and beliefs that form the organizational culture.

HR development (HRD) is a wider concept than the one of HR training. Training is mainly applied to improve the technical skills that cover short term needs of an organization. It is essential for workers in industry production business environments. Development includes training but is considered as a more strategic aspect. It refers basically to the key personnel of the organization. HRD facilitates the development of core capabilities that are critical in developing and maintaining sustained competitive advantage [14]. Core capabilities include positive behavior and ability to adapt to a rapidly changing environment and rational decision making, creativity development, motivation, human behavior understanding skills. The above mentioned are some examples of what is called management development [12], i.e., the development of specific capabilities of the future leaders of an organization.

3.2 APPLICATION LEVEL

Related enterprises and organizations should adjust their roles, to change service providers play by the traditional role of the manager's role, but also to change the location of mechanical, routine of their own, to play the initiative for the rural human resources to provide services. Management Department of rural human resource in its basic functions of the case, to make the management and practice to coordinate, and vigorously in practice, of course, said the enthusiasm to help the enterprises to mobilize human resources from the fundamental, to serve the development of enterprises.

Operation of the system, the rural human resources system maintenance work can take the relevant departments within the system of mutual cooperation; reduce the manpower, financial expenditure. Of course, with the overall quality of rural human resource enhancement, grasp the computer level, also can let them finish related work, so as to mobilize the enthusiasm of the migrant workers, the enterprise management personnel, also can liberate part of the labor force, to spend more time and energy into the development strategy of the enterprise. Migrant workers, give full play to the spirit of master, which is shown in Figure 2.

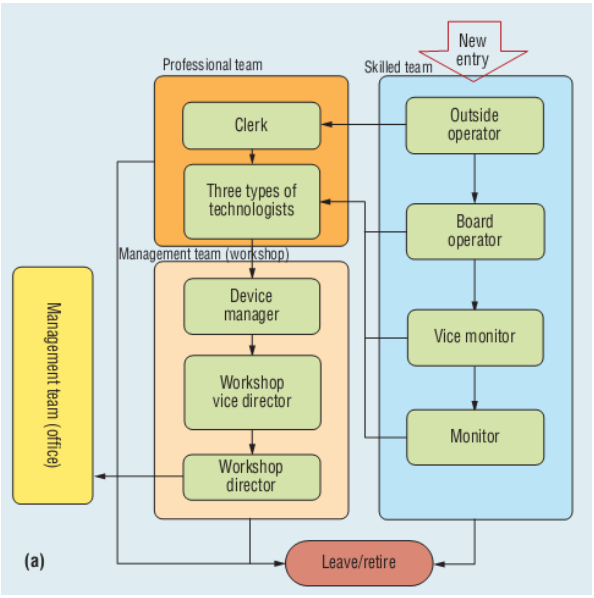

FIGURE 2 Potential employee career paths.

Enterprise organization should according to the characteristics of the rural human resources present and characteristic of the enterprise, make the rural human resources development management system continuous improvement system function, make the platform more open, more flexibility and innovation ability value, increasing rural human resource management information system and the outside resources embedded together, so as to enhance the efficiency, reduce the cost of.

Of course, with the maturity and application of the system of rural human resources, a bridge of communication with management system to complete between managers and workers, this time facing managers rely too much on the computer and the opportunity to meet the workers reduced risk, as a communication tool, we don't want is highly dependent on the human resource management system on how to improve the quality and reduce labor, enhance enterprise mission. At the same time, with the development of network technology, as well as to the rural human resources system to recognize and its operation process standardization, in particular with the advanced idea promotion, how to make the rural human resources information system more flexible, excellent price, more humane and the function is more perfect, for the design of the HRIS producers is grim the challenge, for enterprises using the HRIS system is a very real problem.

3.3 RELATION BETWEEN COMPONENTS

During personnel selection process, information on technical skills, abilities, professional experience and even personality is gathered through either self–report tests or interviews, methods that does not picture the future performance. For instance, successful management of a project team in a previous workplace does not ensure the success in managing a similar team in this organization. Selection process can only be a predictor of performance. Thus, the objective is to design as better a predictive system as possible. Employee appraisal is the phase that confirms the application of particular competences, based on performance standards and demands of the specific position. Employee appraisal can comprise a critical tool monitoring the relevance of the selection process. For example, following a specific methodology for the selection of an IT manager, the organization leads to the choice of a candidate with many years of experience in similar position, with strong academic background and with developed interpersonal, team management and creativity skills, among others. In case employee appraisal reveals behaviors and performance results that do not correspond to the initial evaluation (during selection process), there are several issues to be considered. Either the wrong person for the organization and the position was selected or external factors (e.g. the current situation of the market and the economy) affected the performance negatively or the standards and the criteria of the appraisal had not been set correctly.

The first one of the above mentioned potential reasons is closely related to the selection process. Wrong selection methods, wrong selection criteria or bad choice of criteria weights can result in wrong decisions. Moreover, inadequate evaluators/interviewers usually affect the whole process. Thus, a well-designed employee appraisal, can give feedback, through learning mechanisms, to the

selection process in order that the right people are hired, placed and promoted in the right positions.

There are two dominant compensation strategies. The first one uses academic titles and professional experience as the only decision criteria in order to set the level and type of salary. The other follows the concept of linking each job position with a respective wage. These two practices, bearing in mind that high level positions are occupied by experienced personnel, tend to become identical. As an employee acquires more experience, he occupies higher positions and receives higher wage. With these approaches, two employees, just having the same years of experience and the same studies, get equal pay. Similarly, two employees, just being at the same level of hierarchy, get equal pay. The fact that one may have achieved the targets set in comparison to the other is not taken into consideration in the compensation process. In addition, one may add value to the organization in financial (e.g. contribution to sales increase, cost reduction) or social terms (contribution to colleagues motivation, creativity behavior) and not be rewarded for this. The above mentioned situations can lead to injustice feelings and negative attitudes. For these reasons, compensation should be associated to a well-designed, objective employee appraisal process so that a good organizational environment to be secured. In parallel, compensation strategy can play a motivational role to performance improvement. That means a two way relationship between employee appraisal and compensation.

3.4 CONFIGURATION OF HRM SYSTEM

As mentioned in a previous section, HRD plays a dual, both tactical and strategic role, targeting on the one hand the coverage of specific short term technical needs of an organization (mainly through technical training) and on the other hand the management and development of potential future leaders and their careers. The decisions that should be made refer to when, on what and who to be trained. The answer can be supported by the employee appraisal process. Appraising employees, it is possible to sort them into categories, each one to be linked to particular training and development programs or even to create individual programs for each one of them. Giving an example, the appraisal of a programmer/developer can reveal weaknesses on specific features of performance (e.g. inefficiency on programming techniques). A personal training program can be designed using material relevant to these weaknesses. Similarly, a positive output of an appraisal of a programmer can be an indication for further development of the technical skills and in parallel a guide for future evolution into higher hierarchical levels (e.g. IT manager). Thus, an appropriate development program must be designed, with all necessary technical and managerial knowledge to be provided.

In general, there is a two way relationship between training/development and employee appraisal process. Theoretically, training output advances an improved future performance for the trainee. This indeed must be proved in practice. An effective training can be confirmed through the next employee appraisal. If this appraisal is positive, it could be at a certain degree due to the applied training program. If not, it is possible that the training practice should be redesigned. In other words, a learning mechanism is essential, which allows the respective HR practices to be adjusted dynamically.

Training can be closely linked to personnel selection practice. It is common, due to limited time or budget or because of the inadequacy of the recruitment phase to attract high quality candidates, the final selection decision not to be the ideal one. In that case, a gap analysis between the required and the available competences of the employee should be conducted so that the latter to be trained accordingly. Thus, training and development practice should receive feedback from selection process and provide the necessary tools to close a potential competence shortage.

4 Discussions and suggestions

Intelligent system and soft computing technologies are new technological platforms, whereby intelligent logic is now usually inherent in the processing of all decision support tools. HR DSS as a part of Intelligent System applications play the same roles to assist decision making process. In addition, applications and intelligent techniques of HR DSS need a lot of attention and efforts, from both academicians and practitioners. From this study, we can see the potential of HR DSS applications for future works. Firstly, there are many problem domains in HRM that can be explored by intelligent system researchers. In this case, the researchers should have the effort to identify problem domains where tools are needed to transform uncertain and incomplete data into useful knowledge. For that reason, we are trying to explore HR DSS applications for human resource decision. Secondly, researchers agree that hybrid intelligent techniques are the best approach to support decision making especially in reasoning and learning. We have embedded the HR DSS framework using hybrid techniques i.e., Knowledge-based system and Artificial Neural Network (ANN) approaches. Thirdly, the academicians and practitioners should continuously improve the core knowledge of effective HR DSS. This process can be enhanced by continuous development in web-enable tools, wireless protocol and group decision support system, which can expand the interactivities and perverseness decision support technologies. In our system development, we plan to use this technology to expand the capabilities of the application.

5 Conclusions

Effective human resource management facilitates the success of an organization and the progress of a society. We describe an evolutionary computer model that simu-

lates different modes of interaction between people and their environment. A two-level genotype-phenotype structure is used to represent the characteristics of an individual. The environment is modelled as a two-dimensional array of regions in which each region is characterized by a set of regional features and organizational culture (e.g., leadership strategies). Human resource decisions are subject to limitations, because they always depend on human knowledge, judgement and preference. Decision support applications can be used to provide fair and consistent decisions, besides to improve the effectiveness of decision making processes. This study consists of three parts; the first part is to understand the IDSS concepts, applications and related research in human resources decision making application known as HR DSS. The second part is to identify the potential intelligent techniques that can be used in HR DSS application, and the third part is to suggest the HR DSS framework that is related to human resource decisions. Finally, the paper proposed the HR DSS framework and the potential intelligent techniques that can be used to develop the IDSS application in any phases of decision making processes.

PCA-based analysis on factors of English translation ability

Ting Hong*

Zijin College, Nanjing University of Science and Technology, Nanjing, 210000, China

Received 1 March 2014, www.cmnt.lv

Abstract

This work studied the relationship between English proficiency and translation ability as well as that between English and translation teaching among English majors. PCA is utilized to quantify and analyze the relationship between translation ability and English skills such as listening, reading, error correction and writing. Then we obtain the quantitative relation between translation ability and its factors, providing decision basis for the improvement of English translation skills and teaching.

Keywords: PCA analysis, translation ability, English teaching, quantitative analysis

1 Introduction

With the deepening of economic globalization, there is a growing demand for talents of foreign language translation. Therefore, the improvement of students' English translation ability has become an important task for college English major and common English teaching.

For a long time, translation ability has been regarded as a language skill due to unclear concepts about translation and English teaching. Currently, the mainstream of translation teaching still focuses on language skills. While strengthening the teaching of language knowledge, it neglects the variability of texts for translation, differences in translators' cognition and some non-linguistic factors (social, historical and cultural). However, translation behavior is a dynamically-generated process of translation and also a reflection of translators' comprehensive abilities. As many scholars interpreting the nature of translation capabilities, they made it clear that comprehensive ability is not equal to language application ability.

2 Principal component analysis (PCA)

2.1 BASIC IDEAS OF PCA

Principal component analysis utilizes the method of mathematical dimension reduction to substitute comprehensive variables for original ones. These unrelated, comprehensive variables contain the information of the original ones as much as possible. The statistical analysis method converting several variables into few unrelated, comprehensive ones is called as principal component analysis (PCA).

2.2 MATHEMATICAL MODELS OF PCA ANALYSIS

For a data sample, p variables $(x_1, x_2, \cdots, x_p)$ are observed to form the data matrix of n samples as follows.

$$X = \begin{pmatrix} x_{11} & x_{12} & \cdots & x_{1p} \\ x_{21} & x_{22} & \cdots & x_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{np} \end{pmatrix} = \left(x_1, x_2, \cdots, x_p\right),$$

where

$$x_j = \begin{pmatrix} x_{1j} \\ x_{2j} \\ \vdots \\ x_{nj} \end{pmatrix}, \qquad j = 1, 2, \cdots, p.$$

PCA can integrate p observed variables into p new comprehensive ones.

$$\begin{cases} F_1 = a_{11}x_1 + a_{12}x_2 + \cdots + a_{1p}x_p \\ F_2 = a_{21}x_1 + a_{22}x_2 + \cdots + a_{2p}x_p \\ \cdots \\ F_p = a_{p1}x_1 + a_{p2}x_2 + \cdots + a_{pp}x_p \end{cases}.$$

Namely

$$F_j = \alpha_{j1}x_1 + \alpha_{j2}x_2 + \cdots + \alpha_{jp}x_p,$$
$$j = 1, 2, \cdots, p$$

The model should meet the following criteria.

1) F_i, F_j $(i \neq j,\ i, j = 1, 2, \cdots, p)$ are unrelated to each other.

2) F_1 has a larger variance than F_2, and F_2 has a larger variance than F_3, etc.

3) $a_{k1}{}^2 + a_{k2}{}^2 + \cdots + a_{kp}{}^2 = 1, \qquad k = 1, 2, \cdots, p.$

There are p principal components. F_1 is called as the first principal component; F_2 as the second principal

* ***Corresponding author's*** e-mail: zj_ht123@163.com

component, and so on; a_{ij} as the principal component factor.

The model can be represented by a matrix. A is the principal component coefficient matrix.

$$F = \begin{pmatrix} F_1 \\ F_2 \\ \vdots \\ F_p \end{pmatrix}, \qquad X = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_p \end{pmatrix}.$$

$F = AX$, where

$$A = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{p1} & a_{p2} & \cdots & a_{pp} \end{pmatrix} = \begin{pmatrix} a_1 \\ a_2 \\ \vdots \\ a_p \end{pmatrix}.$$

3 Data sources

As psychological characteristics, English translation and language skills cannot be measured only by one's external manifestations or characteristics.

As the study objective of this work, TEM-8 score of a college includes a total score and individual score. TEM-8, with high reliability and validity, is the most authoritative, standardized test for measuring students' English proficiency.

For data processing and analysis, listening and dictation are merged into listening comprehension, measuring students' listening ability; Reading One and Two are merged into reading comprehension to measure English reading ability; translation from English-Chinese and Chinese-English translation are also combined together.

In terms of differences in English translation ability of candidates, translation scores are divided into two groups – one with scores not less than 48 points (qualifying criterion) and the other less than 48 points.

4 Results analysis

4.1 MEAN CONTRAST OF CHINESE-ENGLISH TRANSLATION SCORES

Mean data contrast of the two groups and T-test results of independent samples are shown in Table 1, Table 2, respectively.

According to Table 1 and Table 2, the results of Levene variance homogeneity test are F = 0.772 and P = 0.381> 0.05, so the two groups of students have equal variance in Chinese-English translation score; t = 3.303, and P = 0.001 <0.05. Thus, the difference between two groups in Chinese-English translation has statistical significance.

TABLE 1 Mean contrast for two groups of Chinese-English translation scores

Translation Score	N	Mean	Std.Deviation	Std.Error Mean
>=48.00	40	6.35	.796	.140
<48.00	94	5.71	1.031	.112

TABLE 2 Independent samples T-test for two groups of Chinese-English translation scores

Levene's Test for Equality of Variances		T-test for Equality of Means							
	F	Sig.	t	df	Sig.(2-tailed)	Mean Difference	Std.Error Difference	95% Confidence Interval of the Difference	
								Lower	Upper
Equal variance assumed Equal variance not assumed	.772	.381	3.303	122	.001	.64	.194	.257	1.024
			3.693	80.182	.000	.64	.173	.295	.985

4.2 MEAN CONTRAST OF CHINESE-ENGLISH TRANSLATION

Table 3 and Table 4 show the mean contrast, independent sample T-test of two groups of data, respectively.

According to Table 3 and Table 4, the results of Levene variance homogeneity test are F = 2.534 and P = 0.115> 0.05, so variances of two groups of Chinese-English translation scores are equal: t = 3.158, and P = 0.002 <0.05. Thus, the difference between the two groups in Chinese-English translation has statistical significance.

TABLE 3 Mean contrast of two groups of Chinese-English translation scores

Translation Score	N	Mean	Std.Deviation	Std.Error Mean
>=48.00	40	6.74	1.067	.183
<48.00	94	5.89	1.457	.161

TABLE 4 Independent samples T-test of two groups of Chinese-English translation scores

Levene's Test for Equality of Variances		T-test for Equality of Means							
	F	Sig.	t	df	Sig.(2-tailed)	Mean Difference	Std.Error Difference	95% Confidence Interval of the Difference	
								Lower	Upper
Equal variance assumed	2.534	0.115	3.158	122	.002	.86	.275	.320	1.391
Equal variance not assumed			3.613	85.121	.002	.86	.237	.385	1.330

The statistical contrast in Chinese-English and English-Chinese translation shows that students with stronger English ability are doing better in English translation.

4.3 PEARSON CORRELATION ANALYSIS

For data of all the samples, Table 5 shows pearson correlation coefficients among Chinese-English and English-Chinese translation, listening comprehension, reading comprehension, error correction, writing and translation score.

TABLE 5 Pearson correlation analysis results

		Listening Comprehension	Reading Comprehension	Error Correction	Writing	Translation Score	Chinese to English	English to Chinese
Chinese to English	Pearson Correlation	.273(**)	.214(*)	.332(**)	.124	.333(**)	1	.454(**)
	Sig.(2-tailed)	.002	.017	.000	.171	.000	.000	.000
English to Chinese	Pearson Correlation	.403(**)	.348(**)	.271(**)	.041	.431(**)	.454(**)	1
	Sig.(2-tailed)	.000	.000	.002	.650	.000	.000	.000

** Correlation is significant at level 0.01 (2-tailed)
* Correlation is significant at level 0.05 (2-tailed)

According to Table 5, Chinese-English translation has the biggest correlation coefficient (0.454) with English-Chinese translation. It indicates that Chinese-English and English-Chinese ability are correlative, so teaching for the two kinds of translations should be complementary; Chinese-English translation has strong correlation (0.333) with translation score, so it is closely related to listening, writing and reading; error correction and Chinese-English score have the strongest correlation (0.332) among all individual scores. With language knowledge including grammar, rhetoric and language structure, error correction can greatly influence translation ability by identifying faulty wording or formulation and proposing corrective approach.

4.4 PCA ANALYSIS

4.4.1 Statistical test

After setting the significance level as 0.05, KMO and Bartlett's Test of Sphericity are conducted on the selected data. Results are shown in Figure 1.

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.604
Bartlett's Test of Sphericity	Approx. Chi-Square	56.843
	df	28
	Sig.	.001

FIGURE 1 KMO and Bartlett's Test of Sphericity

In Figure 1, KMO statistic is 0.604 > 0.5; Bartlett spherical statistic 56.843; significant probability 0.001 <0.05. Then the null hypothesis in Bartlett Test of Sphericity is rejected, and PCA analysis is more suitable for the index data of translation ability.

4.4.2 Determination of common factors

In this work, eigenvalues is greater than one, and the cumulative contribution rate greater than 80%. Figure 2 shows the PCA extraction results.

In Figure 2, the characteristic curve shows a turning point at factor 5, so common factors can be extracted from the first five factors. In Table 6, among the five factors with eigenvalue greater than one, the first four factors contribute to 80.571% (> 80%) of cumulative rate. Therefore, the four factors can reflect the influencing factors of English translation ability.
